Adds a new item at the end of the collection.

Pascal

```
function Add: TButtonCategory;
```

C++

```
__fastcall TButtonCategory Add();
```

19.1.2.3.2 TButtonCategories.AddItem Method

Adds an item to the category at the specified index.

Pascal

```
function AddItem(Item: TButtonCategory; Index: Integer): TButtonCategory;
```

C++

```
__fastcall TButtonCategory AddItem(TButtonCategory Item, int Index);
```

Description

The scope determines whether the method adds a new category or a new button.

19.1.2.3.3 TButtonCategories.BeginUpdate Method

Begins the update procedure to update the button list whenever the categories or buttons within the categories are modified.

Pascal

```
procedure BeginUpdate; override;
```

C++

```
virtual __fastcall BeginUpdate();
```

19.1.2.3.4 TButtonCategories.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

19.1.2.3.5 TButtonCategories.IndexOf Method

Pascal

```
function IndexOf(const Caption: string): Integer;
```

C++

```
__fastcall int IndexOf(const AnsiString Caption);
```

Description

This is IndexOf, a member of class TButtonCategories.

19.1.2.3.6 TButtonCategories.Insert Method

Inserts a new item at the specified index.

Pascal

```
function Insert(Index: Integer): TButtonCategory;
```

C++

```
__fastcall TButtonCategory Insert(int Index);
```

19.1.2.3.7 TButtonCategories.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

See Also

Changed (see page 2740)

Changed (see page 2758)

19.1.2.4 TButtonCategories Properties

The properties of the TButtonCategories class are listed here.

Public Properties

	Name	Description
R	ButtonGroup (see page 2428)	A specified button group within the category button container.
	Items (see page 2429)	The number of categories in the category button container.

19.1.2.4.1 TButtonCategories.ButtonGroup Property

A specified button group within the category button container.

Pascal

```
property ButtonGroup: TCategoryButtons;
```

C++

```
__property TCategoryButtons ButtonGroup;
```

19.1.2.4.2 TButtonCategories.Items Property

The number of categories in the category button container.

Pascal

```
property Items [Index: Integer]: TButtonCategory;
```

C++

```
__property TButtonCategory Items[int Index];
```

19.1.3 TButtonCategory Class

TButtonCategory is an individual button category of a TCategoryButtons (see page 2452) control.

Class Hierarchy

Pascal

```
TButtonCategory = class(TCollectionItem);
```

C++

```
class TButtonCategory : public TCollectionItem;
```

File

CategoryButtons

19.1.3.1 TButtonCategory Members

The following tables list the members exposed by TButtonCategory.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetDisplayName (see page 2758)	Returns the name of the collection item as it appears in the collection editor.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2433)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2432)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2431)	Creates and initializes a TCollectionItem instance.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2431)	Destroys the TCollectionItem instance and frees its memory.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	IndexOf (see page 2432)	This is IndexOf, a member of class TButtonCategory.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScrollIntoView (see page 2433)	Scrolls a button to make it visible within a group or category.

Public Properties

	Name	Description
R	Categories (see page 2434)	Retrieves the owning ButtonCategories object.
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	Data (see page 2434)	This is Data, a member of class TButtonCategory.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).
	InterfaceData (see page 2435)	Interface data for the button category object.

Published Properties

	Name	Description
	Caption (see page 2434)	Specifies the caption for the button category.
	Collapsed (see page 2434)	Specifies whether or not the button in the collection is collapsed.
	Color (see page 2434)	Specifies the color of the category item.
	GradientColor (see page 2435)	Specifies the colors used for a gradient fill on the category label in a category button object.
	Items (see page 2435)	Specify the button items in this category.
	TextColor (see page 2435)	Specify the color used for the font in category captions.

19.1.3.2 TButtonCategory.Create Constructor

Creates and initializes a TCollectionItem instance.

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TButtonCategory(TCollection Collection);
```

Description

Do not call Create to instantiate a collection item. Instead, call the Add method of the collection to which the item should belong.

Collection identifies the TCollection instance to which the new item belongs.

See Also

Add (see page 2736)

Collection (see page 2761)

19.1.3.3 TButtonCategory.Destroy Destructor

Destroys the TCollectionItem instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TButtonCategory();
```

Description

Destroy is called indirectly by TCollection's Clear or Delete method.

See Also

Clear (see page 2741)

Delete (see page 2741)

Free (see page 22300)

19.1.3.4 TButtonCategory Methods

The methods of the TButtonCategory class are listed here.

Protected Methods

	Name	Description
	SetIndex (see page 2433)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	Assign (see page 2432)	Copies the contents of another, similar object.
	IndexOf (see page 2432)	This is IndexOf, a member of class TButtonCategory.
	ScrollIntoView (see page 2433)	Scrolls a button to make it visible within a group or category.

19.1.3.4.1 TButtonCategory.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent calls the source object's AssignTo method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

See Also

AssignTo (see page 2931)

EConvertError (see page 22724)

19.1.3.4.2 TButtonCategory.IndexOf Method

Pascal

```
function IndexOf(const Caption: string): Integer;
```

C++

```
__fastcall int IndexOf(const AnsiString Caption);
```

Description

This is IndexOf, a member of class TButtonCategory.

19.1.3.4.3 TButtonCategory.ScrollIntoView Method

Scrolls a button to make it visible within a group or category.

Pascal

```
procedure ScrollIntoView;
```

C++

```
__fastcall ScrollIntoView();
```

Description

Supply the following value for this method:

Parameter	Description
Index	An Integer representing the button you want scrolled into view.

19.1.3.4.4 TButtonCategory.SetIndex Method

Moves the collection item to a specified position in the parent collection.

Pascal

```
procedure SetIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetIndex(int Value);
```

Description

SetIndex is the protected write implementation of the Index property. The Value parameter specifies the new (0-based) position for the item in its parent collection.

See Also

Index (see page 2762)

19.1.3.5 TButtonCategory Properties

The properties of the TButtonCategory class are listed here.

Public Properties

	Name	Description
R	Categories (see page 2434)	Retrieves the owning ButtonCategories object.
	Data (see page 2434)	This is Data, a member of class TButtonCategory.
	InterfaceData (see page 2435)	Interface data for the button category object.

Published Properties

	Name	Description
	Caption (see page 2434)	Specifies the caption for the button category.
	Collapsed (see page 2434)	Specifies whether or not the button in the collection is collapsed.
	Color (see page 2434)	Specifies the color of the category item.
	GradientColor (see page 2435)	Specifies the colors used for a gradient fill on the category label in a category button object.
	Items (see page 2435)	Specify the button items in this category.
	TextColor (see page 2435)	Specify the color used for the font in category captions.

19.1.3.5.1 TButtonCategory.Caption Property

Specifies the caption for the button category.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

19.1.3.5.2 TButtonCategory.Categories Property

Retrieves the owning ButtonCategories object.

Pascal

```
property Categories: TButtonCategories;
```

C++

```
__property TButtonCategories Categories;
```

19.1.3.5.3 TButtonCategory.Collapsed Property

Specifies whether or not the button in the collection is collapsed.

Pascal

```
property Collapsed: Boolean;
```

C++

```
__property Boolean Collapsed;
```

Description

If set to **True**, the button is collapsed, otherwise, when set to **False**, the button is expanded.

19.1.3.5.4 TButtonCategory.Color Property

Specifies the color of the category item.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

The category appears as either a vertical or horizontal bar within the category button container. This property applies to the background of the container.

19.1.3.5.5 TButtonCategory.Data Property

Pascal

```
property Data: Pointer;
```

C++

```
__property void * Data;
```

Description

This is Data, a member of class TButtonCategory.

19.1.3.5.6 TButtonCategory.GradientColor Property

Specifies the colors used for a gradient fill on the category label in a category button object.

Pascal

```
property GradientColor: TColor;
```

C++

```
__property TColor GradientColor;
```

Description

Inherits from TColor.

19.1.3.5.7 TButtonCategory.InterfaceData Property

Interface data for the button category object.

Pascal

```
property InterfaceData: IInterface;
```

C++

```
__property IInterface InterfaceData;
```

19.1.3.5.8 TButtonCategory.Items Property

Specify the button items in this category.

Pascal

```
property Items: TButtonCollection;
```

C++

```
__property TButtonCollection Items;
```

Description

You define items from within the context of the **Categories (see page 2434) Editor**. When the **Categories (see page 2434) Editor** is displayed, the **Object Inspector** changes to reflect what is in the **Categories (see page 2434) Editor**. In the **Object Inspector**, you can click the Items property to display the **Items Editor**. Use the **Items Editor** to add buttons to the category.

19.1.3.5.9 TButtonCategory.TextColor Property

Specify the color used for the font in category captions.

Pascal

```
property TextColor: TColor;
```

C++

```
__property TColor TextColor;
```

19.1.4 TButtonCollection Class

Defines a collection of buttons that appear in a TButtonCategory (see page 2429).

Class Hierarchy

System::TObject → Classes.TPersistent → Classes.TCollection → CategoryButtons.TButtonCollection

Pascal

```
TButtonCollection = class(TCollection);
```

C++

```
class TButtonCollection : public TCollection;
```

File

CategoryButtons

19.1.4.1 TButtonCollection Members

The following tables list the members exposed by TButtonCollection.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 2438)	Returns the owner of an object.
V	Notify (see page 2439)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 2440)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 2438)	Adds a button to the end of the collection.
	AddItem (see page 2438)	Adds a button to a collection at a specified index.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 2438)	The constructor for the collection.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2439)	Inserts a button in the collection at the specified index.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Category (see page 2440)	The name of the current category.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 2440)	Defines the button items in a category.

19.1.4.2 TButtonCollection.Create Constructor

The constructor for the collection.

Pascal

```
constructor Create(const ACategory: TButtonCategory);
```

C++

```
__fastcall TButtonCollection(const TButtonCategory ACategory);
```

19.1.4.3 TButtonCollection Methods

The methods of the TButtonCollection class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 2438)	Returns the owner of an object.
	Notify (see page 2439)	Responds when items are added to or removed from the collection.
	Update (see page 2440)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 2438)	Adds a button to the end of the collection.
	AddItem (see page 2438)	Adds a button to a collection at a specified index.
	Insert (see page 2439)	Inserts a button in the collection at the specified index.

19.1.4.3.1 TButtonCollection.Add Method

Adds a button to the end of the collection.

Pascal

```
function Add: TButtonItem;
```

C++

```
__fastcall TButtonItem Add();
```

19.1.4.3.2 TButtonCollection.AddItem Method

Adds a button to a collection at a specified index.

Pascal

```
function AddItem(Item: TButtonItem; Index: Integer): TButtonItem;
```

C++

```
__fastcall TButtonItem AddItem(TButtonItem Item, int Index);
```

19.1.4.3.3 TButtonCollection.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

19.1.4.3.4 TButtonCollection.Insert Method

Inserts a button in the collection at the specified index.

Pascal

```
function Insert(Index: Integer): TButtonItem;
```

C++

```
__fastcall TButtonItem Insert(int Index);
```

19.1.4.3.5 TButtonCollection.Notify Method

Responds when items are added to or removed from the collection.

Pascal

```
procedure Notify(Item: TCollectionItem; Action: TCollectionNotification); override;
```

C++

```
virtual __fastcall Notify(TCollectionItem Item, TCollectionNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Item is the item that was just added to or that is about to be removed from the collection.

Action indicates whether item was added, is about to be removed, or is about to be deleted:

As implemented in TCollection, Notify calls Added when Action is cnAdded and calls Deleting when Action is cnDeleting. TCollection ignores the cnExtracting action. Descendant classes can override Notify to modify this behavior.

See Also

Added (see page 2736)

Deleting (see page 2741)

19.1.4.3.6 TButtonCollection.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

19.1.4.4 TButtonCollection Properties

The properties of the TButtonCollection class are listed here.

Public Properties

	Name	Description
R	Category (see page 2440)	The name of the current category.
	Items (see page 2440)	Defines the button items in a category.

19.1.4.4.1 TButtonCollection.Category Property

The name of the current category.

Pascal

```
property Category: TButtonCategory;
```

C++

```
__property TButtonCategory Category;
```

19.1.4.4.2 TButtonCollection.Items Property

Defines the button items in a category.

Pascal

```
property Items [Index: Integer]: TButtonItem;
```

C++

```
__property TButtonItem Items[int Index];
```

19.1.5 TButtonItem Class

An instance of a button in a TCategoryButtons (see page 2452) control.

Class Hierarchy

System::TObject → Classes.TPersistent → Classes.TCollectionItem → CategoryButtons.TBaseButtonItem → CategoryButtons.TButtonItem

Pascal

```
TButtonItem = class(TBaseButtonItem);
```

C++

```
class TButtonItem : public TBaseButtonItem;
```

File

CategoryButtons

Description

You add button items to the category by using the **Items Editor**. The **Items Editor** can be invoked from the Items property in the **Object Inspector**, only when the **Categories Editor** is displayed and a category is selected.

19.1.5.1 TButtonItem Members

The following tables list the members exposed by TButtonItem.

Protected Methods

	Name	Description
	ActionChange (see page 2420)	This is ActionChange, a member of class TBaseButtonItem.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetActionLinkClass (see page 2421)	This is GetActionLinkClass, a member of class TBaseButtonItem.
	GetDisplayName (see page 2421)	Returns the name of the collection item as it appears in the collection editor.
	GetDisplayName (see page 2758)	Returns the name of the collection item as it appears in the collection editor.
	GetNotifyTarget (see page 2444)	This is GetNotifyTarget, a member of class TButtonItem.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Protected Properties

	Name	Description
	ActionLink (see page 2422)	This is ActionLink, a member of class TBaseButtonItem.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2443)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2419)	Creates and initializes a TCollectionItem instance.
V	Create (see page 2757)	Creates and initializes a TCollectionItem (see page 2755) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2757)	Destroys the TCollectionItem (see page 2755) instance and frees its memory.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ScrollIntoView (see page 2444)	Scrolls a button to make it visible within a button group.

Public Properties

	Name	Description
R	Category (see page 2445)	The parent category for the given button item.
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	Data (see page 2423)	This is Data, a member of class TBaseButtonItem.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).
	InterfaceData (see page 2445)	Interface data for the button item.

Published Events

	Name	Description
	OnClick (see page 2423)	This is OnClick, a member of class TBaseButtonItem.

Published Properties

	Name	Description
	Action (see page 2422)	Specifies the action the button executes when clicked.
R	ButtonGroup (see page 2444)	The parent button group of the given button item.

	Caption (see page 2422)	This is Caption, a member of class TBaseButtonItem.
	Hint (see page 2423)	This is Hint, a member of class TBaseButtonItem.
	ImageIndex (see page 2423)	The index of a specified image.

19.1.5.2 TButtonItem Methods

The methods of the TButtonItem class are listed here.

Protected Methods

	Name	Description
	GetNotifyTarget (see page 2444)	This is GetNotifyTarget, a member of class TButtonItem.

Public Methods

	Name	Description
	Assign (see page 2443)	Copies the contents of another, similar object.
	ScrollIntoView (see page 2444)	Scrolls a button to make it visible within a button group.

19.1.5.2.1 TButtonItem.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent calls the source object's AssignTo method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

See Also

AssignTo (see page 2931)

EConvertError (see page 22724)

19.1.5.2.2 TButtonItem.GetNotifyTarget Method

Pascal

```
function GetNotifyTarget: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetNotifyTarget();
```

Description

This is GetNotifyTarget, a member of class TButtonItem.

19.1.5.2.3 TButtonItem.ScrollIntoView Method

Scrolls a button to make it visible within a button group.

Pascal

```
procedure ScrollIntoView; override;
```

C++

```
virtual __fastcall ScrollIntoView();
```

Description

Supply the following value for this method:

Parameter	Description
Index	An Integer representing the button you want scrolled into view.

19.1.5.3 TButtonItem Properties

The properties of the TButtonItem class are listed here.

Public Properties

	Name	Description
R	Category (see page 2445)	The parent category for the given button item.
	InterfaceData (see page 2445)	Interface data for the button item.

Published Properties

	Name	Description
R	ButtonGroup (see page 2444)	The parent button group of the given button item.

19.1.5.3.1 TButtonItem.ButtonGroup Property

The parent button group of the given button item.

Pascal

```
property ButtonGroup: TCategoryButtons;
```

C++

```
__property TCategoryButtons ButtonGroup;
```

19.1.5.3.2 TButtonItem.Category Property

The parent category for the given button item.

Pascal

```
property Category: TButtonCategory;
```

C++

```
__property TButtonCategory Category;
```

19.1.5.3.3 TButtonItem.InterfaceData Property

Interface data for the button item.

Pascal

```
property InterfaceData: IInterface;
```

C++

```
__property IInterface InterfaceData;
```

19.1.6 TButtonItemActionLink Class

TButtonItemActionLink is an action link designed specifically for controls using TButtonItem (see page 2441).

Class Hierarchy

Pascal

```
TButtonItemActionLink = class(TActionLink);
```

C++

```
class TButtonItemActionLink : public TActionLink;
```

File

CategoryButtons

19.1.6.1 TButtonItemActionLink Members

The following tables list the members exposed by TButtonItemActionLink.

Protected Fields

	Name	Description
	FAction (see page 2722)	This is FAction, a member of class TBasicActionLink.
	FClient (see page 2447)	This is FClient, a member of class TButtonItemActionLink.

Protected Methods

	Name	Description
	AssignClient (see page 2448)	This is AssignClient, a member of class TButtonItemActionLink.

	Change (see page 2723)	This is Change, a member of class TBasicActionLink.
	IsCaptionLinked (see page 2448)	Indicates whether the Caption properties for the action and client are linked.
	IsCheckedLinked (see page 269)	Indicates whether the Checked properties for the action and client are linked.
	IsEnabledLinked (see page 269)	Indicates whether the Enabled properties for the action and client are linked.
	IsGroupIndexLinked (see page 270)	Indicates whether the GroupIndex property for the action controls client behavior.
	IsHelpContextLinked (see page 270)	Indicates whether the HelpContext properties for the action and client controls are linked.
	IsHelpLinked (see page 271)	Indicates whether the help properties for the action and client are linked.
	IsHintLinked (see page 2449)	Indicates whether the Hint properties for the action and client are linked.
	IsImageIndexLinked (see page 2449)	Indicates whether the image index for the action and the client are linked.
	IsOnExecuteLinked (see page 2450)	This is IsOnExecuteLinked, a member of class TButtonItemActionLink.
	IsShortCutLinked (see page 272)	Indicates whether the ShortCut properties for the action and client are linked.
	IsVisibleLinked (see page 273)	Indicates whether the Visible properties for the action and client are linked.
	SetAction (see page 2724)	This is SetAction, a member of class TBasicActionLink.
	SetAutoCheck (see page 274)	Introduces an interface for setting the AutoCheck property of a client.
	SetCaption (see page 2450)	Introduces an interface for setting the caption on a client.
	SetChecked (see page 274)	Introduces an interface for setting the checked state of a client.
	SetEnabled (see page 275)	Introduces an interface for setting the enabled state of a client.
	SetGroupIndex (see page 275)	Introduces an interface for setting the GroupIndex property of a client.
	SetHelpContext (see page 276)	Introduces an interface for setting the help context of a client.
	SetHelpKeyword (see page 276)	Introduces an interface for setting the help keyword of a client.
	SetHelpType (see page 277)	Introduces an interface for setting the HelpType property of a client.
	SetHint (see page 2450)	Introduces an interface for setting the hint for a client.
	SetImageIndex (see page 2451)	Introduces an interface for setting the image index for a client.
	SetOnExecute (see page 2452)	This is SetOnExecute, a member of class TButtonItemActionLink.
	SetShortCut (see page 279)	Introduces an interface for setting the shortcut for a client.
	SetVisible (see page 279)	Introduces an interface for setting the visible state of a client.

Public Events

	Name	Description
	OnChange (see page 2725)	Occurs when an OnChange event is triggered on the action.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2721)	Instantiates and initializes a TBasicActionLink (see page 2720) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2722)	Destroys an instance of an action link object.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoShowHint (see page 2448)	This is DoShowHint, a member of class TButtonItemActionLink.
	Execute (see page 2723)	Invokes the action's Execute method.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Update (see page 2724)	Invokes the action's Update method.

Public Properties

	Name	Description
	Action (see page 2725)	Indicates which action the link connects to its client.

19.1.6.2 TButtonItemActionLink Fields

The fields of the TButtonItemActionLink class are listed here.

Protected Fields

	Name	Description
	FClient (see page 2447)	This is FClient, a member of class TButtonItemActionLink.

19.1.6.2.1 TButtonItemActionLink.FClient Field

Pascal

```
FClient: TBaseButtonItem;
```

C++

```
TBaseButtonItem FClient;
```

Description

This is FClient, a member of class TButtonItemActionLink.

19.1.6.3 TButtonItemActionLink Methods

The methods of the TButtonItemActionLink class are listed here.

Protected Methods

	Name	Description
	AssignClient (see page 2448)	This is AssignClient, a member of class TButtonItemActionLink.
	IsCaptionLinked (see page 2448)	Indicates whether the Caption properties for the action and client are linked.
	IsHintLinked (see page 2449)	Indicates whether the Hint properties for the action and client are linked.
	IsImageIndexLinked (see page 2449)	Indicates whether the image index for the action and the client are linked.
	IsOnExecuteLinked (see page 2450)	This is IsOnExecuteLinked, a member of class TButtonItemActionLink.
	SetCaption (see page 2450)	Introduces an interface for setting the caption on a client.
	SetHint (see page 2450)	Introduces an interface for setting the hint for a client.

	SetImageIndex (see page 2451)	Introduces an interface for setting the image index for a client.
	SetOnExecute (see page 2452)	This is SetOnExecute, a member of class TButtonItemActionLink.

Public Methods

	Name	Description
	DoShowHint (see page 2448)	This is DoShowHint, a member of class TButtonItemActionLink.

19.1.6.3.1 TButtonItemActionLink.AssignClient Method

Pascal

```
procedure AssignClient(AClient: TObject); override;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

This is AssignClient, a member of class TButtonItemActionLink.

19.1.6.3.2 TButtonItemActionLink.DoShowHint Method

Pascal

```
function DoShowHint(var HintStr: string): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoShowHint(AnsiString HintStr);
```

Description

This is DoShowHint, a member of class TButtonItemActionLink.

19.1.6.3.3 TButtonItemActionLink.IsCaptionLinked Method

Indicates whether the Caption properties for the action and client are linked.

Pascal

```
function IsCaptionLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCaptionLinked();
```

Description

TActionLink descendants call IsCaptionLinked to determine whether they need to propagate changes to the Caption property of the action so that they are reflected by the client object. When IsCaptionLinked returns true, the action controls the Caption property: Changes to the Caption property of the action are reflected by changes to the corresponding property of the client object. When IsCaptionLinked returns false, the client object does not reflect the Caption property of its action, either because it does not have a corresponding property, or, more commonly, because it manages the value of its corresponding property independently.

As implemented in TActionLink, IsCaptionLinked merely checks that the Action property specifies a descendant of TCustomAction (that is, it is an action that has a Caption property). Descendant classes override IsCaptionLinked to determine whether the Caption property is linked with the appropriate client property.

See Also

Caption (see page 308)

Caption (see page 5806)

SetCaption (see page 274)

Action (see page 2725)

19.1.6.3.4 TButtonItemActionLink.IsHintLinked Method

Indicates whether the Hint properties for the action and client are linked.

Pascal

```
function IsHintLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsHintLinked();
```

Description

TActionLink descendants call IsHintLinked to determine whether they need to propagate changes to the Hint property of the action so that they are reflected by the client object. When IsHintLinked returns true, the action controls the Hint property: Changes to the Hint property of the action are reflected by changes to the corresponding property of the client object. When IsHintLinked returns false, the client object does not reflect the Hint property of its action, either because it does not have a corresponding property, or, more commonly, because it manages the value of its corresponding property independently.

As implemented in TActionLink, IsHintLinked merely checks that the Action property specifies a descendant of TCustomAction (that is, it is an action that has a Hint property). Descendant classes override IsHintLinked to determine whether the Hint property is linked with the appropriate client property.

See Also

Hint (see page 312)

Hint (see page 5827)

Hint (see page 16148)

SetHint (see page 278)

Action (see page 2725)

19.1.6.3.5 TButtonItemActionLink.IsImageIndexLinked Method

Indicates whether the image index for the action and the client are linked.

Pascal

```
function IsImageIndexLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsImageIndexLinked();
```

Description

TActionLink descendants call IsImageIndexLinked to determine whether they need to propagate changes to the ImageIndex property of the action so that they are reflected by the client object. When IsImageIndexLinked returns true, the action controls the ImageIndex property: Changes to the ImageIndex property of the action are reflected by changes to the corresponding property of the client object. When IsImageIndexLinked returns false, the client object does not reflect the ImageIndex property of its action, either because it does not have a corresponding property, or, more commonly, because it manages the value of its corresponding property independently.

As implemented in TActionLink, IsImageIndexLinked merely checks that the Action property specifies a descendant of

TCustomAction (that is, it is an action that has an ImageIndex property). Descendant classes override IsImageIndexLinked to determine whether the ImageIndex property is linked with the appropriate client property.

See Also

ImageIndex (see page 313)

ImageIndex (see page 16148)

SetImageIndex (see page 278)

Action (see page 2725)

19.1.6.3.6 TButtonItemActionLink.IsOnExecuteLinked Method

Pascal

```
function IsOnExecuteLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsOnExecuteLinked();
```

Description

This is IsOnExecuteLinked, a member of class TButtonItemActionLink.

19.1.6.3.7 TButtonItemActionLink.SetCaption Method

Introduces an interface for setting the caption on a client.

Pascal

```
procedure SetCaption(const Value: string); override;
```

C++

```
virtual __fastcall SetCaption(const AnsiString Value);
```

Description

The associated action calls SetCaption when its Caption property changes so that the action link can propagate the new Caption value to the client object.

Value specifies the string to which the caption should be set.

As implemented in TActionLink, SetCaption does nothing. Descendant classes override SetCaption to set the client property that corresponds to the action's Caption property if the IsCaptionLinked method returns true.

See Also

Caption (see page 308)

Caption (see page 5806)

IsCaptionLinked (see page 268)

Action (see page 2725)

19.1.6.3.8 TButtonItemActionLink.SetHint Method

Introduces an interface for setting the hint for a client.

Pascal

```
procedure SetHint(const Value: string); override;
```

C++

```
virtual __fastcall SetHint(const AnsiString Value);
```

Description

The associated action calls SetHint when its Hint property changes so that the action link can propagate the new Hint value to the client object.

Value specifies the new value of the Hint property.

As implemented in TActionLink, SetHint does nothing. Descendant classes override SetHint to set the client property that corresponds to the action's Hint property if the IsHintLinked method returns true.

See Also

Hint (see page 312)

Hint (see page 5827)

Hint (see page 16148)

Action (see page 2725)

IsHintLinked (see page 271)

19.1.6.3.9 TButtonItemActionLink.SetImageIndex Method

Introduces an interface for setting the image index for a client.

Pascal

```
procedure SetImageIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetImageIndex(int Value);
```

Description

The associated action calls SetImageIndex when its ImageIndex property changes so that the action link can propagate the new ImageIndex value to the client object.

Value specifies the new value of the ImageIndex property.

As implemented in TActionLink, SetImageIndex does nothing. Descendant classes override SetImageIndex to set the client property that corresponds to the action's ImageIndex property if the IsImageIndexLinked method returns true.

See Also

ImageIndex (see page 313)

ImageIndex (see page 16148)

Action (see page 2725)

IsImageIndexLinked (see page 272)

19.1.6.3.10 TButtonItemActionLink.SetOnExecute Method

Pascal

```
procedure SetOnExecute(Value: TNotifyEvent); override;
```

C++

```
virtual __fastcall SetOnExecute(TNotifyEvent Value);
```

Description

This is SetOnExecute, a member of class TButtonItemActionLink.

19.1.7 TCategoryButtons Class

Defines a group of categorized buttons.

Class Hierarchy

Pascal

```
TCategoryButtons = class(TCustomControl);
```

C++

```
class TCategoryButtons : public TCustomControl;
```

File

CategoryButtons

Description

TCategoryButtons is used for creating groups of buttons that can be categorized, as on a tool palette. It provides more flexibility than a tool bar.

The TCategoryButtons object can contain TButtonCategory (see page 2429) objects, each representing a set of buttons in the same category. Each TButtonCategory (see page 2429) object can contain TButtonItem (see page 2441) objects. The TButtonCategory (see page 2429) and TButtonItem (see page 2441) objects can be dynamically reordered. For instance, a button may be dragged or copied from one category to another. Categories (see page 2486) can be expanded to show all buttons or collapsed to hide them.

See Also

TButtonCategory (see page 2429)

TButtonItem (see page 2441)

19.1.7.1 TCategoryButtons Members

The following tables list the members exposed by TCategoryButtons.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	BeginAutoDrag (see page 2466)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.

	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	CMFontchanged (see page 2466)	This is CMFontchanged, a member of class TCategoryButtons.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 2466)	Creates underlying screen object.
	CreateParams (see page 2467)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DoBeginDrag (see page 2467)	This is DoBeginDrag, a member of class TCategoryButtons.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCopyButton (see page 2468)	This is DoCopyButton, a member of class TCategoryButtons.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 2468)	OnEndDrag event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoHotButton (see page 2468)	This is DoHotButton, a member of class TCategoryButtons.
	DoItemClicked (see page 2469)	This is DoItemClicked, a member of class TCategoryButtons.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 2469)	OnMouseWheelDown event dispatcher.
	DoMouseWheelUp (see page 2469)	OnMouseWheelUp event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoReorderButton (see page 2470)	This is DoReorderButton, a member of class TCategoryButtons.
	DoReorderCategory (see page 2470)	This is DoReorderCategory, a member of class TCategoryButtons.

	DoSelectedItemChanged (see page 2470)	This is DoSelectedItemChanged, a member of class TCategoryButtons.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
V	DoStartDrag (see page 2470)	OnStartDrag event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
V	DragOver (see page 2471)	OnDragOver event dispatcher.
V	DrawButton (see page 2472)	This is DrawButton, a member of class TCategoryButtons.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetAllowReorder (see page 2472)	This is GetAllowReorder, a member of class TCategoryButtons.
V	GetButtonCategoriesClass (see page 2473)	This is GetButtonCategoriesClass, a member of class TCategoryButtons.
V	GetButtonCategoryClass (see page 2473)	This is GetButtonCategoryClass, a member of class TCategoryButtons.
V	GetButtonItemClass (see page 2473)	This is GetButtonItemClass, a member of class TCategoryButtons.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 2474)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetScrollPos (see page 2474)	This is GetScrollPos, a member of class TCategoryButtons.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.

	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 2475)	OnMouseDown event dispatcher.
V	MouseMove (see page 2475)	Respond to mouse moving over control area..
V	MouseUp (see page 2476)	OnMouseUp event dispatcher.
V	Notification (see page 2476)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 2477)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
V	Resize (see page 2477)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollRectIntoView (see page 2478)	This is ScrollRectIntoView, a member of class TCategoryButtons.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.

	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetScrollPos (see page 2478)	This is SetScrollPos, a member of class TCategoryButtons.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.

	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2465)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 2464)	Creates instance of TCategoryButtons (see page 2452).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2464)	Destroys instance of TCategoryButtons (see page 2452).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
V	DragDrop (see page 2471)	Handles user dragging button.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GenerateDragImage (see page 2472)	Allows drag images to be generated from outside the control.
	GetButtonAt (see page 2472)	Retrieves button at specified position.
	GetButtonRect (see page 2473)	Retrieves specified button's bounding rectangle.
	GetCategoryAt (see page 2473)	Retrieves category at specified position.
	GetCategoryRect (see page 2474)	Retrieves specified button's bounding rectangle.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTargetAt (see page 2474)	Gives you the target insertion point in the given group. TargetButton may be nil while the TargetCategory is not, or both may be nil.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	RemoveInsertionPoints (see page 2477)	Removes insertion points in the container.
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollIntoView (see page 2478)	This is the overview for the ScrollIntoView method overload.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetInsertionButton (see page 2478)	Sets the current insertion mark.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateAllButtons (see page 2479)	Repaints or refreshes all buttons.
	UpdateButton (see page 2479)	Repaints or refreshes the button.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.

	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragButton (see page 2490)	Button being dragged.
	DragCategory (see page 2490)	Category being dragged.
R	DragImageList (see page 2491)	List of images used during drag or dock operations.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	FocusedItem (see page 2494)	Specifies the button that currently has focus.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.

	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelectedItem (see page 2502)	Returns the selected button.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAfterDrawButton (see page 2508)	Fired after a button is drawn
	OnAlignInsertBefore (see page 2508)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2508)	Occurs when an object with custom alignment is aligned.
	OnBeforeDrawButton (see page 2509)	Fired before a button is drawn
	OnButtonClicked (see page 2509)	Fired when a button is clicked, if OnClick (see page 2510) event is not present
	OnCategoryCollapase (see page 2509)	Fired when a category is collapsed
	OnClick (see page 2510)	Occurs when mouse button goes up.
	OnContextPopup (see page 2510)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCopyButton (see page 2511)	Fired when a button is copied
	OnDockDrop (see page 2511)	Occurs when another control is docked to the control.
	OnDockOver (see page 2513)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 2515)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2517)	Occurs when the user drags an object over a control.
	OnDrawButton (see page 2519)	Fired when a button needs to be redrawn; it prevents default drawing.
	OnDrawIcon (see page 2520)	Fired when an icon needs to be redrawn; it prevents default drawing.
	OnDrawText (see page 2520)	Fired when a caption needs to be redrawn; it prevents default drawing.
	OnEndDock (see page 2520)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2520)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2521)	Occurs when a control receives the input focus.
	OnExit (see page 2524)	Occurs when the input focus shifts away from one control to another.
	OnGetHint (see page 2525)	Fired when a hint string is being retrieved
	OnHotButton (see page 2526)	Fired when the "hot" button changes
	OnKeyDown (see page 2526)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2529)	Occurs when a key is pressed.
	OnKeyUp (see page 2530)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2531)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2532)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2535)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2535)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2535)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2537)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 2540)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 2540)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 2540)	Occurs when the mouse wheel is rotated upward.
	OnReorderButton (see page 2541)	Fired when buttons are reordered
	OnReorderCategory (see page 2541)	Fired when categories are reordered
	OnSelectedItemChange (see page 2541)	Fired when the selected item changes

	OnStartDock (see page 2541)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2542)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2480)	Determines how control aligns within its parent control.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 2480)	Specifies how the control is anchored to its parent.
	BackgroundGradientColor (see page 2481)	Specifies the color for a gradient fill in the background of a category.
	BackgroundGradientDirection (see page 2481)	Direction of background gradient fill.
	BevelEdges (see page 2481)	Specifies which edges of the control are beveled.
	BevelInner (see page 2482)	Determines the style of the inner bevel of a control.
	BevelKind (see page 2482)	Specifies the control's bevel style.
	BevelOuter (see page 2483)	Determines the style of the outer bevel of a control.
	BevelWidth (see page 2483)	Width (see page 2506) of outer and inner bevels.
	BorderStyle (see page 2484)	Determines whether control has single line border or none.
	BorderWidth (see page 2484)	Width (see page 2506) of border.
	ButtonFlow (see page 2484)	Specifies the direction of buttons in a category.
	ButtonHeight (see page 2485)	Height (see page 2496) of buttons in a category.
	ButtonOptions (see page 2485)	Specifies options for button display and behavior.
	ButtonWidth (see page 2486)	Width (see page 2506) of buttons in a category.
	Categories (see page 2486)	Specifies the categories represented in the category buttons object.
	Color (see page 2486)	Category buttons background color
	Cursor (see page 2486)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DockSite (see page 2489)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 2491)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2492)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2492)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2494)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2494)	Controls the attributes of text written on or in the control.
	GradientDirection (see page 2495)	Specifies the direction of gradient fill for the category object.
	Height (see page 2496)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HotButtonColor (see page 2497)	Specifies the color of a hot button, if necessary.
	Images (see page 2497)	List of button images.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PopupMenu (see page 2497)	Identifies the pop-up menu associated with the control.
	RegularButtonColor (see page 2502)	Specifies the color of a button in the normal, unselected state.
	SelectedButtonColor (see page 2502)	Specifies the color of the button when a user selects it.
	ShowHint (see page 2502)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2504)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2504)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

	Visible (see page 2505)	Determines whether the component appears onscreen.
	Width (see page 2506)	Specifies the horizontal size of the control or form in pixels.

19.1.7.2 TCategoryButtons.Create Constructor

Creates instance of TCategoryButtons (see page 2452).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCategoryButtons(TComponent * AOwner);
```

Description

This method creates an instance of TCategoryButtons (see page 2452). Create sets default values for a variety of attributes, including width, height, control style, button options, and colors.

See Also

Destroy (see page 2464)

19.1.7.3 TCategoryButtons.Destroy Destructor

Destroys instance of TCategoryButtons (see page 2452).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCategoryButtons();
```

Description

This method destroys an instance of TCategoryButtons (see page 2452), freeing all it resources.

See Also

Create (see page 2464)

19.1.7.4 TCategoryButtons Methods

The methods of the TCategoryButtons class are listed here.

Protected Methods

	Name	Description
	BeginAutoDrag (see page 2466)	Begin Automatic Drag.
	CMFontchanged (see page 2466)	This is CMFontchanged, a member of class TCategoryButtons.
	CreateHandle (see page 2466)	Creates underlying screen object.
	CreateParams (see page 2467)	Initializes a window-creation parameter data structure.
	DoBeginDrag (see page 2467)	This is DoBeginDrag, a member of class TCategoryButtons.
	DoCopyButton (see page 2468)	This is DoCopyButton, a member of class TCategoryButtons.
	DoEndDrag (see page 2468)	OnEndDrag event dispatcher.
	DoHotButton (see page 2468)	This is DoHotButton, a member of class TCategoryButtons.
	DoItemClicked (see page 2469)	This is DoItemClicked, a member of class TCategoryButtons.

	DoMouseWheelDown (see page 2469)	OnMouseWheelDown event dispatcher.
	DoMouseWheelUp (see page 2469)	OnMouseWheelUp event dispatcher.
	DoReorderButton (see page 2470)	This is DoReorderButton, a member of class TCategoryButtons.
	DoReorderCategory (see page 2470)	This is DoReorderCategory, a member of class TCategoryButtons.
	DoSelectedItemChanged (see page 2470)	This is DoSelectedItemChanged, a member of class TCategoryButtons.
	DoStartDrag (see page 2470)	OnStartDrag event dispatcher.
	DragOver (see page 2471)	OnDragOver event dispatcher.
	DrawButton (see page 2472)	This is DrawButton, a member of class TCategoryButtons.
	GetAllowReorder (see page 2472)	This is GetAllowReorder, a member of class TCategoryButtons.
	GetButtonCategoriesClass (see page 2473)	This is GetButtonCategoriesClass, a member of class TCategoryButtons.
	GetButtonCategoryClass (see page 2473)	This is GetButtonCategoryClass, a member of class TCategoryButtons.
	GetButtonItemClass (see page 2473)	This is GetButtonItemClass, a member of class TCategoryButtons.
	GetDragImages (see page 2474)	Returns the control's image list containing the image to be displayed while dragging.
	GetScrollPos (see page 2474)	This is GetScrollPos, a member of class TCategoryButtons.
	MouseDown (see page 2475)	OnMouseDown event dispatcher.
	MouseMove (see page 2475)	Respond to mouse moving over control area..
	MouseUp (see page 2476)	OnMouseUp event dispatcher.
	Notification (see page 2476)	Responds to notifications that components are being created or destroyed.
	Paint (see page 2477)	Renders the image of a custom control.
	Resize (see page 2477)	Respond to control resize.
	ScrollRectIntoView (see page 2478)	This is ScrollRectIntoView, a member of class TCategoryButtons.
	SetScrollPos (see page 2478)	This is SetScrollPos, a member of class TCategoryButtons.

Public Methods

	Name	Description
	Assign (see page 2465)	Copies the contents of another, similar object.
	DragDrop (see page 2471)	Handles user dragging button.
	GenerateDragImage (see page 2472)	Allows drag images to be generated from outside the control.
	GetButtonAt (see page 2472)	Retrieves button at specified position.
	GetButtonRect (see page 2473)	Retrieves specified button's bounding rectangle.
	GetCategoryAt (see page 2473)	Retrieves category at specified position.
	GetCategoryRect (see page 2474)	Retrieves specified button's bounding rectangle.
	GetTargetAt (see page 2474)	Gives you the target insertion point in the given group. TargetButton may be nil while the TargetCategory is not, or both may be nil.
	RemoveInsertionPoints (see page 2477)	Removes insertion points in the container.
	ScrollIntoView (see page 2478)	This is the overview for the ScrollIntoView method overload.
	SetInsertionButton (see page 2478)	Sets the current insertion mark.
	UpdateAllButtons (see page 2479)	Repaints or refreshes all buttons.
	UpdateButton (see page 2479)	Repaints or refreshes the button.

19.1.7.4.1 TCategoryButtons.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. In particular, copy the Categories (see page 2486), ButtonHeight (see page 2485), ButtonWidth (see page 2486), ButtonOptions (see page 2485) properties.

See Also

ButtonHeight (see page 2485)

ButtonOptions (see page 2485)

ButtonWidth (see page 2486)

Categories (see page 2486)

Assign (see page 2930)

19.1.7.4.2 TCategoryButtons.BeginAutoDrag Method

Begin Automatic Drag.

Pascal

```
procedure BeginAutoDrag; override;
```

C++

```
virtual __fastcall BeginAutoDrag();
```

Description

BeginAutoDrag is called automatically when a user drags a control whose DragMode is dmAutomatic. Do not call BeginAutoDrag in application code.

As implemented in TControl, BeginAutoDrag calls BeginDrag, passing in the global Mouse variable's DragImmediate and DragThreshold properties.

See Also

DragKind (see page 5819)

DragMode (see page 5819)

EndDrag (see page 5757)

Mouse (see page 6321)

DragImmediate (see page 6100)

DragThreshold (see page 6101)

Mouse (see page 6321)

19.1.7.4.3 TCategoryButtons.CMFontchanged Method

Pascal

```
procedure CMFontchanged(var Message: TMessage); message CM_FONTCHANGED;
```

C++

```
__fastcall CMFontchanged(TMessage Message);
```

Description

This is CMFontchanged, a member of class TCategoryButtons.

19.1.7.4.4 TCategoryButtons.CreateHandle Method

Creates underlying screen object.

Pascal

```
procedure CreateHandle; override;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

CreateHandle creates the Microsoft Windows screen object that underlies the control. if it does not already exist. The new window handle becomes the value of the Handle property.

CreateHandle creates or locates the parent control's window before it creates a window for the control itself.

Note: If the Parent property is nil (Delphi) or NULL (C++), CreateHandle raises an exception.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

Handle (see page 6207)

Parent (see page 5832)

19.1.7.4.5 TCategoryButtons.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

19.1.7.4.6 TCategoryButtons.DoBeginDrag Method

Pascal

```
procedure DoBeginDrag(Immediate: Boolean; Threshold: Integer); virtual;
```

C++

```
virtual __fastcall DoBeginDrag(Boolean Immediate, int Threshold);
```

Description

This is DoBeginDrag, a member of class TCategoryButtons.

19.1.7.4.7 TCategoryButtons.DoCopyButton Method

Pascal

```
procedure DoCopyButton(const Button: TButtonItem; const TargetCategory: TButtonCategory; const
TargetButton: TButtonItem); dynamic;
```

C++

```
__fastcall DoCopyButton(const TButtonItem Button, const TButtonCategory TargetCategory, const
TButtonItem TargetButton);
```

Description

This is DoCopyButton, a member of class TCategoryButtons.

19.1.7.4.8 TCategoryButtons.DoEndDrag Method

OnEndDrag event dispatcher.

Pascal

```
procedure DoEndDrag(Target: TObject; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall DoEndDrag(TObject * Target, int X, int Y);
```

Description

DoEndDrag calls any event handler attached to the OnEndDrag event. When creating a component that descends from TControl, override DoEndDrag to provide other responses in addition to the inherited event-handler call when the user drops an object or cancels a drag-and-drop operation.

See Also

DoStartDrag (see page 5753)

OnEndDrag (see page 5860)

19.1.7.4.9 TCategoryButtons.DoHotButton Method

Pascal

```
procedure DoHotButton; dynamic;
```

C++

```
__fastcall DoHotButton();
```

Description

This is DoHotButton, a member of class TCategoryButtons.

19.1.7.4.10 TCategoryButtons.DoItemClicked Method

Pascal

```
procedure DoItemClicked(const Button: TButtonItem); dynamic;
```

C++

```
__fastcall DoItemClicked(const TButtonItem Button);
```

Description

This is DoItemClicked, a member of class TCategoryButtons.

19.1.7.4.11 TCategoryButtons.DoMouseWheelDown Method

OnMouseWheelDown event dispatcher.

Pascal

```
function DoMouseWheelDown(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelDown(TShiftState Shift, TPoint MousePos);
```

Description

The DoMouseWheel method calls DoMouseWheelDown to generate an OnMouseWheelDown event.

The Shift parameter indicates the state of the Shift, Alt, and Ctrl keys.

The MousePos parameter indicates the position of the mouse pointer.

DoMouseWheelDown returns true if an event handler indicates that it handled the message, and false otherwise.

Override DoMouseWheelDown to perform class-specific tasks in addition to calling the event handler when the mouse wheel is rotated downward.

See Also

OnMouseWheelDown (see page 5869)

DoMouseWheel (see page 5751)

19.1.7.4.12 TCategoryButtons.DoMouseWheelUp Method

OnMouseWheelUp event dispatcher.

Pascal

```
function DoMouseWheelUp(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelUp(TShiftState Shift, TPoint MousePos);
```

Description

The DoMouseWheel method calls DoMouseWheelUp to generate an OnMouseWheelUp event.

The Shift parameter indicates the state of the Shift, Alt, and Ctrl keys.

The MousePos parameter indicates the position of the mouse pointer.

DoMouseWheelUp returns true if an event handler indicates that it handled the message, and false otherwise.

Override DoMouseWheelUp to perform class-specific tasks in addition to calling the event handler when the mouse wheel is rotated upward.

See Also

OnMouseWheelUp (see page 5870)

DoMouseWheel (see page 5751)

19.1.7.4.13 TCategoryButtons.DoReorderButton Method

Pascal

```
procedure DoReorderButton(const Button: TButtonItem; const TargetCategory: TButtonCategory;
const TargetButton: TButtonItem); dynamic;
```

C++

```
__fastcall DoReorderButton(const TButtonItem Button, const TButtonCategory TargetCategory,
const TButtonItem TargetButton);
```

Description

This is DoReorderButton, a member of class TCategoryButtons.

19.1.7.4.14 TCategoryButtons.DoReorderCategory Method

Pascal

```
procedure DoReorderCategory(const SourceCategory: TButtonCategory; const TargetCategory:
TButtonCategory); dynamic;
```

C++

```
__fastcall DoReorderCategory(const TButtonCategory SourceCategory, const TButtonCategory
TargetCategory);
```

Description

This is DoReorderCategory, a member of class TCategoryButtons.

19.1.7.4.15 TCategoryButtons.DoSelectedItemChanged Method

Pascal

```
procedure DoSelectedItemChanged(const Button: TButtonItem); dynamic;
```

C++

```
__fastcall DoSelectedItemChanged(const TButtonItem Button);
```

Description

This is DoSelectedItemChanged, a member of class TCategoryButtons.

19.1.7.4.16 TCategoryButtons.DoStartDrag Method

OnStartDrag event dispatcher.

Pascal

```
procedure DoStartDrag(var DragObject: TDragObject); override;
```

C++

```
virtual __fastcall DoStartDrag(TDragObject DragObject);
```

Description

DoStartDrag calls any event handler attached to the OnStartDrag event. When creating a component that descends from TControl, override DoStartDrag to provide other responses in addition to the inherited event-handler call when the user starts a drag-and-drop operation.

See Also

DoEndDrag (see page 5751)

OnStartDrag (see page 5871)

19.1.7.4.17 TCategoryButtons.DragDrop Method

Handles user dragging button.

Pascal

```
procedure DragDrop(Source: TObject; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall DragDrop(TObject * Source, int X, int Y);
```

Description

The **Source** parameter is the object that was dropped onto the button group. The **X** and Y parameters are the mouse coordinates where the object was dropped.

This method handles reordering TButtonCategory (see page 2429) and TButtonItem (see page 2441) objects in a TCategoryButtons (see page 2452) object in response to user drag drop operations. Users can drag TButtonCategory (see page 2429) objects to reorder them. They can also drag TCategoryButtons (see page 2452) objects to reorder them or move them to another category. Pressing `Ctrl` while dragging copies the button. This method calls RemoveInsertionPoints (see page 2477) to remove insertion points.

See Also

TButtonCategory (see page 2429)

TButtonItem (see page 2441)

RemoveInsertionPoints (see page 2477)

19.1.7.4.18 TCategoryButtons.DragOver Method

OnDragOver event dispatcher.

Pascal

```
procedure DragOver(Source: TObject; X: Integer; Y: Integer; State: TDragState; var Accept:
Boolean); override;
```

C++

```
virtual __fastcall DragOver(TObject * Source, int X, int Y, TDragState State, Boolean Accept);
```

Description

Override DragOver to add additional code that executes before the OnDragOver event handler is called.

DragOver sets the Accept parameter to true to indicate that the user can drop the dragged object on the control. It sets Accept to

false to indicate that the user cannot drop the dragged object on the control.

The Source parameter is the object being dragged. The State parameter indicates how the dragged object is moving in relation to the control. X and Y indicate the current position of the mouse.

See Also

DragDrop (see page 5754)

OnDragOver (see page 5857)

19.1.7.4.19 TCategoryButtons.DrawButton Method

Pascal

```
procedure DrawButton(const Button: TButtonItem; Canvas: TCanvas; Rect: TRect; State:
TButtonDrawState); virtual;
```

C++

```
virtual __fastcall DrawButton(const TButtonItem Button, TCanvas Canvas, TRect Rect,
TButtonDrawState State);
```

Description

This is DrawButton, a member of class TCategoryButtons.

19.1.7.4.20 TCategoryButtons.GenerateDragImage Method

Allows drag images to be generated from outside the control.

Pascal

```
procedure GenerateDragImage;
```

C++

```
__fastcall GenerateDragImage();
```

Description

Use the GenerateDragImage method to allow drag images to be generated from outside the control.

19.1.7.4.21 TCategoryButtons.GetAllowReorder Method

Pascal

```
function GetAllowReorder: Boolean; dynamic;
```

C++

```
__fastcall Boolean GetAllowReorder();
```

Description

This is GetAllowReorder, a member of class TCategoryButtons.

19.1.7.4.22 TCategoryButtons.GetButtonAt Method

Retrieves button at specified position.

Pascal

```
function GetButtonAt(X: Integer; Y: Integer; Category: TButtonCategory = nil): TButtonItem;
```

C++

```
__fastcall TButtonItem GetButtonAt(int X, int Y, TButtonCategory Category = nil);
```

19.1.7.4.23 TCategoryButtons.GetButtonCategoriesClass Method

Pascal

```
function GetButtonCategoriesClass: TButtonCategoriesClass; virtual;
```

C++

```
virtual __fastcall TButtonCategoriesClass GetButtonCategoriesClass();
```

Description

This is GetButtonCategoriesClass, a member of class TCategoryButtons.

19.1.7.4.24 TCategoryButtons.GetButtonCategoryClass Method

Pascal

```
function GetButtonCategoryClass: TButtonCategoryClass; virtual;
```

C++

```
virtual __fastcall TButtonCategoryClass GetButtonCategoryClass();
```

Description

This is GetButtonCategoryClass, a member of class TCategoryButtons.

19.1.7.4.25 TCategoryButtons.GetButtonItemClass Method

Pascal

```
function GetButtonItemClass: TButtonItemClass; virtual;
```

C++

```
virtual __fastcall TButtonItemClass GetButtonItemClass();
```

Description

This is GetButtonItemClass, a member of class TCategoryButtons.

19.1.7.4.26 TCategoryButtons.GetButtonRect Method

Retrieves specified button's bounding rectangle.

Pascal

```
function GetButtonRect(const Button: TButtonItem): TRect;
```

C++

```
__fastcall TRect GetButtonRect(const TButtonItem Button);
```

19.1.7.4.27 TCategoryButtons.GetCategoryAt Method

Retrieves category at specified position.

Pascal

```
function GetCategoryAt(X: Integer; Y: Integer): TButtonCategory;
```

C++

```
__fastcall TButtonCategory GetCategoryAt(int X, int Y);
```

19.1.7.4.28 TCategoryButtons.GetCategoryRect Method

Retrieves specified button's bounding rectangle.

Pascal

```
function GetCategoryRect(const Category: TButtonCategory): TRect;
```

C++

```
__fastcall TRect GetCategoryRect(const TButtonCategory Category);
```

19.1.7.4.29 TCategoryButtons.GetDragImages Method

Returns the control's image list containing the image to be displayed while dragging.

Pascal

```
function GetDragImages: TDragImageList; override;
```

C++

```
virtual __fastcall TDragImageList GetDragImages();
```

Description

Override GetDragImages to provide a custom image list for the control. As implemented in TControl, GetDragImages returns nil (Delphi) or NULL (C++).

See Also

DragCursor (see page 5818)

OnStartDrag (see page 5871)

19.1.7.4.30 TCategoryButtons.GetScrollPos Method

Pascal

```
function GetScrollPos: Integer;
```

C++

```
__fastcall int GetScrollPos();
```

Description

This is GetScrollPos, a member of class TCategoryButtons.

19.1.7.4.31 TCategoryButtons.GetTargetAt Method

Gives you the target insertion point in the given group. TargetButton may be nil while the TargetCategory is not, or both may be nil.

Pascal

```
procedure GetTargetAt(X: Integer; Y: Integer; var TargetButton: TButtonItem; var
TargetCategory: TButtonCategory);
```

C++

```
__fastcall GetTargetAt(int X, int Y, TButtonItem TargetButton, TButtonCategory TargetCategory);
```

19.1.7.4.32 TCategoryButtons.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

See Also

MouseMove (see page 5773)

MouseUp (see page 5774)

OnMouseDown (see page 5862)

19.1.7.4.33 TCategoryButtons.MouseMove Method

Respond to mouse moving over control area..

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseMove method to provide other responses in addition to calling the OnMouseMove event handler when the user moves the mouse.

A control calls MouseMove in response to any of the Windows mouse-move messages (WM_MOUSEMOVE), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively.

As the mouse cursor moves across a control, this method is called repeatedly. Each time it is called, it is with the new coordinates that reflect the continuous path of the mouse cursor across the screen real estate covered by the control's visual representation.

See Also

MouseDown (see page 5773)

MouseUp (see page 5774)

OnMouseMove (see page 5865)

19.1.7.4.34 TCategoryButtons.MouseUp Method

OnMouseUp event dispatcher.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user releases a previously pressed mouse button while the cursor's hotspot is over the control.

A control calls MouseUp in response to any of the Windows mouse-up messages (WM_LBUTTONUP, WM_MBUTTONUP, WM_RBUTTONUP), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was released: left, right, or middle

See Also

MouseDown (see page 5773)

MouseMove (see page 5773)

OnMouseUp (see page 5867)

19.1.7.4.35 TCategoryButtons.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

19.1.7.4.36 TCategoryButtons.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

See Also

Canvas (see page 5921)

PaintWindow (see page 5920)

GetDeviceContext (see page 6155)

ClipRect (see page 14486)

19.1.7.4.37 TCategoryButtons.RemoveInsertionPoints Method

Removes insertion points in the container.

Pascal

```
procedure RemoveInsertionPoints;
```

C++

```
__fastcall RemoveInsertionPoints();
```

19.1.7.4.38 TCategoryButtons.Resize Method

Respond to control resize.

Pascal

```
procedure Resize; override;
```

C++

```
virtual __fastcall Resize();
```

Description

Resize is called automatically immediately after the control's dimensions change. As implemented in TControl, Resize calls the control's OnResize event handler if it is assigned.

See Also

OnResize (see page 5870)

19.1.7.4.39 ScrollIntoView Method

This is the overview for the ScrollIntoView method overload.

Overload List

	Name	Description
	TCategoryButtons.ScrollIntoView (TButtonCategory) (see page 2478)	Scrolls a button to make it visible in the container.
	TCategoryButtons.ScrollIntoView (TButtonItem) (see page 2478)	Scrolls a button to make it visible in the container.

19.1.7.4.39.1 TCategoryButtons.ScrollIntoView Method (TButtonCategory)

Scrolls a button to make it visible in the container.

Pascal

```
procedure ScrollIntoView(const Button: TButtonItem); overload;
procedure ScrollIntoView(const Category: TButtonCategory); overload;
```

C++

```
__fastcall ScrollIntoView(const TButtonItem Button);
__fastcall ScrollIntoView(const TButtonCategory Category);
```

19.1.7.4.40 TCategoryButtons.ScrollRectIntoView Method

Pascal

```
procedure ScrollRectIntoView(const Rect: TRect);
```

C++

```
__fastcall ScrollRectIntoView(const TRect Rect);
```

Description

This is ScrollRectIntoView, a member of class TCategoryButtons.

19.1.7.4.41 TCategoryButtons.SetInsertionButton Method

Sets the current insertion mark.

Pascal

```
procedure SetInsertionButton(InsertionButton: TButtonItem; InsertionCategory: TButtonCategory);
```

C++

```
__fastcall SetInsertionButton(TButtonItem InsertionButton, TButtonCategory InsertionCategory);
```

19.1.7.4.42 TCategoryButtons.SetScrollPos Method

Pascal

```
procedure SetScrollPos(const Value: Integer);
```

C++

```
__fastcall SetScrollPos(const int Value);
```

Description

This is SetScrollPos, a member of class TCategoryButtons.

19.1.7.4.43 TCategoryButtons.UpdateAllButtons Method

Repaints or refreshes all buttons.

Pascal

```
procedure UpdateAllButtons;
```

C++

```
__fastcall UpdateAllButtons();
```

19.1.7.4.44 TCategoryButtons.UpdateButton Method

Repaints or refreshes the button.

Pascal

```
procedure UpdateButton(const Button: TButtonItem);
```

C++

```
__fastcall UpdateButton(const TButtonItem Button);
```

19.1.7.5 TCategoryButtons Properties

The properties of the TCategoryButtons class are listed here.

Public Properties

	Name	Description
	DragButton (see page 2490)	Button being dragged.
	DragCategory (see page 2490)	Category being dragged.
R	DragImageList (see page 2491)	List of images used during drag or dock operations.
	FocusedItem (see page 2494)	Specifies the button that currently has focus.
	SelectedItem (see page 2502)	Returns the selected button.

Published Properties

	Name	Description
	Align (see page 2480)	Determines how control aligns within its parent control.
	Anchors (see page 2480)	Specifies how the control is anchored to its parent.
	BackgroundGradientColor (see page 2481)	Specifies the color for a gradient fill in the background of a category.
	BackgroundGradientDirection (see page 2481)	Direction of background gradient fill.
	BevelEdges (see page 2481)	Specifies which edges of the control are beveled.
	BevelInner (see page 2482)	Determines the style of the inner bevel of a control.
	BevelKind (see page 2482)	Specifies the control's bevel style.
	BevelOuter (see page 2483)	Determines the style of the outer bevel of a control.
	BevelWidth (see page 2483)	Width (see page 2506) of outer and inner bevels.
	BorderStyle (see page 2484)	Determines whether control has single line border or none.
	BorderWidth (see page 2484)	Width (see page 2506) of border.
	ButtonFlow (see page 2484)	Specifies the direction of buttons in a category.
	ButtonHeight (see page 2485)	Height (see page 2496) of buttons in a category.
	ButtonOptions (see page 2485)	Specifies options for button display and behavior.
	ButtonWidth (see page 2486)	Width (see page 2506) of buttons in a category.
	Categories (see page 2486)	Specifies the categories represented in the category buttons object.

	Color (see page 2486)	Category buttons background color
	Cursor (see page 2486)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DockSite (see page 2489)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 2491)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2492)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2492)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2494)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 2494)	Controls the attributes of text written on or in the control.
	GradientDirection (see page 2495)	Specifies the direction of gradient fill for the category object.
	Height (see page 2496)	Specifies the vertical size of the control in pixels.
	HotButtonColor (see page 2497)	Specifies the color of a hot button, if necessary.
	Images (see page 2497)	List of button images.
	PopupMenu (see page 2497)	Identifies the pop-up menu associated with the control.
	RegularButtonColor (see page 2502)	Specifies the color of a button in the normal, unselected state.
	SelectedButtonColor (see page 2502)	Specifies the color of the button when a user selects it.
	ShowHint (see page 2502)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 2504)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2504)	Determines if the user can tab to a control.
	Visible (see page 2505)	Determines whether the component appears onscreen.
	Width (see page 2506)	Specifies the horizontal size of the control or form in pixels.

19.1.7.5.1 TCategoryButtons.Align Property

Determines how control aligns within its parent control.

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

TCategoryButtons (see page 2452) uses the Align property inherited from TControl.

See Also

TControl (see page 5724)

Align (see page 5798)

19.1.7.5.2 TCategoryButtons.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

TCategoryButtons (see page 2452) uses the Anchors property inherited from TControl.

See Also

TControl (see page 5724)

Anchors (see page 5802)

19.1.7.5.3 TCategoryButtons.BackgroundGradientColor Property

Specifies the color for a gradient fill in the background of a category.

Pascal

```
property BackgroundGradientColor: TColor;
```

C++

```
__property TColor BackgroundGradientColor;
```

19.1.7.5.4 TCategoryButtons.BackgroundGradientDirection Property

Direction of background gradient fill.

Pascal

```
property BackgroundGradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection BackgroundGradientDirection;
```

Description

The following values are available:

Parameter	Description
gdHorizontal	The gradient appears horizontally on the background of the container. Default.
gdVertical	The gradient appears vertically on the background of the container.

19.1.7.5.5 TCategoryButtons.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner (see page 2482), BevelOuter (see page 2483), BevelWidth (see page 2483) and BevelKind (see page 2482) properties determine the appearance of the specified edges.

See Also

BevelInner (see page 2482)

BevelKind (see page 2482)

BevelOuter (see page 2483)

BevelWidth (see page 2483)

19.1.7.5.6 TCategoryButtons.BevelInner Property

Determines the style of the inner bevel of a control.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to provide the control with a three-dimensional beveled look. A control has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel BevelOuter (see page 2483), separated by the number of pixels specified in the BorderWidth (see page 2484) property. The width of the bevels, if they are drawn, is the BevelWidth (see page 2483) property.

See Also

BorderWidth (see page 2484)

BevelEdges (see page 2481)

BevelKind (see page 2482)

BevelOuter (see page 2483)

BevelWidth (see page 2483)

19.1.7.5.7 TCategoryButtons.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth (see page 2483) and the cut of the bevel specified by BevelInner (see page 2482) or BevelOuter (see page 2483), can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 2481)

BevelInner (see page 2482)

BevelOuter (see page 2483)

BevelWidth (see page 2483)

19.1.7.5.8 TCategoryButtons.BevelOuter Property

Determines the style of the outer bevel of a control.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelOuter to provide the control with a three-dimensional beveled look. A control has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel BevelOuter, separated by the number of pixels specified in the BorderWidth (see page 2484) property. The width of the bevels, if they are drawn, is the BevelWidth (see page 2483) property.

See Also

BorderWidth (see page 2484)

BevelEdges (see page 2481)

BevelInner (see page 2482)

BevelKind (see page 2482)

BevelWidth (see page 2483)

19.1.7.5.9 TCategoryButtons.BevelWidth Property

Width (see page 2506) of outer and inner bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelInner (see page 2482) and BeveOuter to provide the control with a three-dimensional beveled look. A control has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel BevelOuter (see page 2483), separated by the number of pixels specified in the BorderWidth (see page 2484) property. The width of the bevels, if they are drawn, is the BevelWidth property.

See Also

BorderWidth (see page 2484)

BevelEdges (see page 2481)

BevelInner (see page 2482)

BevelKind (see page 2482)

BevelOuter (see page 2483)

19.1.7.5.10 TCategoryButtons.BorderStyle Property

Determines whether control has single line border or none.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the control stands out. BorderStyle can have a value of either **bsSingle** or **bsNone**. If BorderStyle is **bsSingle**, the control has a single-line border around the client area. If BorderStyle is **bsNone**, there is no border.

See Also

BorderWidth (see page 2484)

19.1.7.5.11 TCategoryButtons.BorderWidth Property

Width (see page 2506) of border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

A control has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel BevelOuter (see page 2483), separated by the number of pixels specified in the BorderWidth property.

See Also

BevelInner (see page 2482)

BevelOuter (see page 2483)

19.1.7.5.12 TCategoryButtons.ButtonFlow Property

Specifies the direction of buttons in a category.

Pascal

```
property ButtonFlow: TCatButtonFlow;
```

C++

```
__property TCatButtonFlow ButtonFlow;
```

Description

Use one of the following values:

Parameter	Description
cbfVertical	Organizes the buttons in the category vertically.
cbfHorizontal	Organizes the buttons in the category horizontally.

19.1.7.5.13 TCategoryButtons.ButtonHeight Property

Height (see page 2496) of buttons in a category.

Pascal

```
property ButtonHeight: Integer;
```

C++

```
__property int ButtonHeight;
```

Description

ButtonHeight specifies the height of buttons in each of the TButtonCategory (see page 2429) objects.

See Also

TButtonCategory (see page 2429)

TButtonItem (see page 2441)

ButtonWidth (see page 2486)

19.1.7.5.14 TCategoryButtons.ButtonOptions Property

Specifies options for button display and behavior.

Pascal

```
property ButtonOptions: TCatButtonOptions;
```

C++

```
__property TCatButtonOptions ButtonOptions;
```

Description

The following options are available:

Option	Description
boAllowReorder	Allows the user to reorder buttons within a category at runtime.
boAllowCopyingButtons	Allows the user to copy buttons at runtime.
boFullSize	Sets the width of the buttons in a category to the maximum size, which is the entire width of the TButtonCategory (see page 2429) object. In this case, each button appears on its own line.
boGradientFill	The color of the TButtonCategory (see page 2429) button is shaded along a gradient. Otherwise, the color is solid.
boShowCaptions	Toggles the button captions. The category captions remain displayed.
boVerticalCategoryCaptions	The caption for a category appears on the side vertically when the group is expanded. Otherwise, it appears above the group.
boBoldCaptions	Make category captions bold.
boUsePlusMinus	Use plus/minus signs for expanding or collapsing a category. Otherwise, use arrows.
boCaptionOnlyBorder	When a category is collapsed so that only its caption button is displayed, draw a border around this button.

See Also

TButtonCategory (see page 2429)

19.1.7.5.15 TCategoryButtons.ButtonWidth Property

Width (see page 2506) of buttons in a category.

Pascal

```
property ButtonWidth: Integer;
```

C++

```
__property int ButtonWidth;
```

Description

ButtonWidth specifies the width of buttons in each of the TButtonCategory (see page 2429) objects.

See Also

TButtonCategory (see page 2429)

TButtonItem (see page 2441)

ButtonHeight (see page 2485)

19.1.7.5.16 TCategoryButtons.Categories Property

Specifies the categories represented in the category buttons object.

Pascal

```
property Categories: TButtonCategories;
```

C++

```
__property TButtonCategories Categories;
```

19.1.7.5.17 TCategoryButtons.Color Property

Category buttons background color

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Color specifies the background color of the TCategoryButtons (see page 2452) object.

19.1.7.5.18 TCategoryButtons.Cursor Property

Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.

Pascal

```
property Cursor: TCursor;
```

C++

```
__property TCursor Cursor;
```

Description

Change the value of Cursor to provide feedback to the user when the mouse pointer enters the control. The value of Cursor is

the index of the cursor in the list of cursors maintained by the global variable, Screen. In addition to the built-in cursors provided by TScreen, applications can add custom cursors to the list.

C++ Examples:

```
/*
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
*/
Graphics::TBitmap *bmpMask, *bmpColor;
TIconInfo *iconInfo;

const crMyCursor = 5;

  void __fastcall TForm1::Button2Click(TObject *Sender)
{
  bmpMask = new Graphics::TBitmap();
  bmpColor = new Graphics::TBitmap();
  iconInfo = new TIconInfo();

  bmpMask->LoadFromFile("../SquareMask.bmp");
  bmpColor->LoadFromFile("../Square.bmp");

  iconInfo->fIcon = false;
  iconInfo->xHotspot = 15;
  iconInfo->yHotspot = 15;
  iconInfo->hbmMask = bmpMask->Handle;
  iconInfo->hbmColor = bmpColor->Handle;

  Screen->Cursors[crMyCursor] = CreateIconIndirect(iconInfo);

  Screen->Cursor = crMyCursor;

  delete bmpMask;
  delete bmpColor;
  delete iconInfo;
}
```

Delphi Examples:

```
{
This example uses a splitter and two image controls to
create a "slide show" effect.  The example displays an image
(the current "slide"), which can be hidden behind a screen
that looks like a venetian blind. When the blind is pulled
down to completely cover the current slide, the slide changes
to a different image.  When the blind is raised, the new
image appears.
To prepare this example, follow these steps:
1. Place an image control on the form.
Set the picture property to a bitmap of a venetian blind,
Set the Stretch property to True.
Set the Align property to alTop.
2. Add a splitter control to the form.
Set the Align property to alTop.
Set the Cursor property to crVSplit.
Set the OnMoved event handler to the code that appears below.
Set the MinSize property to 1.
3. Add a second image control to the form.
Set the Align property to alClient.
Set the Stretch property to True.
4. Select the form and add the OnCreate and OnDestroy event
   handlers that appear below.
5. Add the global variables below to the unit.
}
```

```
var
  CurImage: Integer;
  BMPs: Array[1..5] of TBitmap;

procedure TForm1.Splitter1Moved(Sender: TObject);
begin
  { check if the blind is closed }
  if Image2.Height <= 1 then
  begin
    { the blind is closed, change the current slide }
    CurImage := CurImage + 1;
    if CurImage = 6 then
       CurImage := 1;
    Image2.Picture.Bitmap := BMPs[CurImage];
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { Initialize the array of slides.
    These must be freed in the OnDestroy event handler. }
  BMPs[1] := TBitmap.Create;
  BMPs[1].LoadFromFile('Factory.bmp');
  BMPs[2] := TBitmap.Create;
  BMPs[2].LoadFromFile('Rhododendron.bmp');
  BMPs[3] := TBitmap.Create;
  BMPs[3].LoadFromFile('littleB_64.bmp');
  BMPs[4] := TBitmap.Create;
  BMPs[4].LoadFromFile('Soap bubbles.bmp');
  BMPs[5] := TBitmap.Create;
  BMPs[5].LoadFromFile('Gone Fishing.bmp');
  CurImage := 1;
  Image2.Picture.Bitmap := BMPs[1];
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  { clean up }
  for I := 1 to 5 do
    BMPs[I].Free;
end;
{
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
}
var
  bmpMask : TBitmap;
  bmpColor : TBitmap;
  iconInfo : TIconInfo;
const
  crMyCursor = 5;

procedure TForm1.Button2Click(Sender: TObject);
begin
  bmpMask := TBitmap.Create;
  bmpColor := TBitmap.Create;

  bmpMask.LoadFromFile('SquareMask.bmp');
  bmpColor.LoadFromFile('Square.bmp');

  with iconInfo do
  begin
```

```
      fIcon := false;
      xHotspot := 15;
      yHotspot := 15;
      hbmMask := bmpMask.Handle;
      hbmColor := bmpColor.Handle;
    end;

    Screen.Cursors[crMyCursor] := CreateIconIndirect(iconInfo);

    Screen.Cursor := crMyCursor;

    bmpMask.Free;
    bmpColor.Free;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    DestroyIcon(Screen.Cursors[crMyCursor]);
  end;
```

DragCursor (see page 5818)

Cursors (see page 14212)

Screen (see page 14385)

ProcessMessages (see page 13691)

19.1.7.5.19 TCategoryButtons.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite: Boolean;
```

C++

```
__property Boolean DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
```

```
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

19.1.7.5.20 TCategoryButtons.DragButton Property

Button being dragged.

Pascal

```
property DragButton: TButtonItem;
```

C++

```
__property TButtonItem DragButton;
```

Description

DragButton specifies the button being dragged. You can write to this to control the button dragged.

See Also

DragCategory (see page 2490)

DragCursor (see page 2491)

DragImageList (see page 2491)

DragKind (see page 2492)

DragMode (see page 2492)

19.1.7.5.21 TCategoryButtons.DragCategory Property

Category being dragged.

Pascal

```
property DragCategory: TButtonCategory;
```

C++

```
__property TButtonCategory DragCategory;
```

Description

DragCategory specifies the category being dragged. You can write to this to control the category dragged.

See Also

TButtonCategory (see page 2429)

DragButton (see page 2490)

DragCursor (see page 2491)

DragImageList (see page 2491)

DragKind (see page 2492)

DragMode (see page 2492)

19.1.7.5.22 TCategoryButtons.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

19.1.7.5.23 TCategoryButtons.DragImageList Property

List of images used during drag or dock operations.

Pascal

```
property DragImageList: TDragImageList;
```

C++

```
__property TDragImageList DragImageList;
```

Description

DragImageList holds a list of images that are displayed during drag and drop or drag and dock operations. Categories (see page 2486) and buttons may be dragged in a CategoryButtons (see page 2415) object.

See Also

TDragImageList (see page 6021)

DragButton (see page 2490)

DragCategory (see page 2490)

DragCursor (see page 2491)

DragKind (see page 2492)

DragMode (see page 2492)

19.1.7.5.24 TCategoryButtons.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

19.1.7.5.25 TCategoryButtons.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
```

```
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

19.1.7.5.26 TCategoryButtons.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

Enabling Mouse

19.1.7.5.27 TCategoryButtons.FocusedItem Property

Specifies the button that currently has focus.

Pascal

```
property FocusedItem: TButtonItem;
```

C++

```
__property TButtonItem FocusedItem;
```

19.1.7.5.28 TCategoryButtons.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
```

```
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

19.1.7.5.29 TCategoryButtons.GradientDirection Property

Specifies the direction of gradient fill for the category object.

Pascal

```
property GradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection GradientDirection;
```

Description

There are three primary objects that take color in the category buttons control. The first object is the container itself, which takes a background gradient. The second object is the category, which appears as a rounded rectangle within the container. The category also takes a gradient. The third object is an individual button, which appears as a rectangle in the category. The button takes a solid color.

GradientDirection applies to the category.

19.1.7.5.30 TCategoryButtons.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
```

```
        HideSelection := False;
    end;
end;
```

19.1.7.5.31 TCategoryButtons.HotButtonColor Property

Specifies the color of a hot button, if necessary.

Pascal

```
property HotButtonColor: TColor;
```

C++

```
__property TColor HotButtonColor;
```

19.1.7.5.32 TCategoryButtons.Images Property

List of button images.

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

Images is a TCustomImageList object containing the button images for the CategoryButtons (see page 2415). Each button has an index into the image list.

See Also

TCustomImageList (see page 15361)

19.1.7.5.33 TCategoryButtons.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
```

```
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
```

```
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
```

```
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}
```

19.1.7.5.34 TCategoryButtons.RegularButtonColor Property

Specifies the color of a button in the normal, unselected state.

Pascal

```
property RegularButtonColor: TColor;
```

C++

```
__property TColor RegularButtonColor;
```

19.1.7.5.35 TCategoryButtons.SelectedButtonColor Property

Specifies the color of the button when a user selects it.

Pascal

```
property SelectedButtonColor: TColor;
```

C++

```
__property TColor SelectedButtonColor;
```

19.1.7.5.36 TCategoryButtons.SelectedItem Property

Returns the selected button.

Pascal

```
property SelectedItem: TButtonItem;
```

C++

```
__property TButtonItem SelectedItem;
```

19.1.7.5.37 TCategoryButtons.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine

whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
```

```
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

19.1.7.5.38 TCategoryButtons.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

19.1.7.5.39 TCategoryButtons.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

19.1.7.5.40 TCategoryButtons.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
```

```
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

19.1.7.5.41 TCategoryButtons.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

19.1.7.6 TCategoryButtons Events

The events of the TCategoryButtons class are listed here.

Published Events

	Name	Description
	OnAfterDrawButton (see page 2508)	Fired after a button is drawn
	OnAlignInsertBefore (see page 2508)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2508)	Occurs when an object with custom alignment is aligned.
	OnBeforeDrawButton (see page 2509)	Fired before a button is drawn
	OnButtonClicked (see page 2509)	Fired when a button is clicked, if OnClick (see page 2510) event is not present
	OnCategoryCollapase (see page 2509)	Fired when a category is collapsed
	OnClick (see page 2510)	Occurs when mouse button goes up.
	OnContextPopup (see page 2510)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCopyButton (see page 2511)	Fired when a button is copied
	OnDockDrop (see page 2511)	Occurs when another control is docked to the control.
	OnDockOver (see page 2513)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 2515)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2517)	Occurs when the user drags an object over a control.
	OnDrawButton (see page 2519)	Fired when a button needs to be redrawn; it prevents default drawing.
	OnDrawIcon (see page 2520)	Fired when an icon needs to be redrawn; it prevents default drawing.
	OnDrawText (see page 2520)	Fired when a caption needs to be redrawn; it prevents default drawing.
	OnEndDock (see page 2520)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2520)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2521)	Occurs when a control receives the input focus.
	OnExit (see page 2524)	Occurs when the input focus shifts away from one control to another.
	OnGetHint (see page 2525)	Fired when a hint string is being retrieved
	OnHotButton (see page 2526)	Fired when the "hot" button changes
	OnKeyDown (see page 2526)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2529)	Occurs when a key is pressed.
	OnKeyUp (see page 2530)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 2531)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2532)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2535)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2535)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2535)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2537)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 2540)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 2540)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 2540)	Occurs when the mouse wheel is rotated upward.
	OnReorderButton (see page 2541)	Fired when buttons are reordered

	OnReorderCategory (see page 2541)	Fired when categories are reordered
	OnSelectedItemChange (see page 2541)	Fired when the selected item changes
	OnStartDock (see page 2541)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2542)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

19.1.7.6.1 TCategoryButtons.OnAfterDrawButton Event

Fired after a button is drawn

Pascal

```
property OnAfterDrawButton: TCatButtonDrawEvent;
```

C++

```
__property TCatButtonDrawEvent OnAfterDrawButton;
```

19.1.7.6.2 TCategoryButtons.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

19.1.7.6.3 TCategoryButtons.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment

parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

19.1.7.6.4 TCategoryButtons.OnBeforeDrawButton Event

Fired before a button is drawn

Pascal

```
property OnBeforeDrawButton: TCatButtonDrawEvent;
```

C++

```
__property TCatButtonDrawEvent OnBeforeDrawButton;
```

19.1.7.6.5 TCategoryButtons.OnButtonClicked Event

Fired when a button is clicked, if OnClick (see page 2510) event is not present

Pascal

```
property OnButtonClicked: TCatButtonEvent;
```

C++

```
__property TCatButtonEvent OnButtonClicked;
```

19.1.7.6.6 TCategoryButtons.OnCategoryCollapase Event

Fired when a category is collapsed

Pascal

```
property OnCategoryCollapase: TCategoryCollapseEvent;
```

C++

```
__property TCategoryCollapseEvent OnCategoryCollapase;
```

19.1.7.6.7 TCategoryButtons.OnClick Event

Occurs when mouse button goes up.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

OnClick occurs when the mouse button goes up. If there is no handler for this event, the OnButtonClicked (see page 2509) event is triggered.

See Also

OnButtonClicked

19.1.7.6.8 TCategoryButtons.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

19.1.7.6.9 TCategoryButtons.OnCopyButton Event

Fired when a button is copied

Pascal

```
property OnCopyButton: TCatButtonCopyEvent;
```

C++

```
__property TCatButtonCopyEvent OnCopyButton;
```

19.1.7.6.10 TCategoryButtons.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop: TDockDropEvent;
```

C++

```
__property TDockDropEvent OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
```

```
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
```

```
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

DockSite (see page 6204)

OnDockOver (see page 6216)

19.1.7.6.11 TCategoryButtons.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver: TDockOverEvent;
```

C++

```
__property TDockOverEvent OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
```

```
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
```

```
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

19.1.7.6.12 TCategoryButtons.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
```

```
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

19.1.7.6.13 TCategoryButtons.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
```

```
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
```

```
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

19.1.7.6.14 TCategoryButtons.OnDrawButton Event

Fired when a button needs to be redrawn; it prevents default drawing.

Pascal

```
property OnDrawButton: TCatButtonDrawEvent;
```

C++

```
__property TCatButtonDrawEvent OnDrawButton;
```

19.1.7.6.15 TCategoryButtons.OnDrawIcon Event

Fired when an icon needs to be redrawn; it prevents default drawing.

Pascal

```
property OnDrawIcon: TCatButtonDrawIconEvent;
```

C++

```
__property TCatButtonDrawIconEvent OnDrawIcon;
```

19.1.7.6.16 TCategoryButtons.OnDrawText Event

Fired when a caption needs to be redrawn; it prevents default drawing.

Pascal

```
property OnDrawText: TCatButtonDrawEvent;
```

C++

```
__property TCatButtonDrawEvent OnDrawText;
```

19.1.7.6.17 TCategoryButtons.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

19.1.7.6.18 TCategoryButtons.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

19.1.7.6.19 TCategoryButtons.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
```

```
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also

19.1.7.6.20 TCategoryButtons.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

```
property OnGetHint: TCatButtonGetHint;
```

C++

```
__property TCatButtonGetHint OnGetHint;
```

19.1.7.6.22 TCategoryButtons.OnHotButton Event

Fired when the "hot" button changes

Pascal

```
property OnHotButton: TCatButtonEvent;
```

C++

```
__property TCatButtonEvent OnHotButton;
```

19.1.7.6.23 TCategoryButtons.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
```

```
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);

19.1.7.6.24 TCategoryButtons.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

19.1.7.6.25 TCategoryButtons.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin

19.1.7.6.26 TCategoryButtons.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture (see page 5831)

19.1.7.6.27 TCategoryButtons.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
```

```
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

19.1.7.6.28 TCategoryButtons.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

19.1.7.6.29 TCategoryButtons.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

19.1.7.6.30 TCategoryButtons.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

19.1.7.6.31 TCategoryButtons.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseDown (see page 5862)

OnMouseMove (see page 5865)

Responding to a Mouse-up Action

19.1.7.6.32 TCategoryButtons.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

19.1.7.6.33 TCategoryButtons.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

19.1.7.6.34 TCategoryButtons.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

19.1.7.6.35 TCategoryButtons.OnReorderButton Event

Fired when buttons are reordered

Pascal

```
property OnReorderButton: TCatButtonReorderEvent;
```

C++

```
__property TCatButtonReorderEvent OnReorderButton;
```

19.1.7.6.36 TCategoryButtons.OnReorderCategory Event

Fired when categories are reordered

Pascal

```
property OnReorderCategory: TCategoryReorderEvent;
```

C++

```
__property TCategoryReorderEvent OnReorderCategory;
```

19.1.7.6.37 TCategoryButtons.OnSelectedItemChange Event

Fired when the selected item changes

Pascal

```
property OnSelectedItemChange: TCatButtonEvent;
```

C++

```
__property TCatButtonEvent OnSelectedItemChange;
```

19.1.7.6.38 TCategoryButtons.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is

automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

19.1.7.6.39 TCategoryButtons.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

19.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCatButtonFlow (see page 2543)	Defines the ordering style of category buttons.

19.2.1 CategoryButtons.TCatButtonFlow Enumeration

Defines the ordering style of category buttons.

Pascal

```
TCatButtonFlow = (
  cbfVertical,
  cbfHorizontal
);
```

C++

```
enum TCatButtonFlow {
  cbfVertical,
  cbfHorizontal
};
```

File

CategoryButtons

Description

The following values are available for ordering the category buttons:

Value	Description
cbfVertical	Stacks the buttons vertically.
cbfHorizontal	Arranges the buttons horizontally and sequentially.

19.3 Types

The following table lists types in this documentation.

Types

Name	Description
TBaseButtonItemClass (see page 2544)	Defines button items that are to be included in a container, such as in button groups or category buttons.
TButtonCategoriesClass (see page 2544)	Metaclass of the TButtonCategories (see page 2424) class.
TButtonCategoryClass (see page 2545)	Metaclass of TButtonCategory (see page 2429).
TButtonDrawState (see page 2545)	Values indicating the drawing state of buttons.
TButtonItemActionLinkClass (see page 2546)	Metaclass of TButtonItemActionLink (see page 2445).
TButtonItemClass (see page 2546)	Defines the button item class.
TCatButtonCopyEvent (see page 2546)	This is type CategoryButtons.TCatButtonCopyEvent.
TCatButtonDrawEvent (see page 2547)	This is type CategoryButtons.TCatButtonDrawEvent.
TCatButtonDrawIconEvent (see page 2547)	This is type CategoryButtons.TCatButtonDrawIconEvent.
TCatButtonEvent (see page 2547)	This is type CategoryButtons.TCatButtonEvent.
TCatButtonGetHint (see page 2548)	This is type CategoryButtons.TCatButtonGetHint.
TCatButtonOptions (see page 2548)	Defines button options for category buttons.
TCatButtonReorderEvent (see page 2549)	This is type CategoryButtons.TCatButtonReorderEvent.
TCategoryCollapseEvent (see page 2549)	This is type CategoryButtons.TCategoryCollapseEvent.
TCategoryReorderEvent (see page 2549)	This is type CategoryButtons.TCategoryReorderEvent.

19.3.1 CategoryButtons.TBaseButtonItemClass Type

Defines button items that are to be included in a container, such as in button groups or category buttons.

Pascal

```
TBaseButtonItemClass = class of TBaseButtonItem;
```

C++

```
TBaseButtonItem TBaseButtonItemClass;
```

File

CategoryButtons

19.3.2 CategoryButtons.TButtonCategoriesClass Type

Metaclass of the TButtonCategories (see page 2424) class.

Pascal

```
TButtonCategoriesClass = class of TButtonCategories;
```

C++

```
TButtonCategories TButtonCategoriesClass;
```

File

CategoryButtons

19.3.3 CategoryButtons.TButtonCategoryClass Type

Metaclass of TButtonCategory (see page 2429).

Pascal

```
TButtonCategoryClass = class of TButtonCategory;
```

C++

```
TButtonCategory TButtonCategoryClass;
```

File

CategoryButtons

Description

You can pass this type in a function at runtime when you do not necessarily know the type.

19.3.4 CategoryButtons.TButtonDrawState Type

Values indicating the drawing state of buttons.

Pascal

```
TButtonDrawState = set of (bdsSelected, bdsHot, bdsFocused, bdsDown, bdsDragged,
bdsInsertLeft, bdsInsertTop, bdsInsertRight, bdsInsertBottom);
```

C++

```
(bdsSelected, bdsHot, bdsFocused, bdsDown, bdsDragged, bdsInsertLeft, bdsInsertTop,
bdsInsertRight, bdsInsertBottom) TButtonDrawState;
```

File

CategoryButtons

Description

You can use the following parameters to set the drawing state of the buttons:

Parameter	Description
bdsSelected	Item is selected and in the down state.
bdsHot	Item has the mouse over it
bdsFocused	Item should show focus.
bdsDown	Item is being pressed by the user.
bdsDragged	The drag image for that button is being drawn.
bdsInsertLeft	Shows that an item can be inserted to the left of this item.
bdsInsertTop	Shows that an item can be inserted above this item.
bdsInsertRight	Shows that an item can be inserted to the right of this item.

bdsInsertBottom	Show that an item can be inserted below this item.

19.3.5 CategoryButtons.TButtonItemActionLinkClass Type

Metaclass of TButtonItemActionLink (see page 2445).

Pascal

```
TButtonItemActionLinkClass = class of TButtonItemActionLink;
```

C++

```
TButtonItemActionLink TButtonItemActionLinkClass;
```

File

CategoryButtons

19.3.6 CategoryButtons.TButtonItemClass Type

Defines the button item class.

Pascal

```
TButtonItemClass = class of TButtonItem;
```

C++

```
TButtonItem TButtonItemClass;
```

File

CategoryButtons

Description

Inherits from the TBaseButtonItemClass (see page 2544).

19.3.7 CategoryButtons.TCatButtonCopyEvent Type

Pascal

```
TCatButtonCopyEvent = procedure (Sender: TObject; const SourceButton, CopiedButton:
TButtonItem) of object;
```

C++

```
(Sender: TObject; const SourceButton, CopiedButton: TButtonItem) ( TCatButtonCopyEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonCopyEvent.

19.3.8 CategoryButtons.TCatButtonDrawEvent Type

Pascal

```
TCatButtonDrawEvent = procedure (Sender: TObject; const Button: TButtonItem; Canvas: TCanvas;
Rect: TRect; State: TButtonDrawState) of object;
```

C++

```
(Sender: TObject; const Button: TButtonItem; Canvas: TCanvas; Rect: TRect; State:
TButtonDrawState) ( TCatButtonDrawEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonDrawEvent.

19.3.9 CategoryButtons.TCatButtonDrawIconEvent Type

Pascal

```
TCatButtonDrawIconEvent = procedure (Sender: TObject; const Button: TButtonItem; Canvas:
TCanvas; Rect: TRect; State: TButtonDrawState; var TextOffset: Integer) of object;
```

C++

```
(Sender: TObject; const Button: TButtonItem; Canvas: TCanvas; Rect: TRect; State:
TButtonDrawState; var TextOffset: Integer) ( TCatButtonDrawIconEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonDrawIconEvent.

19.3.10 CategoryButtons.TCatButtonEvent Type

Pascal

```
TCatButtonEvent = procedure (Sender: TObject; const Button: TButtonItem) of object;
```

C++

```
(Sender: TObject; const Button: TButtonItem) ( TCatButtonEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonEvent.

19.3.11 CategoryButtons.TCatButtonGetHint Type

Pascal

```
TCatButtonGetHint = procedure (Sender: TObject; const Button: TButtonItem; const Category:
TButtonCategory; var HintStr: string; var Handled: Boolean) of object;
```

C++

```
(Sender: TObject; const Button: TButtonItem; const Category: TButtonCategory; var HintStr:
string; var Handled: Boolean) ( TCatButtonGetHint)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonGetHint.

19.3.12 CategoryButtons.TCatButtonOptions Type

Defines button options for category buttons.

Pascal

```
TCatButtonOptions = set of (boAllowReorder, boAllowCopyingButtons, boFullSize, boGradientFill,
boShowCaptions, boVerticalCategoryCaptions, boBoldCaptions, boUsePlusMinus,
boCaptionOnlyBorder);
```

C++

```
(boAllowReorder, boAllowCopyingButtons, boFullSize, boGradientFill, boShowCaptions,
boVerticalCategoryCaptions, boBoldCaptions, boUsePlusMinus, boCaptionOnlyBorder)
TCatButtonOptions;
```

File

CategoryButtons

Description

The following options are supported:

Option	Description
boAllowReorder	Allows the user to reorder buttons at runtime.
boAllowCopyingButtons	Allows the user to copy buttons, typically with a drag operation.
boFullSize	Sets the buttons to full size, meaning they are stacked vertically and their horizontal length takes up the entire width of the container.
boGradientFill	Sets a gradiant fill.
boShowCaptions	Displays the captions on buttons.
boVerticalCategoryCaptions	Sets category captions to a vertical orientation.
boBoldCaptions	Sets captions to bold.
boUsePlusMinus	Sets a plus and minus collapse control on the left-hand side of the category.

boCaptionOnlyBorder	When category is expanded, shows only the caption in a slight section of the category gradient. When set to **False**, the border shows the gradient around the entire group of buttons in the category.

19.3.13 CategoryButtons.TCatButtonReorderEvent Type

Pascal

```
TCatButtonReorderEvent = procedure (Sender: TObject; const Button: TButtonItem; const
SourceCategory, TargetCategory: TButtonCategory) of object;
```

C++

```
(Sender: TObject; const Button: TButtonItem; const SourceCategory, TargetCategory:
TButtonCategory) ( TCatButtonReorderEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCatButtonReorderEvent.

19.3.14 CategoryButtons.TCategoryCollapseEvent Type

Pascal

```
TCategoryCollapseEvent = procedure (Sender: TObject; const Category: TButtonCategory) of
object;
```

C++

```
(Sender: TObject; const Category: TButtonCategory) ( TCategoryCollapseEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCategoryCollapseEvent.

19.3.15 CategoryButtons.TCategoryReorderEvent Type

Pascal

```
TCategoryReorderEvent = procedure (Sender: TObject; const SourceCategory, TargetCategory:
TButtonCategory) of object;
```

C++

```
(Sender: TObject; const SourceCategory, TargetCategory: TButtonCategory) (
TCategoryReorderEvent)();
```

File

CategoryButtons

Description

This is type CategoryButtons.TCategoryReorderEvent.

19.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
crDragCopy (see page 2551)	This is constant CategoryButtons.crDragCopy.

19.4.1 CategoryButtons.crDragCopy Constant

Pascal

```
crDragCopy = TCursor(-23);
```

C++

```
crDragCopy = TCursor(-23);
```

File

CategoryButtons

Description

This is constant CategoryButtons.crDragCopy.

20 CGIApp Namespace

This is namespace CGIApp.

Topics

Name	Description
Classes (see page 2554)	The following table lists classes in this documentation.

Classes

	Name	Description
	TCGIApplication (see page 2554)	TCGIApplication encapsulates a CGI server application.
	TCGIFactory (see page 2559)	

20.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCGIApplication (see page 2554)	TCGIApplication encapsulates a CGI server application.
	TCGIFactory (see page 2559)	

20.1.1 TCGIApplication Class

TCGIApplication encapsulates a CGI server application.

Class Hierarchy

Pascal

```
TCGIApplication = class(TWebApplication);
```

C++

```
class TCGIApplication : public TWebApplication;
```

File

CGIApp

Description

TCGIApplication provides the fundamental behavior of a CGI server application. TCGIApplication starts running when the CGI server receives an HTTP request message. It creates TCGIRequest and TCGIResponse objects to represent the request message and any response that should be sent in return, passes these to the dispatcher so that the response can be filled in, and sends the response if it was not already sent by a TWebActionItem.

Each CGI server project automatically declares an Application variable of type TCGIApplication as the instance of the application. This declaration overrides the Application variable declared in the Forms (see page 13657) unit if the CGIApp (see page 2553) unit is declared last in the uses list of the project file. Every CGI server application must include the CGIApp (see page 2553) unit.

To work with an Apache server, use the TApacheApplication object. To work with an ISAPI or NSAPI server, use the TISAPIApplication object instead.

See Also

TISAPIApplication (see page 15648)

20.1.1.1 TCGIApplication Members

The following tables list the members exposed by TCGIApplication.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActivateWebModules (see page 25453)	Activates a Web module for the application and returns it.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	DeactivateWebModules (see page 25453)	Deactivates the Web module of the application.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleRequest (see page 25454)	Responds to an HTTP request message received by the server.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.

	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddWebModuleFactory (see page 25453)	Adds a Web module factory to the request handler.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	Create (see page 24622)	Creates an instance of TWebApplication (see page 24618).
V	Create (see page 25452)	Creates an instance of TWebRequestHandler (see page 25448).
V	CreateForm (see page 24623)	Registers the single Web module with the Web application.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2557)	Frees the memory associated with the TCGIApplication (see page 2554) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HandleException (see page 25454)	Responds to exceptions related to TWebRequestHandler (see page 25448) objects.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

V	Initialize (see page 24623)	Introduces an interface for a method that initializes the application.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Run (see page 2558)	Executes the CGI application in response to an HTTP request message.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ActiveCount (see page 25455)	Indicates the number of active connections currently being serviced by the application.
	CacheConnections (see page 25455)	Determines whether the Web modules used by the application are cached for re-use.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	InactiveCount (see page 25456)	Indicates the number of Web modules cached for later reuse.
	MaxConnections (see page 25457)	Sets or returns the MaxConnections used by the socket.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Title (see page 24624)	Specifies a title for the Web application.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	WebModuleClass (see page 25457)	Contains a reference to a Web module.
R	WebModuleFactory (see page 25457)	A list of Web module factory objects.
R	WebModuleFactoryCount (see page 25458)	The number of Web module factories in use by the request handler.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

20.1.1.2 TCGIApplication.Destroy Destructor

Frees the memory associated with the TCGIApplication (see page 2554) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCGIApplication();
```

Description

Do not call Destroy. The global Application variable is freed when the application shuts down.

20.1.1.3 TCGIApplication Methods

The methods of the TCGIApplication class are listed here.

Public Methods

	Name	Description
	Run (see page 2558)	Executes the CGI application in response to an HTTP request message.

20.1.1.3.1 TCGIApplication.Run Method

Executes the CGI application in response to an HTTP request message.

Pascal

```
procedure Run; override;
```

C++

```
virtual __fastcall Run();
```

Description

When creating a new project, the IDE automatically creates a main program block in the project file that calls the Run method. When the application is started in response to an HTTP request message, the CGI application's Run method is called.

After calling the inherited Run method to set up the default error handler and shut down sequence for the application, TCGIApplication (see page 2554)'s Run method creates the appropriate request and response objects for the HTTP request message that started the CGI application. Run calls the HandleRequest method to pass the request and response on to the dispatcher where the response is filled out and sent. Finally, Run frees the request and response objects.

See Also

TCGIRequest (see page 2564)

TCGIResponse (see page 2572)

TWebDispatcher (see page 15147)

TWinCGIRequest (see page 2583)

TWinCGIResponse (see page 2590)

HandleRequest (see page 25454)

20.1.2 TCGIFactory Class

Class Hierarchy

System::TObject → CGIApp.TCGIFactory

Pascal

```
TCGIFactory = class(TObject);
```

C++

```
class TCGIFactory : public TObject;
```

File

CGIApp

See Also

TCGIApplication (see page 2554)

20.1.2.1 TCGIFactory Members

The following tables list the members exposed by TCGIFactory.

Protected Methods

	Name	Description
	NewRequest (see page 2560)	
	NewResponse (see page 2561)	

Protected Properties

	Name	Description
	OutputFileName (see page 2561)	This is OutputFileName, a member of class TCGIFactory.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2560)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

20.1.2.2 TCGIFactory.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
__fastcall TCGIFactory();
```

Description

Do not create instances of Create. Instead, construct descendants of Create using the new keyword, passing any arguments for the descendant object's constructor.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

Destroy (see page 22287)

new

20.1.2.3 TCGIFactory Methods

The methods of the TCGIFactory class are listed here.

Protected Methods

	Name	Description
V	NewRequest (see page 2560)	
V	NewResponse (see page 2561)	

20.1.2.3.1 TCGIFactory.NewRequest Method

Pascal

```
function NewRequest: TCGIRequest; virtual;
```

C++

```
virtual __fastcall TCGIRequest NewRequest();
```

See Also

TCGIResponse (see page 2572)

NewResponse (see page 2561)

20.1.2.3.2 TCGIFactory.NewResponse Method

Pascal

```
function NewResponse(CGIRequest: TCGIRequest): TCGIResponse; virtual;
```

C++

```
virtual __fastcall TCGIResponse NewResponse(TCGIRequest CGIRequest);
```

See Also

TCGIResponse (see page 2572)

NewRequest (see page 2560)

Request_Object

20.1.2.4 TCGIFactory Properties

The properties of the TCGIFactory class are listed here.

Protected Properties

	Name	Description
	OutputFileName (see page 2561)	This is OutputFileName, a member of class TCGIFactory.

20.1.2.4.1 TCGIFactory.OutputFileName Property

Pascal

```
property OutputFileName: string;
```

C++

```
__property AnsiString OutputFileName;
```

Description

This is OutputFileName, a member of class TCGIFactory.

21 CGIHTTP Namespace

This is namespace CGIHTTP.

Topics

Name	Description
Classes (see page 2564)	The following table lists classes in this documentation.
Types (see page 2591)	The following table lists types in this documentation.

Classes

	Name	Description
	TCGIRequest (see page 2564)	TCGIRequest represents client request information that is passed to a CGI Web server application.
	TCGIResponse (see page 2572)	TCGIResponse represents HTTP messages sent by a CGI application in response to an HTTP request message.
	TWinCGIRequest (see page 2583)	TWinCGIRequest represents client request information that is passed to a Windows hosted CGI Web server application.
	TWinCGIResponse (see page 2590)	TWinCGIResponse represents HTTP messages sent by a Windows hosted CGI application in response to an HTTP request message.

Types

Name	Description
TCGIRequestClass (see page 2591)	This is type CGIHTTP.TCGIRequestClass.
TCGIResponseClass (see page 2591)	This is type CGIHTTP.TCGIResponseClass.
TWinCGIRequestClass (see page 2592)	This is type CGIHTTP.TWinCGIRequestClass.
TWinCGIResponseClass (see page 2592)	This is type CGIHTTP.TWinCGIResponseClass.

21.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCGIRequest (see page 2564)	TCGIRequest represents client request information that is passed to a CGI Web server application.
	TCGIResponse (see page 2572)	TCGIResponse represents HTTP messages sent by a CGI application in response to an HTTP request message.
	TWinCGIRequest (see page 2583)	TWinCGIRequest represents client request information that is passed to a Windows hosted CGI Web server application.
	TWinCGIResponse (see page 2590)	TWinCGIResponse represents HTTP messages sent by a Windows hosted CGI application in response to an HTTP request message.

21.1.1 TCGIRequest Class

TCGIRequest represents client request information that is passed to a CGI Web server application.

Class Hierarchy

Pascal

```
TCGIRequest = class(TWebRequest);
```

C++

```
class TCGIRequest : public TWebRequest;
```

File

CGIHTTP

Description

Use TCGIRequest to interpret an HTTP request to a CGI server application.

CGI application objects create TCGIRequest objects to capture client requests. The properties of TCGIRequest are obtained from the Web server. The CGI application uses TCGIRequest objects to create corresponding TCGIResponse (see page 2572) objects. The TWebDispatcher for the application then invokes the TWebActionItem that is associated with the path portion of the URL of the TCGIRequest object.

See Also

TCGIApplication (see page 2554)

TCGIResponse (see page 2572)

TWebActionItem (see page 15130)

TWebDispatcher (see page 15147)

TWinCGIRequest (see page 2583)

Accessing Client Request Information

21.1.1.1 TCGIRequest Members

The following tables list the members exposed by TCGIRequest.

Protected Methods

	Name	Description
	GetDateVariable (see page 2567)	Provides the abstract (pure virtual) prototype for a method to extract a date value from an indexed table of HTTP header variables.
	GetIntegerVariable (see page 2568)	Provides the abstract (pure virtual) prototype for a method to extract an integer value from an indexed table of HTTP header variables.
	GetInternalPathInfo (see page 15169)	This is GetInternalPathInfo, a member of class TWebRequest.
	GetInternalScriptName (see page 15169)	This is GetInternalScriptName, a member of class TWebRequest.
	GetStringVariable (see page 2569)	Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.
	UpdateMethodType (see page 15172)	Provides the abstract prototype for a method to write a pure virtual method for updating the client method type.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2567)	Creates an instance of TCGIRequest (see page 2564).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 15165)	Destroys an instance of TWebRequest (see page 15161).
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExtractContentFields (see page 15166)	Parses the Content (see page 15176) property into its constituent fields.
	ExtractCookieFields (see page 15166)	Parses the Cookie (see page 15180) property into its constituent fields.
	ExtractFields (see page 15167)	Parses a multi-valued string into its constituent fields.
	ExtractQueryFields (see page 15167)	Parses the Query (see page 15186) property into its constituent fields.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetFieldByName (see page 2568)	Provides a method that returns the value of the HTTP header variable specified by the Name parameter.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ReadClient (see page 2570)	Provides a method to read from the HTTP request into a buffer.
	ReadString (see page 2570)	Provides the method to read Count bytes from the HTTP request into a string.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	TranslateURI (see page 2570)	Provides a method to translate a Uniform Resource Identifier (URI) into an internal representation of a location on the server.
	WriteClient (see page 2571)	Provides a method to write Count bytes from Buffer back to the HTTP client.
	WriteHeaders (see page 2571)	Writes an HTTP header string.
	WriteString (see page 2572)	Provides a method for writingthe string AString back to the HTTP client.

Public Properties

	Name	Description
	Accept (see page 15174)	Reports the value of the Accept header of the HTTP request message.
	Authorization (see page 15175)	Reports the value of the Authorization header of the HTTP request message.
	CacheControl (see page 15175)	Reports the value of the Cache-Control header of the HTTP request message.
	Connection (see page 15176)	Reports the value of the Connection header of the HTTP request message.
	Content (see page 15176)	Represents the unparsed contents of the HTTP request message.
	ContentEncoding (see page 15177)	Reports the value of the Content (see page 15176)-Encoding header of the HTTP request message.
	ContentFields (see page 15177)	Reports the parsed content of a POST request message.
	ContentLength (see page 15178)	Reports the value of the Content (see page 15176)-Length header of the HTTP request message.
	ContentParser (see page 15178)	Refers to the object's content parser object.
	ContentType (see page 15179)	Reports the value of the Content (see page 15176)-Type header of the HTTP request message.
	ContentVersion (see page 15179)	Reports the value of the Content (see page 15176)-Version header of the HTTP request message.
	Cookie (see page 15180)	Reports the value of the Cookie header of the HTTP request message.
	CookieFields (see page 15180)	Represents the parsed contents of the Cookie (see page 15180) header of an HTTP request message.
	Date (see page 15181)	Reports the value of the Date header of the HTTP request message.
	DerivedFrom (see page 15181)	Reports the value of the Derived-From (see page 15182) header of the HTTP request message.
	Expires (see page 15182)	Reports the value of the Expires header of the HTTP request message.
	Files (see page 15182)	Provides access to the files uploaded in the HTTP request.
	From (see page 15182)	Reports the value of the From header of the HTTP request message.
	Host (see page 15183)	Reports the value of the Host header of the HTTP request message.
	IfModifiedSince (see page 15183)	Reports the value of the If-Modified-Since header of the HTTP request message.
	InternalPathInfo (see page 15184)	Returns the path info portion of the URL (see page 15190).
	InternalScriptName (see page 15184)	Returns the ScriptName (see page 15189) part of the URL (see page 15190).
	Method (see page 15185)	This is Method, a member of class TWebRequest.
	MethodType (see page 15185)	This is MethodType, a member of class TWebRequest.
	PathInfo (see page 15185)	Reports the value of the path information (if any) of the URL (see page 15190) specified in the HTTP request message.
	PathTranslated (see page 15186)	Represents a translation of the PathInfo (see page 15185) property to a fully qualified path on the Web server.
	ProtocolVersion (see page 15186)	Reports the version number of the HTTP protocol specified in the initial header of the HTTP request message.
	Query (see page 15186)	Indicates the value of the query information (if any) of the URL (see page 15190) specified in the HTTP request message.
	QueryFields (see page 15187)	Represents the parsed contents of the Query (see page 15186) in the URL (see page 15190) of the HTTP request message.
	Referer (see page 15188)	Reports the value of the Referer header of the HTTP request message.
	RemoteAddr (see page 15188)	Indicates the remote IP address of the client associated with the HTTP request message.
	RemoteHost (see page 15188)	Reports the fully qualified reverse domain lookup of the client associated with the HTTP request message.

R	ScriptName (see page 15189)	Indicates the value of the script information (if any) of the URL (see page 15190) specified in the HTTP request message.
R	ServerPort (see page 15189)	Indicates the port number of the port on the Web server that receives the HTTP request message.
R	Title (see page 15190)	Reports the value of the Title header of the HTTP request message.
R	URL (see page 15190)	Reports the Uniform Resource Identifier (URI) specified by the HTTP request message to identify the target of the request.
R	UserAgent (see page 15191)	Reports the value of the User-Agent header of the HTTP request message.

21.1.1.2 TCGIRequest.Create Constructor

Creates an instance of TCGIRequest (see page 2564).

Pascal

```
constructor Create;
```

C++

```
__fastcall TCGIRequest();
```

Description

Applications shouldn't need to directly instantiate a CGI request object. The TCGIApplication object creates a TCGIRequest (see page 2564) object whenever it receives a client request.

See Also

TCGIApplication (see page 2554)

21.1.1.3 TCGIRequest Methods

The methods of the TCGIRequest class are listed here.

Protected Methods

	Name	Description
V	GetDateVariable (see page 2567)	Provides the abstract (pure virtual) prototype for a method to extract a date value from an indexed table of HTTP header variables.
V	GetIntegerVariable (see page 2568)	Provides the abstract (pure virtual) prototype for a method to extract an integer value from an indexed table of HTTP header variables.
V	GetStringVariable (see page 2569)	Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.

Public Methods

	Name	Description
V	GetFieldByName (see page 2568)	Provides a method that returns the value of the HTTP header variable specified by the Name parameter.
V	ReadClient (see page 2570)	Provides a method to read from the HTTP request into a buffer.
V	ReadString (see page 2570)	Provides the method to read Count bytes from the HTTP request into a string.
V	TranslateURI (see page 2570)	Provides a method to translate a Uniform Resource Identifier (URI) into an internal representation of a location on the server.
V	WriteClient (see page 2571)	Provides a method to write Count bytes from Buffer back to the HTTP client.
V	WriteHeaders (see page 2571)	Writes an HTTP header string.
V	WriteString (see page 2572)	Provides a method for writingthe string AString back to the HTTP client.

21.1.1.3.1 TCGIRequest.GetDateVariable Method

Provides the abstract (pure virtual) prototype for a method to extract a date value from an indexed table of HTTP header

variables.

Pascal

```
function GetDateVariable(Index: Integer): TDateTime; override;
```

C++

```
virtual __fastcall TDateTime GetDateVariable(int Index);
```

Description

Descendants of TWebRequest implement GetDateVariable to provide a method by which the date-time values are read from the header strings of the HTTP request message. The request object uses GetDateVariable to access the properties that represent dates from the HTTP request headers.

See Also

Date (see page 15181)

Expires (see page 15182)

IfModifiedSince (see page 15183)

21.1.1.3.2 TCGIRequest.GetFieldByName Method

Provides a method that returns the value of the HTTP header variable specified by the Name parameter.

Pascal

```
function GetFieldByName(const Name: string): string; override;
```

C++

```
virtual __fastcall AnsiString GetFieldByName(const AnsiString Name);
```

Description

Use GetFieldByName to read the value of an HTTP header variable that is not surfaced as one of the properties of TCGIRequest (see page 2564). For information on possible HTTP request header variables, see the current Internet standards documents.

See Also

GetStringVariable (see page 15169)

21.1.1.3.3 TCGIRequest.GetIntegerVariable Method

Provides the abstract (pure virtual) prototype for a method to extract an integer value from an indexed table of HTTP header variables.

Pascal

```
function GetIntegerVariable(Index: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetIntegerVariable(int Index);
```

Description

Descendants of TWebRequest implement GetIntegerVariable to provide a method by which the integer values are read from the header strings of the HTTP request message. The request object uses GetIntegerVariable to access the properties that represent integers from the HTTP request headers.

See Also

ContentLength (see page 15178)

ServerPort (see page 15189)

21.1.1.3.4 TCGIRequest.GetStringVariable Method

Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.

Pascal

```
function GetStringVariable(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetStringVariable(int Index);
```

Description

Descendants of TWebRequest implement GetStringVariable to provide a method by which the string values are read from the header strings of the HTTP request message. The request object uses GetStringVariable to access the properties that represent strings from the HTTP request headers.

See Also

Accept (see page 15174)

CacheControl (see page 15175)

Connection (see page 15176)

Content (see page 15176)

ContentEncoding (see page 15177)

ContentType (see page 15179)

ContentVersion (see page 15179)

Cookie (see page 15180)

DerivedFrom (see page 15181)

From (see page 15182)

Host (see page 15183)

TWebRequest (see page 15161)

PathInfo (see page 15185)

PathTranslated (see page 15186)

ProtocolVersion (see page 15186)

Query (see page 15186)

Referer (see page 15188)

RemoteAddr (see page 15188)

RemoteHost (see page 15188)

ScriptName (see page 15189)

Title (see page 15190)

URL (see page 15190)

UserAgent (see page 15191)

21.1.1.3.5 TCGIRequest.ReadClient Method

Provides a method to read from the HTTP request into a buffer.

Pascal

```
function ReadClient(var Buffer; Count: Integer): Integer; override;
```

C++

```
virtual __fastcall int ReadClient( Buffer, int Count);
```

Description

Use ReadClient to get the next chunk of information when the content of the request message is too large for the Content property.

Use Buffer to provide a buffer to contain the content information. Use Count to specify the number of bytes to read. ReadClient returns the number of bytes actually read.

See Also

Content (see page 15176)

ReadString (see page 2570)

WriteClient (see page 2571)

21.1.1.3.6 TCGIRequest.ReadString Method

Provides the method to read Count bytes from the HTTP request into a string.

Pascal

```
function ReadString(Count: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString ReadString(int Count);
```

Description

ReadString is used to load content information from the HTTP request into a string. Use ReadString to get the next chunk of information when the content of the request message is too large for the Content property.

See Also

Content (see page 15176)

ReadClient (see page 2570)

WriteString (see page 2572)

21.1.1.3.7 TCGIRequest.TranslateURI Method

Provides a method to translate a Uniform Resource Identifier (URI) into an internal representation of a location on the server.

Pascal

```
function TranslateURI(const URI: string): string; override;
```

C++

```
virtual __fastcall AnsiString TranslateURI(const AnsiString URI);
```

Description

Descendants of TCGIRequest (see page 2564) implement TranslateURI. TranslateURI is used to translate the URI specified in a client request into a format that can be used by the server application. TranslateURI is not relevant to CGI applications.

See Also

PathTranslated (see page 15186)

URL (see page 15190)

21.1.1.3.8 TCGIRequest.WriteClient Method

Provides a method to write Count bytes from Buffer back to the HTTP client.

Pascal

```
function WriteClient(var Buffer; Count: Integer): Integer; override;
```

C++

```
virtual __fastcall int WriteClient( Buffer, int Count);
```

Description

WriteClient is used by TCGIResponse (see page 2572) to send the contents of a response to the CGI client.

See Also

TWebResponse (see page 15191)

ReadClient (see page 2570)

WriteString (see page 2572)

WriteHeaders (see page 2571)

21.1.1.3.9 TCGIRequest.WriteHeaders Method

Writes an HTTP header string.

Pascal

```
function WriteHeaders(StatusCode: Integer; const StatusString: string; const Headers: string):
Boolean; override;
```

C++

```
virtual __fastcall Boolean WriteHeaders(int StatusCode, const AnsiString StatusString, const
AnsiString Headers);
```

Description

WriteHeaders writes the HTTP headers of the response message before a call to the WriteClient (see page 2571) method. These headers are used on the HTTP message that the WriteClient (see page 2571) method sends in response to this request.

StatusCode is the status code of the response. This informs the client of the status of the request. For a list of status code values, see the StatusCode property of TWebResponse.

StatusString is a text string that describes the status that StatusCode indicates.

Headers is a formatted string that includes any other HTTP headers to add. It represents each header as a string of the form 'Headername: Value', where name/value pairs are separated by line breaks.

WriteHeaders returns true if it succeeds in writing the specified headers.

See Also

WriteClient (see page 2571)

WriteString (see page 2572)

StatusCode (see page 15215)

21.1.1.3.10 TCGIRequest.WriteString Method

Provides a method for writingthe string AString back to the HTTP client.

Pascal

```
function WriteString(const AString: string): Boolean; override;
```

C++

```
virtual __fastcall Boolean WriteString(const AnsiString AString);
```

Description

WriteString is used by TCGIResponse (see page 2572) to send the contents of a response to the CGI client.

See Also

ReadString (see page 2570)

TCGIResponse (see page 2572)

WriteClient (see page 2571)

21.1.2 TCGIResponse Class

TCGIResponse represents HTTP messages sent by a CGI application in response to an HTTP request message.

Class Hierarchy

Pascal

```
TCGIResponse = class(TWebResponse);
```

C++

```
class TCGIResponse : public TWebResponse;
```

File

CGIHTTP

Description

Use TCGIResponse to specify the response to an HTTP request message in a CGI application.

The CGI application creates a TCGIResponse object based on the TCGIRequest (see page 2564) object for an incoming web client request message. The TWebDispatcher for the application then passes the TCGIResponse object to the TWebActionItem associated with the TCGIRequest (see page 2564) object. The TWebActionItem sets the properties of the TCGIResponse object.

See Also

TCGIApplication (see page 2554)

TCGIRequest (see page 2564)

TWebActionItem (see page 15130)

TWebDispatcher (see page 15147)

TWinCGIResponse (see page 2590)

Creating HTTP Response Messages

21.1.2.1 TCGIResponse Members

The following tables list the members exposed by TCGIResponse.

Protected Fields

	Name	Description
	FCustomHeaders (see page 15195)	This is FCustomHeaders, a member of class TWebResponse.
	FHTTPRequest (see page 15196)	This is FHTTPRequest, a member of class TWebResponse.

Protected Methods

	Name	Description
	AddCustomHeaders (see page 15197)	Appends the custom headers specified by the CustomHeaders (see page 15211) property to the Headers parameter.
	FormatAuthenticate (see page 15197)	Lists of one or more comma-separated challenges provided when the request fails with StatusCode (see page 15215) 401 (Unauthorized).
V	GetContent (see page 2576)	Provides the abstract (pure virtual) prototype of a method to access the Content property.
V	GetDateVariable (see page 2576)	Provides the abstract (pure virtual) prototype of a method to extract a date value from an indexed table of HTTP header variables.
V	GetIntegerVariable (see page 2577)	Provides the abstract (in C++ terminology, pure vitrual) prototype of a method to extract an integer value from an indexed table of HTTP header variables.
V	GetLogMessage (see page 2577)	Provides the abstract (pure virtual) prototype of a method to access the LogMessage property.
V	GetStatusCode (see page 2578)	Provides the abstract (pure virtual) prototype of a method to access the StatusCode property.
V	GetStringVariable (see page 2578)	Provides the prototype of a method to extract a string value from an indexed table of HTTP header variables.
V	InitResponse (see page 2579)	This is InitResponse, a member of class TCGIResponse.
V	SetContent (see page 2580)	Provides the abstract (pure virtual) prototype of a method to set the Content property.
V	SetContentStream (see page 15203)	Sets the value of the ContentStream (see page 15209) property to the Value parameter.
V	SetDateVariable (see page 2581)	Provides the abstract (pure virtual) prototype of a method to set a date-time valued HTTP header property.
V	SetIntegerVariable (see page 2581)	Provides the abstract (pure virtual) prototype of a method to set an integer valued HTTP header property.
V	SetLogMessage (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set the value of the LogMessage property.
V	SetStatusCode (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set the value of the StatusCode property.
V	SetStringVariable (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set a string valued HTTP header property.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2575)	Creates an instance of TCGIResponse (see page 2572) to represent the response to the HTTPRequest parameter.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 15195)	Disposes of an object instance.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetCustomHeader (see page 15198)	Returns the value of the custom header with the specified name.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SendRedirect (see page 2579)	Sends the response with a StatusCode of 301 (Moved Permanently) and a Location of URI.
V	SendResponse (see page 2579)	Sends the HTTP response message to the web client.
V	SendStream (see page 2580)	Sends the HTTP response message with the contents set to the contents of AStream.
V	Sent (see page 2580)	Indicates whether the HTTP response message has already been sent.
	SetCookieField (see page 15203)	Adds a cookie header to the response message.
	SetCustomHeader (see page 15203)	Replaces the value of a specified custom header.

Public Properties

	Name	Description
	Allow (see page 15207)	Lists the HTTP request methods that the application can service.
	Content (see page 15207)	Contains the information sent to the web client in response to an HTTP request message.
	ContentEncoding (see page 15208)	Lists the mechanisms, if any, that are used to encode the content of the HTTP response message.
	ContentLength (see page 15208)	Specifies the length, in bytes, of the Content (see page 15207) property.
	ContentStream (see page 15209)	Specifies the stream object for writing the contents of the HTTP response message to the web client.
	ContentType (see page 15209)	Indicates the media type of the Content (see page 15207) of the HTTP response message.
	ContentVersion (see page 15210)	Represents the version associated with the Content (see page 15207) of the HTTP response message.
R	Cookies (see page 15210)	Lists all cookie headers that should be sent with the response.
	CustomHeaders (see page 15211)	Lists message header strings that are added to the response message before it is sent.
	Date (see page 15211)	Indicates the time and date when the HTTP response message is sent to the web client.
	DerivedFrom (see page 15212)	Specifies the URI of the resource where the Content (see page 15207) of the HTTP response originated.

	Expires (see page 15212)	Specifies the date and time after which the Content (see page 15207) of the HTTP response message should be considered invalid.
R	HTTPRequest (see page 15213)	Represents the HTTP request message for which this is a response.
	LastModified (see page 15213)	Indicates the date and time that the value of the Content (see page 15207) property was last updated.
	Location (see page 15214)	Specifies the URI of a resource the web client should point to for the completion of its request.
	LogMessage (see page 15214)	Describes the HTTP response message for event logging purposes.
	Realm (see page 15214)	Specifies the set of protected-access URIs that includes the URL specified by the HTTP request message.
	ReasonString (see page 15215)	Indicates the status of the response to the web client request as a human-readable string.
	Server (see page 15215)	Provides information about the software used by the server application to handle the request.
	StatusCode (see page 15215)	Indicates the status of the response to the HTTP request message as a 3-digit integer.
	Title (see page 15217)	Specifies a title for the Content (see page 15207) of the HTTP response message.
	Version (see page 15217)	Specifies the HTTP protocol version number that the web client is using.
	WWWAuthenticate (see page 15218)	Lists of one or more comma-separated challenges provided when the request fails with StatusCode (see page 15215) 401 (Unauthorized).

21.1.2.2 TCGIResponse.Create Constructor

Creates an instance of TCGIResponse (see page 2572) to represent the response to the HTTPRequest parameter.

Pascal

```
constructor Create(HTTPRequest: TWebRequest);
```

C++

```
__fastcall TCGIResponse(TWebRequest HTTPRequest);
```

Description

Applications shouldn't need to call Create to instantiate a CGI response object. The TCGIApplication object creates a TCGIResponse (see page 2572) for each TCGIRequest (see page 2564) it creates.

See Also

TCGIApplication (see page 2554)

TCGIRequest (see page 2564)

21.1.2.3 TCGIResponse Methods

The methods of the TCGIResponse class are listed here.

Protected Methods

	Name	Description
V	GetContent (see page 2576)	Provides the abstract (pure virtual) prototype of a method to access the Content property.
V	GetDateVariable (see page 2576)	Provides the abstract (pure virtual) prototype of a method to extract a date value from an indexed table of HTTP header variables.
V	GetIntegerVariable (see page 2577)	Provides the abstract (in C++ terminology, pure vitrual) prototype of a method to extract an integer value from an indexed table of HTTP header variables.
V	GetLogMessage (see page 2577)	Provides the abstract (pure virtual) prototype of a method to access the LogMessage property.
V	GetStatusCode (see page 2578)	Provides the abstract (pure virtual) prototype of a method to access the StatusCode property.

	GetStringVariable (see page 2578)	Provides the prototype of a method to extract a string value from an indexed table of HTTP header variables.
	InitResponse (see page 2579)	This is InitResponse, a member of class TCGIResponse.
	SetContent (see page 2580)	Provides the abstract (pure virtual) prototype of a method to set the Content property.
	SetDateVariable (see page 2581)	Provides the abstract (pure virtual) prototype of a method to set a date-time valued HTTP header property.
	SetIntegerVariable (see page 2581)	Provides the abstract (pure virtual) prototype of a method to set an integer valued HTTP header property.
	SetLogMessage (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set the value of the LogMessage property.
	SetStatusCode (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set the value of the StatusCode property.
	SetStringVariable (see page 2582)	Provides the abstract (pure virtual) prototype of a method to set a string valued HTTP header property.

Public Methods

	Name	Description
	SendRedirect (see page 2579)	Sends the response with a StatusCode of 301 (Moved Permanently) and a Location of URI.
	SendResponse (see page 2579)	Sends the HTTP response message to the web client.
	SendStream (see page 2580)	Sends the HTTP response message with the contents set to the contents of AStream.
	Sent (see page 2580)	Indicates whether the HTTP response message has already been sent.

21.1.2.3.1 TCGIResponse.GetContent Method

Provides the abstract (pure virtual) prototype of a method to access the Content property.

Pascal

```
function GetContent: string; override;
```

C++

```
virtual __fastcall AnsiString GetContent();
```

Description

Descendants of TWebResponse implement GetContent to provide an access method for their internal representation of the Content property. This method is abstract (pure virtual) because response objects for different types of HTTP applications store the value of the Content property differently.

See Also

Content (see page 15207)

SetContent (see page 15202)

21.1.2.3.2 TCGIResponse.GetDateVariable Method

Provides the abstract (pure virtual) prototype of a method to extract a date value from an indexed table of HTTP header variables.

Pascal

```
function GetDateVariable(Index: Integer): TDateTime; override;
```

C++

```
virtual __fastcall TDateTime GetDateVariable(int Index);
```

Description

Descendants of TWebResponse implement GetDateVariable to provide a method by which date-time values are read from the

internal table used to store HTTP header variables. The response object uses GetDateVariable to access the properties that represent dates.

See Also

Date (see page 15211)

Expires (see page 15212)

LastModified (see page 15213)

SetDateVariable (see page 15204)

21.1.2.3.3 TCGIResponse.GetIntegerVariable Method

Provides the abstract (in C++ terminology, pure vitrual) prototype of a method to extract an integer value from an indexed table of HTTP header variables.

Pascal

```
function GetIntegerVariable(Index: Integer): Integer; override;
```

C++

```
virtual __fastcall int GetIntegerVariable(int Index);
```

Description

Descendants of TWebResponse implement GetIntegerVariable to provide a method by which integer values are read from the internal table used to store HTTP header variables. The response object uses GetIntegerVariable to access the properties that represent integers.

See Also

ContentLength (see page 15208)

SetIntegerVariable (see page 15204)

21.1.2.3.4 TCGIResponse.GetLogMessage Method

Provides the abstract (pure virtual) prototype of a method to access the LogMessage property.

Pascal

```
function GetLogMessage: string; override;
```

C++

```
virtual __fastcall AnsiString GetLogMessage();
```

Description

Descendants of TWebResponse implement GetLogMessage to provide an access method for internal representation of the LogMessage property. This method is abstract (pure virtual) because response objects for different types of HTTP applications store the value of the LogMessage property differently.

See Also

LogMessage (see page 15214)

SetLogMessage (see page 15205)

21.1.2.3.5 TCGIResponse.GetStatusCode Method

Provides the abstract (pure virtual) prototype of a method to access the StatusCode property.

Pascal

```
function GetStatusCode: Integer; override;
```

C++

```
virtual __fastcall int GetStatusCode();
```

Description

Descendants of TWebResponse implement GetStatusCode to provide an access method for internal representation of the StatusCode property. This method is abstract (pure virtual) because response objects for different types of HTTP applications store the value of the StatusCode property differently.

See Also

StatusCode (see page 15215)

SetStatusCode (see page 15205)

21.1.2.3.6 TCGIResponse.GetStringVariable Method

Provides the prototype of a method to extract a string value from an indexed table of HTTP header variables.

Pascal

```
function GetStringVariable(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetStringVariable(int Index);
```

Description

GetStringVariable provides the abstract (pure virtual) prototype of a method to extract a string value from an indexed table of HTTP header variables. Descendants of TWebResponse implement GetStringVariable to provide a method by which the string values are read from the internal table used to store HTTP header variables. The response object uses GetStringVariable to access the properties that represent strings.

See Also

Allow (see page 15207)

ContentEncoding (see page 15208)

ContentType (see page 15209)

ContentVersion (see page 15210)

DerivedFrom (see page 15212)

Location (see page 15214)

Realm (see page 15214)

ReasonString (see page 15215)

Server (see page 15215)

SetStringVariable (see page 15205)

Title (see page 15217)

Version (see page 15217)

WWWAuthenticate (see page 15218)

21.1.2.3.7 TCGIResponse.InitResponse Method

Pascal

```
procedure InitResponse; virtual;
```

C++

```
virtual __fastcall InitResponse();
```

Description

This is InitResponse, a member of class TCGIResponse.

21.1.2.3.8 TCGIResponse.SendRedirect Method

Sends the response with a StatusCode of 301 (Moved Permanently) and a Location of URI.

Pascal

```
procedure SendRedirect(const URI: string); override;
```

C++

```
virtual __fastcall SendRedirect(const AnsiString URI);
```

Description

Call SendRedirect to redirect the web client request to another URI that is the proper target of the request. SendRedirect does the same thing as setting the StatusCode to 301, the Location to URI, and calling SendResponse (see page 2579).

See Also

Location (see page 15214)

SendResponse (see page 2579)

StatusCode (see page 15215)

21.1.2.3.9 TCGIResponse.SendResponse Method

Sends the HTTP response message to the web client.

Pascal

```
procedure SendResponse; override;
```

C++

```
virtual __fastcall SendResponse();
```

Description

Call SendResponse after setting the properties of the HTTP response object to specify the response that should be made to the web client. If the request should be redirected to another URI, it is more efficient to call SendRedirect (see page 2579) instead.

See Also

SendRedirect (see page 2579)

21.1.2.3.10 TCGIResponse.SendStream Method

Sends the HTTP response message with the contents set to the contents of AStream.

Pascal

```
procedure SendStream(AStream: TStream); override;
```

C++

```
virtual __fastcall SendStream(TStream AStream);
```

Description

Only call SendStream after first calling SendResponse (see page 2579). Unlike SendStream, SendResponse (see page 2579) fills the header of the HTTP response message, based on the properties of the TCGIResponse (see page 2572) object. If SendResponse (see page 2579) has not been called first to set the header of the HTTP response message, set the ContentStream property to AStream, and call SendResponse (see page 2579).

See Also

ContentStream (see page 15209)

SendResponse (see page 2579)

Sent (see page 2580)

21.1.2.3.11 TCGIResponse.Sent Method

Indicates whether the HTTP response message has already been sent.

Pascal

```
function Sent: Boolean; override;
```

C++

```
virtual __fastcall Boolean Sent();
```

Description

TCGIResponse (see page 2572) checks whether the message was sent and returns True or False true or false as appropriate.

TCGIApplication objects read Sent and send unsent responses to the web client.

See Also

SendRedirect (see page 2579)

SendStream (see page 2580)

TCGIApplication (see page 2554)

21.1.2.3.12 TCGIResponse.SetContent Method

Provides the abstract (pure virtual) prototype of a method to set the Content property.

Pascal

```
procedure SetContent(const Value: string); override;
```

C++

```
virtual __fastcall SetContent(const AnsiString Value);
```

Description

Descendants of TWebResponse implement SetContent to provide a method for setting the Content property. This method is abstract (pure virtual) because response objects for different types of HTTP applications can store the value of the Content property differently.

See Also

Content (see page 15207)

GetContent (see page 15198)

21.1.2.3.13 TCGIResponse.SetDateVariable Method

Provides the abstract (pure virtual) prototype of a method to set a date-time valued HTTP header property.

Pascal

```
procedure SetDateVariable(Index: Integer; const Value: TDateTime); override;
```

C++

```
virtual __fastcall SetDateVariable(int Index, const TDateTime Value);
```

Description

Descendants of TWebResponse implement SetDateVariable to provide a method by which date-time values are written to the internal table used to store HTTP header variables. The response object uses SetDateVariable to set the properties that represent dates.

See Also

Date (see page 15211)

Expires (see page 15212)

GetDateVariable (see page 15198)

LastModified (see page 15213)

21.1.2.3.14 TCGIResponse.SetIntegerVariable Method

Provides the abstract (pure virtual) prototype of a method to set an integer valued HTTP header property.

Pascal

```
procedure SetIntegerVariable(Index: Integer; Value: Integer); override;
```

C++

```
virtual __fastcall SetIntegerVariable(int Index, int Value);
```

Description

Descendants of TWebResponse implement SetIntegerVariable to provide a method by which integer values are written to the internal table used to store HTTP header variables. The response object uses SetIntegerVariable to set the properties that represent integers.

See Also

ContentLength (see page 15208)

GetIntegerVariable (see page 15199)

21.1.2.3.15 TCGIResponse.SetLogMessage Method

Provides the abstract (pure virtual) prototype of a method to set the value of the LogMessage property.

Pascal

```
procedure SetLogMessage(const Value: string); override;
```

C++

```
virtual __fastcall SetLogMessage(const AnsiString Value);
```

Description

Descendants of TWebResponse implement SetLogMessage to provide a method to set the internal representation of the LogMessage property. This method is abstract (pure virtual) because response objects for different types of HTTP applications store the value of the LogMessage property differently.

See Also

GetLogMessage (see page 15199)

LogMessage (see page 15214)

21.1.2.3.16 TCGIResponse.SetStatusCode Method

Provides the abstract (pure virtual) prototype of a method to set the value of the StatusCode property.

Pascal

```
procedure SetStatusCode(Value: Integer); override;
```

C++

```
virtual __fastcall SetStatusCode(int Value);
```

Description

Descendants of TWebResponse implement SetStatusCode to provide a method to set the internal representation of the StatusCode property. This method is abstract (pure virtual) because response objects for different types of HTTP applications store the value of the StatusCode property differently.

See Also

GetStatusCode (see page 15199)

StatusCode (see page 15215)

21.1.2.3.17 TCGIResponse.SetStringVariable Method

Provides the abstract (pure virtual) prototype of a method to set a string valued HTTP header property.

Pascal

```
procedure SetStringVariable(Index: Integer; const Value: string); override;
```

C++

```
virtual __fastcall SetStringVariable(int Index, const AnsiString Value);
```

Description

Descendants of TWebResponse implement SetStringVariable to provide a method by which string values are written to the internal table used to store HTTP header variables. The response object uses SetStringVariable to set the properties that represent strings.

See Also

Allow (see page 15207)

ContentEncoding (see page 15208)

ContentType (see page 15209)

ContentVersion (see page 15210)

DerivedFrom (see page 15212)

GetStringVariable (see page 15200)

Location (see page 15214)

Realm (see page 15214)

ReasonString (see page 15215)

Server (see page 15215)

Title (see page 15217)

Version (see page 15217)

WWWAuthenticate (see page 15218)

21.1.3 TWinCGIRequest Class

TWinCGIRequest represents client request information that is passed to a Windows hosted CGI Web server application.

Class Hierarchy

Pascal

```
TWinCGIRequest = class(TCGIRequest);
```

C++

```
class TWinCGIRequest : public TCGIRequest;
```

File

CGIHTTP

Description

Use TWinCGIRequest to interpret a client request to a Windows hosted CGI Web server application.

CGI application objects create TWinCGIRequest objects to capture client requests. The properties of the TWinCGIRequest objects are obtained from the Web server. The CGI application uses TWinCGIRequest objects to create corresponding TWinCGIResponse (see page 2590) objects. The TWebDispatcher object for the application then invokes the TWebActionItem that is associated with the path portion of the URL of the TWinCGIRequest object.

See Also

TCGIApplication (see page 2554)

TWebActionItem (see page 15130)

TWebDispatcher (see page 15147)

TWinCGIResponse (see page 2590)

21.1.3.1 TWinCGIRequest Members

The following tables list the members exposed by TWinCGIRequest.

Protected Methods

	Name	Description
V	GetDateVariable (see page 2567)	Provides the abstract (pure virtual) prototype for a method to extract a date value from an indexed table of HTTP header variables.
A	GetDateVariable (see page 15168)	Provides the abstract (pure virtual) prototype for a method to extract a date value from an indexed table of HTTP header variables.
V	GetIntegerVariable (see page 2568)	Provides the abstract (pure virtual) prototype for a method to extract an integer value from an indexed table of HTTP header variables.
A	GetIntegerVariable (see page 15169)	Provides the abstract (pure virtual) prototype for a method to extract an integer value from an indexed table of HTTP header variables.
V	GetInternalPathInfo (see page 15169)	This is GetInternalPathInfo, a member of class TWebRequest.
V	GetInternalScriptName (see page 15169)	This is GetInternalScriptName, a member of class TWebRequest.
V	GetStringVariable (see page 2587)	Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.
	UpdateMethodType (see page 15172)	Provides the abstract prototype for a method to write a pure virtual method for updating the client method type.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2586)	Creates an instance of TWinCGIRequest (see page 2583).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2586)	Destroys an instance of TWebRequest.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExtractContentFields (see page 15166)	Parses the Content (see page 15176) property into its constituent fields.
	ExtractCookieFields (see page 15166)	Parses the Cookie (see page 15180) property into its constituent fields.
	ExtractFields (see page 15167)	Parses a multi-valued string into its constituent fields.
	ExtractQueryFields (see page 15167)	Parses the Query (see page 15186) property into its constituent fields.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
V	GetFieldByName (see page 2587)	A specific GetFieldByName method for the TWinCGIRequest (see page 2583) object.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	ReadClient (see page 2588)	A specific method for reading from the HTTP request into a buffer.
V	ReadString (see page 2589)	A specific method for reading Count bytes from the HTTP request into a string.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	TranslateURI (see page 2570)	Provides a method to translate a Uniform Resource Identifier (URI) into an internal representation of a location on the server.
A	TranslateURI (see page 15171)	Provides the abstract (pure virtual) prototype for a method to translate a Uniform Resource Identifier (URI) into an internal representation of a location on the server.
V	WriteClient (see page 2589)	A specific method for writing Count bytes from Buffer back to the HTTP client.
V	WriteHeaders (see page 2571)	Writes an HTTP header string.
A	WriteHeaders (see page 15172)	Provides the abstract (pure virtual) prototype for a method to write an HTTP header string.
V	WriteString (see page 2589)	A specific method for writing the string AString back to the HTTP client.

Public Properties

	Name	Description
R	Accept (see page 15174)	Reports the value of the Accept header of the HTTP request message.
R	Authorization (see page 15175)	Reports the value of the Authorization header of the HTTP request message.
R	CacheControl (see page 15175)	Reports the value of the Cache-Control header of the HTTP request message.
R	Connection (see page 15176)	Reports the value of the Connection header of the HTTP request message.
R	Content (see page 15176)	Represents the unparsed contents of the HTTP request message.
R	ContentEncoding (see page 15177)	Reports the value of the Content (see page 15176)-Encoding header of the HTTP request message.
R	ContentFields (see page 15177)	Reports the parsed content of a POST request message.
R	ContentLength (see page 15178)	Reports the value of the Content (see page 15176)-Length header of the HTTP request message.
R	ContentParser (see page 15178)	Refers to the object's content parser object.
R	ContentType (see page 15179)	Reports the value of the Content (see page 15176)-Type header of the HTTP request message.
R	ContentVersion (see page 15179)	Reports the value of the Content (see page 15176)-Version header of the HTTP request message.
R	Cookie (see page 15180)	Reports the value of the Cookie header of the HTTP request message.
R	CookieFields (see page 15180)	Represents the parsed contents of the Cookie (see page 15180) header of an HTTP request message.
R	Date (see page 15181)	Reports the value of the Date header of the HTTP request message.
R	DerivedFrom (see page 15181)	Reports the value of the Derived-From (see page 15182) header of the HTTP request message.
R	Expires (see page 15182)	Reports the value of the Expires header of the HTTP request message.
R	Files (see page 15182)	Provides access to the files uploaded in the HTTP request.
R	From (see page 15182)	Reports the value of the From header of the HTTP request message.
R	Host (see page 15183)	Reports the value of the Host header of the HTTP request message.
R	IfModifiedSince (see page 15183)	Reports the value of the If-Modified-Since header of the HTTP request message.
R	InternalPathInfo (see page 15184)	Returns the path info portion of the URL (see page 15190).
R	InternalScriptName (see page 15184)	Returns the ScriptName (see page 15189) part of the URL (see page 15190).
R	Method (see page 15185)	This is Method, a member of class TWebRequest.
R	MethodType (see page 15185)	This is MethodType, a member of class TWebRequest.
R	PathInfo (see page 15185)	Reports the value of the path information (if any) of the URL (see page 15190) specified in the HTTP request message.
R	PathTranslated (see page 15186)	Represents a translation of the PathInfo (see page 15185) property to a fully qualified path on the Web server.
R	ProtocolVersion (see page 15186)	Reports the version number of the HTTP protocol specified in the initial header of the HTTP request message.

R	Query (see page 15186)	Indicates the value of the query information (if any) of the URL (see page 15190) specified in the HTTP request message.
R	QueryFields (see page 15187)	Represents the parsed contents of the Query (see page 15186) in the URL (see page 15190) of the HTTP request message.
R	Referer (see page 15188)	Reports the value of the Referer header of the HTTP request message.
R	RemoteAddr (see page 15188)	Indicates the remote IP address of the client associated with the HTTP request message.
R	RemoteHost (see page 15188)	Reports the fully qualified reverse domain lookup of the client associated with the HTTP request message.
R	ScriptName (see page 15189)	Indicates the value of the script information (if any) of the URL (see page 15190) specified in the HTTP request message.
R	ServerPort (see page 15189)	Indicates the port number of the port on the Web server that receives the HTTP request message.
R	Title (see page 15190)	Reports the value of the Title header of the HTTP request message.
R	URL (see page 15190)	Reports the Uniform Resource Identifier (URI) specified by the HTTP request message to identify the target of the request.
R	UserAgent (see page 15191)	Reports the value of the User-Agent header of the HTTP request message.

21.1.3.2 TWinCGIRequest.Create Constructor

Creates an instance of TWinCGIRequest (see page 2583).

Pascal

```
constructor Create(IniFileName: string; ContentFile: string; OutputFile: string);
```

C++

```
__fastcall TWinCGIRequest(AnsiString IniFileName, AnsiString ContentFile, AnsiString
OutputFile);
```

Description

Applications shouldn't need to call Create to instantiate a CGI request object. The TCGIApplication object creates a TWinCGIRequest (see page 2583) object whenever it receives a client request.

See Also

TCGIApplication (see page 2554)

21.1.3.3 TWinCGIRequest.Destroy Destructor

Destroys an instance of TWebRequest.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWinCGIRequest();
```

Description

Do not call Destroy. When the request message is fully handled, TWebApplication destroys the request object by calling its Free method.

Destroy frees the TStrings objects used to represent the ContentFields, CookieFields, and QueryFields properties.

See Also

ContentFields (see page 15177)

CookieFields (see page 15180)

Free (see page 22300)

QueryFields (see page 15187)

TWebApplication (see page 24618)

21.1.3.4 TWinCGIRequest Methods

The methods of the TWinCGIRequest class are listed here.

Protected Methods

	Name	Description
	GetStringVariable (see page 2587)	Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.

Public Methods

	Name	Description
	GetFieldByName (see page 2587)	A specific GetFieldByName method for the TWinCGIRequest (see page 2583) object.
	ReadClient (see page 2588)	A specific method for reading from the HTTP request into a buffer.
	ReadString (see page 2589)	A specific method for reading Count bytes from the HTTP request into a string.
	WriteClient (see page 2589)	A specific method for writing Count bytes from Buffer back to the HTTP client.
	WriteString (see page 2589)	A specific method for writing the string AString back to the HTTP client.

21.1.3.4.1 TWinCGIRequest.GetFieldByName Method

A specific GetFieldByName method for the TWinCGIRequest (see page 2583) object.

Pascal

```
function GetFieldByName(const Name: string): string; override;
```

C++

```
virtual __fastcall AnsiString GetFieldByName(const AnsiString Name);
```

Description

GetFieldByName returns the Name field found in the Extra Headers section of the initialization file specified by the application.

See Also

GetFieldByName (see page 15168)

21.1.3.4.2 TWinCGIRequest.GetStringVariable Method

Provides the abstract (pure virtual) prototype for a method to extract a string value from an indexed table of HTTP header variables.

Pascal

```
function GetStringVariable(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetStringVariable(int Index);
```

Description

Descendants of TWebRequest implement GetStringVariable to provide a method by which the string values are read from the header strings of the HTTP request message. The request object uses GetStringVariable to access the properties that represent

strings from the HTTP request headers.

21.1.3.4.3 TWinCGIRequest.ReadClient Method

A specific method for reading from the HTTP request into a buffer.

Pascal

```
function ReadClient(var Buffer; Count: Integer): Integer; override;
```

C++

```
virtual __fastcall int ReadClient( Buffer, int Count);
```

Description

ReadClient is a specific instance of the method ReadClient (inherited from TWebRequest) for the class TWinCGIRequest (see page 2583). See the documentation for the inherited method for more information.

See Also

ReadClient (see page 15170)

WriteClient (see page 2589)

21.1.3.4.4 TWinCGIRequest.ReadString Method

A specific method for reading Count bytes from the HTTP request into a string.

Pascal

```
function ReadString(Count: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString ReadString(int Count);
```

Description

ReadString is a specific instance of the method ReadString (inherited from TWebRequest) for the class TWinCGIRequest (see page 2583). See the documentation for the inherited method for more information.

See Also

ReadString (see page 15171)

WriteString (see page 15173)

21.1.3.4.5 TWinCGIRequest.WriteClient Method

A specific method for writing Count bytes from Buffer back to the HTTP client.

Pascal

```
function WriteClient(var Buffer; Count: Integer): Integer; override;
```

C++

```
virtual __fastcall int WriteClient( Buffer, int Count);
```

Description

WriteClient is a specific instance of the method WriteClient (inherited from TWebRequest) for the class TWinCGIRequest (see page 2583). See the documentation for the inherited method for more information.

See Also

WriteClient (see page 15172)

ReadClient (see page 2588)

21.1.3.4.6 TWinCGIRequest.WriteString Method

A specific method for writing the string AString back to the HTTP client.

Pascal

```
function WriteString(const AString: string): Boolean; override;
```

C++

```
virtual __fastcall Boolean WriteString(const AnsiString AString);
```

Description

WriteString is a specific instance of the method WriteString (inherited from TWebRequest) for the class TWinCGIRequest (see page 2583). See the documentation for the inherited method for more information.

See Also

WriteString (see page 15173)

ReadString (see page 2589)

21.1.4 TWinCGIResponse Class

TWinCGIResponse represents HTTP messages sent by a Windows hosted CGI application in response to an HTTP request message.

Class Hierarchy

Pascal

```
TWinCGIResponse = class(TCGIResponse);
```

C++

```
class TWinCGIResponse : public TCGIResponse;
```

File

CGIHTTP

Description

Use TWinCGIResponse to specify the response to an HTTP request message.

A CGI application creates a TWinCGIResponse object based on the TWinCGIRequest (see page 2583) object for an incoming web client request message. The Web dispatcher for the application then passes the TWinCGIResponse object to the TWebActionItem associated with the TWinCGIRequest (see page 2583) object. The TWebActionItem sets the properties of the TWinCGIResponse object.

See Also

TCGIApplication (see page 2554)

TWebActionItem (see page 15130)

TWebDispatcher (see page 15147)

TWinCGIRequest (see page 2583)

21.2 Types

The following table lists types in this documentation.

Types

Name	Description
TCGIRequestClass (see page 2591)	This is type CGIHTTP.TCGIRequestClass.
TCGIResponseClass (see page 2591)	This is type CGIHTTP.TCGIResponseClass.
TWinCGIRequestClass (see page 2592)	This is type CGIHTTP.TWinCGIRequestClass.
TWinCGIResponseClass (see page 2592)	This is type CGIHTTP.TWinCGIResponseClass.

21.2.1 CGIHTTP.TCGIRequestClass Type

Pascal

```
TCGIRequestClass = class of TCGIRequest;
```

C++

```
TCGIRequest TCGIRequestClass;
```

File

CGIHTTP

Description

This is type CGIHTTP.TCGIRequestClass.

21.2.2 CGIHTTP.TCGIResponseClass Type

Pascal

```
TCGIResponseClass = class of TCGIResponse;
```

C++

```
TCGIResponse TCGIResponseClass;
```

File

CGIHTTP

Description

This is type CGIHTTP.TCGIResponseClass.

21.2.3 CGIHTTP.TWinCGIRequestClass Type

Pascal

```
TWinCGIRequestClass = class of TWinCGIRequest;
```

C++

```
TWinCGIRequest TWinCGIRequestClass;
```

File

CGIHTTP

Description

This is type CGIHTTP.TWinCGIRequestClass.

21.2.4 CGIHTTP.TWinCGIResponseClass Type

Pascal

```
TWinCGIResponseClass = class of TWinCGIResponse;
```

C++

```
TWinCGIResponse TWinCGIResponseClass;
```

File

CGIHTTP

Description

This is type CGIHTTP.TWinCGIResponseClass.

22 CheckLst Namespace

This is namespace CheckLst.

Topics

Name	Description
Classes (see page 2594)	The following table lists classes in this documentation.

Classes

	Name	Description
	TCheckListBox (see page 2594)	TCheckListBox displays a scrollable list with check boxes next to each item.

22.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCheckListBox (see page 2594)	TCheckListBox displays a scrollable list with check boxes next to each item.

22.1.1 TCheckListBox Class

TCheckListBox displays a scrollable list with check boxes next to each item.

Class Hierarchy

Pascal

```
TCheckListBox = class(TCustomListBox);
```

C++

```
class TCheckListBox : public TCustomListBox;
```

File

CheckLst

Description

TCheckListBox is similar to TListBox, except that each item has a check box next to it. Users can check or uncheck items in the list.

See Also

TCheckBox (see page 20996)

TCustomCheckBox (see page 21138)

TCustomListBox (see page 21308)

TListBox (see page 21598)

List Controls

List Boxes and Check-list Boxes

22.1.1.1 TCheckListBox Members

The following tables list the members exposed by TCheckListBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FMoving (see page 21321)	This is FMoving, a member of class TCustomListBox.
	FMultiSelect (see page 5956)	This is FMultiSelect, a member of class TCustomMultiSelectListControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.

	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ClickCheck (see page 2607)	This is ClickCheck, a member of class TCheckListBox.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 2607)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 2608)	Creates a Windows control corresponding to the list box component.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DeleteString (see page 2609)	Deletes a string from the list box.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21326)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFindData (see page 21326)	Returns the index of a string in the list box.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoGetData (see page 21327)	Returns a string in the list box given its index.
	DoGetDataObject (see page 21327)	Returns the object associated with an item in a virtual list box.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
V	DragCanceled (see page 21328)	Sends a mouse message canceling the drag-and-drop operation.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
V	DrawItem (see page 2609)	Generates an OnDrawItem event.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetCheckWidth (see page 2609)	This is GetCheckWidth, a member of class TCheckListBox.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetCount (see page 21329)	Returns the value of the Count (see page 21346) property.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetItemData (see page 2610)	Returns a 32-bit value associated with the specified item in a list box.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetItemIndex (see page 21329)	Returns the value of the ItemIndex property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
A	GetSelCount (see page 5956)	Returns the value of the SelCount (see page 5957) property.
V	GetSelCount (see page 21330)	Returns the number of selected items.

	GetSelected (see page 21330)	Indicates whether a particular item is selected.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InternalGetItemData (see page 2610)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 2610)	Associates an integer with a specified item in the list box.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 2611)	Responds when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	LoadRecreateItems (see page 2611)	This is LoadRecreateItems, a member of class TCheckListBox.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MeasureItem (see page 21335)	Generates an OnMeasureItem (see page 21360) event.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 2611)	OnMouseDown event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetContent (see page 2612)	Removes all of the items from a list box.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	SaveRecreateItems (see page 2612)	This is SaveRecreateItems, a member of class TCheckListBox.

	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetItemData (see page 2612)	Sets the 32-bit value associated with the specified item in a list box.
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
V	SetItemIndex (see page 21336)	Gives focus to the item with a specified index.
A	SetMultiSelect (see page 5956)	Sets the value of the MultiSelect (see page 5957) property.
V	SetMultiSelect (see page 21337)	Sets the MultiSelect property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.

	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WndProc (see page 21337)	Handles Windows messages.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ExtendedSelect (see page 21346)	This is ExtendedSelect, a member of class TCustomListBox.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddItem (see page 5940)	Adds an item to the list control.
	AddItem (see page 21322)	Adds an item to the list box
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5940)	Deletes all of the items from the list control.
	Clear (see page 21322)	Deletes all items from the list box.
	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.

V	ClearSelection (see page 21323)	Deselects all selected items in the list box, if possible.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
V	CopySelection (see page 21323)	Copies the selected items to another list-type control
V	Create (see page 2606)	Instantiates a list box control.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	DeleteSelected (see page 21325)	Deletes the selected items from the list box
V	Destroy (see page 2606)	Destroys the TCheckListBox (see page 2594) instance and frees its memory.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.

	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ItemAtPos (see page 21331)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 21333)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	MoveSelection (see page 5942)	Moves all selected items to another list control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SelectAll (see page 5943)	Selects all items or all text in the selected item.

V	SelectAll (see page 21336)	Selects the entire block of text in the list box.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	AutoCompleteDelay (see page 21342)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 21343)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 21358) event of an owner-draw list box.
	Checked (see page 2621)	Indicates which items are checked.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Count (see page 21346)	Indicates the number of items in the list box.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.

	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	Header (see page 2628)	Indicates which items act as headers.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemEnabled (see page 2631)	Enables or disables individual items in the list.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	MultiSelect (see page 5957)	Specifies whether the user can select more than one item.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ScrollWidth (see page 21351)	Specifies the width, in pixels, by which the list box can scroll horizontally.
R	SelCount (see page 5957)	Indicates the number of selected items.
	Selected (see page 21351)	Indicates whether a particular item is selected.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	State (see page 2645)	Indicates which items are checked.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopIndex (see page 21356)	Specifies the index number of the item that appears at the top of the list box.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 2649)	Occurs when the user clicks the control.
	OnClickCheck (see page 2651)	Occurs when the user selects or deselects an item's check box.
	OnContextPopup (see page 2652)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2652)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2653)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2653)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2654)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2654)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2656)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2659)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2661)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2661)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2662)	Occurs when a control receives the input focus.
	OnExit (see page 2665)	Occurs when the input focus shifts away from one control to another.

	OnKeyDown (see page 2666)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2669)	Occurs when a key is pressed.
	OnKeyUp (see page 2670)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2672)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2673)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2674)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2677)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2677)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2677)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2679)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2682)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2682)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 2614)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AllowGrayed (see page 2617)	Determines whether check box can be in a "grayed" state.
	Anchors (see page 2618)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2618)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 2619)	Specifies which edges of the control are beveled.
	BevelInner (see page 2619)	Specifies the cut of the inner bevel.
	BevelKind (see page 2619)	Specifies the control's bevel style.
	BevelOuter (see page 2620)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2620)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2621)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2621)	Determines whether the list box has a border.
	Color (see page 2622)	Specifies the background color of the control.
	Columns (see page 2623)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2623)	Specifies the size constraints for the control.
	Ctl3D (see page 2624)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 2624)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2625)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2625)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2627)	Controls whether the control responds to mouse, keyboard, and timer events.
	Flat (see page 2627)	Determines whether the check boxes appear three-dimensional.
	Font (see page 2627)	Controls the attributes of text written on or in the control.
	HeaderBackgroundColor (see page 2629)	Specifies the background color for a header item in the listbox.
	HeaderColor (see page 2629)	Specifies the font color for a header item in the list box.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 2630)	Determines the behavior of the input method editor (IME).

	ImeName (see page 2630)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2631)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2632)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2632)	Contains the strings that appear in the list box.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBiDiMode (see page 2635)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2635)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2636)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 2636)	Determines where a control looks for its font information.
	ParentShowHint (see page 2637)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2637)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2642)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2643)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 2645)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2646)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2647)	Determines if the user can tab to a control.
	TabWidth (see page 2647)	Specifies the size of the tabs in the list box.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 2647)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

22.1.1.2 TCheckListBox.Create Constructor

Instantiates a list box control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCheckListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a list box control at runtime. For list boxes created at design time, Create is called automatically.AOwner is the component that is responsible for freeing the list box. It becomes the value of the Owner property. If AOwner is nil, the caller is responsible for explicitly freeing the control.

See Also

Owner (see page 2807)

22.1.1.3 TCheckListBox.Destroy Destructor

Destroys the TCheckListBox (see page 2594) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCheckListBox();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the check list box is not nil before it calls Destroy.

See Also

Free (see page 22300)

22.1.1.4 TCheckListBox Methods

The methods of the TCheckListBox class are listed here.

Protected Methods

	Name	Description
	ClickCheck (see page 2607)	This is ClickCheck, a member of class TCheckListBox.
V	CreateParams (see page 2607)	Initializes the window-creation parameter record passed in the Params parameter.
V	CreateWnd (see page 2608)	Creates a Windows control corresponding to the list box component.
V	DeleteString (see page 2609)	Deletes a string from the list box.
V	DrawItem (see page 2609)	Generates an OnDrawItem event.
	GetCheckWidth (see page 2609)	This is GetCheckWidth, a member of class TCheckListBox.
V	GetItemData (see page 2610)	Returns a 32-bit value associated with the specified item in a list box.
V	InternalGetItemData (see page 2610)	Retrieves the data associated with an item in the list box.
V	InternalSetItemData (see page 2610)	Associates an integer with a specified item in the list box.
V	KeyPress (see page 2611)	Responds when the user presses a key.
V	LoadRecreateItems (see page 2611)	This is LoadRecreateItems, a member of class TCheckListBox.
V	MouseDown (see page 2611)	OnMouseDown event dispatcher.
V	ResetContent (see page 2612)	Removes all of the items from a list box.
V	SaveRecreateItems (see page 2612)	This is SaveRecreateItems, a member of class TCheckListBox.
V	SetItemData (see page 2612)	Sets the 32-bit value associated with the specified item in a list box.

22.1.1.4.1 TCheckListBox.ClickCheck Method

Pascal

```
procedure ClickCheck; dynamic;
```

C++

```
__fastcall ClickCheck();
```

Description

This is ClickCheck, a member of class TCheckListBox.

22.1.1.4.2 TCheckListBox.CreateParams Method

Initializes the window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams is used to pass information, in its Params parameter, to CreateWindowHandle when the list box control is created.

TCustomListBox overrides CreateParams to customize the representation of the window. It uses information from the list box Columns, ExtendedSelect, IntegralHeight, MultiSelect, Sorted and Style properties and sets WS_HSCROLL, WS_VSCROLL, LBS_HASSTRINGS and LBS_NOTIFY Windows styles for creation of the list box.

When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

See Also

Columns (see page 21346)

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

extendedselect (see page 21346)

IntegralHeight (see page 21347)

MultiSelect

Sorted (see page 21353)

Style (see page 21354)

22.1.1.4.3 TCheckListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns (see page 21346)

CreateHandle (see page 6135)

CreateParams (see page 21324)

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

ItemIndex

Items (see page 21348)

TabWidth (see page 21355)

TopIndex (see page 21356)

22.1.1.4.4 TCheckListBox.DeleteString Method

Deletes a string from the list box.

Pascal

```
procedure DeleteString(Index: Integer); override;
```

C++

```
virtual __fastcall DeleteString(int Index);
```

Description

DeleteString deletes the string, specified by the Index parameter, from the list box control.

22.1.1.4.5 TCheckListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight (see page 21347)

MeasureItem (see page 21335)

OnDrawItem (see page 21358)

OnMeasureItem (see page 21360)

Style (see page 21354)

22.1.1.4.6 TCheckListBox.GetCheckWidth Method

Pascal

```
function GetCheckWidth: Integer;
```

C++

```
__fastcall int GetCheckWidth();
```

Description

This is GetCheckWidth, a member of class TCheckListBox.

22.1.1.4.7 TCheckListBox.GetItemData Method

Returns a 32-bit value associated with the specified item in a list box.

Pascal

```
function GetItemData(Index: Integer): LongInt; override;
```

C++

```
virtual __fastcall LongInt GetItemData(int Index);
```

Description

GetItemData retrieves the data associated with a particular item in the list box. This value can be displayed as that list box item, or can be a value (such as a pointer) associated with the list box item.

See Also

SetItemData (see page 21336)

22.1.1.4.8 TCheckListBox.InternalGetItemData Method

Retrieves the data associated with an item in the list box.

Pascal

```
function InternalGetItemData(Index: Integer): Longint; override;
```

C++

```
virtual __fastcall Longint InternalGetItemData(int Index);
```

Description

InternalGetItemData is the low-level protected method for fetching the data associated with an item in the list box. It retrieves a reference pointer to the object associated with the specified item, as an integer.

Index is the index of the item whose data is to be fetched.

See Also

GetItemData (see page 21329)

22.1.1.4.9 TCheckListBox.InternalSetItemData Method

Associates an integer with a specified item in the list box.

Pascal

```
procedure InternalSetItemData(Index: Integer; AData: Longint); override;
```

C++

```
virtual __fastcall InternalSetItemData(int Index, Longint AData);
```

Description

InternalSetItemData is the low-level protected method for associating data with an item in the list box. It associates the item that has the index specified by Index with the integer specified by AData.

See Also

SetItemData (see page 21336)

22.1.1.4.10 TCheckListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress (see page 6227)

22.1.1.4.11 TCheckListBox.LoadRecreateItems Method

Pascal

```
procedure LoadRecreateItems(RecreateItems: TStrings); override;
```

C++

```
virtual __fastcall LoadRecreateItems(TStrings RecreateItems);
```

Description

This is LoadRecreateItems, a member of class TCheckListBox.

22.1.1.4.12 TCheckListBox.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

See Also

MouseMove (see page 5773)

MouseUp (see page 5774)

OnMouseDown (see page 5862)

22.1.1.4.13 TCheckListBox.ResetContent Method

Removes all of the items from a list box.

Pascal

```
procedure ResetContent; override;
```

C++

```
virtual __fastcall ResetContent();
```

Description

ResetContent is used to remove the items from the list box. ResetContent is used, for example, by the Clear method.

See Also

Clear (see page 21322)

22.1.1.4.14 TCheckListBox.SaveRecreateItems Method

Pascal

```
procedure SaveRecreateItems(RecreateItems: TStrings); override;
```

C++

```
virtual __fastcall SaveRecreateItems(TStrings RecreateItems);
```

Description

This is SaveRecreateItems, a member of class TCheckListBox.

22.1.1.4.15 TCheckListBox.SetItemData Method

Sets the 32-bit value associated with the specified item in a list box.

Pascal

```
procedure SetItemData(Index: Integer; AData: LongInt); override;
```

C++

```
virtual __fastcall SetItemData(int Index, LongInt AData);
```

Description

Use SetItemData to set the data associated with a particular item in a list box. This value can be displayed as that list box item, or it can be a value (such as a pointer) represented by the list box item.

See Also

GetItemData (see page 21329)

22.1.1.5 TCheckListBox Properties

The properties of the TCheckListBox class are listed here.

Public Properties

	Name	Description
	Checked (see page 2621)	Indicates which items are checked.
	Header (see page 2628)	Indicates which items act as headers.
	ItemEnabled (see page 2631)	Enables or disables individual items in the list.
	State (see page 2645)	Indicates which items are checked.

Published Properties

	Name	Description
	Align (see page 2614)	Determines how the control aligns within its container (parent control).
	AllowGrayed (see page 2617)	Determines whether check box can be in a "grayed" state.
	Anchors (see page 2618)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 2618)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 2619)	Specifies which edges of the control are beveled.
	BevelInner (see page 2619)	Specifies the cut of the inner bevel.
	BevelKind (see page 2619)	Specifies the control's bevel style.
	BevelOuter (see page 2620)	Specifies the cut of the outer bevel.
	BevelWidth (see page 2620)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 2621)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 2621)	Determines whether the list box has a border.
	Color (see page 2622)	Specifies the background color of the control.
	Columns (see page 2623)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 2623)	Specifies the size constraints for the control.
	Ctl3D (see page 2624)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 2624)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 2625)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 2625)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 2627)	Controls whether the control responds to mouse, keyboard, and timer events.
	Flat (see page 2627)	Determines whether the check boxes appear three-dimensional.
	Font (see page 2627)	Controls the attributes of text written on or in the control.
	HeaderBackgroundColor (see page 2629)	Specifies the background color for a header item in the listbox.
	HeaderColor (see page 2629)	Specifies the font color for a header item in the list box.
	ImeMode (see page 2630)	Determines the behavior of the input method editor (IME).
	ImeName (see page 2630)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 2631)	Determines whether the list box displays the partial items.
	ItemHeight (see page 2632)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 2632)	Contains the strings that appear in the list box.
	ParentBiDiMode (see page 2635)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 2635)	Determines where a control looks for its color information.
	ParentCtl3D (see page 2636)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 2636)	Determines where a control looks for its font information.
	ParentShowHint (see page 2637)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 2637)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 2642)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 2643)	Specifies whether the items in a list box are arranged alphabetically.

	Style (see page 2645)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 2646)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 2647)	Determines if the user can tab to a control.
	TabWidth (see page 2647)	Specifies the size of the tabs in the list box.
	Visible (see page 2647)	Determines whether the component appears onscreen.

22.1.1.5.1 TCheckListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);
```

```
  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
```

```
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
```

```
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

Parent (see page 5832)

Anchors (see page 5802)

22.1.1.5.2 TCheckListBox.AllowGrayed Property

Determines whether check box can be in a "grayed" state.

Pascal

```
property AllowGrayed: Boolean;
```

C++

```
__property Boolean AllowGrayed;
```

Description

If AllowGrayed is set to true, each item has three possible states: checked, unchecked, and grayed. If AllowGrayed is set to false, each item has only two possible states: checked and unchecked.

Note: It is also possible to disable individual items while still showing whether they are checked or unchecked. To disable items without using the grayed state, use the ItemEnabled (see page 2631) property.

See Also

Checked (see page 2621)

State (see page 2645)

ItemEnabled (see page 2631)

22.1.1.5.3 TCheckListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

22.1.1.5.4 TCheckListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

22.1.1.5.5 TCheckListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

22.1.1.5.6 TCheckListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

22.1.1.5.7 TCheckListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

22.1.1.5.8 TCheckListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

22.1.1.5.9 TCheckListBox.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

22.1.1.5.10 TCheckListBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

22.1.1.5.11 TCheckListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D (see page 6198)

22.1.1.5.12 TCheckListBox.Checked Property

Indicates which items are checked.

Pascal

```
property Checked [Index: Integer]: Boolean;
```

C++

```
__property Boolean Checked[int Index];
```

Description

For each member of the Items (see page 2632) array, Checked is true if a check mark appears in the item's check box. Checked corresponds to the cbChecked state; that is, Checked is true when State (see page 2645) = cbChecked and false when State (see page 2645) = cbUnchecked or State (see page 2645) = cbGrayed.

Note: Items (see page 2632) that have been disabled using the ItemEnabled (see page 2631) property may still have a state of cbChecked and a Checked property of true.

See Also

AllowGrayed (see page 2617)

Items (see page 21348)

Selected (see page 21351)

State (see page 2645)

ItemEnabled (see page 2631)

22.1.1.5.13 TCheckListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

22.1.1.5.14 TCheckListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 21347)

Width (see page 5849)

22.1.1.5.15 TCheckListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

22.1.1.5.16 TCheckListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

22.1.1.5.17 TCheckListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

22.1.1.5.18 TCheckListBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

22.1.1.5.19 TCheckListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
```

```
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

OnStartDrag (see page 5871)

DragKind (see page 5819)

Arranging the Order of Persistent Columns

22.1.1.5.20 TCheckListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

22.1.1.5.21 TCheckListBox.Flat Property

Determines whether the check boxes appear three-dimensional.

Pascal

```
property Flat: Boolean;
```

C++

```
__property Boolean Flat;
```

Description

When Flat is true (the default), the check boxes in the list box have flat borders. Setting Flat to false gives the check boxes raised borders, which create a three-dimensional look.

See Also

Ctl3D (see page 6198)

22.1.1.5.22 TCheckListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

22.1.1.5.23 TCheckListBox.Header Property

Indicates which items act as headers.

Pascal

```
property Header [Index: Integer]: Boolean;
```

C++

```
__property Boolean Header[int Index];
```

Description

Set Header to true to specify that an item in the check listbox acts as a header rather than a selectable item. By setting Header to true for various items in the list, you can divide the check listbox into multiple sections, where each header labels the beginning of a section.

When Header is true for an item, the list box does not display a check box next to the item, but rather, it displays only the item's text. This item is drawn with a background color of HeaderBackgroundColor (see page 2629) and a font color of HeaderColor (see page 2629), which can be used to make it visually distinct from the checkable items in the list box.

Index is the index of the item.

See Also

HeaderColor (see page 2629)

HeaderBackgroundColor (see page 2629)

22.1.1.5.24 TCheckListBox.HeaderBackgroundColor Property

Specifies the background color for a header item in the listbox.

Pascal

```
property HeaderBackgroundColor: TColor;
```

C++

```
__property TColor HeaderBackgroundColor;
```

Description

Set HeaderBackgroundColor to indicate the color that appears as the background of header items. Header (see page 2628) items are items in the list box for which the Header (see page 2628) property is true. HeaderBackgroundColor can make a header item visually more distinct from the checkable items in the list box.

See Also

Header (see page 2628)

HeaderColor (see page 2629)

22.1.1.5.25 TCheckListBox.HeaderColor Property

Specifies the font color for a header item in the list box.

Pascal

```
property HeaderColor: TColor;
```

C++

```
__property TColor HeaderColor;
```

Description

Set HeaderColor to indicate the font color of header items. Header (see page 2628) items are items in the list box for which the Header (see page 2628) property is true. HeaderColor should be a color that provides contrast with the

HeaderBackgroundColor (see page 2629) property, which specifies the background color for header items.

See Also

Header (see page 2628)

HeaderBackgroundColor (see page 2629)

22.1.1.5.26 TCheckListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

22.1.1.5.27 TCheckListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently

installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

22.1.1.5.28 TCheckListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 21347)

Style (see page 21354)

Using TDBListBox and TDBComboBox

22.1.1.5.29 TCheckListBox.ItemEnabled Property

Enables or disables individual items in the list.

Pascal

```
property ItemEnabled [Index: Integer]: Boolean;
```

C++

```
__property Boolean ItemEnabled[int Index];
```

Description

Use ItemEnabled to enable or disable individual list items without using the cbGrayed state. Using ItemEnabled allows the list box to display check marks for items with a state of cbChecked while still graying the item and preventing the user from changing its state.

For each member of the Items (see page 2632) array, ItemEnabled is true if the user can change the state of the item. Enabled (see page 2627) items have a state of cbChecked or cbUnchecked.

ItemEnabled is false when State (see page 2645) =cbGrayed or when the item has been explicitly disabled using this property.

See Also

State (see page 2645)

Checked (see page 2621)

22.1.1.5.30 TCheckListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

See Also

DrawItem (see page 21328)

IntegralHeight (see page 21347)

Items (see page 21348)

MeasureItem (see page 21335)

Style (see page 21354)

Using TDBListBox and TDBComboBox

22.1.1.5.31 TCheckListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          AnsiString("File " + FileListBox1->Items->Strings[i] + "not found").c_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(FileListBox1->Items->Strings[i].c_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(statbuf.st_size));
      fclose(F);
    }
  }
}
/*
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int I = 0; I < ListBox1->Items->Count; I++)
```

```
    ListBox1->Items->Strings[I] = UpperCase(ListBox1->Items->Strings[I]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], 1);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode 1.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
    end;
   finally
   { do something here }
   end;
  end;
end;
{
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
}

22.1.1.5.32 TCheckListBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

22.1.1.5.33 TCheckListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

22.1.1.5.34 TCheckListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

22.1.1.5.35 TCheckListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

22.1.1.5.36 TCheckListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

22.1.1.5.37 TCheckListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
```

```
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
```

```
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}
```

22.1.1.5.38 TCheckListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
```

```
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

22.1.1.5.39 TCheckListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
}
```

Delphi Examples:

```
{
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

procedure TForm1.AddClick(Sender: TObject);
begin
  ListBox1.Items.Add(Edit1.Text);
end;

procedure TForm1.SortClick(Sender: TObject);
begin
  ListBox1.Sorted := True;
```

```
end;
```

22.1.1.5.40 TCheckListBox.State Property

Indicates which items are checked.

Pascal

```
property State [Index: Integer]: TCheckBoxState;
```

C++

```
__property TCheckBoxState State[int Index];
```

Description

For each member of the Items (see page 2632) array, State indicates whether its check box is selected (cbChecked), deselected (cbUnchecked), or grayed (cbGrayed).

State combines the information provided by the Boolean Checked (see page 2621) property and the Boolean ItemEnabled (see page 2631) property:

When Checked (see page 2621) is true, State is cbChecked. (However, when Checked (see page 2621) is false, State may be either cbUnchecked or cbGrayed.)

When State is cbGrayed, ItemEnabled (see page 2631) is false. (However, ItemEnabled (see page 2631) may also be false when State is cbUnchecked or cbChecked.)

State (see page 21153)

ItemEnabled (see page 2631)

22.1.1.5.41 TCheckListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

22.1.1.5.42 TCheckListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

22.1.1.5.43 TCheckListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

22.1.1.5.44 TCheckListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

22.1.1.5.45 TCheckListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
```

```
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
```

```
end;
```

22.1.1.6 TCheckListBox Events

The events of the TCheckListBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 2649)	Occurs when the user clicks the control.
	OnClickCheck (see page 2651)	Occurs when the user selects or deselects an item's check box.
	OnContextPopup (see page 2652)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 2652)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 2653)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 2653)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 2654)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 2654)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 2656)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 2659)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 2661)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 2661)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 2662)	Occurs when a control receives the input focus.
	OnExit (see page 2665)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 2666)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 2669)	Occurs when a key is pressed.
	OnKeyUp (see page 2670)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 2672)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 2673)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 2674)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 2677)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 2677)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 2677)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 2679)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 2682)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 2682)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

22.1.1.6.1 TCheckListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
```

```
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

22.1.1.6.2 TCheckListBox.OnClickCheck Event

Occurs when the user selects or deselects an item's check box.

Pascal

```
property OnClickCheck: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClickCheck;
```

Description

Write an OnClickCheck event handler to implement any special processing that should occur when the user checks or unchecks an item.

Note: This event does not occur for items that are grayed (State (see page 2645)=cbGrayed) or disabled (ItemEnabled (see page 2631)=false).

See Also

Checked (see page 2621)

State (see page 2645)

ItemEnabled (see page 2631)

22.1.1.6.3 TCheckListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

22.1.1.6.4 TCheckListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataFind (see page 21357)

OnDataObject (see page 21358)

Style (see page 21354)

Count (see page 21346)

22.1.1.6.5 TCheckListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 21357)

OnDataObject (see page 21358)

Style (see page 21354)

Count (see page 21346)

22.1.1.6.6 TCheckListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

See Also

OnData (see page 21357)

OnDataFind (see page 21357)

Style (see page 21354)

Count (see page 21346)

22.1.1.6.7 TCheckListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

22.1.1.6.8 TCheckListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
```

```
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
```

```
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

22.1.1.6.9 TCheckListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
```

```
    TForm1(Source).Top := Y;
  end;

  procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := False;
    if (Source is TLabel) and (State = dsDragEnter) then
      (Source as TLabel).EndDrag(False);
  end;
  {
  This code comes from an application that contains a list box
  and three labels, each with a different font and color.  The
  DragMode property for each of the labels is dmAutomatic.
  The user can select a label and drag it to a list box and
  drop it. When the label is dropped, the items in the list
  box assume the color and font of the dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

22.1.1.6.10 TCheckListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight property for fixed owner-draw list boxes or by the response to the OnMeasureItem event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TStringList;
  bitmap0 = new Graphics::TBitmap;
  bitmap1 = new Graphics::TBitmap;
  bitmap2 = new Graphics::TBitmap;
//  MyList->Add("Animal");
//  MyList->Add("Flowers");
//  MyList->Add("Butterfly");
//  ListBox1.Items->AddStrings(MyList);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
```

```
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = (Graphics::TBitmap *)((TListBox *)Control)->Items->Objects[Index];
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, ((TListBox *)Control)->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
  ListBox1.Items.AddObject('Butterfly', bitmap2);
end;

procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
TOwnerDrawState);
var
  Bitmap: TBitmap;      { temporary variable for the item's bitmap }
  Offset: Integer;      { text offset width }
begin
  Bitmap := TBitmap.Create;
  with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
  begin
    FillRect(Rect);       { clear the rectangle }
    Offset := 2;          { provide default offset }
    Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
    if Bitmap <> nil then
    begin
      BrushCopy(
        Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
        Bitmap,
        Bounds(0, 0, Bitmap.Width, Bitmap.Height),
        clRed);  {render bitmap}
      Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
    end;
```

```
    TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
text }
  end;
end;
```

22.1.1.6.11 TCheckListBox.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

22.1.1.6.12 TCheckListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
```

```
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

22.1.1.6.13 TCheckListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

22.1.1.6.14 TCheckListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
```

```
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

22.1.1.6.15 TCheckListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
```

```
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

    Printer.BeginDoc;
    X := 200;
    Y := 200;
    for I := 0 to 140 do
      if (not Printer.Aborted) then
      begin
        Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
        Y := Y + 80;
        if (Y > (Printer.PageHeight - 300)) then
```

```
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);

22.1.1.6.16 TCheckListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

22.1.1.6.17 TCheckListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
```

```
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
```

```
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
```

22.1.1.6.18 TCheckListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
      int &Height)
{
  Graphics::TBitmap *bitmap = (Graphics::TBitmap *)((TListBox
*)Control)->Items->Objects[Index];
```

```
    if (bitmap && bitmap->Height > Height)
      Height = bitmap->Height;
  }

  void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
        TRect &Rect, TOwnerDrawState State)
  {
    Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
    int     Offset = 2;   // default text offset width
    // note that we draw on the listbox's canvas, not on the form
    TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
    pCanvas->FillRect(Rect); // clear the rectangle
    pBitmap = (Graphics::TBitmap *)((TListBox *)Control)->Items->Objects[Index];
    if (pBitmap)
    {
      pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
  pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
      Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
    }
    // display the text
    pCanvas->TextOut(Rect.Left + Offset, Rect.Top, ((TListBox *)Control)->Items->Strings[Index]);
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Graphics::TBitmap *bitmap0 = new Graphics::TBitmap;
    Graphics::TBitmap *bitmap1 = new Graphics::TBitmap;
    Graphics::TBitmap *bitmap2 = new Graphics::TBitmap;
    bitmap0->LoadFromFile("../littleB_64.bmp");
  //  ImageList1->GetBitmap(0, bitmap0);
    ListBox1->Items->AddObject("Butterfly", bitmap0);
    ImageList1->GetBitmap(3, bitmap1);
    ListBox1->Items->AddObject("Animal", bitmap1); // no bitmap, see if it leaves this height at
  64.
    ImageList1->GetBitmap(4, bitmap2);
    ListBox1->Items->AddObject("Sunflower", bitmap2); // no bitmap, see if it leaves this height
  at 64.

  }

22.1.1.6.19 TCheckListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse

button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

22.1.1.6.20 TCheckListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area

of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

22.1.1.6.21 TCheckListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

22.1.1.6.22 TCheckListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

22.1.1.6.23 TCheckListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

22.1.1.6.24 TCheckListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

Responding to a Mouse-up Action

22.1.1.6.25 TCheckListBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

22.1.1.6.26 TCheckListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

This is namespace Classes.

Topics

Name	Description
Classes (see page 2692)	The following table lists classes in this documentation.
Interfaces (see page 3195)	The following table lists interfaces in this documentation.
Functions (see page 3214)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 3268)	The following table lists structs, records, enums in this documentation.
Types (see page 3282)	The following table lists types in this documentation.
Variables (see page 3309)	The following table lists variables in this documentation.
Constants (see page 3316)	The following table lists constants in this documentation.

Classes

	Name	Description
	EBitsError (see page 2693)	EBitsError is the exception class for invalid attempts to access an array of boolean values.
	EClassNotFound (see page 2694)	EClassNotFound is the exception class for the failure to find a specified component when reading from a stream.
	EComponentError (see page 2694)	EComponentError is the exception class for registering and renaming components.
	EFCreateError (see page 2695)	EFCreateError is the exception class for streaming file-creation errors.
	EFilerError (see page 2696)	EFilerError is the exception class for component stream errors.
	EFileStreamError (see page 2697)	EFileStreamError is the exception class for general stream errors.
	EFOpenError (see page 2699)	EFOpenError is the exception class for file-opening errors during streaming.
	EInvalidImage (see page 2699)	EInvalidImage is the exception class for unsuccessful attempts to read resources.
	EInvalidOperation (see page 2700)	EInvalidOperation is the exception class for invalid operations on a component.
	EListError (see page 2701)	EListError is the exception class for list and string errors.
	EMethodNotFound (see page 2701)	Deprecated, please use EReadError (see page 2703).
	EOutOfResources (see page 2702)	EOutOfResources is the exception class for unsuccessful attempts to allocate handles.
	EParserError (see page 2702)	EParserError is the exception class for text-to-binary streaming conversion errors.
	EReadError (see page 2703)	EReadError is the exception class for unsuccessful attempts to read data from a stream.
	EResNotFound (see page 2704)	EResNotFound is the exception class for unlocatable resources.
	EStreamError (see page 2704)	EStreamError is the exception class for streaming errors.
	EStringListError (see page 2705)	EStringListError is the exception class for invalid listbox references.

	EThread (see page 2706)	EThread is the exception class for thread synchronization errors.
	EWriteError (see page 2706)	EWriteError is the exception class for unsuccessful attempts to write data to a stream.
	TBasicAction (see page 2707)	TBasicAction is the ancestor class for all action objects.
	TBasicActionLink (see page 2720)	TBasicActionLink is the base class for action link classes that handle the communication between actions and clients.
	TBits (see page 2725)	TBits stores an array of Boolean values.
	TClassFinder (see page 2728)	This is class Classes.TClassFinder.
	TCollection (see page 2731)	TCollection is a container for TCollectionItem (see page 2755) objects.
	TCollectionEnumerator (see page 2753)	Enumerates through the TCollectionItems in a TCollection (see page 2731) object.
	TCollectionItem (see page 2755)	TCollectionItem represents an item in a collection.
	TComponent (see page 2762)	TComponent is the common ancestor of all component classes.
	TComponentEnumerator (see page 2812)	TComponentEnumerator allows the components within a containing component to be discovered.
	TCustomMemoryStream (see page 2815)	TCustomMemoryStream is an abstract base class used as the common ancestor for memory streams.
	TDataModule (see page 2824)	TDataModule centralizes the handling of nonvisual components in an application.
	TFiler (see page 2834)	TFiler is the abstract base class for reader and writer objects, which are used for loading and saving components and their properties.
	TFileStream (see page 2841)	TFileStream enables applications to read from and write to a file on disk.
	THandleStream (see page 2845)	THandleStream enables applications to read from and write to communications resources identified by a handle.
	TInterfacedPersistent (see page 2851)	TInterfacedPersistent is an ancestor for persistent objects that implement interfaces.
	TInterfaceList (see page 2855)	TInterfaceList represents a list of interfaces.
	TInterfaceListEnumerator (see page 2866)	Enumerates through the IInterfaces in a TInterfaceList (see page 2855).
	TList (see page 2868)	TList stores an array of pointers.
	TListEnumerator (see page 2900)	Enumerates through the objects in a TList (see page 2868).
	TMemoryStream (see page 2902)	TMemoryStream is a stream that stores its data in dynamic memory.
	TOwnedCollection (see page 2912)	TOwnedCollection is a collection that maintains information about its owner.
	TParser (see page 2915)	TParser allows DFM files to be parsed.
	TPersistent (see page 2928)	TPersistent is the ancestor for all objects that have assignment and streaming capabilities.
	TReader (see page 2933)	TReader is a specialized filer that reads component data from an associated stream.
	TRecall (see page 2964)	TRecall stores the properties of a persistent object so that they can be restored at a later time.
	TResourceStream (see page 2968)	TResourceStream is a memory stream that provides access to the compiled resources in an application.
	TStream (see page 2973)	TStream is the base class type for stream objects that can read from or write to various kinds of storage media, such as disk files, dynamic memory, and so on.
	TStreamAdapter (see page 2997)	TStreamAdapter implements the IStream interface on a TStream (see page 2973) object.
	TStringList (see page 3006)	TStringList maintains a list of strings.
	TStrings (see page 3029)	TStrings is the base class for objects that represent a list of strings.
	TStringsEnumerator (see page 3086)	Enumerates through the strings of a TStrings (see page 3029) object.
	TStringStream (see page 3088)	TStringStream provides file-like access to information stored as a long string.
	TThread (see page 3108)	TThread is an abstract class that enables creation of separate threads of execution in an application.
	TThreadList (see page 3149)	TThreadList represents a thread-safe list.
	TWriter (see page 3175)	TWriter is a specialized filer object that writes data to its associated stream.

Constants

Name	Description
fmCreate (see page 3316)	Specifies a file to be created with a specific name.
MaxListSize (see page 3317)	Defines the maximum capacity of certain list classes and types.
scAlt (see page 3317)	Specifies that the Alt key was pressed in a short cut menu.
scCtrl (see page 3318)	Specifies that the Ctrl key was pressed in a short cut menu.

scNone (see page 3318)	Specifies that none of the Shift, Ctrl or Alt keys were pressed in a short cut menu.
scShift (see page 3319)	Specifies that the Shift was pressed in a short cut menu.
soFromBeginning (see page 3319)	Specifies that a stream seek operation should move relative to the stream beginning.
soFromCurrent (see page 3320)	Specifies that a stream seek operation should move relative to the current position.
soFromEnd (see page 3320)	Specifies that a stream seek operation should move relative to the stream end.
toEOF (see page 3321)	Specifies a TParser (see page 2915) End of file token.
toFloat (see page 3322)	Specifies a TParser (see page 2915) floating point number token.
toInteger (see page 3322)	Specifies a TParser (see page 2915) integer token.
toString (see page 3323)	Specifies a TParser (see page 2915) string token.
toSymbol (see page 3324)	Specifies a TParser (see page 2915) symbol token.
toWString (see page 3324)	Specifies a TParser (see page 2915) wide string token.

Functions

	Name	Description
	ActivateClassGroup (see page 3215)	Activates a group of classes that derive from TPersistent (see page 2928).
	ActiveClassGroup (see page 3216)	Activates a group of classes that derive from TPersistent (see page 2928).
	AllocateHWnd (see page 3217)	DeallocateHWnd (see page 3221) is used to destroy a hidden window created using AllocateHWnd.
	AncestorIsValid (see page 3217)	AncestorIsValid determines if one component is an ancestor of another.
	BeginGlobalLoading (see page 3218)	This is function Classes.BeginGlobalLoading.
	BinToHex (see page 3218)	Converts a binary value into its hexadecimal representation.
	Bounds (see page 3218)	Creates a TRect structure from the top-left coordinate, and width and height values of a rectangle.
	CheckSynchronize (see page 3219)	Allows background threads to synchronize their execution with the main thread.
	ClassGroupOf (see page 3220)	Returns the group of persistent classes a specified class or instance belongs to.
	ClassGroupOf (see page 3220)	Returns the group of persistent classes a specified class or instance belongs to.
	CollectionsEqual (see page 3220)	Compares the contents of two collections.
	CountGenerations (see page 3221)	Returns the number of intermediate classes between a derived class and its ancestor.
	DeallocateHWnd (see page 3221)	Frees a window that was created using AllocateHWnd (see page 3217).
	EndGlobalLoading (see page 3222)	This is function Classes.EndGlobalLoading.
	ExtractStrings (see page 3222)	Fills a string list with substrings parsed from a delimited list.
	FindClass (see page 3223)	Finds and returns a class that is derived from TPersistent (see page 2928).
	FindGlobalComponent (see page 3223)	Returns a top-level container component.
	FindIdentToInt (see page 3224)	Returns the TIdentToInt (see page 3295) conversion routine for a given data type.
	FindIntToIdent (see page 3224)	Returns the TIntToIdent (see page 3296) conversion routine for a given data type.
	FindNestedComponent (see page 3225)	FindNestedComponent returns a component contained within another.
	FindRootDesigner (see page 3225)	This is function Classes.FindRootDesigner.
	FreeObjectInstance (see page 3226)	This is function Classes.FreeObjectInstance.
	GetClass (see page 3226)	Returns a registered persistent class given its name.
	GetFixupInstanceNames (see page 3228)	This is function Classes.GetFixupInstanceNames.
	GetFixupReferenceNames (see page 3228)	This is function Classes.GetFixupReferenceNames.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GlobalFixupReferences (see page 3229)	This is function Classes.GlobalFixupReferences.
	GroupDescendentsWith (see page 3229)	Adds a specified class to the group in which another class appears.
	HexToBin (see page 3230)	Converts a string of hexadecimal digits to the corresponding binary value.
	IdentToInt (see page 3230)	Uses a mapping array to convert string identifiers into their corresponding integer values.
	InitComponentRes (see page 3231)	This is function Classes.InitComponentRes.
	InitInheritedComponent (see page 3231)	Initializes streaming of a form file for an inherited root class.

	IntToIdent (see page 3232)	Uses a mapping array to convert integers into their corresponding string identifiers.
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	IsDefaultPropertyValue (see page 3233)	This is function Classes.IsDefaultPropertyValue.
	IsUniqueGlobalComponentName (see page 3234)	Indicates whether a proposed component name is unambiguous.
	LineStart (see page 3234)	Finds the end of the last whole line in a buffer.
	MakeObjectInstance (see page 3235)	This is function Classes.MakeObjectInstance.
	NotifyGlobalLoading (see page 3235)	This is function Classes.NotifyGlobalLoading.
	ObjectBinaryToText (see page 3235)	Converts the binary representation of an object into more readily understandable text.
	ObjectBinaryToText (see page 3235)	Converts the binary representation of an object into more readily understandable text.
	ObjectResourceToText (see page 3239)	Converts the binary representation of an object resource into more readily understandable text.
	ObjectResourceToText (see page 3239)	Converts the binary representation of an object resource into more readily understandable text.
	ObjectTextToBinary (see page 3240)	Converts a symbolic text representation of an object into the binary version that is used to save the object to files or memory streams.
	ObjectTextToBinary (see page 3240)	Converts a symbolic text representation of an object into the binary version that is used to save the object to files or memory streams.
	ObjectTextToResource (see page 3244)	Converts a symbolic text representation of an object into an internal binary representation.
	ObjectTextToResource (see page 3244)	Converts a symbolic text representation of an object into an internal binary representation.
	Point (see page 3244)	Creates a TPoint structure from a pair of coordinates.
	PointsEqual (see page 3245)	Indicates whether two points have the same coordinates.
	PointsEqual (see page 3245)	Indicates whether two points have the same coordinates.
	ReadComponentRes (see page 3245)	Reads components and their properties from a specified resource.
	ReadComponentResEx (see page 3246)	Reads a component from a resource.
	ReadComponentResFile (see page 3247)	Reads components and their properties from a specified Windows resource file.
	Rect (see page 3249)	Creates a TRect structure from a set of coordinates.
	Rect (see page 3249)	Creates a TRect structure from a set of coordinates.
	RedirectFixupReferences (see page 3250)	This is function Classes.RedirectFixupReferences.
	RegisterClass (see page 3250)	Registers a class of persistent object so that it's class type can be retrieved.
	RegisterClassAlias (see page 3254)	Registers a class that is identical to another class except for the name.
	RegisterClasses (see page 3255)	Registers a set of classes.
	RegisterComponents (see page 3256)	Registers a set of components so that they all appear on the same page of the component palette.
	RegisterFindGlobalComponentProc (see page 3259)	This is function Classes.RegisterFindGlobalComponentProc.
	RegisterIntegerConsts (see page 3259)	Registers conversion functions for string identifiers that represent type values.
	RegisterNoIcon (see page 3260)	Registers a set of components but does not add them to the component palette.
	RegisterNonActiveX (see page 3260)	Prevents a set of components from being made available to the ActiveX wizard.
	RemoveFixupReferences (see page 3261)	This is function Classes.RemoveFixupReferences.
	RemoveFixups (see page 3261)	This is function Classes.RemoveFixups.
	SmallPoint (see page 3262)	Creates a TSmallPoint structure from a pair of coordinates.
	StartClassGroup (see page 3262)	Starts a class group derived from TPersistent (see page 2928).
	TestStreamFormat (see page 3263)	Identifies the format of a form file when reading it from a stream.
	UnRegisterClass (see page 3263)	Unregisters an object class.
	UnRegisterClasses (see page 3264)	Unregisters a set of classes.
	UnregisterFindGlobalComponentProc (see page 3264)	This is function Classes.UnregisterFindGlobalComponentProc.
	UnregisterIntegerConsts (see page 3264)	Unregisters conversion functions for string identifiers that represent type values.
	UnRegisterModuleClasses (see page 3265)	Unregisters all classes defined in a specified module.
	WriteComponentResFile (see page 3266)	Writes components and their properties to a file using a resource file format.

Interfaces

	Name	Description
	IDesignerNotify (see page 3195)	IDesignerNotify is the interface for responding to notifications about changes to components in the designer.
	IInterfaceComponentReference (see page 3197)	IInterfaceComponentReference is the interface for responding to requests for retrieving components.
	IInterfaceList (see page 3198)	IInterfaceList provides access to a list of interfaces.
	IStreamPersist (see page 3207)	IStreamPersist is the interface for responding to requests to load/save an object from/to a persistent stream.
	IStringsAdapter (see page 3208)	This is class Classes.IStringsAdapter.
	IVarStreamable (see page 3210)	IVarStreamable is the interface for loading and saving the values of Variants (see page 23567).
	IVCLComObject (see page 3211)	This is class Classes.IVCLComObject.

Structs, Records, Enums

	Name	Description
	TActiveXRegType (see page 3268)	TActiveXRegType is used when excluding a component class from the ActiveX Wizard.
	TAlignment (see page 3269)	TAlignment specifies how text is aligned within a control.
	TBiDiMode (see page 3269)	TBiDiMode specifies the reading order (bidirectional mode) of a control.
	TCollectionNotification (see page 3270)	TCollectionNotification indicates the type of change that is made to the items in a collection.
	TDuplicates (see page 3271)	TDuplicates indicates the response when an application attempts to add a duplicate entry to a list.
	TFilerFlag (see page 3271)	TFilerFlag indicates information about how a filer should read or write a component and TFilerFlags (see page 3289) is a set of TFilerFlag values.
	THelpType (see page 3272)	THelpType indicates whether components invoke the help system using a context ID or a keyword.
	TIdentMapEntry (see page 3273)	TIdentMapEntry is used to perform ident string to integer value mapping.
	TListAssignOp (see page 3273)	TListAssignOp indicates how two lists should be merged.
	TListNotification (see page 3274)	TListNotification defines list processing action types.
	TOperation (see page 3275)	TOperation represents the types of operations whose occurrence is broadcast by the Notification method.
	TSeekOrigin (see page 3276)	TSeekOrigin indicates where to start a seek operation.
	TStreamOriginalFormat (see page 3276)	TStreamOriginalFormat indicates the format in which a form file is saved.
	TStreamOwnership (see page 3277)	TStreamOwnership indicates whether a stream object should be freed by the object that uses it.
	TStringItem (see page 3277)	TStringItem defines a TStringList (see page 3006) entry.
	TSynchronizeRecord (see page 3278)	This is record Classes.TSynchronizeRecord.
	TThreadPriority (see page 3278)	TThreadPriority indicates the scheduling priority of a thread object on Windows.
	TValueType (see page 3279)	TValueType defines the kinds of values written to and read from filer objects.
	TVerticalAlignment (see page 3280)	TVerticalAlignment specifies how text is vertically aligned within a control.

Types

Name	Description
PPointerList (see page 3283)	PPointerList is a pointer to a TPointerList (see page 3299) type.
PStringItem (see page 3284)	PStringItem is a TStringItem (see page 3277) pointer.
PStringItemList (see page 3284)	PStringItemList is a TStringItemList (see page 3304) pointer.
PSynchronizeRecord (see page 3285)	This is type Classes.PSynchronizeRecord.
TAncestorNotFoundEvent (see page 3285)	TAncestorNotFoundEvent is a procedure called by the TReader (see page 2933) class OnAncestorNotFound event.
TBasicActionClass (see page 3285)	TBasicActionClass defines the metaclass for TBasicAction (see page 2707).
TBasicActionLinkClass (see page 3286)	TBasicActionLinkClass defines the metaclass for TBasicActionLink (see page 2720).
TCollectionItemClass (see page 3286)	TCollectionItemClass defines the metaclass for TCollectionItem (see page 2755).
TComponentClass (see page 3287)	TComponentClass defines the metaclass for TComponent (see page 2762).
TComponentName (see page 3287)	TComponentName is the type for the Name property of all components.

TComponentState (see page 3287)	TComponentState is a set of flags that describe the current state of a component.
TComponentStyle (see page 3288)	TComponentStyle is a set of flags that describe the current Style of a component.
TCreateComponentEvent (see page 3289)	TCreateComponentEvent is a type of procedure called by the TReader (see page 2933) class OnCreateComponentEvent event.
TFilerFlags (see page 3289)	TFilerFlags is the set of TFilerFlag (see page 3271) values.
TFindAncestorEvent (see page 3290)	TFindAncestorEvent is a procedure called by the TWriter (see page 3175) class OnFindAncestor event.
TFindComponentClassEvent (see page 3290)	This is type Classes.TFindComponentClassEvent.
TFindComponentInstanceEvent (see page 3291)	This is type Classes.TFindComponentInstanceEvent.
TFindGlobalComponent (see page 3291)	This is type Classes.TFindGlobalComponent.
TFindMethodEvent (see page 3291)	TFindMethodEvent is a procedure called by the TReader (see page 2933) class OnFindMethod event.
TFindMethodInstanceEvent (see page 3292)	TFindMethodInstanceEvent is a procedure called by the TReader (see page 2933) class OnFindMethodInstance event.
TFindMethodNameEvent (see page 3292)	TFindMethodNameEvent is a procedure called by the TWriter (see page 3175) class OnFindMethodName event.
TGetChildProc (see page 3292)	TGetChildProc is a type of procedure called used internally by the TComponent (see page 2762) class.
TGetClass (see page 3293)	TGetClass is a callback procedure used by the TClassFinder (see page 2728) class.
TGetLookupInfoEvent (see page 3293)	This is type Classes.TGetLookupInfoEvent.
TGetModuleProc (see page 3294)	This is type Classes.TGetModuleProc.
TGetStrProc (see page 3294)	TGetStrProc is a general purpose type of callback procedure invoked for each of a set of strings.
THelpContext (see page 3295)	THelpContext is the range of values that a HelpContext value may have.
TIdentToInt (see page 3295)	TIdentToInt is a type of callback function used by the IdentToInt (see page 3230) routine.
TIntToIdent (see page 3296)	TIntToIdent is a type of callback function used by the IntToIdent (see page 3232) routine.
TIsUniqueGlobalComponentName (see page 3296)	TIsUniqueGlobalComponentName is a type of function used by IsUniqueGlobalComponentName (see page 3234).
TLeftRight (see page 3297)	TLeftRight is a subset of TAlignment (see page 3269) that allows left or right justification.
TListSortCompare (see page 3297)	TListSortCompare is a type of callback function called used internally by the TList (see page 2868) class.
TNotifyEvent (see page 3298)	TNotifyEvent is used for events that do not require parameters.
TParserErrorEvent (see page 3298)	TParserErrorEvent is a callback procedure used by the TClassFinder (see page 2728) class.
TPersistentClass (see page 3299)	TPersistentClass defines the metaclass for TPersistent (see page 2928).
TPointerList (see page 3299)	TPointerList is an array of pointers.
TReadComponentsProc (see page 3300)	TReadComponentsProc is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.
TReaderError (see page 3300)	TReaderError is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.
TReaderProc (see page 3301)	TReaderProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.
TReferenceNameEvent (see page 3301)	TReferenceNameEvent is a procedure called by the TReader (see page 2933) class OnReferenceNameEvent event.
TSetNameEvent (see page 3302)	TSetNameEvent is a procedure called by the TReader (see page 2933) class OnSetNameEvent event.
TShiftState (see page 3302)	TShiftState indicates the state of the Alt, Ctrl, and Shift keys and the mouse buttons.
TShortCut (see page 3303)	TStringsDefined (see page 3306) defines an enumeration of string delimiter names.
TStreamProc (see page 3304)	TStreamProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineBinaryProperty methods.
TStringItemList (see page 3304)	TStringItemList defines an array of TStringItems.
TStringListSortCompare (see page 3305)	TStringListSortCompare is a type of callback function called used internally by the TStringList (see page 3006) class.
TStringsDefined (see page 3306)	This is type Classes.TStringsDefined.
TThreadMethod (see page 3306)	This is type Classes.TThreadMethod.

TTopBottom (see page 3306)	TTopBottom is a subset of TVerticalAlignment (see page 3280) that allows top or bottom alignment.
TWndMethod (see page 3307)	TWndMethod is the type for Windows message procedures.
TWriterProc (see page 3307)	TWriterProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.

Variables

Name	Description
AddDataModule (see page 3309)	Defines a procedure to be called when a TDataModule (see page 2824) class is created.
ApplicationHandleException (see page 3310)	This is variable Classes.ApplicationHandleException.
ApplicationShowException (see page 3310)	This is variable Classes.ApplicationShowException.
CreateVCLComObjectProc (see page 3310)	This is variable Classes.CreateVCLComObjectProc.
CurrentGroup (see page 3311)	Keeps track of which objects are associated with which packages.
GlobalNameSpace (see page 3311)	This is variable Classes.GlobalNameSpace.
IsUniqueGlobalComponentNameProc (see page 3311)	IsUniqueGlobalComponentNameProc is called by IsUniqueGlobalComponentName (see page 3234).
RegisterComponentsProc (see page 3312)	RegisterComponentsProc is called by RegisterComponents (see page 3256).
RegisterNoIconProc (see page 3313)	RegisterNoIconProc is called by RegisterNoIcon (see page 3260).
RegisterNonActiveXProc (see page 3313)	RegisterNonActiveXProc is called by RegisterNonActiveX (see page 3260).
RemoveDataModule (see page 3314)	Defines a procedure to be called when a TDataModule (see page 2824) class is destroyed.
WakeMainThread (see page 3314)	Represents a method (event handler) that is forced into the main thread's queue.

23.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EBitsError (see page 2693)	EBitsError is the exception class for invalid attempts to access an array of boolean values.
	EClassNotFound (see page 2694)	EClassNotFound is the exception class for the failure to find a specified component when reading from a stream.
	EComponentError (see page 2694)	EComponentError is the exception class for registering and renaming components.
	EFCreateError (see page 2695)	EFCreateError is the exception class for streaming file-creation errors.
	EFilerError (see page 2696)	EFilerError is the exception class for component stream errors.
	EFileStreamError (see page 2697)	EFileStreamError is the exception class for general stream errors.
	EFOpenError (see page 2699)	EFOpenError is the exception class for file-opening errors during streaming.
	EInvalidImage (see page 2699)	EInvalidImage is the exception class for unsuccessful attempts to read resources.
	EInvalidOperation (see page 2700)	EInvalidOperation is the exception class for invalid operations on a component.
	EListError (see page 2701)	EListError is the exception class for list and string errors.
	EMethodNotFound (see page 2701)	Deprecated, please use EReadError (see page 2703).
	EOutOfResources (see page 2702)	EOutOfResources is the exception class for unsuccessful attempts to allocate handles.
	EParserError (see page 2702)	EParserError is the exception class for text-to-binary streaming conversion errors.
	EReadError (see page 2703)	EReadError is the exception class for unsuccessful attempts to read data from a stream.
	EResNotFound (see page 2704)	EResNotFound is the exception class for unlocatable resources.
	EStreamError (see page 2704)	EStreamError is the exception class for streaming errors.
	EStringListError (see page 2705)	EStringListError is the exception class for invalid listbox references.
	EThread (see page 2706)	EThread is the exception class for thread synchronization errors.
	EWriteError (see page 2706)	EWriteError is the exception class for unsuccessful attempts to write data to a stream.
	TBasicAction (see page 2707)	TBasicAction is the ancestor class for all action objects.
	TBasicActionLink (see page 2720)	TBasicActionLink is the base class for action link classes that handle the communication between actions and clients.
	TBits (see page 2725)	TBits stores an array of Boolean values.
	TClassFinder (see page 2728)	This is class Classes.TClassFinder.
	TCollection (see page 2731)	TCollection is a container for TCollectionItem (see page 2755) objects.
	TCollectionEnumerator (see page 2753)	Enumerates through the TCollectionItems in a TCollection (see page 2731) object.
	TCollectionItem (see page 2755)	TCollectionItem represents an item in a collection.
	TComponent (see page 2762)	TComponent is the common ancestor of all component classes.
	TComponentEnumerator (see page 2812)	TComponentEnumerator allows the components within a containing component to be discovered.
	TCustomMemoryStream (see page 2815)	TCustomMemoryStream is an abstract base class used as the common ancestor for memory streams.
	TDataModule (see page 2824)	TDataModule centralizes the handling of nonvisual components in an application.
	TFiler (see page 2834)	TFiler is the abstract base class for reader and writer objects, which are used for loading and saving components and their properties.
	TFileStream (see page 2841)	TFileStream enables applications to read from and write to a file on disk.
	THandleStream (see page 2845)	THandleStream enables applications to read from and write to communications resources identified by a handle.
	TInterfacedPersistent (see page 2851)	TInterfacedPersistent is an ancestor for persistent objects that implement interfaces.
	TInterfaceList (see page 2855)	TInterfaceList represents a list of interfaces.

	TInterfaceListEnumerator (see page 2866)	Enumerates through the IInterfaces in a TInterfaceList (see page 2855).
	TList (see page 2868)	TList stores an array of pointers.
	TListEnumerator (see page 2900)	Enumerates through the objects in a TList (see page 2868).
	TMemoryStream (see page 2902)	TMemoryStream is a stream that stores its data in dynamic memory.
	TOwnedCollection (see page 2912)	TOwnedCollection is a collection that maintains information about its owner.
	TParser (see page 2915)	TParser allows DFM files to be parsed.
	TPersistent (see page 2928)	TPersistent is the ancestor for all objects that have assignment and streaming capabilities.
	TReader (see page 2933)	TReader is a specialized filer that reads component data from an associated stream.
	TRecall (see page 2964)	TRecall stores the properties of a persistent object so that they can be restored at a later time.
	TResourceStream (see page 2968)	TResourceStream is a memory stream that provides access to the compiled resources in an application.
	TStream (see page 2973)	TStream is the base class type for stream objects that can read from or write to various kinds of storage media, such as disk files, dynamic memory, and so on.
	TStreamAdapter (see page 2997)	TStreamAdapter implements the IStream interface on a TStream (see page 2973) object.
	TStringList (see page 3006)	TStringList maintains a list of strings.
	TStrings (see page 3029)	TStrings is the base class for objects that represent a list of strings.
	TStringsEnumerator (see page 3086)	Enumerates through the strings of a TStrings (see page 3029) object.
	TStringStream (see page 3088)	TStringStream provides file-like access to information stored as a long string.
	TThread (see page 3108)	TThread is an abstract class that enables creation of separate threads of execution in an application.
	TThreadList (see page 3149)	TThreadList represents a thread-safe list.
	TWriter (see page 3175)	TWriter is a specialized filer object that writes data to its associated stream.

23.1.1 EBitsError Class

EBitsError is the exception class for invalid attempts to access an array of boolean values.

Class Hierarchy

Pascal

```
EBitsError = class(Exception);
```

C++

```
class EBitsError : public Exception;
```

File

Classes

Description

EBitsError is raised when an application attempts to access a boolean array (an instance of the TBits (see page 2725) class) using an index value that is too large or too small. This can occur when the value of the Index parameter of the Bits property is

Less than zero.

Equal to or greater than the Size property.

See Also

TBits (see page 2725)

TBits (see page 2725)

TBits (see page 2725)

ERangeError

23.1.2 EClassNotFound Class

EClassNotFound is the exception class for the failure to find a specified component when reading from a stream.

Class Hierarchy

Pascal

```
EClassNotFound = class(EFilerError);
```

C++

```
class EClassNotFound : public EFilerError;
```

File

Classes

Description

EClassNotFound is raised if a class name that has not been linked into the current application is encountered when reading a component from a stream. This can happen when a component exists on a form, but has been removed from the type declaration.

See Also

FindClass (see page 3223)

TReader (see page 2933)

23.1.3 EComponentError Class

EComponentError is the exception class for registering and renaming components.

Class Hierarchy

Pascal

```
EComponentError = class(Exception);
```

C++

```
class EComponentError : public Exception;
```

File

Classes

Description

EComponentError is raised when:

An attempt to register a component fails.

An application cannot rename a component.

(Windows-only) A request is made to retrieve the COM interface of a component that doesn't support COM.

To register a component, write a procedure called "Register", declared in the interface section (Delphi) or namespace (C++) of the component's unit file. Note that unlike most Delphi procedure names, the name of the Register procedure is case-sensitive. Register must call RegisterComponents (see page 3256) for each component you want to register.

Failure to rename a component occurs when an application tries to rename the component at runtime, and the new name is the same as the name of another component with the same Owner or is not a valid identifier.

See Also

RegisterComponents (see page 3256)

RegisterNoIcon (see page 3260)

TComponent (see page 2762)

TComponent (see page 2762)

TComponent (see page 2762)

TCoolBar (see page 3603)

TDataSet (see page 6894)

TComponent (see page 2762)

23.1.4 EFCreateError Class

EFCreateError is the exception class for streaming file-creation errors.

Class Hierarchy

Pascal

```
EFCreateError = class(EFileStreamError);
```

C++

```
class EFCreateError : public EFileStreamError;
```

File

Classes

Description

EFCreateError is raised when an application unsuccessfully attempts to create a file. This can occur, for example, if a user specifies an invalid file name, or specifies the name of an existing file that cannot be overwritten because the user lacks appropriate access permission.

See Also

EFOpenError (see page 2699)

EFilerError (see page 2696)

TFileStream (see page 2841)

TStrings (see page 3029)

TCustomMemoryStream (see page 2815)

TMemoryStream (see page 2902)

ReadComponentResFile (see page 3247)

WriteComponentResFile (see page 3266)

23.1.5 EFilerError Class

EFilerError is the exception class for component stream errors.

Class Hierarchy

Pascal

```
EFilerError = class(EStreamError);
```

C++

```
class EFilerError : public EStreamError;
```

File

Classes

Description

EFilerError is raised when an error occurs while streaming a component. Some, but not all, component streaming errors raise descendants of EFilerError, as follows.

Exception	Description
EReadError (see page 2703)	Cannot read the specified number of bytes
EWriteError (see page 2706)	Cannot write the specified number of bytes
EClassNotFound (see page 2694)	Component is not linked to application
EInvalidImage (see page 2699)	Cannot read an resource file

EFilerError differs from EFileStreamError (see page 2697), which is raised by errors in general file streams.

See Also

RegisterClass (see page 3250)

EReadError (see page 2703)

EWriteError (see page 2706)

EClassNotFound (see page 2694)

EInvalidImage (see page 2699)

TStream (see page 2973)

TStream (see page 2973)

TStream (see page 2973)

23.1.6 EFileStreamError Class

EFileStreamError is the exception class for general stream errors.

Class Hierarchy

Pascal

```
EFileStreamError = class(EStreamError);
```

C++

```
class EFileStreamError : public EStreamError;
```

File

Classes

Description

EFileStreamError is raised when an error occurs while streaming data. Some, but not all, data streaming errors raise descendants of EFileStreamError, as follows.

Exception	Description
EFCreateError (see page 2695)	Error while creating a new file for streaming.
EFOpenError (see page 2699)	Error while opening an existing file for streaming.

EFileStreamError differs from EFilerError (see page 2696), which is raised by errors in component streams.

See Also

TFileStream (see page 2841)

23.1.6.1 EFileStreamError Members

The following tables list the members exposed by EFileStreamError.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2698)	Creates a new EFileStreamError (see page 2697) object.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.

	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

23.1.6.2 EFileStreamError.Create Constructor

Creates a new EFileStreamError (see page 2697) object.

Pascal

```
constructor Create(ResStringRec: PResStringRec; const FileName: string);
```

C++

```
__fastcall EFileStreamError(PResStringRec ResStringRec, const AnsiString FileName);
```

Description

Create instantiates an exception object with a simple message string. Use the throw keyword with the constructor. For example,

```
throw EFileStreamError ("My error message");
```

Msg is the runtime error message that appears in the exception dialog box.

Args is an array of constants containing values to format according to format specifiers in Msg.

Args_Size is the index of the last constant in Args (one less than the number of entries).

AHelpContext is an integer that specifies the context-sensitive Help ID for the exception.

Ident is the unique ID of the string resource for the error message as specified in the RES file. If Ident is not a valid resource ID, the constructor creates an empty message string for the exception.

ResStringRec is a struct that describes a resourced string by giving its module and resource ID. It is used primarily with Delphi resourcestring values.

23.1.7 EFOpenError Class

EFOpenError is the exception class for file-opening errors during streaming.

Class Hierarchy

Pascal

```
EFOpenError = class(EFileStreamError);
```

C++

```
class EFOpenError : public EFileStreamError;
```

File

Classes

Description

EFOpenError is raised when an application cannot open a specified file. This can occur, for example, because the file doesn't exist or is not in the directory where the application is searching for it.

See Also

EFOpenError

EFilerError (see page 2696)

TFileStream (see page 2841)

TStrings (see page 3029)

TCustomMemoryStream (see page 2815)

TMemoryStream (see page 2902)

ReadComponentResFile

WriteComponentResFile

23.1.8 EInvalidImage Class

EInvalidImage is the exception class for unsuccessful attempts to read resources.

Class Hierarchy

Pascal

```
EInvalidImage = class(EFilerError);
```

C++

```
class EInvalidImage : public EFilerError;
```

File

Classes

Description

EInvalidImage is raised when an application cannot read a resource. This occurs most often because the specified file is not a resource file.

This error can occur if the TStream (see page 2973) object's read and write methods are used inconsistently. Always use ReadComponentRes (see page 3245) to read components written with WriteComponentRes, and ReadComponent to read components written with WriteComponent. Failure to use the corresponding read and write methods can result in EInvalidImage exceptions.

See Also

TStream (see page 2973)

ObjectResourceToText (see page 3239)

23.1.9 EInvalidOperation Class

EInvalidOperation is the exception class for invalid operations on a component.

Class Hierarchy

Pascal

```
EInvalidOperation = class(Exception);
```

C++

```
class EInvalidOperation : public Exception;
```

File

Classes

Description

EInvalidOperation is raised when an application attempts an operation that requires a window or widget handle on a component that does not have a parent (The Parent property is Nil in Delphi or NULL in C++). This exception can also occur if a drag-and-drop operation is attempted from a form (for example, when calling the BeginDrag method of a form).

Note: Do not confuse this object with EInvalidOp.

See Also

TWidgetControl

TWinControl (see page 6112)

BeginDrag

ValidParentForm

EInvalidOp (see page 22738)

23.1.10 EListError Class

EListError is the exception class for list and string errors.

Class Hierarchy

Pascal

```
EListError = class(Exception);
```

C++

```
class EListError : public Exception;
```

File

Classes

Description

EListError is raised when an error is made in a list, TStrings (see page 3029), or TStringList (see page 3006) object. This exception commonly occurs when an application refers to an item that is out of the list's range.

EListError also occurs if an application tries to add a duplicate string to a TStringList (see page 3006) object when the value of the Duplicates property is dupError.

An EListError exception is raised when an application attempts to insert a string into a sorted string list, since the insertion of a string at a specified position may put the list out of order.

See Also

TCollection (see page 2731)

TComponent (see page 2762)

TCustomListBox (see page 21308)

TStringList (see page 3006)

TStringList (see page 3006)

EStringListError (see page 2705)

23.1.11 EMethodNotFound Class

Deprecated, please use EReadError (see page 2703).

Class Hierarchy

Pascal

```
EMethodNotFound = class(EFilerError);
```

C++

```
class EMethodNotFound : public EFilerError;
```

File

Classes

Description

The method EMethodNotFound has been deprecated, please use EReadError (see page 2703) in its place..

See Also

about EReadError

23.1.12 EOutOfResources Class

EOutOfResources is the exception class for unsuccessful attempts to allocate handles.

Class Hierarchy

Pascal

```
EOutOfResources = class(EOutOfMemory);
```

C++

```
class EOutOfResources : public EOutOfMemory;
```

File

Classes

Description

EOutOfResources is raised when an application attempts to create a Windows or widget handle and there are no more handles to allocate.

See Also

TWinControl (see page 6112)

TWinControl (see page 6112)

GetDeviceContext

TApplication (see page 13660)

CreateHandle

TTreeNodes (see page 5266)

InsertObject

EOutOfMemory (see page 22742)

23.1.13 EParserError Class

EParserError is the exception class for text-to-binary streaming conversion errors.

Class Hierarchy

System::TObject → SysUtils.Exception → Classes.EParserError

Pascal

```
EParserError = class(Exception);
```

C++

```
class EParserError : public Exception;
```

File

Classes

Description

EParserError is raised when an error occurs during text-to-binary conversion, usually due to a syntax error in the source text.

See Also

ObjectTextToBinary (see page 3240)

ObjectTextToResource (see page 3244)

23.1.14 EReadError Class

EReadError is the exception class for unsuccessful attempts to read data from a stream.

Class Hierarchy

System::TObject → SysUtils.Exception → Classes.EStreamError → Classes.EFilerError → Classes.EReadError

Pascal

```
EReadError = class(EFilerError);
```

C++

```
class EReadError : public EFilerError;
```

File

Classes

Description

EReadError is raised when an application attempts to read data from a stream but cannot read the specified number of bytes.

An EReadError exception may also be raised if a property cant be read while creating a form. This can occur because a component reads the form resource incorrectly, or because the resource is corrupt.

See Also

TReader (see page 2933)

TStream (see page 2973)

TStream (see page 2973)

TStream (see page 2973)

TStream (see page 2973)

TMemoryStream (see page 2902)

TMemoryStream (see page 2902)

23.1.15 EResNotFound Class

EResNotFound is the exception class for unlocatable resources.

Class Hierarchy

Pascal

```
EResNotFound = class(Exception);
```

C++

```
class EResNotFound : public Exception;
```

File

Classes

Description

EResNotFound is raised when a specified resource (such as a form or bitmap) can't be found in a form file or a resource file, or when the resource is not linked into the application.

If you receive this exception on startup of an application, or when you create a form, check the form's unit file for the compiler directive that links in the form file.

Note: In Delphi, this directive is {$R *.dfm} (for VCL forms)

In Delphi, this directive is {$R *.dfm} (for VCL forms)

Note: In C++, this directive #pragma resource #pragma resource "*.dfm" (for VCL forms)

If this directive is missing or commented out, the form file is not included in the executable and an EResNotFound exception is generated.

See Also

ReadComponentRes (see page 3245)

ReadComponentResEx (see page 3246)

TResourceStream (see page 2968)

23.1.16 EStreamError Class

EStreamError is the exception class for streaming errors.

Class Hierarchy

Pascal

```
EStreamError = class(Exception);
```

C++

```
class EStreamError : public Exception;
```

File

Classes

Description

EStreamError is the ancestor from which all streaming exception classes descend. EStreamError is itself raised when resources cannot be allocated for a memory stream.

See Also

TStream (see page 2973)

TMemoryStream (see page 2902)

TResourceStream (see page 2968)

EFCreateError (see page 2695)

EFOpenError (see page 2699)

EFilerError (see page 2696)

EClassNotFound (see page 2694)

EInvalidImage (see page 2699)

EReadError (see page 2703)

EWriteError (see page 2706)

EInOutError (see page 22732)

23.1.17 EStringListError Class

EStringListError is the exception class for invalid listbox references.

Class Hierarchy

Pascal

```
EStringListError = class(Exception);
```

C++

```
class EStringListError : public Exception;
```

File

Classes

Description

EStringListError is raised when an application attempts to access a list box (for example, to add an item) using an invalid index.

See Also

TCustomListBox (see page 21308)

EListError (see page 2701)

23.1.18 EThread Class

EThread is the exception class for thread synchronization errors.

Class Hierarchy

Pascal

```
EThread = class(Exception);
```

C++

```
class EThread : public Exception;
```

File

Classes

Description

EThread is never raised. It is defined for backward compatibility.

See Also

TThread (see page 3108)

TThread (see page 3108)

23.1.19 EWriteError Class

EWriteError is the exception class for unsuccessful attempts to write data to a stream.

Class Hierarchy

Pascal

```
EWriteError = class(EFilerError);
```

C++

```
class EWriteError : public EFilerError;
```

File

Classes

Description

EWriteError is raised when:

The WriteBuffer method of a stream object is unable to write the specified number of bytes.

The IDE is unable to write one of a component's properties to a stream. This can occur when you try to save a form at design time.

See Also

TStream (see page 2973)

TStream (see page 2973)

23.1.20 TBasicAction Class

TBasicAction is the ancestor class for all action objects.

Class Hierarchy

Pascal

```
TBasicAction = class(TComponent);
```

C++

```
class TBasicAction : public TComponent;
```

File

Classes

Description

TBasicAction introduces the fundamental behavior for an action. Descendants of TBasicAction add functionality for containment in an action list, for being categorized, and for specializing their behavior tailored to particular clients such as controls or menu items. Use TBasicAction if you want to create an action for an object that is neither a menu item nor a control.

23.1.20.1 TBasicAction Members

The following tables list the members exposed by TBasicAction.

Protected Events

	Name	Description
	OnChange (see page 2716)	Occurs when one of the action's properties changes.

Protected Fields

	Name	Description
	FClients (see page 2711)	This is FClients, a member of class TBasicAction.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Change (see page 2712)	Generates an OnChange (see page 2716) event.

	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2713)	Responds when components are created or destroyed.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetOnExecute (see page 2714)	Assigns an OnExecute (see page 2716) event handler.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Events

	Name	Description
	OnExecute (see page 2716)	Occurs when the client event that is linked to it fires.
	OnUpdate (see page 2718)	Occurs when the application is idle or when the action list updates.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.

	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2710)	Instantiates and initializes a TBasicAction (see page 2707) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2711)	Disposes of an instance of a TBasicAction (see page 2707) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 2712)	Generates an OnExecute (see page 2716) event.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	ExecuteTarget (see page 2712)	Introduces an interface for invoking an action on a target client component or control.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HandlesTarget (see page 2713)	Introduces an interface for verifying that the type, and state, of a target component or control are appropriate for the action.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RegisterChanges (see page 2713)	Associates the action with an action link.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)

V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UnRegisterChanges (see page 2714)	Breaks the association between the action and the action link.
V	Update (see page 2714)	Provides an opportunity to execute centralized code when an application is idle.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
V	UpdateTarget (see page 2715)	Introduces an interface for a method of notifying a client when the action updates itself.

Public Properties

	Name	Description
	ActionComponent (see page 2715)	Indicates the client component that caused this action to execute.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

23.1.20.2 TBasicAction.Create Constructor

Instantiates and initializes a TBasicAction (see page 2707) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBasicAction(TComponent * AOwner);
```

Description

Applications do not need to instantiate TBasicAction (see page 2707) directly. Actions are created automatically when you choose New Action in the action list editor. If you want to create an action at runtime, call Create and assign a TActionList component to its ActionList property.

Create calls the inherited constructor and then creates its sub-objects, which includes a list of clients that are action links.

See Also

Create (see page 2766)

TActionList (see page 280)

ActionList (see page 295)

23.1.20.3 TBasicAction.Destroy Destructor

Disposes of an instance of a TBasicAction (see page 2707) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBasicAction();
```

Description

You do not need to call the destructor for an action. An action is a component and is automatically destroyed by its owner, which was passed to the constructor when it is created. If you must destroy an action manually, call Free instead, which safely invokes the destructor.

See Also

Free (see page 22300)

23.1.20.4 TBasicAction Fields

The fields of the TBasicAction class are listed here.

Protected Fields

	Name	Description
	FClients (see page 2711)	This is FClients, a member of class TBasicAction.

23.1.20.4.1 TBasicAction.FClients Field

Pascal

```
FClients: TList;
```

C++

```
TList FClients;
```

Description

This is FClients, a member of class TBasicAction.

23.1.20.5 TBasicAction Methods

The methods of the TBasicAction class are listed here.

Protected Methods

	Name	Description
V	Change (see page 2712)	Generates an OnChange (see page 2716) event.
V	Notification (see page 2713)	Responds when components are created or destroyed.
V	SetOnExecute (see page 2714)	Assigns an OnExecute (see page 2716) event handler.

Public Methods

	Name	Description
	Execute (see page 2712)	Generates an OnExecute (see page 2716) event.

	ExecuteTarget (see page 2712)	Introduces an interface for invoking an action on a target client component or control.
	HandlesTarget (see page 2713)	Introduces an interface for verifying that the type, and state, of a target component or control are appropriate for the action.
	RegisterChanges (see page 2713)	Associates the action with an action link.
	UnRegisterChanges (see page 2714)	Breaks the association between the action and the action link.
	Update (see page 2714)	Provides an opportunity to execute centralized code when an application is idle.
	UpdateTarget (see page 2715)	Introduces an interface for a method of notifying a client when the action updates itself.

23.1.20.5.1 TBasicAction.Change Method

Generates an OnChange (see page 2716) event.

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

Change is called automatically when the action's properties change. This method calls the OnChange (see page 2716) event handler, if one is assigned.

See Also

OnChange (see page 2716)

23.1.20.5.2 TBasicAction.Execute Method

Generates an OnExecute (see page 2716) event.

Pascal

```
function Execute: Boolean; dynamic;
```

C++

```
__fastcall Boolean Execute();
```

Description

Execute calls the OnExecute (see page 2716) event handler, if one is assigned, with the action as the Sender. Execute returns true if an event handler is called, false otherwise.

See Also

OnExecute (see page 2716)

23.1.20.5.3 TBasicAction.ExecuteTarget Method

Introduces an interface for invoking an action on a target client component or control.

Pascal

```
procedure ExecuteTarget(Target: TObject); virtual;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

ExecuteTarget does nothing in TBasicAction (see page 2707). ExecuteTarget was introduced in TBasicAction (see page 2707) so that descendants can override it to initiate the action on the target. For example, an edit action that performs copying might copy the contents of an edit control to the clipboard.

See Also

OnExecute (see page 2716)

HandlesTarget (see page 2713)

23.1.20.5.4 TBasicAction.HandlesTarget Method

Introduces an interface for verifying that the type, and state, of a target component or control are appropriate for the action.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

HandlesTarget does nothing in TBasicAction (see page 2707). HandlesTarget was introduced in TBasicAction (see page 2707) so that descendants can override it to check the type and state of a target. Handles target can verify any information about a target that is relevant for the action. HandlesTarget returns true if the target meets the specified criteria, false otherwise.

See Also

ExecuteTarget (see page 2712)

23.1.20.5.5 TBasicAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction (see page 2707) overrides the Notification method to check whether the component that is the value of the ActionComponent (see page 2715) property is about to be freed. If so, it sets the ActionComponent (see page 2715) property to nil (Delphi) or NULL (C++).

See Also

ActionComponent (see page 2715)

23.1.20.5.6 TBasicAction.RegisterChanges Method

Associates the action with an action link.

Pascal

```
procedure RegisterChanges(Value: TBasicActionLink);
```

C++

```
__fastcall RegisterChanges(TBasicActionLink Value);
```

Description

RegisterChanges is called when the action and link are connected, for example, when a link sets a new action. Value is the action link with which the action associates itself. The link is added to the action's client list.

See Also

UnRegisterChanges (see page 2714)

23.1.20.5.7 TBasicAction.SetOnExecute Method

Assigns an OnExecute (see page 2716) event handler.

Pascal

```
procedure SetOnExecute(Value: TNotifyEvent); virtual;
```

C++

```
virtual __fastcall SetOnExecute(TNotifyEvent Value);
```

Description

SetOnExecute is the property write method for the OnExecute (see page 2716) event. In addition to assigning the value of OnExecute (see page 2716), SetOnExecute propagates the event handler to all client objects and generates an OnChange (see page 2716) event.

See Also

OnExecute (see page 2716)

OnChange (see page 2716)

23.1.20.5.8 TBasicAction.UnRegisterChanges Method

Breaks the association between the action and the action link.

Pascal

```
procedure UnRegisterChanges(Value: TBasicActionLink);
```

C++

```
__fastcall UnRegisterChanges(TBasicActionLink Value);
```

Description

UnRegisterChanges is called when the action and link should no longer be associated. UnRegisterChanges is called, for example, in the destructor or when a link sets a new action. Value is the action link with which the association is broken.

See Also

RegisterChanges (see page 2713)

23.1.20.5.9 TBasicAction.Update Method

Provides an opportunity to execute centralized code when an application is idle.

Pascal

```
function Update: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Update();
```

Description

Update triggers the OnUpdate (see page 2718) event handler. Update returns true if a handler was found for that event, false otherwise. When the application is idle, the OnUpdate (see page 2718) event occurs for every action. This provides an opportunity for applications to execute centralized code for enabling and disabling, checking and unchecking, and so on.

See Also

OnUpdate (see page 2718)

23.1.20.5.10 TBasicAction.UpdateTarget Method

Introduces an interface for a method of notifying a client when the action updates itself.

Pascal

```
procedure UpdateTarget(Target: TObject); virtual;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

UpdateTarget does nothing in TBasicAction (see page 2707). UpdateTarget was introduced in TBasicAction (see page 2707) so that descendants can override it to correspondingly update a target when the action updates. For examples, see the TEditAction objects in the stdactns unit.

See Also

HandlesTarget (see page 2713)

OnUpdate (see page 2718)

23.1.20.6 TBasicAction Properties

The properties of the TBasicAction class are listed here.

Public Properties

	Name	Description
	ActionComponent (see page 2715)	Indicates the client component that caused this action to execute.

23.1.20.6.1 TBasicAction.ActionComponent Property

Indicates the client component that caused this action to execute.

Pascal

```
property ActionComponent: TComponent;
```

C++

```
__property TComponent * ActionComponent;
```

Description

Use ActionComponent to discern which client component caused this action to execute. For example, examine ActionComponent from an OnExecute (see page 2716) event handler if you need to know what user action triggered this action.

When the user clicks a client control, that client sets ActionComponent before calling the action's Execute (see page 2712) method. After the action executes, the action resets ActionComponent to nil (Delphi) or NULL (C++).

See Also

Execute (see page 2712)

OnExecute (see page 2716)

23.1.20.7 TBasicAction Events

The events of the TBasicAction class are listed here.

Protected Events

	Name	Description
	OnChange (see page 2716)	Occurs when one of the action's properties changes.

Public Events

	Name	Description
	OnExecute (see page 2716)	Occurs when the client event that is linked to it fires.
	OnUpdate (see page 2718)	Occurs when the application is idle or when the action list updates.

23.1.20.7.1 TBasicAction.OnChange Event

Occurs when one of the action's properties changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Applications can't use the protected OnChange event. It is used internally to manage the relationship between the properties of the action and the corresponding properties of the action's clients.

Component writers can use OnChange in descendant objects to respond when the action's properties change.

23.1.20.7.2 TBasicAction.OnExecute Event

Occurs when the client event that is linked to it fires.

Pascal

```
property OnExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExecute;
```

Description

Write an OnExecute event handler when you want to respond when the user triggers the client object's default event (typically an OnClick event). For most target clients, OnExecute is triggered on a Click method, and is associated with the OnClick event.

OnExecute also occurs when the user types the shortcut (or one of the secondary shortcuts) associated with the action or its client.

Warning: If you assign an OnExecute event handler to a predefined action, the default behavior of that action will not occur.

C++ Examples:

```
/*
This example requires a TApplicationEvents, a TActionList
and a TListBox in the form.  Select the TApplicationEvents,
double click on the OnActionExecute event and add the
following code to the handler.  Create an TAction named
MyAction in a TActionList.  The TActionList must have no
OnExecute event handler, and the TAction has an OnExecute
event handler called MyActionExecute.  Then set an object's
(such as a button) Action to MyAction.  The Handled
parameter of the event handler returns false by default. If
the handler handles the event, it should change Handled to
true, thereby preventing further attempts to handle the
action.
*/
void __fastcall TAppEventForm::ApplicationEventsActionExecute(
      TBasicAction *Action, bool &Handled)
{
    lbOther->Items->Add("Event OnActionExecute");
}

void __fastcall TAppEventForm::ActionExecute(TObject *Sender)
{
    ShowMessage("Action executed");
}
/*
When a client component or control is clicked, the OnExecute
event occurs for it’s associated action. For example, the
following code illustrates the OnExecute event handler for
an action that toggles the visibility of a toolbar when the
action is executed. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TActionList must have no OnExecute event handler, and the
TAction has an OnExecute event handler called Action1Execute.
Then set an object's (such as a button or menu item) Action
to Action1.  Set the TToolbar color to something that will
make it obvious when it is visible.  Also remember to uncheck
Project|Options|Applications|Enable runtime themes.
*/
void __fastcall TMainForm::Action1Execute(TObject *Sender)
{
  // Toggle Toolbar1's visibility
  ToolBar1->Visible = !ToolBar1->Visible;
  if (ToolBar1->Visible)
    lbOther->Items->Add("Event Action1Execute: toolbar visible");
  else
    lbOther->Items->Add("Event Action1Execute: toolbar not visible");
}
```

Delphi Examples:

```
{
```

```
This example requires a TApplicationEvents, a TActionList
and a TListBox in the form.  Select the TApplicationEvents,
double click on the OnActionExecute event and add the
following code to the handler.  Create an TAction named
MyAction in a TActionList.  The TActionList must have no
OnExecute event handler, and the TAction has an OnExecute
event handler called MyActionExecute.  Then set an object's
(such as a button) Action to MyAction.  The Handled
parameter of the event handler returns false by default. If
the handler handles the event, it should change Handled to
true, thereby preventing further attempts to handle the
action.
}
procedure TMainForm.ApplicationEventsActionExecute(Action: TBasicAction;
  var Handled: Boolean);
begin
  lbOther.Items.Add('Event OnActionExecute');
end;

procedure TMainForm.MyActionExecute(Sender: TObject);
begin
  ShowMessage('Action executed');
end;
{
When a client component or control is clicked, the OnExecute
event occurs for it’s associated action. For example, the
following code illustrates the OnExecute event handler for
an action that toggles the visibility of a toolbar when the
action is executed. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TActionList must have no OnExecute event handler, and the
TAction has an OnExecute event handler called Action1Execute.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Execute(Sender: TObject);
begin
    { Toggle Toolbar1’s visibility }
    ToolBar1.Visible := not ToolBar1.Visible;
  if ToolBar1.Visible then
    lbOther.Items.Add('Event Action1Execute: toolbar visible')
  else
    lbOther.Items.Add('Event Action1Execute: toolbar not visible')
end;
```

OnClick (see page 5851)

ShortCut (see page 314)

23.1.20.7.3 TBasicAction.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to

update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (pa->Checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     pa->Checked = ToolBar1->Visible;
   }
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction (see page 2790)

23.1.21 TBasicActionLink Class

TBasicActionLink is the base class for action link classes that handle the communication between actions and clients.

Class Hierarchy

Pascal

```
TBasicActionLink = class(TObject);
```

C++

```
class TBasicActionLink : public TObject;
```

File

Classes

Description

TBasicActionLink is the base class from which all other action link classes ultimately descend. TBasicAction (see page 2707) link lays the foundation for the connection between action and the client. The client is a parameter to the TBasicActionLink constructor, and the action object is indicated by the Action (see page 2725) property. TBasicActionLink sets up the link between the action and client execution and updating events.

23.1.21.1 TBasicActionLink Members

The following tables list the members exposed by TBasicActionLink.

Protected Fields

	Name	Description
	FAction (see page 2722)	This is FAction, a member of class TBasicActionLink.

Protected Methods

	Name	Description
	AssignClient (see page 2723)	This is AssignClient, a member of class TBasicActionLink.
	Change (see page 2723)	This is Change, a member of class TBasicActionLink.
	IsOnExecuteLinked (see page 2723)	This is IsOnExecuteLinked, a member of class TBasicActionLink.
	SetAction (see page 2724)	This is SetAction, a member of class TBasicActionLink.
	SetOnExecute (see page 2724)	This is SetOnExecute, a member of class TBasicActionLink.

Public Events

	Name	Description
	OnChange (see page 2725)	Occurs when an OnChange event is triggered on the action.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.

	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2721)	Instantiates and initializes a TBasicActionLink (see page 2720) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2722)	Destroys an instance of an action link object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Execute (see page 2723)	Invokes the action's Execute method.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Update (see page 2724)	Invokes the action's Update method.

Public Properties

	Name	Description
	Action (see page 2725)	Indicates which action the link connects to its client.

23.1.21.2 TBasicActionLink.Create Constructor

Instantiates and initializes a TBasicActionLink (see page 2720) object.

Pascal

```
constructor Create(AClient: TObject); virtual;
```

C++

```
virtual __fastcall TBasicActionLink(TObject * AClient);
```

Description

Applications do not need to call the constructor directly. Instances of TBasicActionLink (see page 2720) are created automatically when you connect an action with a client in the action list editor. The AClient parameter is the client for the link. The link connects this client to its action.

Create ensures that the client is of the appropriate type for the particular type of link. Descendant classes can progressively specify more customized client types. For example, there are action link classes for controls, for windowed controls, and for button controls.

See Also

Action (see page 5797)

ActionLink (see page 5798)

23.1.21.3 TBasicActionLink.Destroy Destructor

Destroys an instance of an action link object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBasicActionLink();
```

Description

You do not need to destroy the action link; it is automatically destroyed by the client that was passed to its constructor when it was created.

If you want to destroy the action link manually, do not call the destructor directly. Call Free instead. Free checks that the link is not nil, and only then invokes the destructor.

See Also

Free (see page 22300)

23.1.21.4 TBasicActionLink Fields

The fields of the TBasicActionLink class are listed here.

Protected Fields

	Name	Description
	FAction (see page 2722)	This is FAction, a member of class TBasicActionLink.

23.1.21.4.1 TBasicActionLink.FAction Field

Pascal

```
FAction: TBasicAction;
```

C++

```
TBasicAction FAction;
```

Description

This is FAction, a member of class TBasicActionLink.

23.1.21.5 TBasicActionLink Methods

The methods of the TBasicActionLink class are listed here.

Protected Methods

	Name	Description
	AssignClient (see page 2723)	This is AssignClient, a member of class TBasicActionLink.
	Change (see page 2723)	This is Change, a member of class TBasicActionLink.
	IsOnExecuteLinked (see page 2723)	This is IsOnExecuteLinked, a member of class TBasicActionLink.
	SetAction (see page 2724)	This is SetAction, a member of class TBasicActionLink.
	SetOnExecute (see page 2724)	This is SetOnExecute, a member of class TBasicActionLink.

Public Methods

	Name	Description
	Execute (see page 2723)	Invokes the action's Execute method.
	Update (see page 2724)	Invokes the action's Update method.

23.1.21.5.1 TBasicActionLink.AssignClient Method

Pascal

```
procedure AssignClient(AClient: TObject); virtual;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

This is AssignClient, a member of class TBasicActionLink.

23.1.21.5.2 TBasicActionLink.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TBasicActionLink.

23.1.21.5.3 TBasicActionLink.Execute Method

Invokes the action's Execute method.

Pascal

```
function Execute(AComponent: TComponent = nil): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Execute(TComponent * AComponent = nil);
```

Description

Execute calls the action's Execute method and returns true if the action has an assigned OnExecute event handler, false otherwise.

AComponent is the client component that the user clicked to execute the action.

See Also

Execute (see page 2712)

OnExecute (see page 2716)

23.1.21.5.4 TBasicActionLink.IsOnExecuteLinked Method

Pascal

```
function IsOnExecuteLinked: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsOnExecuteLinked();
```

Description

This is IsOnExecuteLinked, a member of class TBasicActionLink.

23.1.21.5.5 TBasicActionLink.SetAction Method

Pascal

```
procedure SetAction(Value: TBasicAction); virtual;
```

C++

```
virtual __fastcall SetAction(TBasicAction Value);
```

Description

This is SetAction, a member of class TBasicActionLink.

23.1.21.5.6 TBasicActionLink.SetOnExecute Method

Pascal

```
procedure SetOnExecute(Value: TNotifyEvent); virtual;
```

C++

```
virtual __fastcall SetOnExecute(TNotifyEvent Value);
```

Description

This is SetOnExecute, a member of class TBasicActionLink.

23.1.21.5.7 TBasicActionLink.Update Method

Invokes the action's Update method.

Pascal

```
function Update: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Update();
```

Description

Update calls the action's Update method and returns true if the action has an assigned OnUpdate event handler, false otherwise. The action link's Update method is called if the client is linked to the action for this event.

See Also

Update (see page 2714)

OnUpdate (see page 2718)

23.1.21.6 TBasicActionLink Properties

The properties of the TBasicActionLink class are listed here.

Public Properties

	Name	Description
	Action (see page 2725)	Indicates which action the link connects to its client.

23.1.21.6.1 TBasicActionLink.Action Property

Indicates which action the link connects to its client.

Pascal

```
property Action: TBasicAction;
```

C++

```
__property TBasicAction Action;
```

Description

Action is the action object that the link associates with its client.

See Also

Action (see page 5797)

ActionLink (see page 5798)

23.1.21.7 TBasicActionLink Events

The events of the TBasicActionLink class are listed here.

Public Events

	Name	Description
	OnChange (see page 2725)	Occurs when an OnChange event is triggered on the action.

23.1.21.7.1 TBasicActionLink.OnChange Event

Occurs when an OnChange event is triggered on the action.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler when you want to respond to a change that occurs when the associated action fires an OnChange event.

See Also

RegisterChanges (see page 2713)

23.1.22 TBits Class

TBits stores an array of Boolean values.

Class Hierarchy

Classes.TBits

Pascal

```
TBits = class;
```

C++

```
class TBits;
```

File

Classes

Description

Use TBits to store and access an indefinite number of boolean values. TBits can store as many of boolean values as can fit in available memory, automatically expanding its storage space as needed. If the number of boolean values is limited to 32, the same functionality can be achieved using a 32-bit integer with the bitwise AND (Delphi) or & (C++) and OR (Delphi) or | (C++) operators.

See Also

TList (see page 2868)

23.1.22.1 TBits Members

The following tables list the members exposed by TBits.

Public Methods

	Name	Description
	Destroy (see page 2726)	Destroys an instance of TBits (see page 2725).
	OpenBit (see page 2727)	Returns the index of the first false value.

Public Properties

	Name	Description
	Bits (see page 2727)	Provides indexed access to the array of Boolean values that the TBits (see page 2725) object represents.
	Size (see page 2728)	Represents the number of boolean values the TBits (see page 2725) object can hold.

23.1.22.2 TBits.Destroy Destructor

Destroys an instance of TBits (see page 2725).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBits();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TBits (see page 2725) object is not nil and only then calls Destroy.

Destroy frees the memory used to store the array of boolean values.

See Also

Bits (see page 2727)

Free (see page 22300)

23.1.22.3 TBits Methods

The methods of the TBits class are listed here.

Public Methods

	Name	Description
	OpenBit (see page 2727)	Returns the index of the first false value.

23.1.22.3.1 TBits.OpenBit Method

Returns the index of the first false value.

Pascal

```
function OpenBit: Integer;
```

C++

```
__fastcall int OpenBit();
```

Description

Use OpenBit to find the first bit in the array that has not been set to true.

See Also

Bits (see page 2727)

23.1.22.4 TBits Properties

The properties of the TBits class are listed here.

Public Properties

	Name	Description
	Bits (see page 2727)	Provides indexed access to the array of Boolean values that the TBits (see page 2725) object represents.
	Size (see page 2728)	Represents the number of boolean values the TBits (see page 2725) object can hold.

23.1.22.4.1 TBits.Bits Property

Provides indexed access to the array of Boolean values that the TBits (see page 2725) object represents.

Pascal

```
property Bits [Index: Integer]: Boolean;
```

C++

```
__property Boolean Bits[int Index];
```

Description

Use Bits to read or set a particular Boolean value, as indexed by the Index parameter. If Index is not in the range 0..Size (see

page 2728) - 1, an EBitsError (see page 2693) exception is raised.

Note: In Delphi, Bits is the default property for TBits (see page 2725). This means that the property name can be omitted in code. That is, the statement

MyBitsObject.Bits[0];

Can be written

MyBitsObject[0];

Note: In C++, Bits can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

EBitsError (see page 2693)

Size (see page 2728)

operator_sb

23.1.22.4.2 TBits.Size Property

Represents the number of boolean values the TBits (see page 2725) object can hold.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

Set Size to expand or shrink the number of values in the array. When expanding the size, new entries are set to false. When shrinking the size, values whose indexes are less than or equal to the new size are preserved; entries whose indexes are greater than the new size are lost.

See Also

Bits (see page 2727)

23.1.23 TClassFinder Class

Class Hierarchy

Pascal

```
TClassFinder = class;
```

C++

```
class TClassFinder;
```

File

Classes

Description

This is class Classes.TClassFinder.

23.1.23.1 TClassFinder Members

The following tables list the members exposed by TClassFinder.

Public Methods

	Name	Description
	Create (see page 2729)	Creates a TClassFinder (see page 2728) class instance.
V	Destroy (see page 2729)	Frees the memory associated with the TClassFinder (see page 2728) object.
	GetClass (see page 2730)	Retrieves a registered, persistent class reference by name.
	GetClasses (see page 2731)	Retrieves the registered, persistent class references.

23.1.23.2 TClassFinder.Create Constructor

Creates a TClassFinder (see page 2728) class instance.

Pascal

```
constructor Create(AClass: TPersistentClass = nil; AIncludeActiveGroups: Boolean = False);
```

C++

```
__fastcall TClassFinder(TPersistentClass AClass = nil, Boolean AIncludeActiveGroups = False);
```

Description

Call Create to instantiate a TClassFinder (see page 2728) object at runtime.

The **AClass** optional parameter limits the scope of returned classes to the specified class and its ancestors. A nil value does not limit the returned classes.

If true, the **AIncludeActiveGroups** optional parameter will append to the list of classes those that are active in the current application.

See Also

TPersistentClass (see page 3299)

23.1.23.3 TClassFinder.Destroy Destructor

Frees the memory associated with the TClassFinder (see page 2728) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TClassFinder();
```

Description

Do not call Destroy directly. Instead, use the delete keyword on the object, which causes Destroy to be invoked automatically.

See Also

delete

23.1.23.4 TClassFinder Methods

The methods of the TClassFinder class are listed here.

Public Methods

	Name	Description
	GetClass (see page 2730)	Retrieves a registered, persistent class reference by name.
	GetClasses (see page 2731)	Retrieves the registered, persistent class references.

23.1.23.4.1 TClassFinder.GetClass Method

Retrieves a registered, persistent class reference by name.

Pascal

```
function GetClass(const AClassName: string): TPersistentClass;
```

C++

```
__fastcall TPersistentClass GetClass(const AnsiString AClassName);
```

Description

Call GetClass to retrieve a class reference of the specified **AClassName** name.

A nil value is returned if the specified class is not in the list of registered persistent classes.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
TMetaClass *MetaClass;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(Graphics::TBitmap); // bmp
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TMetafile); // emf
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TShape);  // nographic extension
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TImage); // nographic extension
  RegisterClasses(&MetaClass, 0);
}
```

Delphi Examples:

```
{
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
}

uses ExtCtrls;

procedure TForm1.Button1Click(Sender: TObject);
var
  myClassFinder: TClassFinder;
  mygraphclass: TGraphicClass;
begin
  { make sure the classes are registered so that GetClass will work -- }
  { Usually, this goes in the initialization section where it is only executed once }
  RegisterClasses([TIcon, TBitmap, TButton, TShape, TImage, TMetafile]);
  try
    myClassFinder := TClassFinder.Create(TIcon, False);
    mygraphclass := TGraphicClass(myClassFinder.GetClass(Edit2.Text));
//    mygraphclass := TGraphicClass(GetClass(Edit2.Text));  // works as well
    Edit1.Text := GraphicExtension(mygraphclass);
  except
    on EAccessViolation do
      MessageDlg('Invalid class name.', mtError, [mbOK], 0)
  end;
end;
```

See Also

GetClasses (see page 2731)

23.1.23.4.2 TClassFinder.GetClasses Method

Retrieves the registered, persistent class references.

Pascal

```
procedure GetClasses(Proc: TGetClass);
```

C++

```
__fastcall GetClasses(TGetClass Proc);
```

Description

Call GetClasses to retrieve class references of all registered, persistent classes.

Proc specifies a call back procedure that is called for each class reference in the list. For example, you might declare such a procedure to add the returned class names to a list.

See Also

GetClass (see page 2730)

23.1.24 TCollection Class

TCollection is a container for TCollectionItem (see page 2755) objects.

Class Hierarchy

Pascal

```
TCollection = class(TPersistent);
```

C++

```
class TCollection : public TPersistent;
```

File

Classes

Description

Each TCollection holds a group of TCollectionItem (see page 2755) descendants. TCollection maintains an index of the collection items in its Items (see page 2751) array. The Count (see page 2749) property contains the number of items in the collection. Use the Add (see page 2736) and Delete (see page 2741) methods to add items to the collection and delete items from the collection.

Objects descended from TCollection can contain objects descended from TCollectionItem (see page 2755). Thus, for each TCollection descendant, there is a corresponding TCollectionItem (see page 2755) descendant. The following table lists some typical descendants of TCollection with the corresponding TCollectionItem (see page 2755) descendant and the component that uses each pair.

TCollection descendant	TCollectionItem (see page 2755) descendant	Component
TAggregates	TAggregate	TClientDataSet
TCookieCollection	TCookie	TWebResponse
TCoolBands	TCoolBand	TCoolBar
TDBGridColumns	TColumn	TDBGrid
TDependencies	TDependency	TService
TDisplayDims	TDisplayDim	TDecisionGrid
TFieldDefs	TFieldDef	TDataSet
THeaderSections	THeaderSection	THeaderControl
TIndexDefs	TIndexDef	TTable
TListColumns	TListColumn	TListView
TParams	TParam	many datasets
TStatusPanels	TStatusPanel	TStatusBar
TWorkAreas	TWorkArea	TListView

The controls that use TCollection and TCollectionItem (see page 2755) descendants have a published property that holds a collection. (For example, the Panels property of TStatusBar holds a TStatusPanels.) A standard property editor, referred to generically as the Collection editor, can be invoked from the Object Inspector to edit the items in the collection.

Note: When writing a TCollection descendant that is used by another control, be sure to override the protected GetOwner (see page 2932) method of the collection so that it can appear in the Object Inspector.

See Also

TCollectionItem (see page 2755)

Working with Lists

23.1.24.1 TCollection Members

The following tables list the members exposed by TCollection.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
	GetOwner (see page 2932)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 2747)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 2736)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 2734)	Creates and initializes a collection.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 2751)	Lists the items in the collection.

23.1.24.2 TCollection.Create Constructor

Creates and initializes a collection.

Pascal

```
constructor Create(ItemClass: TCollectionItemClass);
```

C++

```
__fastcall TCollection(TCollectionItemClass ItemClass);
```

Description

Call Create to instantiate a TCollection (see page 2731) object at runtime. Typically, TCollection (see page 2731) descendants are created by a component that uses the collection to implement a property.

ItemClass (see page 2751) identifies TCollectionItem (see page 2755) descendant that must be used to represent the items in the collection. The Add (see page 2736) method uses this class to create items of the appropriate type.

See Also

Add (see page 2736)

23.1.24.3 TCollection.Destroy Destructor

Destroys the collection and each item in it.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCollection();
```

Description

Destroy calls the Clear (see page 2741) method to free each item referenced in the Items (see page 2751) array, then destroys the collection itself.

See Also

Clear (see page 2741)

Free (see page 22300)

23.1.24.4 TCollection Methods

The methods of the TCollection class are listed here.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 2747)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 2736)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	Clear (see page 2741)	Deletes all items from the collection.
	Delete (see page 2741)	Deletes a single item from the collection.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.

	Owner (see page 2746)	Returns the Owner of the collection.

23.1.24.4.1 TCollection.Add Method

Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.

Pascal

```
function Add: TCollectionItem;
```

C++

```
__fastcall TCollectionItem Add();
```

Description

Call Add to create an item in the collection. The new item is placed at the end of the Items (see page 2751) array.

Add returns the new collection item.

See Also

Items (see page 2751)

Insert (see page 2746)

Create (see page 2734)

Delete (see page 2741)

23.1.24.4.2 TCollection.Added Method

Responds when items are added to the collection.

Pascal

```
procedure Added(var Item: TCollectionItem); virtual; deprecated;
```

C++

```
virtual __fastcall Added(TCollectionItem Item);
```

Description

Applications can't call the protected Added method. It is called automatically immediately after items are added to the collection.

Item is the item that was just added to the collection.

Added is a deprecated method. Descendant classes should override the Notify (see page 2746) method instead when responding to changes in the list of items.

See Also

Add (see page 2736)

Items (see page 2751)

Notify (see page 2746)

23.1.24.4.3 TCollection.Assign Method

Copies the contents of another collection to the object where the method is executed.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to copy the contents of one TCollection (see page 2731) instance to another. The Assign method deletes all items from the destination collection (the object where it is executed), then adds a copy of each item in the source collection's Items (see page 2751) array.

Source is another object (typically another collection) that contains the items that replace this collection's items.

Delphi Examples:

```
{
  This example saves params from a ClientDataSet, alters them
  and restores them.
}
procedure TForm1.SaveParamsClick(Sender: TObject);
begin
  { Save the parameters for the TDataSet }
  SavedParams.Assign(CDS.Params);
end;

procedure TForm1.AlterParamsClick(Sender: TObject);
var
  I : Integer;
  ListItem: string;
begin
  CDS.Params.CreateParam(ftString, 'stringParam', ptInput);  // you can also edit the params
in the CDS dynamically
  CDS.Params.CreateParam(ftSmallInt, 'smallIntParam', ptInput);
  CDS.Params.CreateParam(ftInteger, 'intParam', ptInput);
  CDS.Params.CreateParam(ftWord, 'wordParam', ptInput);
  CDS.Params.CreateParam(ftBoolean, 'boolParam', ptInput);
  CDS.Params.CreateParam(ftFloat, 'floatParam', ptInput);
  CDS.Params.CreateParam(ftCurrency, 'currencyParam', ptInput);
  CDS.Params.CreateParam(ftBCD, 'bcdParam', ptInput);
  CDS.Params.CreateParam(ftDate, 'dateParam', ptInput);
  CDS.Params.CreateParam(ftTime, 'timeParam', ptInput);
  CDS.Params.CreateParam(ftDateTime, 'dateTimeParam', ptInput);
  { Call FetchParams to ensure parameters reflect server metadata }
  CDS.FetchParams;
  with CDS.Params do
  begin
    for I := 0 to Count - 1 do
    begin
      ListItem := ListBox1.Items[I];
      case Items[I].DataType of
        ftString:
          Items[I].AsString := ListItem;
        ftSmallInt:
          Items[I].AsSmallInt := StrToIntDef(ListItem, 0);
        ftInteger:
          Items[I].AsInteger := StrToIntDef(ListItem, 0);
        ftWord:
          Items[I].AsWord := StrToIntDef(ListItem, 0);
        ftBoolean:
          begin
            if ListItem = 'True' then
              Items[I].AsBoolean := True
            else
              Items[I].AsBoolean := False;
          end;
        ftFloat:
          Items[I].AsFloat := StrToFloat(ListItem);
```

```
          ftCurrency:
            Items[I].AsCurrency := StrToFloat(ListItem);
          ftBCD:
            Items[I].AsBCD := StrToCurr(ListItem);
          ftDate:
            Items[I].AsDate := StrToDate(ListItem);
          ftTime:
            Items[I].AsTime := StrToTime(ListItem);
          ftDateTime:
            Items[I].AsDateTime := StrToDateTime(ListItem);
        end;
      end;
    end;
  end;

  procedure TForm1.RestoreParamsClick(Sender: TObject);
  begin
    { Restore the parameters to TDataSet }
    CDS.Params.AssignValues(SavedParams);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    { Initialize SavedParams }
    SavedParams := TParams.Create;
    ListBox1.Items.Add('Here is a string');
    ListBox1.Items.Add('4');
    ListBox1.Items.Add('3456789');
    ListBox1.Items.Add('34');
    ListBox1.Items.Add('0');
    ListBox1.Items.Add('12.56');
    ListBox1.Items.Add('4.23');
    ListBox1.Items.Add('99.5');
    ListBox1.Items.Add('4/12/53');
    ListBox1.Items.Add('7:45:00');
    ListBox1.Items.Add('4/12/53 7:45:00');
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    SavedParams.Free;
  end;
  {
    This example saves params from a ClientDataSet, alters them
    and restores them.
  }
  procedure TForm1.SaveParamsClick(Sender: TObject);
  begin
    { Save the parameters for the TDataSet }
    SavedParams.Assign(CDS.Params);
  end;

  procedure TForm1.AlterParamsClick(Sender: TObject);
  var
    I : Integer;
  begin
    CDS.Params.CreateParam(ftInteger, 'StateParam', ptInput);
    CDS.Params.CreateParam(ftInteger, 'MyParam', ptInput);
    for I := 0 to CDS.Params.Count - 1 do
      if (CDS.Params.Items[I].IsNull) and
         (CDS.Params.Items[I].DataType = ftInteger) then
        { Items is the default property, so you can omit its name }
        CDS.Params[I].AsInteger := -1;
  end;

  procedure TForm1.RestoreParamsClick(Sender: TObject);
```

```
begin
  { Restore the parameters to TDataSet }
  CDS.Params.AssignValues(SavedParams);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { Initialize SavedParams }
  SavedParams := TParams.Create;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  SavedParams.Free;
end;
```

See Also

Assign (see page 2930)

TListColumns (see page 4245)

23.1.24.4.4 TCollection.BeginUpdate Method

Suspends screen repainting.

Pascal

```
procedure BeginUpdate; virtual;
```

C++

```
virtual __fastcall BeginUpdate();
```

Description

The BeginUpdate method suspends screen repainting until the EndUpdate (see page 2742) method is called. Use BeginUpdate to speed processing and avoid flicker while items are added to or deleted from a collection.

C++ Examples:

```
/*
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int PanelIndex;

  StatusBar1->Panels->BeginUpdate();
  PanelIndex = StatusBar1->Panels->Count - 1;
  try
  {
    StatusBar1->Panels->Add();
    PanelIndex++;
    StatusBar1->Panels->Items[PanelIndex]->Text = "Panel" + IntToStr(PanelIndex);
  }
  __finally
  {
    StatusBar1->Panels->EndUpdate();
  }
}
```

Delphi Examples:

```
{
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  PanelIndex : Integer;
begin
  with StatusBar1 do
  begin
    Panels.BeginUpdate;
    PanelIndex := StatusBar1.Panels.Count - 1;
    try
      Panels.Add;
      Inc(PanelIndex);
      Panels.Items[PanelIndex].Text :=
        'Panel' + IntToStr(PanelIndex);
    finally
      Panels.EndUpdate;
    end;
  end;
end;
```

See Also

EndUpdate (see page 2742)

23.1.24.4.5 TCollection.Changed Method

Responds when the collection or any of its items changes.

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

Changed is called automatically when items in the collection change or when the EndUpdate (see page 2742) method signals that an update is complete. It checks the value of UpdateCount (see page 2753), and if it is 0, calls the Update (see page 2747) method, which performs any necessary updates.

When writing a TCollection (see page 2731) descendant, there is no need to call Changed. Instead, bracket any changes by calls to BeginUpdate (see page 2739) and EndUpdate (see page 2742).

See Also

Changed (see page 2758)

Update (see page 2747)

EndUpdate (see page 2742)

UpdateCount (see page 2753)

23.1.24.4.6 TCollection.Clear Method

Deletes all items from the collection.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Clear empties the Items (see page 2751) array and destroys each TCollectionItem (see page 2755).

See Also

Items (see page 2751)

TCollectionItem (see page 2755)

Delete (see page 2741)

23.1.24.4.7 TCollection.Delete Method

Deletes a single item from the collection.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Delete removes the specified collection item, moving up any items that come after that item in the Items (see page 2751) property array.

Index identifies the item to delete. This is the index of the item in the Items (see page 2751) property array. That is, 0 specifies the first item, 1 specifies the second item, and so on.

See Also

Items (see page 2751)

TCollectionItem (see page 2755)

Clear (see page 2741)

23.1.24.4.8 TCollection.Deleting Method

Responds when items are deleted from the collection.

Pascal

```
procedure Deleting(Item: TCollectionItem); virtual; deprecated;
```

C++

```
virtual __fastcall Deleting(TCollectionItem Item);
```

Description

Applications can't call the protected Deleting method. The Delete (see page 2741) method calls Deleting immediately before it

removes an item from the collection.

Item is the item that is about to be removed.

Deleting is a deprecated method. Descendant classes should override the Notify (see page 2746) method instead when responding to changes in the list of items.

See Also

Delete (see page 2741)

Notify (see page 2746)

23.1.24.4.9 TCollection.EndUpdate Method

Re-enables screen repainting.

Pascal

```
procedure EndUpdate; virtual;
```

C++

```
virtual __fastcall EndUpdate();
```

Description

Use EndUpdate to re-enable screen repainting that was turned off with the BeginUpdate (see page 2739) method.

C++ Examples:

```
/*
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int PanelIndex;

  StatusBar1->Panels->BeginUpdate();
  PanelIndex = StatusBar1->Panels->Count - 1;
  try
  {
    StatusBar1->Panels->Add();
    PanelIndex++;
    StatusBar1->Panels->Items[PanelIndex]->Text = "Panel" + IntToStr(PanelIndex);
  }
  __finally
  {
    StatusBar1->Panels->EndUpdate();
  }
}
```

Delphi Examples:

```
{
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  PanelIndex : Integer;
begin
  with StatusBar1 do
  begin
    Panels.BeginUpdate;
    PanelIndex := StatusBar1.Panels.Count - 1;
    try
      Panels.Add;
      Inc(PanelIndex);
      Panels.Items[PanelIndex].Text :=
        'Panel' + IntToStr(PanelIndex);
    finally
      Panels.EndUpdate;
    end;
  end;
end;
```

See Also

BeginUpdate (see page 2739)

23.1.24.4.10 TCollection.FindItemID Method

Returns the item with the specified ID.

Pascal

```
function FindItemID(ID: Integer): TCollectionItem;
```

C++

```
__fastcall TCollectionItem FindItemID(int ID);
```

Description

The FindItemID method returns the item in the collection whose ID property is passed to it as a parameter. If no item has the specified ID, FindItemID returns nil (Delphi) or NULL (C++).

See Also

ID (see page 2761)

23.1.24.4.11 TCollection.GetAttr Method

Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.

Pascal

```
function GetAttr(Index: Integer): string; dynamic;
```

C++

```
__fastcall AnsiString GetAttr(int Index);
```

Description

TCollection (see page 2731) descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. The GetAttr method returns the name of an attribute.

Index identifies the attribute whose name is requested. This is a value between 0 and n-1, where n is the value returned by GetAttrCount (see page 2744).

As implemented by TCollection (see page 2731), GetAttr always returns an empty string, because TCollection (see page 2731) defines no custom attributes.

See Also

GetAttrCount (see page 2744)

GetItemAttr (see page 2745)

23.1.24.4.12 TCollection.GetAttrCount Method

Returns the number of custom attributes associated with items in the collection.

Pascal

```
function GetAttrCount: Integer; dynamic;
```

C++

```
__fastcall int GetAttrCount();
```

Description

TCollection (see page 2731) descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetAttrCount returns the number of distinct attributes assigned to each item in the collection.

As implemented in TCollection (see page 2731), GetAttrCount always returns 0, because TCollection (see page 2731) defines no custom attributes.

See Also

GetAttr (see page 2743)

GetItemAttr (see page 2745)

23.1.24.4.13 TCollection.GetEnumerator Method

Returns a TCollection (see page 2731) enumerator.

Pascal

```
function GetEnumerator: TCollectionEnumerator;
```

C++

```
__fastcall TCollectionEnumerator GetEnumerator();
```

Description

GetEnumerator returns a TCollectionEnumerator (see page 2753) reference, which enumerates all items in the collection.

To do so, call the TCollectionEnumerator (see page 2753) GetCurrent method within a While MoveNext do loop.

See Also

TCollectionEnumerator (see page 2753)

23.1.24.4.14 TCollection.GetItem Method

Returns a specified item in the collection.

Pascal

```
function GetItem(Index: Integer): TCollectionItem;
```

C++

```
__fastcall TCollectionItem GetItem(int Index);
```

Description

GetItem is the protected read implementation of the Items (see page 2751) property.

See Also

Items (see page 2751)

23.1.24.4.15 TCollection.GetItemAttr Method

Returns the value of a custom attribute assigned to one of the collection's items.

Pascal

```
function GetItemAttr(Index: Integer; ItemIndex: Integer): string; dynamic;
```

C++

```
__fastcall AnsiString GetItemAttr(int Index, int ItemIndex);
```

Description

TCollection (see page 2731) descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetItemAttr returns the value of one of these attributes for a specified item in the collection.

Index identifies which attribute's value is desired. This is a value between 0 and n-1, where n is the value returned by GetAttrCount (see page 2744).

ItemIndex identifies the item whose attribute value is desired. This is an index into the Items (see page 2751) property array.

As implemented in TCollection (see page 2731), GetItemAttr always returns an empty string, because TCollection (see page 2731) defines no custom attributes.

See Also

GetAttr (see page 2743)

GetAttrCount (see page 2744)

23.1.24.4.16 TCollection.GetNamePath Method

Returns a string used by the Object Inspector.

Pascal

```
function GetNamePath: string; override;
```

C++

```
virtual __fastcall AnsiString GetNamePath();
```

Description

If the collection has no owner, GetNamePath returns the name of the collection's actual (runtime) type. If the collection is owned, GetNamePath returns the owner's name followed, if applicable, by a dot and the name of the owner's property that holds the collection. For example, GetNamePath might return "TreeView1.Items (see page 2751)".

Note: For a collection to have an owner, it must override the GetOwner (see page 2932) method.

See Also

GetOwner (see page 2932)

23.1.24.4.17 TCollection.Insert Method

Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.

Pascal

```
function Insert(Index: Integer): TCollectionItem;
```

C++

```
__fastcall TCollectionItem Insert(int Index);
```

Description

Call Insert to add a new item at a specified position in the collection. Existing items (starting from the specified position) are moved up in the Items (see page 2751) array.

Insert returns the new collection item.

See Also

Add (see page 2736)

Items (see page 2751)

23.1.24.4.18 TCollection.Notify Method

Responds when items are added to or removed from the collection.

Pascal

```
procedure Notify(Item: TCollectionItem; Action: TCollectionNotification); virtual;
```

C++

```
virtual __fastcall Notify(TCollectionItem Item, TCollectionNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Item is the item that was just added to or that is about to be removed from the collection.

Action indicates whether item was added, is about to be removed, or is about to be deleted:

As implemented in TCollection (see page 2731), Notify calls Added (see page 2736) when Action is cnAdded and calls Deleting (see page 2741) when Action is cnDeleting. TCollection (see page 2731) ignores the cnExtracting action. Descendant classes can override Notify to modify this behavior.

See Also

Added (see page 2736)

Deleting (see page 2741)

23.1.24.4.19 TCollection.Owner Method

Returns the Owner of the collection.

Pascal

```
function Owner: TPersistent;
```

C++

```
__fastcall TPersistent * Owner();
```

Description

Call Owner to obtain a reference to the object that owns this collection. Typically, the owner uses the collection to implement one of its properties.

23.1.24.4.20 TCollection.SetItem Method

Copies the properties of another item to a specified item in the collection.

Pascal

```
procedure SetItem(Index: Integer; Value: TCollectionItem);
```

C++

```
__fastcall SetItem(int Index, TCollectionItem Value);
```

Description

SetItem is the protected write implementation of the Items (see page 2751) property. It calls the Assign (see page 2736) method of the item specified by Index, so that the properties of the item specified by Value are copied to that item.

See Also

Items (see page 2751)

Assign (see page 2930)

23.1.24.4.21 TCollection.SetItemName Method

Initializes the name of a newly inserted collection item.

Pascal

```
procedure SetItemName(Item: TCollectionItem); virtual;
```

C++

```
virtual __fastcall SetItemName(TCollectionItem Item);
```

Description

The Insert (see page 2746) method calls SetItemName to initialize the Name property of items when it inserts them into the collection.

As implemented in TCollection (see page 2731), SetItemName does nothing. Some TCollection (see page 2731) descendants override this method to provide collection items with default names.

See Also

Insert (see page 2746)

Name (see page 2805)

23.1.24.4.22 TCollection.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); virtual;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection (see page 2731), Update does nothing. Descendant classes override this method to make any necessary adjustments.

See Also

Changed (see page 2740)

Changed (see page 2758)

23.1.24.5 TCollection Properties

The properties of the TCollection class are listed here.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 2751)	Lists the items in the collection.

23.1.24.5.1 TCollection.Capacity Property

Provides access to the internal TList (see page 2868) Capacity property.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

The Capacity property specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object. This value is set to the number of pointers the list will need to contain.

23.1.24.5.2 TCollection.Count Property

Returns the number of items in the collection.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Count contains the number of items in the Items (see page 2751) array. Since Items (see page 2751) is indexed starting with 0, the value of Count is always one greater than the index of the last member of Items (see page 2751).

C++ Examples:

```
/*
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int PanelIndex;

  StatusBar1->Panels->BeginUpdate();
  PanelIndex = StatusBar1->Panels->Count - 1;
  try
  {
    StatusBar1->Panels->Add();
    PanelIndex++;
    StatusBar1->Panels->Items[PanelIndex]->Text = "Panel" + IntToStr(PanelIndex);
  }
  __finally
  {
    StatusBar1->Panels->EndUpdate();
  }
}
/*
This example uses the IndexName property to sort the records
in a client dataset on the Field2 field.
*/
void __fastcall TForm1::Button3Click(TObject *Sender)
{
  // If Active is True, Update will remove Fields added in FormCreate
  // and add the DEFAULT_ORDER and CHANGEINDEX Fields
  CDS2->Active = False;
  // Get the current available indices
  CDS2->IndexDefs->Update();
  // Find a field named "Field2"
  for (int I = 0; I < CDS2->IndexDefs->Count; I++)
    if (CDS2->IndexDefs->Items[I]->Fields == "Field2")
    {
      // set that index as the current index for the dataset}
      CDS2->IndexName = CDS2->IndexDefs->Items[I]->Name;
    }
  CDS2->Active = True;
}
/*
This example requires a TClientDataSet and a button on a form.
```

```
Put swSystem in the uses clause for gsAppPath.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
for (int I = 0; I < CDS->Params->Count; I++)
{
  if (CDS->Params->Items[I]->IsNull &&
      CDS->Params->Items[I]->DataType == ftInteger)
    CDS->Params->Items[I]->AsInteger = -1;
}}

#include <swSystem.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CDS->LoadFromFile(gsAppPath + "../CDS.XML");
  CDS->Params->CreateParam(ftInteger, "StateParam", ptInput);
  CDS->Params->CreateParam(ftInteger, "MyParam", ptInput);
}
```

Delphi Examples:

```
{
The following example adds a panel to the status bar control
when the user clicks the button and adds a caption to the
panel. The code uses BeginUpdate and EndUpdate to prevent
repaints until the operation is complete.  A try...finally
block ensures EndUpdate is called even when an exception
occurs.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  PanelIndex : Integer;
begin
  with StatusBar1 do
  begin
    Panels.BeginUpdate;
    PanelIndex := StatusBar1.Panels.Count - 1;
    try
      Panels.Add;
      Inc(PanelIndex);
      Panels.Items[PanelIndex].Text :=
        'Panel' + IntToStr(PanelIndex);
    finally
      Panels.EndUpdate;
    end;
  end;
end;
{
This example uses the IndexName property to sort the records
in a client dataset on the Field2 field.
}
procedure TForm1.Button3Click(Sender: TObject);
var
  I : Integer;
begin
  // If Active is True, Update will remove Fields added in FormCreate
  // and add the DEFAULT_ORDER and CHANGEINDEX Fields
  CDS2.Active := False;
  { Get the current available indices }
  CDS2.IndexDefs.Update;
  { Find a field named 'Field2' }
  for I := 0 to CDS2.IndexDefs.Count - 1 do
    if CDS2.IndexDefs.Items[I].Fields = 'Field2' then
    begin
      { set that index as the current index for the dataset}
      CDS2.IndexName := CDS2.IndexDefs.Items[I].Name;
```

```
      end;
    CDS2.Active := True;
  end;
  {
  This example requires a TClientDataSet and a button on a form.
  Put swSystem in the uses clause for gsAppPath.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I : Integer;
  begin
  { Assign -1 to any integer parameter which does not have a value. }
  for I := 0 to CDS.Params.Count - 1 do
    if (CDS.Params.Items[I].IsNull) and
       (CDS.Params.Items[I].DataType = ftInteger) then
      { Items is the default property, so you can omit its name }
      CDS.Params[I].AsInteger := -1;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    CDS.LoadFromFile(gsAppPath + 'CDS.XML');
    CDS.Params.CreateParam(ftInteger, 'StateParam', ptInput);
    CDS.Params.CreateParam(ftInteger, 'MyParam', ptInput);
  end;
```

See Also

Items (see page 2751)

23.1.24.5.3 TCollection.ItemClass Property

Indicates the class to which the collection's items belong.

Pascal

```
property ItemClass: TCollectionItemClass;
```

C++

```
__property TCollectionItemClass ItemClass;
```

Description

ItemClass is the class (descended from TCollectionItem (see page 2755)) to which the items in the collection belong. For example, in an instance of the TCollection (see page 2731) descendant THeaderSections, the value of the ItemClass property is THeaderSection.

See Also

Items (see page 2751)

TCollectionItem (see page 2755)

23.1.24.5.4 TCollection.Items Property

Lists the items in the collection.

Pascal

```
property Items [Index: Integer]: TCollectionItem;
```

C++

```
__property TCollectionItem Items[int Index];
```

Description

Use Items to access individual items in the collection. The value of the Index parameter corresponds to the Index property of TCollectionItem (see page 2755). It represents the position of the item in the collection.

See Also

Count (see page 2749)

ItemClass (see page 2751)

Index (see page 2762)

Add (see page 2736)

Insert (see page 2746)

23.1.24.5.5 TCollection.NextID Property

Specifies a unique ID that can be assigned to the next added collection item.

Pascal

```
property NextID: Integer;
```

C++

```
__property int NextID;
```

Description

TCollection (see page 2731) uses NextID internally to assign unique identifiers to collection items. When a new item is added to the collection, it's ID property is given the value of NextID and NextID is incremented.

See Also

ID (see page 2761)

23.1.24.5.6 TCollection.PropName Property

Specifies the name of the property that the collection implements.

Pascal

```
property PropName: string;
```

C++

```
__property AnsiString PropName;
```

Description

The GetNamePath (see page 2745) method uses this protected property to assemble the name of the collection as it appears in the Object Inspector. It identifies the name of the property in the object returned by the protected GetOwner (see page 2932) method that is implemented using this collection object.

See Also

GetNamePath (see page 2745)

GetOwner (see page 2932)

23.1.24.5.7 TCollection.UpdateCount Property

Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Pascal

```
property UpdateCount: Integer;
```

C++

```
__property int UpdateCount;
```

Description

UpdateCount keeps track of calls to BeginUpdate (see page 2739) and EndUpdate (see page 2742) so that they can be nested. Every call to BeginUpdate (see page 2739) increments UpdateCount. Every call to EndUpdate (see page 2742) decrements it. When UpdateCount returns to 0, the collection updates itself to reflect all changes that occurred since the first call to BeginUpdate (see page 2739).

See Also

BeginUpdate (see page 2739)

EndUpdate (see page 2742)

23.1.25 TCollectionEnumerator Class

Enumerates through the TCollectionItems in a TCollection (see page 2731) object.

Class Hierarchy

Classes.TCollectionEnumerator

Pascal

```
TCollectionEnumerator = class;
```

C++

```
class TCollectionEnumerator;
```

File

Classes

Description

TCollectionEnumerator provides an enumerator for TCollection (see page 2731) objects.

23.1.25.1 TCollectionEnumerator Members

The following tables list the members exposed by TCollectionEnumerator.

Public Methods

	Name	Description
	Create (see page 2754)	Creates a TCollection (see page 2731) enumerator.
	GetCurrent (see page 2754)	Gets the current TCollectionItem (see page 2755).

	MoveNext (see page 2754)	Moves the enumerator to the next TCollectionItem (see page 2755) in the collection.

Public Properties

	Name	Description
	Current (see page 2755)	The current TCollection (see page 2731) object.

23.1.25.2 TCollectionEnumerator.Create Constructor

Creates a TCollection (see page 2731) enumerator.

Pascal

```
constructor Create(ACollection: TCollection);
```

C++

```
__fastcall TCollectionEnumerator(TCollection ACollection);
```

Description

Creates an instance of TCollectionEnumerator (see page 2753).

23.1.25.3 TCollectionEnumerator Methods

The methods of the TCollectionEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 2754)	Gets the current TCollectionItem (see page 2755).
	MoveNext (see page 2754)	Moves the enumerator to the next TCollectionItem (see page 2755) in the collection.

23.1.25.3.1 TCollectionEnumerator.GetCurrent Method

Gets the current TCollectionItem (see page 2755).

Pascal

```
function GetCurrent: TCollectionItem;
```

C++

```
__fastcall TCollectionItem GetCurrent();
```

Description

Use GetCurrent to get the current TCollectionItem (see page 2755) of the TCollection (see page 2731) object being enumerated.

23.1.25.3.2 TCollectionEnumerator.MoveNext Method

Moves the enumerator to the next TCollectionItem (see page 2755) in the collection.

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

Use MoveNext to move the TCollectionEnumerator (see page 2753) to the next TCollectionItem (see page 2755) in the TCollection (see page 2731) object.

23.1.25.4 TCollectionEnumerator Properties

The properties of the TCollectionEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 2755)	The current TCollection (see page 2731) object.

23.1.25.4.1 TCollectionEnumerator.Current Property

The current TCollection (see page 2731) object.

Pascal

```
property Current: TCollectionItem;
```

C++

```
__property TCollectionItem Current;
```

Description

Current contains the current TCollectionItem (see page 2755) in the TCollection (see page 2731) object.

23.1.26 TCollectionItem Class

TCollectionItem represents an item in a collection.

Class Hierarchy

Pascal

```
TCollectionItem = class(TPersistent);
```

C++

```
class TCollectionItem : public TPersistent;
```

File

Classes

Description

A TCollection (see page 2731) holds a group of TCollectionItem objects. TCollectionItems are created and destroyed by TCollection (see page 2731)'s Add and Clear methods. Each TCollectionItem has a Collection (see page 2761) property that points to the TCollection (see page 2731) object to which the item belongs.

Objects descended from TCollection (see page 2731) can contain objects descended from TCollectionItem. For example, a TDBGridColumns object contains TColumn objects; these two classes are used by TDBGrid to represent grid columns.

See Also

TCollection (see page 2731)

23.1.26.1 TCollectionItem Members

The following tables list the members exposed by TCollectionItem.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetDisplayName (see page 2758)	Returns the name of the collection item as it appears in the collection editor.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2757)	Creates and initializes a TCollectionItem (see page 2755) instance.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2757)	Destroys the TCollectionItem (see page 2755) instance and frees its memory.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

23.1.26.2 TCollectionItem.Create Constructor

Creates and initializes a TCollectionItem (see page 2755) instance.

Pascal

```
constructor Create(Collection: TCollection); virtual;
```

C++

```
virtual __fastcall TCollectionItem(TCollection Collection);
```

Description

Do not call Create to instantiate a collection item. Instead, call the Add method of the collection to which the item should belong.

Collection (see page 2761) identifies the TCollection (see page 2731) instance to which the new item belongs.

See Also

Add (see page 2736)

Collection (see page 2761)

23.1.26.3 TCollectionItem.Destroy Destructor

Destroys the TCollectionItem (see page 2755) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCollectionItem();
```

Description

Destroy is called indirectly by TCollection (see page 2731)'s Clear or Delete method.

See Also

Clear (see page 2741)

Delete (see page 2741)

Free (see page 22300)

23.1.26.4 TCollectionItem Methods

The methods of the TCollectionItem class are listed here.

Protected Methods

	Name	Description
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
V	GetDisplayName (see page 2758)	Returns the name of the collection item as it appears in the collection editor.
V	GetOwner (see page 2759)	Returns the collection to which this item belongs.
V	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
V	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
V	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.

23.1.26.4.1 TCollectionItem.Changed Method

Updates the collection to reflect changes to the collection item.

Pascal

```
procedure Changed(AllItems: Boolean);
```

C++

```
__fastcall Changed(Boolean AllItems);
```

Description

Changed is called automatically when a collection item changes in a way that must be reflected by the collection to which the item belongs. For example, when an item's Index (see page 2762) property changes, the collection must update the indexes of all other items. Call this method in the implementation of a descendant class when making changes that require the collection to update.

The AllItems parameter indicates whether the change affects just the collection item (such as a change to its DisplayName (see page 2761) property) or whether it requires corresponding changes to other items in the collection (such as a change to the Index (see page 2762) property).

See Also

Index (see page 2762)

DisplayName (see page 2761)

Collection (see page 2761)

23.1.26.4.2 TCollectionItem.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName (see page 2761) property.

See Also

DisplayName (see page 2761)

GetNamePath (see page 2759)

23.1.26.4.3 TCollectionItem.GetNamePath Method

Returns a string used by the Object Inspector.

Pascal

```
function GetNamePath: string; override;
```

C++

```
virtual __fastcall AnsiString GetNamePath();
```

Description

GetNamePath determines the text that represents the collection in the Object Inspector. TCollectionItem (see page 2755) overrides the inherited method to return the name of the collection followed by the index of the item within that collection.

23.1.26.4.4 TCollectionItem.GetOwner Method

Returns the collection to which this item belongs.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath (see page 2759) method to find the collection that owns of the collection item, allowing the collection item to appear in the Object Inspector. It returns the value of the Collection (see page 2761) property.

Note: The Owner of a collection item is not synonymous with a component's Owner. It has no implications about the freeing of objects but merely serves to represent relationships to the Object Inspector.

See Also

GetNamePath (see page 2759)

Collection (see page 2761)

Owner (see page 2807)

23.1.26.4.5 TCollectionItem.SetCollection Method

Sets the value of the Collection (see page 2761) property.

Pascal

```
procedure SetCollection(Value: TCollection); virtual;
```

C++

```
virtual __fastcall SetCollection(TCollection Value);
```

Description

SetCollection is the protected write implementation of the Collection (see page 2761) property.

Value specifies the collection to which this item should be added.

SetCollection removes this item from the collection to which it currently belongs and adds it to the collection specified by Value.

See Also

Collection (see page 2761)

23.1.26.4.6 TCollectionItem.SetDisplayName Method

Sets the name of the collection item as it appears in the collection editor.

Pascal

```
procedure SetDisplayName(const Value: string); virtual;
```

C++

```
virtual __fastcall SetDisplayName(const AnsiString Value);
```

Description

SetDisplayName is the protected write implementation of the DisplayName (see page 2761) property.

Value specifies the name for the item that should appear in the collection editor.

See Also

DisplayName (see page 2761)

23.1.26.4.7 TCollectionItem.SetIndex Method

Moves the collection item to a specified position in the parent collection.

Pascal

```
procedure SetIndex(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetIndex(int Value);
```

Description

SetIndex is the protected write implementation of the Index (see page 2762) property. The Value parameter specifies the new (0-based) position for the item in its parent collection.

See Also

Index (see page 2762)

23.1.26.5 TCollectionItem Properties

The properties of the TCollectionItem class are listed here.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

23.1.26.5.1 TCollectionItem.Collection Property

Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.

Pascal

```
property Collection: TCollection;
```

C++

```
__property TCollection Collection;
```

Description

Each TCollectionItem (see page 2755) belongs to the TCollection (see page 2731) which creates it. The Collection property points to the collection object to which the item belongs.

23.1.26.5.2 TCollectionItem.DisplayName Property

The name displayed in the Collection (see page 2761) editor.

Pascal

```
property DisplayName: string;
```

C++

```
__property AnsiString DisplayName;
```

Description

DisplayName is the string that represents the item in the Collection (see page 2761) editor. When the item is selected in the Collection (see page 2761) editor, the DisplayName can also appear in the Object Inspector as the value of another property (for example, as the Text property of THeaderSection or TStatusPanel). By default, DisplayName is the name of the TCollectionItem (see page 2755) descendant class of which the item is an instance.

23.1.26.5.3 TCollectionItem.ID Property

A unique, permanent index for the item.

Pascal

```
property ID: Integer;
```

C++

```
__property int ID;
```

Description

In most cases, ID is the value of the item's Index (see page 2762) property when it was first added to the collection. But, unlike Index (see page 2762) values, ID values are never changed or reassigned. If an item is removed from a collection, its ID not used again.

An item's Index (see page 2762) may change when other items are deleted from the collection or when items are rearranged. ID provides a unique identifier for each item that is unchanged for the life of the collection.

See Also

Index (see page 2762)

23.1.26.5.4 TCollectionItem.Index Property

Returns the item's position in the Items array of TCollection (see page 2731).

Pascal

```
property Index: Integer;
```

C++

```
__property int Index;
```

Description

Each TCollectionItem (see page 2755) is indexed in the Items array of the TCollection (see page 2731) to which it belongs. The Index property of the TCollectionItem (see page 2755) contains the item's index value in that array. Read the value of Index to determine the collection item's position. Set the value of Index to move the collection item to a new position.

Items is a zero-based array. The first member of the collection has an index value of 0, the second member has an index value of 1, and so forth.

See Also

ID (see page 2761)

Items (see page 2751)

23.1.27 TComponent Class

TComponent is the common ancestor of all component classes.

Class Hierarchy

Pascal

```
TComponent = class(TPersistent, IInterface, IInterfaceComponentReference);
```

C++

```
class TComponent : public TPersistent, public IInterface, public IInterfaceComponentReference;
```

File

Classes

Description

TComponent is the base class for all components. TComponent implements the following features:

Components (see page 2799) are persistent objects that have the following capabilities:

IDE integration. The ability to appear on an IDE palette and be manipulated in a form designer.

Ownership. The ability to manage other components. If component A owns component B, then A is responsible for destroying B when A is destroyed.

Streaming and filing. Enhancements of the persistence features inherited from TPersistent (see page 2928).

COM support. Components (see page 2799) can be converted into ActiveX controls or other COM objects using wizards provided with Windows products. Components (see page 2799) can serve as wrappers for COM objects.

Note: COM features are present in all implementations of TComponent, including those provided with Linux development tools. However, these features are only useful in Windows applications, and are marked in this documentation as "Windows only". Do not use these features in cross-platform applications.

TComponent does not provide any user interface or display features. These features are provided by two classes that directly descend from TComponent.

TControl, in the QControls unit, is the base class for "visual" components in cross-platform applications.

TControl, in the Controls (see page 5711) unit, is the base class for "visual" components in Windows-only applications.

Note: The Controls (see page 5711) unit and other Windows-specific units are not provided with Linux development tools.

Components (see page 2799) that can be visible at runtime are sometimes called "visual components". Other components, which are never visible at runtime, are sometimes called "non-visual components". However it is more common to refer to "visual components" as "controls" and "non-visual components" simply as "components."

Do not create instances of TComponent. Use TComponent as a base class when declaring non-visual components that can appear on the component palette and be used in the form designer. Properties and methods of TComponent provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

TComponent Branch

VCL Overview

23.1.27.1 TComponent Members

The following tables list the members exposed by TComponent.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.

	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

23.1.27.2 TComponent.Create Constructor

Allocates memory and constructs a safely initialized instance of a component.

Pascal

```
constructor Create(AOwner: TComponent); virtual;
```

C++

```
virtual __fastcall TComponent(TComponent * AOwner);
```

Description

All objects have a Create method that constructs the object. TComponent (see page 2762) redefines Create so that, for components, Create also:

establishes the relationship of a component and its Owner (see page 2807), as indicated by the AOwner parameter

sets the ComponentStyle (see page 2805) property to csInheritable, meaning that the component can be inherited by a descendant form type

It is not necessary to explicitly create components added in the form designer. These components are created automatically when the application is run, and they are destroyed when the application is closed.

For components created programmatically, that is, not created in the form designer, call Create and pass in an owner component as the AOwner parameter. The owner disposes of the component when it is destroyed. If the component is not owned, then use Free when it needs to be destroyed.

Tip: When passing in Self as the Owner (see page 2807) parameter, consider what Self references. If a component creates another component in one of its methods, then Self refers to the first component and not the component being created, which is then owned by the first component.

Note: The TComponent (see page 2762) constructor is virtual in part to allow polymorphic instantiation of class references. This is critical to the streaming system and to the form designer. Do not forget to use the override directive when declaring a new component's Create constructor.

Components (see page 2799)

ComponentStyle (see page 2805)

Create (see page 22287)

Destroy (see page 2766)

Free (see page 22300)

Owner (see page 2807)

23.1.27.3 TComponent.Destroy Destructor

Disposes of the component and its owned components.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComponent();
```

Description

Do not call Destroy directly. Call Free instead. Free verifies that the component is not nil, and only then calls Destroy.

Never explicitly free a component in one of its own event handlers, nor free a component from the event handler of a component that it owns or contains.

To destroy a form, call its Release method. Release waits for all the form's event handlers and the event handlers of the form's components to finish executing before destroying the form.

Note: A form owns all the controls and non-visual components that are placed on it in design mode. When it is freed, all of these components are automatically freed as well. By default, all forms are owned by the global Application object. When an application terminates, it frees the global Application object, which frees all forms. For objects that are not components, and for components created with a nil owner, be sure to call Free after finishing with the object; otherwise the memory allocated for the object will be lost until the application terminates.

23.1.27.4 TComponent Fields

The fields of the TComponent class are listed here.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

23.1.27.4.1 TComponent.FComponentStyle Field

Pascal

```
FComponentStyle: TComponentStyle;
```

C++

```
TComponentStyle FComponentStyle;
```

Description

This is FComponentStyle, a member of class TComponent.

23.1.27.5 TComponent Methods

The methods of the TComponent class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

23.1.27.5.1 TComponent._AddRef Method

Called when an application uses a component interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef is a basic implementation of the IInterface method, _AddRef.

Note: If the component is a wrapper for a COM object, __AddRef calls the _AddRef method of that COM object, and returns the resulting reference count.

In all other cases, __AddRef simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __AddRef to implement reference counting.

See Also

Invoke (see page 2781)

QueryInterface (see page 2784)

_Release (see page 2769)

ComObject (see page 2793)

_AddRef (see page 22397)

23.1.27.5.2 TComponent._Release Method

Called when an application releases a component interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release is a basic implementation of the IInterface method, _Release.

__Release returns the resulting value of the reference count for the component's interface.

Note:

In all other cases, __Release simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __Release to implement reference counting.

See Also

Invoke (see page 2781)

QueryInterface (see page 2784)

_AddRef (see page 2769)

ComObject (see page 2793)

23.1.27.5.3 TComponent.BeforeDestruction Method

Performs any necessary actions before the first destructor is called.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

BeforeDestruction is called automatically immediately before the component's first destructor executes. Do not call it explicitly in your applications.

As implemented in TComponent (see page 2762), BeforeDestruction checks whether the Destroying (see page 2772) method has been called, and if not, calls it. Descendants that override this method to perform other actions before a component is destroyed should call the inherited method first to ensure that this check takes place.

See Also

Destroy (see page 2766)

Destroying (see page 2772)

AfterConstruction (see page 22289)

23.1.27.5.4 TComponent.ChangeName Method

Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.

Pascal

```
procedure ChangeName(const NewName: TComponentName);
```

C++

```
__fastcall ChangeName(const TComponentName NewName);
```

Description

Do not use ChangeName directly in an application. Instead, use the Name (see page 2805) property.

Note: The property setter for Name (see page 2805), SetName (see page 2789), uses ChangeName to change the component's name. ChangeName is not virtual; do not override it.

See Also

Name (see page 2805)

SetName (see page 2789)

ValidateRename (see page 2792)

23.1.27.5.5 TComponent.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent (see page 2762) overrides the DefineProperties method defined in TPersistent (see page 2928) to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

See Also

Ancestor (see page 2839)

DefineBinaryProperty (see page 2837)

DefineProperties (see page 2931)

DefineProperty (see page 2838)

23.1.27.5.6 TComponent.DestroyComponents Method

Destroys all owned components.

Pascal

```
procedure DestroyComponents;
```

C++

```
__fastcall DestroyComponents();
```

Description

DestroyComponents iterates through the components owned by the component, removing each from the list of owned components and destroying it.

It is not necessary to call DestroyComponents directly. DestroyComponents is automatically called when the component is

destroyed.

See Also

Destroy (see page 2766)

Destroying (see page 2772)

Free (see page 22300)

Owner (see page 2807)

23.1.27.5.7 TComponent.Destroying Method

Indicates that the component and its owned components are about to be destroyed.

Pascal

```
procedure Destroying;
```

C++

```
__fastcall Destroying();
```

Description

Destroying sets the csDestroying flag in the ComponentState (see page 2804) property. It then calls the Destroying method for each owned component so that their csDestroying flags are also set. If csDestroying is already set, Destroying does nothing.

It is not necessary to call Destroying directly. Destroying is automatically called when the component is destroyed.

See Also

ComponentState (see page 2804)

Destroy (see page 2766)

DestroyComponents (see page 2771)

Free (see page 22300)

Owner (see page 2807)

23.1.27.5.8 TComponent.ExecuteAction Method

Pascal

```
function ExecuteAction(Action: TBasicAction): Boolean; dynamic;
```

C++

```
__fastcall Boolean ExecuteAction(TBasicAction Action);
```

Description

This is ExecuteAction, a member of class TComponent.

23.1.27.5.9 TComponent.FindComponent Method

Indicates whether a given component is owned by the component.

Pascal

```
function FindComponent(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindComponent(const AnsiString AName);
```

Description

FindComponent returns the component in the Components (see page 2799) property array with the name that matches the string in the AName parameter. Use FindComponent to determine whether a given component is owned by another.

Component name matches are not case sensitive.

C++ Examples:

```
/*
This code resizes the active control to twice as wide and
half as high:
*/
void __fastcall TForm1::ButtonTSClick(TObject *Sender)
{
  TRect MyRect;
  if (myActiveControl == NULL) exit;
  MyRect = myActiveControl->BoundsRect;
  MyRect.Right = MyRect.Left + (MyRect.Right - MyRect.Left) / 2;
  MyRect.Bottom = MyRect.Top + 2 * (MyRect.Bottom - MyRect.Top);
  myActiveControl->BoundsRect = MyRect;
}
void __fastcall TForm1::ButtonSFClick(TObject *Sender)
{
  TRect MyRect;
  if (myActiveControl == NULL) exit;
  MyRect = myActiveControl->BoundsRect;
  MyRect.Right = MyRect.Left + 2 * (MyRect.Right - MyRect.Left);
  MyRect.Bottom = MyRect.Top + (MyRect.Bottom - MyRect.Top) / 2;
  myActiveControl->BoundsRect = MyRect;
}
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TComponent *Temp;
  TListItem *ListItem;
  ListView1->ViewStyle = vsList;
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Components: ";
  for (int I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    ListItem = ListView1->Items->Add();
    ListItem->Caption = Temp->Name;
  }
}
void __fastcall TForm1::ListView1SelectItem(TObject *Sender, TListItem *Item,
      bool Selected)
{
  TComponent *comp = FindComponent(Item->Caption);
  if (dynamic_cast<TWinControl *>(comp) != NULL)
    myActiveControl = (TWinControl *)comp;
}
/*
The following example creates 20 edit boxes, using
FindComponent with the edit box name to access each newly
created edit box.
*/
const int EditBoxCount = 20;
const int LeftCoordinate = 10;
TEdit* pe[20];
void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const char* pszNamePrefix = "MyEdit";
```

```
    for (int i=0;i<EditBoxCount;i++)
    {
        pe[i] = new TEdit(this);
        pe[i]->Name = pszNamePrefix + IntToStr(i+1);
        pe[i]->Left = LeftCoordinate;
        pe[i]->Top = i*EditBoxCount;
        pe[i]->Parent = this;
    }
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<EditBoxCount;i++)
    delete pe[i];
}
```

Delphi Examples:

```
{
This code resizes the active control to twice as wide and
half as high:
}
procedure TForm1.ButtonSFClick(Sender: TObject);
var
  MyRect: TRect;
begin
  if (myActiveControl = nil) then exit;
  MyRect := myActiveControl.BoundsRect;
  MyRect.Right := MyRect.Left + (MyRect.Right - MyRect.Left) * 2;
  MyRect.Bottom := MyRect.Top + (MyRect.Bottom - MyRect.Top) div 2;
  myActiveControl.BoundsRect := MyRect;
end;

procedure TForm1.ButtonTSClick(Sender: TObject);
var
  MyRect: TRect;
begin
  if (myActiveControl = nil) then exit;
  MyRect := myActiveControl.BoundsRect;
  MyRect.Right := MyRect.Left + (MyRect.Right - MyRect.Left) div 2;
  MyRect.Bottom := MyRect.Top + (MyRect.Bottom - MyRect.Top) * 2;
  myActiveControl.BoundsRect := MyRect;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
  Temp: TComponent;
  ListItem: TListItem;
begin
  ListView1.ViewStyle := vsList;
  ListItem := ListView1.Items.Add;
  ListItem.Caption := 'Components: ';
  for I := ComponentCount - 1 downto 0 do
  begin
    Temp := Components[I];
    begin
      ListItem := ListView1.Items.Add;
      ListItem.Caption := Temp.Name;
    end;
  end;
end;

procedure TForm1.ListView1SelectItem(Sender: TObject; Item: TListItem;
  Selected: Boolean);
var comp: TComponent;
begin
```

```
    comp := FindComponent(Item.Caption);
    if comp is TWinControl then
      myActiveControl := TWinControl(comp);
  end;
  {
  The following example creates 20 edit boxes, using
  FindComponent with the edit box name to access each newly
  created edit box.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    i: Integer;
  const
    NamePrefix = 'MyEdit';
  begin
    for i := 1 to 20 do begin
      TEdit.Create(Self).Name := NamePrefix + IntToStr(i);
      with TEdit(FindComponent(NamePrefix + IntToStr(i))) do
      begin
        Left := 10;
        Top := i * 20;
        Parent := self;
      end;
    end;
  end;
```

See Also

Components (see page 2799)

Owner (see page 2807)

Name (see page 2805)

23.1.27.5.10 TComponent.FreeNotification Method

Ensures that AComponent is notified that the component is going to be destroyed.

Pascal

```
procedure FreeNotification(AComponent: TComponent);
```

C++

```
__fastcall FreeNotification(TComponent * AComponent);
```

Description

Use FreeNotification to register AComponent as a component that should be notified when the component is about to be destroyed. It is only necessary to register components this way when they are in a different form or have a different owner. For example, if AComponent is in another form and uses the component to implement a property, it must call FreeNotification so that its Notification (see page 2783) method is called when the component is destroyed.

For components with the same owner, the Notification (see page 2783) method is called automatically when an application explicitly frees the component. This notification is not sent out when components are freed implicitly, because the Owner (see page 2807) is already being freed.

See Also

Notification (see page 2783)

RemoveFreeNotification (see page 2787)

Owner (see page 2807)

23.1.27.5.11 TComponent.FreeOnRelease Method

Frees the interface reference for components that were created from COM classes.

Pascal

```
procedure FreeOnRelease;
```

C++

```
__fastcall FreeOnRelease();
```

Description

FreeOnRelease is called when an interface implemented by the component is released. FreeOnRelease is used internally and calls the corresponding interface method. It should not be necessary to call FreeOnRelease directly.

See Also

ComObject (see page 2793)

23.1.27.5.12 TComponent.GetChildOwner Method

Returns the owner of a child component being read from a stream.

Pascal

```
function GetChildOwner: TComponent; dynamic;
```

C++

```
__fastcall TComponent * GetChildOwner();
```

Description

GetChildOwner is used internally by the component streaming system. It is rarely necessary to call it directly.

In TComponent (see page 2762), GetChildOwner always returns nil (Delphi) or NULL (C++), indicating that the owner is the root component currently being read (usually a form or data module). The Owner (see page 2807) of a component is responsible for destroying it.

See Also

Create (see page 2766)

Owner (see page 2807)

23.1.27.5.13 TComponent.GetChildParent Method

Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.

Pascal

```
function GetChildParent: TComponent; dynamic;
```

C++

```
__fastcall TComponent * GetChildParent();
```

Description

GetChildParent is used internally in the component streaming system. It is not necessary to call it directly.

As implemented in TComponent (see page 2762), GetChildParent returns Self (Delphi) or this (C++). If GetChildParent returns nil (Delphi) or NULL (C++), the parent is assumed to be the root component currently being read (usually a form).

See Also

GetParentComponent (see page 2778)

23.1.27.5.14 TComponent.GetChildren Method

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); dynamic;
```

C++

```
__fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

This is GetChildren, a member of class TComponent.

23.1.27.5.15 TComponent.GetEnumerator Method

Returns a TComponent (see page 2762) enumerator.

Pascal

```
function GetEnumerator: TComponentEnumerator;
```

C++

```
__fastcall TComponentEnumerator GetEnumerator();
```

Description

GetEnumerator returns a TComponentEnumerator (see page 2812) reference, which enumerates the components contained within a specified containing component.

To process all these sub components, call the TComponentEnumerator (see page 2812) GetCurrent method within a While MoveNext do loop.

See Also

TComponentEnumerator (see page 2812)

23.1.27.5.16 TComponent.GetIDsOfNames Method

Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

GetIDsOfNames implements the IDispatch interface GetIDsOfNames method. For components that support interfaces, GetIDsOfNames calls this method for the interface supported by the component, passing the specified parameters. The returned value can be used on subsequent calls to the Invoke (see page 2781) method.

See Also

GetTypeInfo (see page 2779)

GetTypeInfoCount (see page 2779)

Invoke (see page 2781)

23.1.27.5.17 TComponent.GetNamePath Method

Returns a string used by the Object Inspector.

Pascal

```
function GetNamePath: string; override;
```

C++

```
virtual __fastcall AnsiString GetNamePath();
```

Description

GetNamePath is used to determine the text to display in the Object Inspector for the name of the object being edited. GetNamePath is introduced in TPersistent (see page 2928) so descendants such as collections can appear in the Object Inspector. TComponent (see page 2762) overrides GetNamePath to return the component's name. Do not call GetNamePath directly.

See Also

GetOwner (see page 2778)

GetNamePath (see page 2932)

Name (see page 2805)

23.1.27.5.18 TComponent.GetOwner Method

Returns the owner of a component.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is called by GetNamePath (see page 2778) to find the owner of a component. GetNamePath (see page 2778) and GetOwner are introduced in TPersistent (see page 2928) so descendants such as collections can appear in the Object Inspector. For TComponent (see page 2762), GetOwner returns the value of the Owner (see page 2807) property.

See Also

GetNamePath (see page 2778)

Owner (see page 2807)

GetOwner (see page 2932)

23.1.27.5.19 TComponent.GetParentComponent Method

Returns the containing Component.

Pascal

```
function GetParentComponent: TComponent; dynamic;
```

C++

```
__fastcall TComponent * GetParentComponent();
```

Description

GetParentComponent returns a reference to the component that contains the current component, or nil of there is no container. Use HasParentComponent to determine if a component has a containing component.

For example, a button on a panel on a form will return the panel. The panel will return the form. And the form will return nil.

See Also

HasParentComponent

23.1.27.5.20 TComponent.GetTypeInfo Method

Retrieves the type information for an object.

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

GetTypeInfo implements the IDispatch interface GetTypeInfo method. For components that support interfaces, GetTypeInfo calls the GetTypeInfo method for the interface supported by the component, passing it the specified parameters. Use the returned value to get the type information for an interface implemented by the component.

See Also

GetIDsOfNames (see page 2777)

GetTypeInfoCount (see page 2779)

Invoke (see page 2781)

23.1.27.5.21 TComponent.GetTypeInfoCount Method

Returns the number of type information interfaces that an object provides (either 0 or 1).

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

GetTypeInfoCount implements the IDispatch interface GetTypeInfoCount method. For components that support interfaces, GetTypeInfoCount calls this method for the interface supported by the component. The Count parameter points to a location that receives the number of type information interfaces provided by the object. If the object provides type information, this number is 1; otherwise the number is 0.

See Also

GetIDsOfNames (see page 2777)

GetTypeInfo (see page 2779)

Invoke (see page 2781)

23.1.27.5.22 TComponent.HasParent Method

Pascal

```
function HasParent: Boolean; dynamic;
```

C++

```
__fastcall Boolean HasParent();
```

Description

This is HasParent, a member of class TComponent.

23.1.27.5.23 TComponent.InsertComponent Method

Establishes the component as the owner of a specified component.

Pascal

```
procedure InsertComponent(AComponent: TComponent);
```

C++

```
__fastcall InsertComponent(TComponent * AComponent);
```

Description

InsertComponent adds the component passed in the AComponent parameter to the end of the Components (see page 2799) array property. The inserted component must have no name (no specified Name (see page 2805) property value), or the name must be unique among all others in the Components (see page 2799) list.

When the owning component is destroyed, AComponent is destroyed also.

Components (see page 2799) are automatically inserted and removed when visually manipulating them in the form designer. Use InsertComponent when manually adding components to another Owner (see page 2807) component's Components (see page 2799) list.

C++ Examples:

```
/*
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"#include ComponentCount2.cpp" in ComponentCount.h.
Place a TMemo in each form and a TButton in Form1.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int I;
  TComponent *Temp;
  Memo1->Lines->Add("Components removed: ");
  Form2->Memo1->Lines->Add("Components added: ");
  for (I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    // only move components that are not controls
```

```
      if (dynamic_cast<TControl *>(Temp) == NULL)
      {
        RemoveComponent(Temp);
        Memo1->Lines->Add(Temp->Name);
        Form2->InsertComponent(Temp);
        Form2->Memo1->Lines->Add(Temp->Name);
      }
    }
  }
```

Delphi Examples:

```
{
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"ComponentCount2" at the end of the uses clause of Form1.
Place a TMemo in each form and a TButton in Form1.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
  Temp: TComponent;
begin
  Form1.Memo1.Lines.Add('Components removed: ');
  Form2.Memo1.Lines.Add('Components added: ');
  for I := ComponentCount - 1 downto 0 do
  begin
    Temp := Components[I];
    if not (Temp is TControl) then
    begin
      RemoveComponent(Temp);
      Form1.Memo1.Lines.Add(Temp.Name);
      Form2.InsertComponent(Temp);
      Form2.Memo1.Lines.Add(Temp.Name);
    end;
  end;
end;
```

See Also

Components (see page 2799)

Owner (see page 2807)

23.1.27.5.24 TComponent.Invoke Method

Provides access to Automation properties and methods when the component wraps an Automation object.

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

Invoke is the standard mechanism for accessing the exposed properties and methods of an Automation object. For components that wrap the IDispatch interface of an Automation object, Invoke calls the Invoke method for the interface supported by the component, passing it the parameters specified by the function.

See Also

GetIDsOfNames (see page 2777)

GetTypeInfo (see page 2779)

GetTypeInfoCount (see page 2779)

ComObject (see page 2793)

23.1.27.5.25 TComponent.IsImplementorOf Method

Indicates whether the component implements a specified interface.

Pascal

```
function IsImplementorOf(const I: IInterface): Boolean;
```

C++

```
__fastcall Boolean IsImplementorOf(const IInterface I);
```

Description

Call IsImplementorOf to determine whether the component (or, if the component aggregates its interface with other components, whether the controlling component) supports the interface specified by I. IsImplementorOf is similar to the QueryInterface (see page 2784) method, but it can handle a request for a nil (Delphi) or NULL (C++) interface, and it does not return an interface pointer.

The streaming system that loads and saves components uses IsImplementorOf to resolve property values that are interfaces.

See Also

QueryInterface (see page 2784)

23.1.27.5.26 TComponent.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; virtual;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling

pointers can be used after being streamed in.

As implemented in TComponent (see page 2762), Loaded clears the csLoading flag in the ComponentState (see page 2804) property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

See Also

ComponentState (see page 2804)

Create (see page 2766)

TReader (see page 2933)

23.1.27.5.27 TComponent.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); virtual;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner (see page 2807) is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

23.1.27.5.28 TComponent.PaletteCreated Method

Responds when the component is created from the component palette.

Pascal

```
procedure PaletteCreated; dynamic;
```

C++

```
__fastcall PaletteCreated();
```

Description

PaletteCreated is called automatically at design time when the component has just been created from the component palette. Component writers can override this method to perform adjustments that are required only when the component is created from the component palette.

As implemented in TComponent (see page 2762), PaletteCreated does nothing.

See Also

Create (see page 2766)

Loaded (see page 2782)

23.1.27.5.29 TComponent.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the component supports the interface specified by IID, and if so, returns a reference to that interface as the Obj parameter. If the component does not support the interface, the Obj parameter returns nil (Delphi) or NULL (C++).

Note: For components that act as COM object wrapper, QueryInterface calls the QueryInterface method of the internal COM object.

See Also

_AddRef (see page 2769)

_Release (see page 2769)

QueryInterface

QueryInterface (see page 22398)

Invoke (see page 2781)

ComObject (see page 2793)

23.1.27.5.30 TComponent.ReadState Method

Pascal

```
procedure ReadState(Reader: TReader); virtual;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

This is ReadState, a member of class TComponent.

23.1.27.5.31 TComponent.ReferenceInterface Method

Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.

Pascal

```
function ReferenceInterface(const I: IInterface; Operation: TOperation): Boolean;
```

C++

```
__fastcall Boolean ReferenceInterface(const IInterface I, TOperation Operation);
```

Description

Component writers use ReferenceInterface to ensure that properties whose values are interfaces are informed when the objects that implement those interfaces are destroyed. This notification must be in place for a property whose value is an interface to be saved with the component in a form file (that is, for such a property to persist as a published property).

I is an interface pointer that is the value of the published property of interest.

Operation indicates whether the notification link to the implementer of the interface should be established (opInsert) or removed (opRemove).

ReferenceInterface returns true if it is successful in establishing or removing the notification link. If ReferenceInterface returns false when called with Operation set to opInsert, the specified interface can't be stored as the value of a published property.

Note: A result of false does not necessarily indicate an error, merely that the interface can't be stored by the property streaming system. For example, ReferenceInterface returns false when the specified interface employs true reference counting, independent of component lifetimes.

FreeNotification (see page 2775)

RemoveFreeNotification (see page 2787)

23.1.27.5.32 TComponent.RemoveComponent Method

Removes a specified component specified from the component's Components (see page 2799) list.

Pascal

```
procedure RemoveComponent(AComponent: TComponent);
```

C++

```
__fastcall RemoveComponent(TComponent * AComponent);
```

Description

Components (see page 2799) are automatically inserted and removed when visually manipulating them in the form designer. Use RemoveComponent to programmatically delete the component specified by AComponent from its Owner (see page 2807) component.

C++ Examples:

```
/*
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
```

```
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"#include ComponentCount2.cpp" in ComponentCount.h.
Place a TMemo in each form and a TButton in Form1.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int I;
  TComponent *Temp;
  Memo1->Lines->Add("Components removed: ");
  Form2->Memo1->Lines->Add("Components added: ");
  for (I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    // only move components that are not controls
    if (dynamic_cast<TControl *>(Temp) == NULL)
    {
      RemoveComponent(Temp);
      Memo1->Lines->Add(Temp->Name);
      Form2->InsertComponent(Temp);
      Form2->Memo1->Lines->Add(Temp->Name);
    }
  }
}
```

Delphi Examples:

```
{
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"ComponentCount2" at the end of the uses clause of Form1.
Place a TMemo in each form and a TButton in Form1.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
  Temp: TComponent;
begin
  Form1.Memo1.Lines.Add('Components removed: ');
  Form2.Memo1.Lines.Add('Components added: ');
  for I := ComponentCount - 1 downto 0 do
  begin
    Temp := Components[I];
    if not (Temp is TControl) then
    begin
      RemoveComponent(Temp);
      Form1.Memo1.Lines.Add(Temp.Name);
      Form2.InsertComponent(Temp);
      Form2.Memo1.Lines.Add(Temp.Name);
    end;
  end;
end;
```

See Also

Components (see page 2799)

Notification (see page 2783)

Owner (see page 2807)

23.1.27.5.33 TComponent.RemoveFreeNotification Method

Disables destruction notification that was enabled by FreeNotification (see page 2775)

Pascal

```
procedure RemoveFreeNotification(AComponent: TComponent);
```

C++

```
__fastcall RemoveFreeNotification(TComponent * AComponent);
```

Description

RemoveFreeNotification removes the component specified by the AComponent parameter from the internal list of objects to be notified that the component is about to be destroyed. AComponent is added to this list by a previous call to the FreeNotification (see page 2775) method.

Most applications have no need to call RemoveFreeNotification. It is used by TComponent (see page 2762) to detect loops where two components are notifying each other of their impending destruction.

See Also

FreeNotification (see page 2775)

23.1.27.5.34 TComponent.SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur. TComponent (see page 2762) calls the implementation of this method for the interface supported by the component, if it exists. If the component does not support interfaces, this method calls the SafeCallException method inherited from TObject, which returns E_UNEXPECTED. This is a default return value that is appropriate for classes that do not support any interfaces.

See Also

SafeCallException

23.1.27.5.35 TComponent.SetAncestor Method

Pascal

```
procedure SetAncestor(Value: Boolean);
```

C++

```
__fastcall SetAncestor(Boolean Value);
```

Description

This is SetAncestor, a member of class TComponent.

23.1.27.5.36 TComponent.SetChildOrder Method

Pascal

```
procedure SetChildOrder(Child: TComponent; Order: Integer); dynamic;
```

C++

```
__fastcall SetChildOrder(TComponent * Child, int Order);
```

Description

This is SetChildOrder, a member of class TComponent.

23.1.27.5.37 TComponent.SetDesigning Method

Ensures that components inserted at design time have their design-mode flag set.

Pascal

```
procedure SetDesigning(Value: Boolean; SetChildren: Boolean = True);
```

C++

```
__fastcall SetDesigning(Boolean Value, Boolean SetChildren = True);
```

Description

SetDesigning is used internally by the Form designer. Do not call SetDesigning directly.

SetDesigning sets the csDesigning flag in the ComponentState (see page 2804) property if Value is true; otherwise, it removes csDesigning.

If the SetChildren parameter is true, SetDesigning then calls the SetDesigning methods of any owned components, passing Value, so that the owned components' ComponentState (see page 2804) properties are synchronized with the owner's.

The InsertComponent (see page 2780) and RemoveComponent (see page 2785) methods call SetDesigning for inserted or removed components to ensure that their design-mode flags are set properly.

See Also

ComponentState (see page 2804)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

23.1.27.5.38 TComponent.SetDesignInstance Method

Ensures that components inserted at design time have their design-mode flag set.

Pascal

```
procedure SetDesignInstance(Value: Boolean);
```

C++

```
__fastcall SetDesignInstance(Boolean Value);
```

Description

SetDesignInstance is used internally by the Form designer to identify objects that act as a design surface. Do not call SetDesignInstance directly.

SetDesignInstance sets the csDesignInstance flag in the ComponentState (see page 2804) property if Value is true; otherwise,

it removes csDesignInstance.

See Also

ComponentState (see page 2804)

SetDesigning (see page 2788)

23.1.27.5.39 TComponent.SetInline Method

Sets the csInline bit of the component's ComponentState (see page 2804) property

Pascal

```
procedure SetInline(Value: Boolean);
```

C++

```
__fastcall SetInline(Boolean Value);
```

Description

SetInline is used internally to indicate whether the component can act as a root component in the designer but also be embedded in a form.

SetInline sets the csInline flag in the ComponentState (see page 2804) property if Value is true; otherwise, it removes csInline.

See Also

ComponentState (see page 2804)

23.1.27.5.40 TComponent.SetName Method

Sets the value of the Name (see page 2805) property.

Pascal

```
procedure SetName(const NewName: TComponentName); virtual;
```

C++

```
virtual __fastcall SetName(const TComponentName NewName);
```

Description

SetName is the virtual property setter for the Name (see page 2805) property. It calls the ChangeName (see page 2770) method, which performs the actual name change.

ChangeName (see page 2770) is not virtual; override SetName instead when modifying the behavior of the Name (see page 2805) property.

Warning: Using SetName to change the name of a component at runtime causes any references to the old name to become undefined. Any subsequent code that uses the old name will cause an exception.

See Also

ChangeName (see page 2770)

Name (see page 2805)

ValidateRename (see page 2792)

23.1.27.5.41 TComponent.SetParentComponent Method

Pascal

```
procedure SetParentComponent(Value: TComponent); dynamic;
```

C++

```
__fastcall SetParentComponent(TComponent * Value);
```

Description

This is SetParentComponent, a member of class TComponent.

23.1.27.5.42 TComponent.SetSubComponent Method

Identifies whether the component is a subcomponent.

Pascal

```
procedure SetSubComponent(IsSubComponent: Boolean);
```

C++

```
__fastcall SetSubComponent(Boolean IsSubComponent);
```

Description

Call SetSubComponent to indicate that this component is or is not a subcomponent. A subcomponent is a component whose Owner (see page 2807) is a component other than the form or data module in which it resides. Unless such a component calls SetSubComponent with IsSubComponent set to true, its published properties will not be saved to the form file.

IsSubComponent indicates whether the component is a subcomponent (true) or not (false).

SetSubComponent is called at design time either

From the constructor of a component that always acts as a subcomponent. In this case, the component calls its own SetSubComponent method from the constructor with IsSubComponent set to true.

Immediately after constructing an instance of the subcomponent. In this case, the Owner (see page 2807) calls the SetSubComponent method of a component it has just instantiated, with IsSubComponent set to true.

See Also

ComponentStyle (see page 2805)

Owner (see page 2807)

23.1.27.5.43 TComponent.UpdateAction Method

Pascal

```
function UpdateAction(Action: TBasicAction): Boolean; dynamic;
```

C++

```
__fastcall Boolean UpdateAction(TBasicAction Action);
```

Description

This is UpdateAction, a member of class TComponent.

23.1.27.5.44 TComponent.Updated Method

Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.

Pascal

```
procedure Updated; dynamic;
```

C++

```
__fastcall Updated();
```

Description

Do not call Updated directly. It is used internally to clear the csUpdating flag of the ComponentState (see page 2804) property. A call to Updated always follows a call to Updating (see page 2791), which sets the flag.

See Also

ComponentState (see page 2804)

Updating (see page 2791)

23.1.27.5.45 TComponent.UpdateRegistry Method

Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.

Pascal

```
class procedure UpdateRegistry(Register: Boolean; const ClassID: string; const ProgID:
string); virtual;
```

C++

```
virtual __fastcall UpdateRegistry(Boolean Register, const AnsiString ClassID, const AnsiString
ProgID);
```

Description

Do not call UpdateRegistry directly. It is for internal use only.

23.1.27.5.46 TComponent.Updating Method

Sets the csUpdating state in the component's ComponentState (see page 2804) property.

Pascal

```
procedure Updating; dynamic;
```

C++

```
__fastcall Updating();
```

Description

Do not call Updating directly. It is used internally to indicate that the component is about to be updated. A call to Updating, which sets the csUpdating flag, is always followed by a call to Updated (see page 2791), which clears the flag.

See Also

ComponentState (see page 2804)

Updated (see page 2791)

23.1.27.5.47 TComponent.ValidateContainer Method

Determines whether an object can be inserted into a container.

Pascal

```
procedure ValidateContainer(AComponent: TComponent); dynamic;
```

C++

```
__fastcall ValidateContainer(TComponent * AComponent);
```

Description

ValidateContainer is called by a component when it is about to be inserted into a container object. By default, ValidateContainer calls the ValidateInsert (see page 2792) method of the component specified by the AComponent parameter.

Descendant components can override ValidateContainer to disallow a component from being inserted into specific containers. To disallow an insertion, raise an exception in the derived method.

See Also

ValidateInsert (see page 2792)

23.1.27.5.48 TComponent.ValidateInsert Method

Provides the interface for a method that validates an child component before it is inserted.

Pascal

```
procedure ValidateInsert(AComponent: TComponent); dynamic;
```

C++

```
__fastcall ValidateInsert(TComponent * AComponent);
```

Description

ValidateInsert does nothing in TComponent (see page 2762). Descendant classes can override it to disallow a component from accepting an object as a child. By default ValidateInsert allows any object to be inserted into the component.

If a component needs to validate only certain objects, descendant classes can override ValidateInsert to filter out those objects. To disallow an insertion, raise an exception in the derived method.

See Also

ValidateContainer (see page 2792)

23.1.27.5.49 TComponent.ValidateRename Method

Ensures that renaming an owned component does not create name conflict.

Pascal

```
procedure ValidateRename(AComponent: TComponent; const CurName: string; const NewName:
string); virtual;
```

C++

```
virtual __fastcall ValidateRename(TComponent * AComponent, const AnsiString CurName, const
AnsiString NewName);
```

Description

ValidateRename checks to see if a component can rename one of its owned components, passed in AComponent, from its

current name (CurName) to the string passed in NewName. If AComponent is nil (Delphi) or NULL (C++) or NewName is already the name of a component in the Components (see page 2799) list, ValidateRename raises an EComponentError (see page 2694) exception.

ValidateRename is used internally when the Name (see page 2805) property is modified. It is not necessary to call it directly.

See Also

ChangeName (see page 2770)

Name (see page 2805)

SetName (see page 2789)

23.1.27.5.50 TComponent.WriteState Method

Pascal

```
procedure WriteState(Writer: TWriter); virtual;
```

C++

```
virtual __fastcall WriteState(TWriter Writer);
```

Description

This is WriteState, a member of class TComponent.

23.1.27.6 TComponent Properties

The properties of the TComponent class are listed here.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

23.1.27.6.1 TComponent.ComObject Property

Specifies the interface reference implemented by the component.

Pascal

```
property ComObject: IUnknown;
```

C++

```
__property IUnknown ComObject;
```

Description

Use ComObject to assign a COM interface implemented by a component to an interface reference. This property is used by components that support COM interfaces.

If the component is not a wrapper for a COM component, trying to read ComObject causes TComponent (see page 2762) to raise an EComponentError (see page 2694) exception.

See Also

EComponentError (see page 2694)

23.1.27.6.2 TComponent.ComponentCount Property

Indicates the number of components owned by the component.

Pascal

```
property ComponentCount: Integer;
```

C++

```
__property int ComponentCount;
```

Description

Use the ComponentCount property to determine the number of components owned by a component, for example, when iterating through the components list to perform some action on all owned components. The ComponentCount property equals the number of items in the components list. This value is one more than the highest Components (see page 2799) index, because the first components index is 0.

C++ Examples:

```
/*
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"#include ComponentCount2.cpp" in ComponentCount.h.
Place a TMemo in each form and a TButton in Form1.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int I;
  TComponent *Temp;
  Memo1->Lines->Add("Components removed: ");
  Form2->Memo1->Lines->Add("Components added: ");
  for (I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    // only move components that are not controls
    if (dynamic_cast<TControl *>(Temp) == NULL)
    {
      RemoveComponent(Temp);
      Memo1->Lines->Add(Temp->Name);
      Form2->InsertComponent(Temp);
      Form2->Memo1->Lines->Add(Temp->Name);
```

```
    }
  }
}
```

Delphi Examples:

```
{
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"ComponentCount2" at the end of the uses clause of Form1.
Place a TMemo in each form and a TButton in Form1.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
  Temp: TComponent;
begin
  Form1.Memo1.Lines.Add('Components removed: ');
  Form2.Memo1.Lines.Add('Components added: ');
  for I := ComponentCount - 1 downto 0 do
  begin
    Temp := Components[I];
    if not (Temp is TControl) then
    begin
      RemoveComponent(Temp);
      Form1.Memo1.Lines.Add(Temp.Name);
      Form2.InsertComponent(Temp);
      Form2.Memo1.Lines.Add(Temp.Name);
    end;
  end;
end;
{
Here is the code on Form1 that fills the list box.
}
var

ComponentIndex (see page 2799)

Components (see page 2799)

23.1.27.6.3 TComponent.ComponentIndex Property

Indicates the position of the component in its owner's Components (see page 2799) property array.

Pascal

```
property ComponentIndex: Integer;
```

C++

```
__property int ComponentIndex;
```

Description

Use ComponentIndex when iterating through the Components (see page 2799) list of the component's owner to perform some action on owned components. It can be used in conjunction with ComponentCount (see page 2794). ComponentIndex is used internally for iterative assignment procedures.

Note: The first component in the list has a ComponentIndex value of 0, the second has a value of 1, and so on. Therefore, when using ComponentIndex with ComponentCount (see page 2794), note that ComponentCount (see page 2794) is always 1 more than the highest Components (see page 2799) index.

See Also

ComponentCount (see page 2794)

Components (see page 2799)

23.1.27.6.4 TComponent.Components Property

Lists all components owned by the component.

Pascal

```
property Components [Index: Integer]: TComponent;
```

C++

```
__property TComponent * Components[int Index];
```

Description

Use Components to access any of the components owned by this component, such as the components owned by a form. The Components property is most useful when referring to owned components by number rather than name. It is also used internally for iterative processing of all owned components.

Index ranges from 0 to ComponentIndex (see page 2799) minus 1.

C++ Examples:

```
/*
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
```

```
"#include ComponentCount2.cpp" in ComponentCount.h.
Place a TMemo in each form and a TButton in Form1.
*/

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int I;
  TComponent *Temp;
  Memo1->Lines->Add("Components removed: ");
  Form2->Memo1->Lines->Add("Components added: ");
  for (I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    // only move components that are not controls
    if (dynamic_cast<TControl *>(Temp) == NULL)
    {
      RemoveComponent(Temp);
      Memo1->Lines->Add(Temp->Name);
      Form2->InsertComponent(Temp);
      Form2->Memo1->Lines->Add(Temp->Name);
    }
  }
}
```

Delphi Examples:

```
{
This code fragment moves any nonvisual components on the
form into a separate data module. Note that the components
are removed starting with the last component, so that the
unprocessed portion of the Components array does not change.
Note: This code does not save the form or data module to disk
after the nonvisual components are moved.  If executed at
runtime, the effect will not persist.
Add a second TForm and name it ComponentCount2.  Put
"ComponentCount2" at the end of the uses clause of Form1.
Place a TMemo in each form and a TButton in Form1.
}

procedure TForm1.Button1Click(Sender: TObject);

23.1.27.6.5 TComponent.ComponentState Property

Describes the current state of the component, indicating when a component needs to avoid certain actions.

Pascal

```
property ComponentState: TComponentState;
```

C++

```
__property TComponentState ComponentState;
```

Description

Components (see page 2799) use the ComponentState property to detect states in which certain kinds of actions are allowed or disallowed. For example, if a component needs to avoid certain behaviors at design time that it performs at runtime, it can check for the csDesigning flag. ComponentState is read-only and its flags are set automatically when appropriate.

Updating (see page 2791)

WriteState (see page 2793)

23.1.27.6.6 TComponent.ComponentStyle Property

Governs the behavior of the component.

Pascal

```
property ComponentStyle: TComponentStyle;
```

C++

```
__property TComponentStyle ComponentStyle;
```

Description

ComponentStyle governs how the component interacts with the streaming system and the Object Inspector. ComponentStyle is a read-only property. Typically, the value of the various component style flags are part of a component's definition, specified in a component's constructor. The one exception to this is the csSubComponent style, which can be set by calling the SetSubComponent (see page 2790) method.

See Also

SetSubComponent (see page 2790)

ComponentState (see page 2804)

23.1.27.6.7 TComponent.DesignInfo Property

Contains information used by the Form designer.

Pascal

```
property DesignInfo: Longint;
```

C++

```
__property Longint DesignInfo;
```

Description

DesignInfo is used internally. Do not use this property in applications.

See Also

IDesigner (see page 11149)

23.1.27.6.8 TComponent.Name Property

Specifies the name of the component as referenced in code.

Pascal

```
property Name: TComponentName;
```

C++

```
__property TComponentName Name;
```

Description

Use Name to change the name of a component to reflect its purpose in the current application. By default, the IDE assigns sequential names based on the type of the component, such as 'Button1', 'Button2', and so on.

Use Name to refer to the component in code.

Warning: Changing Name at runtime causes any references to the old name to become undefined. Any subsequent code that

uses the old name will cause an exception.

C++ Examples:

```
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < ComponentCount; i++)
    ListBox1->Items->InsertObject(0,
                                  Components[i]->Name,
                                  (TObject *)Components[i]);
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  if (Button == mbRight)
  {
    TClass ClassRef;
    int Index = ListBox1->ItemAtPos(Point(X,Y), true);
    // only components that are controls have a position
    // make sure the component is a control
    for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
         ClassRef != NULL;
         ClassRef = ClassRef->ClassParent())
      if (String(ClassRef->ClassName()) == "TControl")
      {
        TControl *TheObject = (TControl *)ListBox1->Items->Objects[Index];
        StatusBar1->SimpleText =
          TheObject->Name + " is at (" +
          IntToStr(TheObject->Left) + ", " +
          IntToStr(TheObject->Top) + ")";
         break;
      }
    if (ClassRef == NULL) // if it wasn't a control
      MessageBeep(0);
  }
}
```

Delphi Examples:

```
{

23.1.27.6.9 TComponent.Owner Property

Indicates the component that is responsible for streaming and freeing this component.

Pascal

```
property Owner: TComponent;
```

C++

```
__property TComponent * Owner;
```

Description

Use Owner to find the owner of a component. The Owner of a component is responsible for two things:

The memory for the owned component is freed when its owner's memory is freed. This means that when a form is destroyed, all the components on the form are also destroyed.

The Owner is responsible for loading and saving the published properties of its owned controls.

By default, a form owns all components that are on it. In turn, the form is owned by the application. Thus when the application shuts down and its memory is freed, the memory for all forms (and all their owned components) is also freed. When a form is loaded into memory, it loads all of the components that are on it.

The owner of a component is determined by the parameter passed to the constructor when the component is created. For components created in the form designer, the form is automatically assigned as the Owner.

Warning: If a component has an Owner other than a form or data module, it will not be saved or loaded with its Owner unless you identify it as a subcomponent. To identify a component as a subcomponent, call the SetSubComponent (see page 2790) method.

23.1.27.6.10 TComponent.Tag Property

Stores an integer value as part of a component.

Pascal

```
property Tag: Longint;
```

C++

```
__property Longint Tag;
```

Description

Tag has no predefined meaning. The Tag property is provided for the convenience of developers. It can be used for storing an additional integer value or it can be typecast to any 32-bit value such as a component reference or a pointer.

C++ Examples:

```
/*
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
```

```
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
*/
void __fastcall TForm1::UpDownClick(TObject *Sender)
{
  CDS2->MoveBy(((TComponent *)Sender)->Tag);
  DBGrid2->SetFocus();
}

void __fastcall TForm1::LeftRightClick(TObject *Sender)
{
  DBGrid2->SelectedIndex = DBGrid2->SelectedIndex + ((TComponent *)Sender)->Tag;
  DBGrid2->SetFocus();
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
}
procedure TForm1.UpDownClick(Sender: TObject);
begin
  CDS.MoveBy(TComponent(Sender).Tag);
  DBGrid1.SetFocus;
end;

procedure TForm1.LeftRightClick(Sender: TObject);
begin
  DBGrid1.SelectedIndex := DBGrid1.SelectedIndex + TComponent(Sender).Tag;
  DBGrid1.SetFocus;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type
  TForm1 = class(TForm)
    AddButton: TButton;
    EditButton: TButton;
    DestroyButton: TButton;
    PopupMenu1: TPopupMenu;
```

```
    procedure AddButtonClick(Sender: TObject);
    procedure EditButtonClick(Sender: TObject);
    procedure DestroyButtonClick(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    procedure PopupMenuItemsClick(Sender: TObject);

  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

procedure TForm1.AddButtonClick(Sender: TObject);
var
  index: Integer;
  NewItem: TMenuItem;
begin
  for index := 0 to 3 do
  begin
    NewItem :=
      TMenuItem.Create(PopupMenu1); // create the new item
    PopupMenu1.Items.Add(NewItem);// add it to the Popupmenu
    NewItem.Caption := 'Menu Item ' + IntToStr(index);
    NewItem.Tag := index;
    NewItem.OnClick :=
      PopupMenuItemsClick; // assign it an event handler
  end;
end;

procedure TForm1.PopupMenuItemsClick(Sender: TObject);
begin
  with Sender as TMenuItem do
  begin
    case Tag of
      0:  ShowMessage('first item clicked');
      1:  ShowMessage('second item clicked');
      2:  ShowMessage('third item clicked');
      3:  ShowMessage('fourth item clicked');
    end;
  end;
end;

{
To edit or destroy an item, grab its pointer via the Items
property.
}
procedure TForm1.EditButtonClick(Sender: TObject);

end;
```

23.1.27.6.11 TComponent.VCLComObject Property

Represents information used internally by components that support COM.

Pascal

```
property VCLComObject: Pointer;
```

C++

```
__property void * VCLComObject;
```

Description

VCLComObject is for internal use only.

See Also

ComObject (see page 2793)

23.1.28 TComponentEnumerator Class

TComponentEnumerator allows the components within a containing component to be discovered.

Class Hierarchy

Classes.TComponentEnumerator

Pascal

```
TComponentEnumerator = class;
```

C++

```
class TComponentEnumerator;
```

File

Classes

Description

The TComponentEnumerator returns references to the components contained within a specified containing component. This allows an application to inspect the contents of a component at run time.

It is useful, for example, for repeated sets of controls in panels on a form. When the user selects one panel (by button press within, for example), the code can determine the parent panel, and then use TComponentEnumerator to get the names of the controls on this particular panel.

See Also

TComponent (see page 2762)

23.1.28.1 TComponentEnumerator Members

The following tables list the members exposed by TComponentEnumerator.

Public Methods

	Name	Description
	Create (see page 2813)	Creates a TComponentEnumerator (see page 2812) class instance.
	GetCurrent (see page 2813)	Retrieves a reference to the current component.
	MoveNext (see page 2814)	Moves to the first, or next component within the containing component.

Public Properties

	Name	Description
R	Current (see page 2814)	Returns the currently selected component.

23.1.28.2 TComponentEnumerator.Create Constructor

Creates a TComponentEnumerator (see page 2812) class instance.

Pascal

```
constructor Create(AComponent: TComponent);
```

C++

```
__fastcall TComponentEnumerator(TComponent * AComponent);
```

Description

Call Create to instantiate a TComponentEnumerator (see page 2812) object at runtime.

The component to be enumerated is defined by **AComponent**.

See Also

TComponent (see page 2762)

23.1.28.3 TComponentEnumerator Methods

The methods of the TComponentEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 2813)	Retrieves a reference to the current component.
	MoveNext (see page 2814)	Moves to the first, or next component within the containing component.

23.1.28.3.1 TComponentEnumerator.GetCurrent Method

Retrieves a reference to the current component.

Pascal

```
function GetCurrent: TComponent;
```

C++

```
__fastcall TComponent * GetCurrent();
```

Description

Before you ever call GetCurrent, you must call MoveNext (see page 2814), successfully, or an exception will be thrown.

MoveNext (see page 2814) moves through the list of components within the parent component specified at class instantiation. GetCurrent returns a reference to the component currently referenced after the last MoveNext (see page 2814) operation.

The Current (see page 2814) property has the same effect as GetCurrent

See Also

Current (see page 2814)

MoveNext (see page 2814)

TComponent (see page 2762)

23.1.28.3.2 TComponentEnumerator.MoveNext Method

Moves to the first, or next component within the containing component.

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

MoveNext moves through the list of components within the parent component specified at class instantiation. A value of true is returned if a component was found, otherwise false. MoveNext is normally used in a while-true block.

Note: Before you ever call GetCurrent (see page 2813), you must call MoveNext successfully, or an exception will be thrown.

See Also

GetCurrent (see page 2813)

TComponent (see page 2762)

23.1.28.4 TComponentEnumerator Properties

The properties of the TComponentEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 2814)	Returns the currently selected component.

23.1.28.4.1 TComponentEnumerator.Current Property

Returns the currently selected component.

Pascal

```
property Current: TComponent;
```

C++

```
__property TComponent * Current;
```

Description

Before you ever use the Current, you must call MoveNext (see page 2814), successfully, or an exception will be thrown.

MoveNext (see page 2814) moves through the list of components within the parent component specified at class instantiation. Current returns a reference to the component currently referenced after the last MoveNext (see page 2814) operation.

The Current property has the same effect as GetCurrent (see page 2813)

See Also

GetCurrent (see page 2813)

TComponent (see page 2762)

23.1.29 TCustomMemoryStream Class

TCustomMemoryStream is an abstract base class used as the common ancestor for memory streams.

Class Hierarchy

Pascal

```
TCustomMemoryStream = class(TStream);
```

C++

```
class TCustomMemoryStream : public TStream;
```

File

Classes

Description

Use TCustomMemoryStream as a base class when defining a stream object that can transfer data that is stored in memory. Memory (see page 2823) streams are useful for providing file-like access to data that is stored in a less accessible medium. Data can be moved to an internal memory buffer when the memory stream is created. After manipulating the data in a memory stream, the data can be written out to its actual storage medium when the memory stream is destroyed.

Do not instantiate an instance of TCustomMemoryStream. It is an abstract class that implements behavior common to all memory streams. To work with an instance of a memory stream, use one of the descendants of TCustomMemoryStream, such as TMemoryStream (see page 2902) or TResourceStream (see page 2968).

See Also

TMemoryStream (see page 2902)

TResourceStream (see page 2968)

23.1.29.1 TCustomMemoryStream Members

The following tables list the members exposed by TCustomMemoryStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	SetPointer (see page 2823)	Replaces the memory buffer associated with the memory stream.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Read (see page 2817)	Reads up to Count bytes from the memory stream into Buffer and advances the current position of the stream by the number of bytes read.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 2818)	Writes the entire contents of the memory stream to the file with a given file name.
	SaveToStream (see page 2818)	Writes the entire contents of the memory stream to the stream object specified by Stream.
V	Seek (see page 2819)	Moves the current position of the stream by Offset bytes, relative to the origin specified by Origin.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
A	Write (see page 2989)	Introduces a pure virtual method for writing to the stream.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
R	Memory (see page 2823)	Provides direct access to the memory pool allocated for the memory stream.
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.29.2 TCustomMemoryStream Methods

The methods of the TCustomMemoryStream class are listed here.

Protected Methods

	Name	Description
	SetPointer (see page 2823)	Replaces the memory buffer associated with the memory stream.

Public Methods

	Name	Description
V	Read (see page 2817)	Reads up to Count bytes from the memory stream into Buffer and advances the current position of the stream by the number of bytes read.
	SaveToFile (see page 2818)	Writes the entire contents of the memory stream to the file with a given file name.
	SaveToStream (see page 2818)	Writes the entire contents of the memory stream to the stream object specified by Stream.
V	Seek (see page 2819)	Moves the current position of the stream by Offset bytes, relative to the origin specified by Origin.

23.1.29.2.1 TCustomMemoryStream.Read Method

Reads up to Count bytes from the memory stream into Buffer and advances the current position of the stream by the number of bytes read.

Pascal

```
function Read(var Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( Buffer, Longint Count);
```

Description

Use Read to read the contents of the memory stream into a buffer, starting at the current position. Read will read up to Count bytes from the current position in Memory (see page 2823). If Count bytes extends beyond the end of the memory buffer, Read will only transfer the data up to the end of the associated memory buffer. Read returns the number of bytes actually transferred to Buffer, and advances the current position accordingly. If the return value is less than Count, it means that reading reached the end of the stream data.

All the other data-reading methods of the memory stream (ReadBuffer (see page 2983), ReadComponent (see page 2983)) call Read to do the actual reading.

Note: Read treats Count as an upper bound. The ReadBuffer (see page 2983) method, by contrast, raises an exception if Count bytes cannot be read.

See Also

Memory (see page 2823)

Position (see page 2996)

ReadBuffer (see page 2983)

ReadComponent (see page 2983)

Write (see page 2989)

23.1.29.2.2 TCustomMemoryStream.SaveToFile Method

Writes the entire contents of the memory stream to the file with a given file name.

Pascal

```
procedure SaveToFile(const FileName: string);
```

C++

```
__fastcall SaveToFile(const AnsiString FileName);
```

Description

Use SaveToFile to write the contents of Memory (see page 2823) to a file. SaveToFile allows an application to write out the contents of the memory stream without having to explicitly create and free a file stream object. If the named file cannot be created or opened, SaveToFile raises an EFCreateError (see page 2695) exception.

See Also

EFcreateError

Memory (see page 2823)

SaveToStream (see page 2818)

TFileStream (see page 2841)

23.1.29.2.3 TCustomMemoryStream.SaveToStream Method

Writes the entire contents of the memory stream to the stream object specified by Stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to copy data that is stored in memory into another storage medium. SaveToStream writes the entire contents of Memory (see page 2823) into the indicated stream object, starting at the current position in the stream that was passed as a parameter.

When the Stream parameter is a TFileStream (see page 2841) object, SaveToStream does much the same thing as the SaveToFile (see page 2818) method. However, SaveToStream writes to the current position in the target stream. Thus, for example, SaveToStream can be used to append the contents of Memory (see page 2823) to a file stream, rather than replace the contents of the file the way SaveToFile (see page 2818) does.

If the entire contents of the memory stream cannot be written to the target stream, SaveToStream raises an EWriteError (see page 2706) exception.

See Also

EWriteError (see page 2706)

Memory (see page 2823)

SaveToFile (see page 2818)

Position (see page 2996)

23.1.29.2.4 TCustomMemoryStream.Seek Method

Moves the current position of the stream by Offset bytes, relative to the origin specified by Origin.

Pascal

```
function Seek(Offset: Longint; Origin: Word): Longint; override;
```

C++

```
virtual __fastcall Longint Seek(Longint Offset, Word Origin);
```

Description

Use Seek to move the current position within the memory stream by the indicated offset. Seek allows an application to read from or write to a particular location within the Memory (see page 2823) associated with the memory stream.

If Offset is a negative number, the seek is backward from the specified origin. The following table shows the different values of Origin and their meanings for seeking.

Value	Meaning
soFromBeginning (see page 3319)	Offset is from the beginning of Memory (see page 2823). Seek moves to the position Offset. Offset must be >= 0.
soFromCurrent (see page 3320)	Offset is from the current position. Seek moves to Position (see page 2996) + Offset.
soFromEnd (see page 3320)	Offset is from the end of Memory (see page 2823). Offset must be <= 0 to indicate a number of bytes before the end of the memory buffer.

Seek returns the new value of the Position (see page 2996) property.

Note: Seek does no error checking on the value provided for Offset. Do not call seek with an offset that would move the current position less than 0 (before the start of Memory (see page 2823)) or greater than Size (see page 2997) (beyond the end of the memory buffer).

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
```

```
    // with the streaming system.

    #pragma startup RegisterClassesWithStreamingSystem

    Classes::RegisterClass(__classid(MyScrollBar));
  }

  MyScrollBar *ScrollBar1;

  AnsiString __fastcall ComponentToString(TComponent *c)
  {
   AnsiString as;
   TMemoryStream* pms = new TMemoryStream();
   TStringStream* pss = new TStringStream(as);

   try
   {
      pms->WriteComponent(c);
      pms->Seek(0, soFromBeginning);
      ObjectBinaryToText(pms, pss);
      pss->Seek(0, soFromBeginning);
      as = pss->DataString;
   }
   catch(...)
   {
      ShowMessage("Streaming error.");
   }

   delete pms;
   delete pss;
   return as;
  }

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    Memo1->Text = ComponentToString(ScrollBar1);
  }

  TComponent *__fastcall StringToComponent(AnsiString as)

  {
   TMemoryStream* pms = new TMemoryStream();
   TStringStream* pss = new TStringStream(as);
   TComponent *pc;

   try
   {
      ObjectTextToBinary(pss, pms);
      pms->Seek(0, soFromBeginning);
   }
   catch(...)
   {
      ShowMessage("Streaming error.");
   }

   pc = pms->ReadComponent(NULL);
   delete pms;
   delete pss;
   return pc;
  }

  void __fastcall TForm1::Button2Click(TObject *Sender)
  {
    TComponent *temp = StringToComponent(Memo1->Text);
    ScrollBar1->Free();
```

```
  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

23.1.29.2.5 TCustomMemoryStream.SetPointer Method

Replaces the memory buffer associated with the memory stream.

Pascal

```
procedure SetPointer(Ptr: Pointer; Size: Longint);
```

C++

```
__fastcall SetPointer(void * Ptr, Longint Size);
```

Description

Use SetPointer to set the internal memory buffer, Memory (see page 2823), to be the value passed in by Ptr. Size (see page 2997) is the number of bytes Ptr points to.

Descendants of TCustomMemoryStream (see page 2815) should use SetPointer to associate the memory stream with the memory buffer that holds the data for the memory stream.

Note: SetPointer does not free the existing value of Memory (see page 2823), if any, when it replaces the memory buffer. Descendants of TCustomMemoryStream (see page 2815) that use SetPointer to replace the stream's memory pool should free the memory pointed to by the Memory (see page 2823) property before calling SetPointer to replace the memory buffer.

See Also

Memory (see page 2823)

Size (see page 2997)

23.1.29.3 TCustomMemoryStream Properties

The properties of the TCustomMemoryStream class are listed here.

Public Properties

	Name	Description
R	Memory (see page 2823)	Provides direct access to the memory pool allocated for the memory stream.

23.1.29.3.1 TCustomMemoryStream.Memory Property

Provides direct access to the memory pool allocated for the memory stream.

Pascal

```
property Memory: Pointer;
```

C++

```
__property void * Memory;
```

Description

Use Memory to get access to the memory for the stream. The memory for the stream holds the data that is being transferred by means of the memory stream. Size (see page 2997) is the number of bytes of Memory that were allocated, and Position (see page 2996) is the current position within Memory.

Note: Memory is a read-only property. Memory can be used to change the contents of the memory, but to set the actual memory the stream works with, descendants of TCustomMemoryStream (see page 2815) must assign a pointer to a memory buffer by calling the SetPointer (see page 2823) method.

See Also

Position (see page 2996)

SetPointer (see page 2823)

Size (see page 2997)

23.1.30 TDataModule Class

TDataModule centralizes the handling of nonvisual components in an application.

Class Hierarchy

Pascal

```
TDataModule = class(TComponent);
```

C++

```
class TDataModule : public TComponent;
```

File

Classes

Description

Use a TDataModule object in an application to provide a location for centralized handling of nonvisual components. Typically these are data access components, such as TSQLDataSet, and TSQLConnection. DataModules are not limited to data access components, they can also contain other nonvisual components, such as TTimer, TOpenDialog, or TImageList).

At design time a TDataModule object provides a visual container into which a developer can place nonvisual components, set their properties, and write event handlers for them. To create a data module at design time, choose File | New Data Module.

In the unit file for the data module a developer may also place any business rules that are to be applied to the application.

To make the data module available to another unit in the application, select that unit, then choose File|Use Unit (when working in Delphi) or File|Include Unit Header (when working in C++) to add the data module to the uses clause for the unit.

TForm (see page 13992)

TFrame (see page 14114)

The Web Module

23.1.30.1 TDataModule Members

The following tables list the members exposed by TDataModule.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
V	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
V	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2827)	Creates an instance of a data module.
V	CreateNew (see page 2828)	Creates an instance of a data module and registers with the global screen object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2829)	Destroys the instance of the data module.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.
	Tag (see page 2808)	Stores an integer value as part of a component.

23.1.30.2 TDataModule.Create Constructor

Creates an instance of a data module.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDataModule(TComponent * AOwner);
```

Description

Call Create to instantiate a data module at runtime if it was not created at design time. Create calls CreateNew (see page 2828). If an error occurs, an exception is raised. Otherwise, if OldCreateOrder (see page 2833) is true, Create calls the OnCreate (see page 2833) event handler for the data module if one is assigned to it.

See Also

CreateNew (see page 2828)

Destroy (see page 2829)

OnCreate (see page 2833)

OldCreateOrder (see page 2833)

23.1.30.3 TDataModule.CreateNew Constructor

Creates an instance of a data module and registers with the global screen object.

Pascal

```
constructor CreateNew(AOwner: TComponent; Dummy: Integer = 0); virtual;
```

C++

```
virtual __fastcall TDataModule(TComponent * AOwner, int Dummy = 0);
```

Description

Use CreateNew instead of Create (see page 2827) to create a data module without using the associated .form file to initialize it.

Warning: Using CreateNew instead of Create (see page 2827) can cause unpredictable results because most data modules are written assuming their controls will be created from the form file.

CreateNew calls the inherited constructor, and then informs the global screen object of the existence of the data module.

The first argument, AOwner, is the owner of the data module (usually the application). The second argument, Dummy, defaults to 0 and is not used by this constructor. The system passes 0 by default if this constructor is passed only the first argument, AOwner.

CreateNew bypasses the streaming in of the previously associated form file. Therefore, you must stream in an external form file to bind the visual components with their classes. You can stream in the previously associated form file by calling InitInheritedComponent (see page 3231). To stream in a different form file, bracket the call to CreateNew with calls to WriteComponentResFile (see page 3266) and ReadComponentResFile (see page 3247). The following code sequence

1. streams out an external form file.
2. creates a new data module disassociated from any form file;
3. streams in the external form file and binds it to this new data module.

```
WriteComponentResFile('Temp.xfm', DataModule1);
...
```

DataModule2 := TDataModule.CreateNew(Application);

```
ReadComponentResFile('Temp.xfm', DataModule2);
```

See Also

Create (see page 2827)

Destroy (see page 2829)

ReadComponentResFile

WriteComponentResFile

InitInheritedCOmponent

23.1.30.4 TDataModule.Destroy Destructor

Destroys the instance of the data module.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataModule();
```

Description

Do not call Destroy directly. Instead call Free, which checks that the data module reference is not nil before calling Destroy.

Before calling the inherited destructor, Destroy removes any fixup references, calls its OnDestroy (see page 2834) event handler (if one is defined and OldCreateOrder (see page 2833) is true), and informs the global screen variable that the data module is going away.

See Also

Create (see page 2827)

Free (see page 22300)

OnDestroy (see page 2834)

23.1.30.5 TDataModule Methods

The methods of the TDataModule class are listed here.

Protected Methods

	Name	Description
	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.
	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.

Public Methods

	Name	Description
	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.

23.1.30.5.1 TDataModule.AfterConstruction Method

Generates an OnCreate (see page 2833) event.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called after the data module's constructor has finished. Do not call it explicitly in applications.

TDataModule (see page 2824) overrides AfterConstruction to generate an OnCreate (see page 2833) event when OldCreateOrder (see page 2833) is false.

See Also

BeforeDestruction (see page 2830)

OnCreate (see page 2833)

OldCreateOrder (see page 2833)

23.1.30.5.2 TDataModule.BeforeDestruction Method

Generates an OnDestroy (see page 2834) event.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

BeforeDestruction is called immediately before the data module's destructor. Do not call it explicitly in applications.

TDataModule (see page 2824) overrides BeforeDestruction to generate an OnDestroy (see page 2834) event when OldCreateOrder (see page 2833) is false.

See Also

AfterConstruction (see page 2829)

OnDestroy (see page 2834)

OldCreateOrder (see page 2833)

23.1.30.5.3 TDataModule.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent overrides the DefineProperties method defined in TPersistent to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

See Also

Ancestor (see page 2839)

DefineBinaryProperty (see page 2837)

DefineProperties (see page 2931)

DefineProperty (see page 2838)

23.1.30.5.4 TDataModule.DoCreate Method

Pascal

```
procedure DoCreate; virtual;
```

C++

```
virtual __fastcall DoCreate();
```

Description

This is DoCreate, a member of class TDataModule.

23.1.30.5.5 TDataModule.DoDestroy Method

Pascal

```
procedure DoDestroy; virtual;
```

C++

```
virtual __fastcall DoDestroy();
```

Description

This is DoDestroy, a member of class TDataModule.

23.1.30.5.6 TDataModule.GetChildren Method

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

This is GetChildren, a member of class TDataModule.

23.1.30.5.7 TDataModule.HandleCreateException Method

Pascal

```
function HandleCreateException: Boolean; dynamic;
```

C++

```
__fastcall Boolean HandleCreateException();
```

Description

This is HandleCreateException, a member of class TDataModule.

23.1.30.5.8 TDataModule.ReadState Method

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

This is ReadState, a member of class TDataModule.

23.1.30.6 TDataModule Properties

The properties of the TDataModule class are listed here.

Public Properties

	Name	Description
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.

Published Properties

	Name	Description
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.

23.1.30.6.1 TDataModule.DesignOffset Property

Specifies the design offset for the data module at design time.

Pascal

```
property DesignOffset: TPoint;
```

C++

```
__property TPoint DesignOffset;
```

Description

An application should never need to set this value. It is used to control the position of the data module at design time.

See Also

DesignSize (see page 2832)

23.1.30.6.2 TDataModule.DesignSize Property

Specifies the design size for the data module at design time.

Pascal

```
property DesignSize: TPoint;
```

C++

```
__property TPoint DesignSize;
```

Description

An application should never need to set this value. It controls the size of the data module window at design time.

See Also

DesignOffset (see page 2832)

23.1.30.6.3 TDataModule.OldCreateOrder Property

Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.

Pascal

```
property OldCreateOrder: Boolean;
```

C++

```
__property Boolean OldCreateOrder;
```

Description

When OldCreateOrder is false (the default) the OnCreate (see page 2833) event occurs after all constructors are finished (from the AfterConstruction (see page 2829) method) and the OnDestroy (see page 2834) event occurs before any destructors are called (from the BeforeDestruction (see page 2830) method).

When OldCreateOrder is true, OnCreate (see page 2833) is triggered from the data module constructor and OnDestroy (see page 2834) from the data module destructor.

Note: This timing differs from Delphi version 3 and previous and from C++Builder version 1, where the OnCreate (see page 2833) event occurred when the TDataModule (see page 2824) constructor executed and the OnDestroy (see page 2834) event occurred when the TDataModule (see page 2824) destructor executed. Applications that require the OnCreate (see page 2833) event and OnDestroy (see page 2834) events to occur from the constructor and destructor of the data module can set OldCreateOrder to true.

See Also

OnCreate (see page 2833)

AfterConstruction (see page 2829)

OnDestroy (see page 2834)

BeforeDestruction (see page 2830)

23.1.30.7 TDataModule Events

The events of the TDataModule class are listed here.

Published Events

	Name	Description
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.

23.1.30.7.1 TDataModule.OnCreate Event

Occurs when an application instantiates a data module.

Pascal

```
property OnCreate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCreate;
```

Description

Write an OnCreate event handler to take specific actions when an application instantiates a data module. For example, if a data module contains database and dataset components, an application may establish a database connection immediately. If the data module contains timers, the application may initialize them.

Note: Use of the OnCreate event is discouraged in C++ because it can interact badly with the data module's constructor (see OldCreateOrder (see page 2833)). It is recommended that you override the constructor instead.

See Also

OnDestroy (see page 2834)

OldCreateOrder (see page 2833)

23.1.30.7.2 TDataModule.OnDestroy Event

Occurs when the data module is about to be destroyed.

Pascal

```
property OnDestroy: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDestroy;
```

Description

Write an OnDestroy event handler to take specific actions when an application frees a data module. For example, if the unit code for the data module instantiates any objects of its own, such as string lists, the OnDestroy event handler can be used to free those objects.

See Also

OnCreate (see page 2833)

OldCreateOrder (see page 2833)

23.1.31 TFiler Class

TFiler is the abstract base class for reader and writer objects, which are used for loading and saving components and their properties.

Class Hierarchy

Pascal

```
TFiler = class(TObject);
```

C++

```
class TFiler : public TObject;
```

File

Classes

Description

TFiler works with stream and component objects. It handles the internal mechanics of the streaming system that reads and writes components and their associated data. This streaming system is the mechanism by which the IDE saves components to or reads components from disk (in form files) and by which it saves and restores temporary in-memory images of components.

TFiler has two descendants, TReader (see page 2933) and TWriter (see page 3175), that implement the methods introduced by TFiler. The filer type is used as a parameter to component methods that can require either a reader or writer object, depending on whether the data is read from or written to a stream. Every filer has an associated stream that is passed as a parameter to its constructor. Filer objects are usually created by the stream that becomes associated with the filer.

TFiler properties provide support for managing the streaming of owned components. Filer objects read and write the properties of components to and from a stream. Filer objects provide buffering of data to speed read and write operations.

TFiler introduces abstract methods that are customized by its descendant reader and writer objects. These include methods that enable components to load and save hidden or complex data as if it was the value of a published property.

Note: Most of the filer properties and methods have public visibility for convenience within the streaming system. The majority of them are never called directly by applications.

See Also

TComponent (see page 2762)

TReader (see page 2933)

TStream (see page 2973)

TWriter (see page 3175)

Using Streams to Read or Write Data

23.1.31.1 TFiler Members

The following tables list the members exposed by TFiler.

Protected Methods

	Name	Description
	SetRoot (see page 2838)	This is SetRoot, a member of class TFiler.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2836)	Creates a filer object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.

A	DefineBinaryProperty (see page 2837)	Introduces an abstract method that allows descendants to read and write unformatted data like a property.
A	DefineProperty (see page 2838)	Introduces an abstract method that allows descendants to read or write data like a property.
V	Destroy (see page 2837)	Destroys a filer object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
A	FlushBuffer (see page 2838)	Introduces an abstract method that allows descendants to synchronize the filer's buffer with its stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Ancestor (see page 2839)	Determines whether to write the properties of inherited components.
	IgnoreChildren (see page 2839)	Enables a writer object to save a component without saving the components it owns.
R	LookupRoot (see page 2840)	Specifies the root component for resolving names while loading and saving components.
	Root (see page 2840)	Indicates which object is the root, or ultimate owner, of the objects read or written by the filer.

23.1.31.2 TFiler.Create Constructor

Creates a filer object.

Pascal

```
constructor Create(Stream: TStream; BufSize: Integer);
```

C++

```
__fastcall TFiler(TStream Stream, int BufSize);
```

Description

Call Create to instantiate a filer descendant at runtime, if necessary. It is seldom necessary to directly create a filer object because the methods and routines that use them automatically create filers.

Create allocates memory for a filer object, and associates it with the stream passed in the Stream parameter, with a buffer of size BufSize.

See Also

ReadComponent (see page 2983)

WriteDescendent (see page 2994)

23.1.31.3 TFiler.Destroy Destructor

Destroys a filer object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFiler();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the filer reference is not nil before calling Destroy.

The Destroy method for filer objects~TFiler (see page 2834) frees memory associated with the buffer. Memory deallocation for the object instance is handled automatically when Destroy is called. TFiler (see page 2834)'s Destroy method is called by descendant objects in their respective destructors.

See Also

Destroy (see page 22287)

Free (see page 22300)

23.1.31.4 TFiler Methods

The methods of the TFiler class are listed here.

Protected Methods

	Name	Description
	SetRoot (see page 2838)	This is SetRoot, a member of class TFiler.

Public Methods

	Name	Description
	DefineBinaryProperty (see page 2837)	Introduces an abstract method that allows descendants to read and write unformatted data like a property.
	DefineProperty (see page 2838)	Introduces an abstract method that allows descendants to read or write data like a property.
	FlushBuffer (see page 2838)	Introduces an abstract method that allows descendants to synchronize the filer's buffer with its stream.

23.1.31.4.1 TFiler.DefineBinaryProperty Method

Introduces an abstract method that allows descendants to read and write unformatted data like a property.

Pascal

```
procedure DefineBinaryProperty(const Name: string; ReadData: TStreamProc; WriteData:
TStreamProc; HasData: Boolean); virtual; abstract;
```

C++

```
virtual __fastcall DefineBinaryProperty(const AnsiString Name, TStreamProc ReadData,
TStreamProc WriteData, Boolean HasData) = 0;
```

Description

Each descendant filer object declares a DefineBinaryProperty method that reads or writes binary data as if the data were a

property.

See Also

DefineProperties (see page 2771)

DefineProperty (see page 2838)

23.1.31.4.2 TFiler.DefineProperty Method

Introduces an abstract method that allows descendants to read or write data like a property.

Pascal

```
procedure DefineProperty(const Name: string; ReadData: TReaderProc; WriteData: TWriterProc;
HasData: Boolean); virtual; abstract;
```

C++

```
virtual __fastcall DefineProperty(const AnsiString Name, TReaderProc ReadData, TWriterProc
WriteData, Boolean HasData) = 0;
```

Description

Each descendant filer object declares a DefineProperty method that defines the data that the descendant object will read or write as if the data were a property.

See Also

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

23.1.31.4.3 TFiler.FlushBuffer Method

Introduces an abstract method that allows descendants to synchronize the filer's buffer with its stream.

Pascal

```
procedure FlushBuffer; virtual; abstract;
```

C++

```
virtual __fastcall FlushBuffer() = 0;
```

Description

Each descendant filer object defines a FlushBuffer method to provide practical implementations for synchronizing the filer object's buffer with the associated stream.

23.1.31.4.4 TFiler.SetRoot Method

Pascal

```
procedure SetRoot(Value: TComponent); virtual;
```

C++

```
virtual __fastcall SetRoot(TComponent * Value);
```

Description

This is SetRoot, a member of class TFiler.

23.1.31.5 TFiler Properties

The properties of the TFiler class are listed here.

Public Properties

	Name	Description
	Ancestor (see page 2839)	Determines whether to write the properties of inherited components.
	IgnoreChildren (see page 2839)	Enables a writer object to save a component without saving the components it owns.
R	LookupRoot (see page 2840)	Specifies the root component for resolving names while loading and saving components.
	Root (see page 2840)	Indicates which object is the root, or ultimate owner, of the objects read or written by the filer.

23.1.31.5.1 TFiler.Ancestor Property

Determines whether to write the properties of inherited components.

Pascal

```
property Ancestor: TPersistent;
```

C++

```
__property TPersistent * Ancestor;
```

Description

Do not use Ancestor directly. It is used internally by the methods of writer objects to write components in inherited forms.

In Visual Form Inheritance, a writer object only needs to write the values of properties that differ from those that are inherited. It tracks each component from which properties can be inherited in Ancestor and compares properties before writing. If Ancestor is nil (Delphi) or NULL (C++), there is no corresponding component from which to inherit, and the writer object writes the component out to the stream completely.

Ancestor is only non-nil (Delphi) or non-NULL (C++) when writing forms created with Visual Form Inheritance. The streaming system uses WriteDescendent and WriteDescendentRes to write such forms to the stream.

When writing or overriding a DefineProperties method, be aware that Ancestor might be set, and it might be necessary to write or omit properties, as appropriate. Normally, DefineProperty (see page 2838) read procedures ignore the value of Ancestor.

See Also

DefineProperties (see page 2771)

WriteComponent (see page 3183)

WriteDescendent (see page 2994)

WriteDescendent (see page 3184)

WriteDescendentRes (see page 2995)

23.1.31.5.2 TFiler.IgnoreChildren Property

Enables a writer object to save a component without saving the components it owns.

Pascal

```
property IgnoreChildren: Boolean;
```

C++

```
__property Boolean IgnoreChildren;
```

Description

Programs rarely use IgnoreChildren directly. Programs use IgnoreChildren internally to avoid writing owned components when the Root (see page 2840) is changed during the streaming process. A few components change Root (see page 2840) while streaming, but this is rare.

If IgnoreChildren is true, the writer writes a component without writing any child components it owns. If IgnoreChildren is false, the writer object writes all owned objects to the stream.

See Also

WriteComponent (see page 3183)

Root (see page 2840)

23.1.31.5.3 TFiler.LookupRoot Property

Specifies the root component for resolving names while loading and saving components.

Pascal

```
property LookupRoot: TComponent;
```

C++

```
__property TComponent * LookupRoot;
```

Description

The Filer sets LookupRoot when loading or saving components to resolve name references in nested frames. This allows the Writer to look up component names relative to a local root component, even when a frame is nested in another root component.

See Also

Root (see page 2840)

23.1.31.5.4 TFiler.Root Property

Indicates which object is the root, or ultimate owner, of the objects read or written by the filer.

Pascal

```
property Root: TComponent;
```

C++

```
__property TComponent * Root;
```

Description

Do not call Root directly. It is used internally to find the root object when streaming owned components. Root represents the ultimate owner of all the components being streamed during the current streaming process.

The ReadRootComponent and WriteRootComponent methods set Root before reading or writing their components and owned components.

See Also

Owner (see page 2959)

ReadRootComponent (see page 2952)

RootAncestor (see page 3192)

WriteRootComponent (see page 3188)

LookupRoot (see page 2840)

23.1.32 TFileStream Class

TFileStream enables applications to read from and write to a file on disk.

Class Hierarchy

Pascal

```
TFileStream = class(THandleStream);
```

C++

```
class TFileStream : public THandleStream;
```

File

Classes

Description

Use TFileStream to access the information in disk files. TFileStream will open a named file and provide methods to read from or write to it. If an application already has a handle to the file, opened in the appropriate mode, use THandleStream (see page 2845) instead.

See Also

ReadComponentResFile (see page 3247)

THandleStream (see page 2845)

WriteComponentResFile (see page 3266)

Setting the Response Content

23.1.32.1 TFileStream Members

The following tables list the members exposed by TFileStream.

Protected Fields

	Name	Description
	FHandle (see page 2848)	This is FHandle, a member of class THandleStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	SetSize (see page 2849)	This is the overview for the SetSize method overload.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 2843)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2844)	Destroys an instance of TFileStream (see page 2841).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Read (see page 2848)	Reads up to Count bytes of data from the resource associated with the handle stream into Buffer.
A	Read (see page 2982)	Introduces an abstract or pure virtual method responsible for reading from the stream.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Seek (see page 2849)	Resets the current position of the handle stream.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
V	Write (see page 2850)	Writes Count bytes from the Buffer to the current position in the resource.
A	Write (see page 2989)	Introduces a pure virtual method for writing to the stream.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
R	FileName (see page 2845)	Preserves the file name of the file associated with the file stream.
R	Handle (see page 2850)	Specifies the handle for the communications resource the stream reads from and writes to.

	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

Strict private Fields

	Name	Description
	FFileName (see page 2844)	This is FFileName, a member of class TFileStream.

23.1.32.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TFileStream.Create (string, Word) (see page 2843)	Creates an instance of TFileStream (see page 2841).
	TFileStream.Create (string, Word, Cardinal) (see page 2843)	Creates an instance of TFileStream (see page 2841).

23.1.32.2.1 TFileStream.Create Constructor (string, Word)

Creates an instance of TFileStream (see page 2841).

Pascal

```
constructor Create(const AFileName: string; Mode: Word); overload;
constructor Create(const AFileName: string; Mode: Word; Rights: Cardinal); overload;
```

C++

```
__fastcall TFileStream(const AnsiString AFileName, Word Mode);
__fastcall TFileStream(const AnsiString AFileName, Word Mode, unsigned Rights);
```

Description

Call Create to instantiate a file stream for reading from or writing to the named file. Specify the name of the file and the way the file should be opened as parameters.

The Mode parameter indicates how the file is to be opened. The Mode parameter consists of an open mode and (possibly) a share mode or'ed together. The open mode must be one of the following values:

Value	Meaning
fmCreate (see page 3316)	Create a file with the given name. If a file with the given name exists, open the file in write mode.
fmOpenRead	Open the file for reading only.
fmOpenWrite	Open the file for writing only. Writing to the file completely replaces the current contents.
fmOpenReadWrite	Open the file to modify the current contents rather than replace them.

The share mode must be one of the following values:

Value	Meaning
fmShareCompat	Sharing is compatible with the way FCBs are opened.
fmShareExclusive	Other applications can not open the file for any reason.
fmShareDenyWrite	Other applications can open the file for reading but not for writing.

fmShareDenyRead	Other applications can open the file for writing but not for reading.
fmShareDenyNone	No attempt is made to prevent other applications from reading from or writing to the file.

The Rights parameter indicates the permission bits with which to create the file on Linux when Mode is fmCreate (see page 3316). Rights is ignored when used on the Windows platform.

If the file can not be opened, Create raises an exception.

See Also

FileCreate (see page 22855)

FileOpen (see page 22867)

23.1.32.3 TFileStream.Destroy Destructor

Destroys an instance of TFileStream (see page 2841).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFileStream();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the TFileStream (see page 2841) reference is not nil and only then calls Destroy.

Destroy closes the Handle (see page 2850) for the file stream before freeing the object.

See Also

FileClose (see page 22852)

Free (see page 22300)

Handle (see page 2850)

23.1.32.4 TFileStream Fields

The fields of the TFileStream class are listed here.

Strict private Fields

	Name	Description
	FFileName (see page 2844)	This is FFileName, a member of class TFileStream.

23.1.32.4.1 TFileStream.FFileName Field

Pascal

```
FFileName: string;
```

C++

```
AnsiString FFileName;
```

Description

This is FFileName, a member of class TFileStream.

23.1.32.5 TFileStream Properties

The properties of the TFileStream class are listed here.

Public Properties

	Name	Description
R	FileName (see page 2845)	Preserves the file name of the file associated with the file stream.

23.1.32.5.1 TFileStream.FileName Property

Preserves the file name of the file associated with the file stream.

Pascal

```
property FileName: string;
```

C++

```
__property AnsiString FileName;
```

Description

Use FileName to display the name of the file that TFileStream (see page 2841) has accessed from disk. This is a read only property.

23.1.33 THandleStream Class

THandleStream enables applications to read from and write to communications resources identified by a handle.

Class Hierarchy

Pascal

```
THandleStream = class(TStream);
```

C++

```
class THandleStream : public TStream;
```

File

Classes

Description

Use THandleStream to access files, sockets, named pipes, mailslots, or other communications resources that provide a handle when opened. For example, the FileOpen function provides a handle for a file on disk. THandleStream allows applications to use a uniform stream interface when performing I/O using a handle.

To avoid the overhead of managing file handles, use TFileStream (see page 2841) to work with disk files.

FileClose

FileCreate

FileOpen

TFileStream (see page 2841)

23.1.33.1 THandleStream Members

The following tables list the members exposed by THandleStream.

Protected Fields

	Name	Description
	FHandle (see page 2848)	This is FHandle, a member of class THandleStream.

Protected Methods

	Name	Description
V	GetSize (see page 2982)	This is GetSize, a member of class TStream.
V	SetSize (see page 2849)	This is the overview for the SetSize method overload.
V	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 2847)	Creates an instance of THandleStream (see page 2845).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Read (see page 2848)	Reads up to Count bytes of data from the resource associated with the handle stream into Buffer.

	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Seek (see page 2849)	Resets the current position of the handle stream.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
V	Write (see page 2850)	Writes Count bytes from the Buffer to the current position in the resource.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
R	Handle (see page 2850)	Specifies the handle for the communications resource the stream reads from and writes to.
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.33.2 THandleStream.Create Constructor

Creates an instance of THandleStream (see page 2845).

Pascal

```
constructor Create(AHandle: Integer);
```

C++

```
__fastcall THandleStream(int AHandle);
```

Description

Call Create to instantiate a THandleStream (see page 2845) for a given handle.

The handle must be obtained by opening or creating the resource in the appropriate mode. For example, to create a handle stream for reading from a file, obtain the file handle by opening the file with an fmOpenRead or fmOpenReadWrite mode. To create a handle stream for writing to a file, obtain the file handle by opening the file with an fmOpenWrite or fmOpenReadWrite mode.

See Also

FileCreate (see page 22855)

FileOpen (see page 22867)

Handle (see page 2850)

23.1.33.3 THandleStream Fields

The fields of the THandleStream class are listed here.

Protected Fields

	Name	Description
	FHandle (see page 2848)	This is FHandle, a member of class THandleStream.

23.1.33.3.1 THandleStream.FHandle Field

Pascal

```
FHandle: Integer;
```

C++

```
int FHandle;
```

Description

This is FHandle, a member of class THandleStream.

23.1.33.4 THandleStream Methods

The methods of the THandleStream class are listed here.

Protected Methods

	Name	Description
	SetSize (see page 2849)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	Read (see page 2848)	Reads up to Count bytes of data from the resource associated with the handle stream into Buffer.
	Seek (see page 2849)	Resets the current position of the handle stream.
	Write (see page 2850)	Writes Count bytes from the Buffer to the current position in the resource.

23.1.33.4.1 THandleStream.Read Method

Reads up to Count bytes of data from the resource associated with the handle stream into Buffer.

Pascal

```
function Read(var Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( Buffer, Longint Count);
```

Description

Use Read to read data from the resource associated with the handle stream when the number of bytes in the file is not known. Read transfers up to Count bytes from the resource, starting at the current position, and then advances the current position in the resource by the number of bytes actually transferred. Read returns the number of bytes actually transferred, which may be less than Count if the end of file marker is encountered.

All other data-reading methods of a handle stream (ReadBuffer (see page 2983), ReadComponent (see page 2983)) call Read to do the actual reading.

See Also

Position (see page 2996)

ReadBuffer (see page 2983)

ReadComponent (see page 2983)

23.1.33.4.2 THandleStream.Seek Method

Resets the current position of the handle stream.

Pascal

```
function Seek(const Offset: Int64; Origin: TSeekOrigin): Int64; override;
```

C++

```
virtual __fastcall Int64 Seek(const Int64 Offset, TSeekOrigin Origin);
```

Description

Use Seek to move the current position within the resource associated with the handle stream by the indicated offset. Seek allows an application to read from or write to a particular location within the resource.

The Origin parameter indicates how to interpret the Offset parameter. Origin should be one of the following values:

Value	Meaning
soFromBeginning (see page 3319)	Offset is from the beginning of the resource. Seek moves to the position Offset. Offset must be >= 0.
soFromCurrent (see page 3320)	Offset is from the current position in the resource. Seek moves to Position (see page 2996) + Offset.
soFromEnd (see page 3320)	Offset is from the end of the resource. Offset must be <= 0 to indicate a number of bytes before the end of the file.

Seek returns the new value of the Position (see page 2996) property, the new current position in the resource.

See Also

Position (see page 2996)

Read (see page 2848)

Write (see page 2850)

23.1.33.4.3 SetSize Method

This is the overview for the SetSize method overload.

Overload List

	Name	Description
	THandleStream.SetSize (Int64) (see page 2849)	Sets the end of file marker to truncate the resource at the indicated position.
	THandleStream.SetSize (Longint) (see page 2849)	Sets the end of file marker to truncate the resource at the indicated position.

23.1.33.4.3.1 THandleStream.SetSize Method (Int64)

Sets the end of file marker to truncate the resource at the indicated position.

Pascal

```
procedure SetSize(NewSize: Longint); override;
procedure SetSize(const NewSize: Int64); override;
```

C++

```
virtual __fastcall SetSize(Longint NewSize);
virtual __fastcall SetSize(const Int64 NewSize);
```

Description

Call SetSize to set the size of the resource. SetSize calls Seek (see page 2849) to go to the indicated position, and then writes an end of file marker. If the size of the resource can not be changed, an exception is raised. For example, calling SetSize for a file handle that was opened in fmOpenRead mode will raise an exception.

See Also

Size (see page 2997)

23.1.33.4.4 THandleStream.Write Method

Writes Count bytes from the Buffer to the current position in the resource.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count);
```

Description

Use Write to write Count bytes to the resource associated with the handle stream, starting at the current position. After writing to the resource, Write advances the current position by the number bytes written, and returns the number of bytes written.

All other data-writing methods of a handle stream (WriteBuffer (see page 2990), WriteComponent (see page 2990)) call Write to do the actual writing.

See Also

Position (see page 2996)

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

23.1.33.5 THandleStream Properties

The properties of the THandleStream class are listed here.

Public Properties

	Name	Description
R	Handle (see page 2850)	Specifies the handle for the communications resource the stream reads from and writes to.

23.1.33.5.1 THandleStream.Handle Property

Specifies the handle for the communications resource the stream reads from and writes to.

Pascal

```
property Handle: Integer;
```

C++

```
__property int Handle;
```

Description

Read (see page 2848) Handle to get the handle for file management functions. To read from or write to the resource, use the methods of the THandleStream (see page 2845) object.

Handle is a read-only property. The handle property cannot be changed to allow the handle stream to switch from reading to writing or vice versa. For example, to change from a file handle that is opened in read-only mode to one that is opened in write mode:

1Free the stream object.

2Call FileClose to close the file.

3Reopen the file in write mode, and use the handle to create a new instance of a handle stream. Alternately, open a TFileStream (see page 2841) object for the file, specifying a write mode for the stream.

Note: Do not call the FileClose function on the Handle until after the THandleStream (see page 2845) object has been destroyed.

See Also

TFileStream (see page 2841)

Create (see page 2847)

FileClose (see page 22852)

FileGetDate (see page 22866)

FileSetDate (see page 22878)

Free (see page 22300)

23.1.34 TInterfacedPersistent Class

TInterfacedPersistent is an ancestor for persistent objects that implement interfaces.

Class Hierarchy

Pascal

```
TInterfacedPersistent = class(TPersistent, IInterface);
```

C++

```
class TInterfacedPersistent : public TPersistent, public IInterface;
```

File

Classes

Description

TInterfacedPersistent, like all persistent objects, supports the ability to read and write its properties to and from a stream. In addition, it supplies a default implementation of the IInterface methods (_AddRef (see page 2853), _Release (see page 2854), and QueryInterface (see page 2854)). This default implementation simply passes these calls on to the interface of the persistent object's Owner, if any.

Do not create instances of TInterfacedPersistent. Use TInterfacedPersistent as a base class when declaring objects that are not components, but that need to be saved to a stream or have their properties assigned to other objects, and that support interfaces.

See Also

TComponent (see page 2762)

TFiler (see page 2834)

TReader (see page 2933)

TStream (see page 2973)

TWriter (see page 3175)

23.1.34.1 TInterfacedPersistent Members

The following tables list the members exposed by TInterfacedPersistent.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Public Methods

	Name	Description
V	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

23.1.34.2 TInterfacedPersistent Methods

The methods of the TInterfacedPersistent class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.

Public Methods

	Name	Description
V	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
V	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.

23.1.34.2.1 TInterfacedPersistent._AddRef Method

Increments the reference count for the interfaced object's interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef implements the IInterface method, __AddRef, which increments the reference count of an interface and returns the current reference count.

If the interfaced persistent object has an Owner and that owner supports an interface, then __AddRef simply calls the __AddRef method of the Owner. Otherwise, it simply returns –1.

See Also

QueryInterface (see page 2854)

_Release (see page 2854)

23.1.34.2.2 TInterfacedPersistent._Release Method

Decrements the reference count for the interfaced object's interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

___Release implements the IInterface method, ___Release, which decrements the reference count of an interface and returns the current reference count. For some interfaces, when this causes the reference count to drop to zero, the object frees itself.

If the interfaced persistent object has an Owner and that owner supports an interface, then ___Release simply calls the ___Release method of the Owner. Otherwise, it simply returns –1.

See Also

QueryInterface (see page 2854)

_AddRef (see page 2853)

23.1.34.2.3 TInterfacedPersistent.AfterConstruction Method

Obtains a reference to the Owner's interface.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is called automatically after the object's last constructor executes. Do not call it explicitly in your applications.

As implemented in TInterfacedPersistent (see page 2851), AfterConstruction calls the GetOwner (see page 2932) method to determine whether this object has an Owner. If so, it obtains a reference to the Owner's interface, to which it can delegate IInterface calls.

See Also

GetOwner (see page 2932)

23.1.34.2.4 TInterfacedPersistent.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface implements the IInterface method, QueryInterface. This method checks whether the interfaced persistent object

supports the interface identified by IID. If so, it returns a reference as the Obj parameter, automatically incrementing the reference count for the interface. If the object does not support the specified interface, it returns a non-zero value.

See Also

_AddRef (see page 2853)

_Release (see page 2854)

23.1.35 TInterfaceList Class

TInterfaceList represents a list of interfaces.

Class Hierarchy

Pascal

```
TInterfaceList = class(TInterfacedObject, IInterfaceList);
```

C++

```
class TInterfaceList : public TInterfacedObject, public IInterfaceList;
```

File

Classes

Description

Use TInterfaceList to manage a list of interfaces.

See Also

Working with Lists

23.1.35.1 TInterfaceList Members

The following tables list the members exposed by TInterfaceList.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	Get (see page 2860)	Returns a specified interface from the list.
	GetCapacity (see page 2860)	Returns the value of the Capacity property.
	GetCount (see page 2861)	Returns the value of the Count property.
	Put (see page 2863)	Replaces an interface in the list with a specified interface.

	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.
	SetCapacity (see page 2864)	Sets the value of the Capacity property.
	SetCount (see page 2864)	Sets the value of the Count property.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	Add (see page 2858)	Adds an interface to the list.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2858)	Clears the interface list.
	Create (see page 2857)	Creates an interface list.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2859)	Deletes an interface from the list.
V	Destroy (see page 2857)	Destroys the interface list.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Exchange (see page 2859)	Swaps the position of two interfaces in the list.
	Expand (see page 2859)	Increases the capacity of the interface list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	First (see page 2860)	Returns the first interface in the list.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2861)	Returns a TInterfaceList (see page 2855) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 2861)	Returns the index of an interface.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2862)	Inserts an interface into the list at a specified position.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Last (see page 2862)	Returns the last interface in the list.
	Lock (see page 2862)	Prevents other threads from accessing the list.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Remove (see page 2863)	Removes an interface from the list.

	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Unlock (see page 2864)	Unlocks the list, allowing other threads to access it.

Public Properties

	Name	Description
	Capacity (see page 2865)	Specifies the list capacity.
	Count (see page 2865)	Specifies the number of interfaces in the list.
	Items (see page 2866)	Provides direct access to an interface in the list.
	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

23.1.35.2 TInterfaceList.Create Constructor

Creates an interface list.

Pascal

```
constructor Create;
```

C++

```
__fastcall TInterfaceList();
```

Description

Call Create to create an interface list.

23.1.35.3 TInterfaceList.Destroy Destructor

Destroys the interface list.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TInterfaceList();
```

Description

Do not call Destroy directly in an application. Instead, call the Free method.

See Also

Free (see page 22300)

23.1.35.4 TInterfaceList Methods

The methods of the TInterfaceList class are listed here.

Protected Methods

	Name	Description
	Get (see page 2860)	Returns a specified interface from the list.
	GetCapacity (see page 2860)	Returns the value of the Capacity property.
	GetCount (see page 2861)	Returns the value of the Count property.
	Put (see page 2863)	Replaces an interface in the list with a specified interface.
	SetCapacity (see page 2864)	Sets the value of the Capacity property.
	SetCount (see page 2864)	Sets the value of the Count property.

Public Methods

	Name	Description
	Add (see page 2858)	Adds an interface to the list.
	Clear (see page 2858)	Clears the interface list.
	Delete (see page 2859)	Deletes an interface from the list.
	Exchange (see page 2859)	Swaps the position of two interfaces in the list.
	Expand (see page 2859)	Increases the capacity of the interface list.
	First (see page 2860)	Returns the first interface in the list.
	GetEnumerator (see page 2861)	Returns a TInterfaceList (see page 2855) enumerator.
	IndexOf (see page 2861)	Returns the index of an interface.
	Insert (see page 2862)	Inserts an interface into the list at a specified position.
	Last (see page 2862)	Returns the last interface in the list.
	Lock (see page 2862)	Prevents other threads from accessing the list.
	Remove (see page 2863)	Removes an interface from the list.
	Unlock (see page 2864)	Unlocks the list, allowing other threads to access it.

23.1.35.4.1 TInterfaceList.Add Method

Adds an interface to the list.

Pascal

```
function Add(const Item: IInterface): Integer;
```

C++

```
__fastcall int Add(const IInterface Item);
```

Description

Call Add to add an interface to the list.

See Also

Count (see page 2865)

Add

Items (see page 2866)

Delete (see page 2859)

Capacity (see page 2865)

23.1.35.4.2 TInterfaceList.Clear Method

Clears the interface list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to remove all interfaces from the list.

See Also

Items (see page 2866)

Delete (see page 2859)

23.1.35.4.3 TInterfaceList.Delete Method

Deletes an interface from the list.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Call Delete to delete an interface from the list.

See Also

Count (see page 2865)

Add (see page 2858)

Items (see page 2866)

Clear (see page 2858)

Remove (see page 2863)

23.1.35.4.4 TInterfaceList.Exchange Method

Swaps the position of two interfaces in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer);
```

C++

```
__fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to move the interface at position Index1 so that it appears at position Index2 and move the interface at position Index2 so that it appears at position Index1. Index1 and Index2 identify two positions (zero offset) in the Items (see page 2866) property array.

See Also

Items (see page 2866)

23.1.35.4.5 TInterfaceList.Expand Method

Increases the capacity of the interface list.

Pascal

```
function Expand: TInterfaceList;
```

C++

```
__fastcall TInterfaceList Expand();
```

Description

If Capacity (see page 2865) is greater than 64, then Capacity (see page 2865) is increased by Capacity (see page 2865) / 4. If Capacity (see page 2865) is between eight and 64, Capacity (see page 2865) is increased by 16. If Capacity (see page 2865) is less than eight, Capacity (see page 2865) is increased by four.

See Also

Count (see page 2865)

Capacity (see page 2865)

23.1.35.4.6 TInterfaceList.First Method

Returns the first interface in the list.

Pascal

```
function First: IInterface;
```

C++

```
__fastcall IInterface First();
```

Description

Call First to obtain the first interface in the list.

See Also

Items (see page 2866)

Last (see page 2862)

23.1.35.4.7 TInterfaceList.Get Method

Returns a specified interface from the list.

Pascal

```
function Get(Index: Integer): IInterface;
```

C++

```
__fastcall IInterface Get(int Index);
```

Description

Get is the read implementation of the Items property.

Index identifies which interface to return, where 0 is the first interface, 1 is the second interface, and so on.

See Also

Items (see page 3206)

23.1.35.4.8 TInterfaceList.GetCapacity Method

Returns the value of the Capacity property.

Pascal

```
function GetCapacity: Integer;
```

C++

```
__fastcall int GetCapacity();
```

Description

GetCapacity is the read implementation of the Capacity property.

See Also

Capacity (see page 3205)

23.1.35.4.9 TInterfaceList.GetCount Method

Returns the value of the Count property.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the read implementation of the Count property.

See Also

Count (see page 3206)

23.1.35.4.10 TInterfaceList.GetEnumerator Method

Returns a TInterfaceList (see page 2855) enumerator.

Pascal

```
function GetEnumerator: TInterfaceListEnumerator;
```

C++

```
__fastcall TInterfaceListEnumerator GetEnumerator();
```

Description

GetEnumerator returns a TInterfaceListEnumerator (see page 2866) reference, which enumerates all IInterfaces in the Interface list.

To do so, call the TInterfaceListEnumerator (see page 2866) GetCurrent method within a While MoveNext do loop.

See Also

TInterfaceListEnumerator (see page 2866)

23.1.35.4.11 TInterfaceList.IndexOf Method

Returns the index of an interface.

Pascal

```
function IndexOf(const Item: IInterface): Integer;
```

C++

```
__fastcall int IndexOf(const IInterface Item);
```

Description

Call IndexOf to obtain the index of an interface.

See Also

Items (see page 2866)

23.1.35.4.12 TInterfaceList.Insert Method

Inserts an interface into the list at a specified position.

Pascal

```
procedure Insert(Index: Integer; const Item: IInterface);
```

C++

```
__fastcall Insert(int Index, const IInterface Item);
```

Description

Call Insert to insert an interface into the list. Item is the interface to insert, and Index indicates the position (zero-offset) where the interface should be added.

See Also

Count (see page 2865)

Add (see page 2858)

Items (see page 2866)

Delete (see page 2859)

Capacity (see page 2865)

23.1.35.4.13 TInterfaceList.Last Method

Returns the last interface in the list.

Pascal

```
function Last: IInterface;
```

C++

```
__fastcall IInterface Last();
```

Description

Call Last to obtain the last interface in the list.

See Also

First (see page 2860)

Items (see page 2866)

23.1.35.4.14 TInterfaceList.Lock Method

Prevents other threads from accessing the list.

Pascal

```
procedure Lock;
```

C++

```
__fastcall Lock();
```

Description

Call Lock to lock the list, preventing other threads from accessing the list.

See Also

Unlock (see page 2864)

23.1.35.4.15 TInterfaceList.Put Method

Replaces an interface in the list with a specified interface.

Pascal

```
procedure Put(Index: Integer; const Item: IInterface);
```

C++

```
__fastcall Put(int Index, const IInterface Item);
```

Description

Put is the write implementation of the Items property.

Index is the index of the interface to replace.

Item is the interface that replaces the interface identified by Index.

See Also

Items (see page 3206)

23.1.35.4.16 TInterfaceList.Remove Method

Removes an interface from the list.

Pascal

```
function Remove(const Item: IInterface): Integer;
```

C++

```
__fastcall int Remove(const IInterface Item);
```

Description

Call Remove to remove an interface from the list.

Remove returns the index of the removed interface, or –1 if the interface was not found.

See Also

Add (see page 2858)

Insert (see page 2862)

Delete (see page 2859)

Clear (see page 2858)

23.1.35.4.17 TInterfaceList.SetCapacity Method

Sets the value of the Capacity property.

Pascal

```
procedure SetCapacity(NewCapacity: Integer);
```

C++

```
__fastcall SetCapacity(int NewCapacity);
```

Description

SetCapacity is the write implementation of the Capacity property.

NewCapacity is the new capacity for the interface list.

See Also

Capacity (see page 3205)

23.1.35.4.18 TInterfaceList.SetCount Method

Sets the value of the Count property.

Pascal

```
procedure SetCount(NewCount: Integer);
```

C++

```
__fastcall SetCount(int NewCount);
```

Description

SetCount is the write implementation of the Count property.

NewCount is the new number of interfaces in the list.

See Also

Count (see page 3206)

23.1.35.4.19 TInterfaceList.Unlock Method

Unlocks the list, allowing other threads to access it.

Pascal

```
procedure Unlock;
```

C++

```
__fastcall Unlock();
```

Description

Call Unlock to unlock the list so that other threads can have access to the interfaces it contains.

See Also

Lock (see page 2862)

23.1.35.5 TInterfaceList Properties

The properties of the TInterfaceList class are listed here.

Public Properties

	Name	Description
	Capacity (see page 2865)	Specifies the list capacity.
	Count (see page 2865)	Specifies the number of interfaces in the list.
	Items (see page 2866)	Provides direct access to an interface in the list.

23.1.35.5.1 TInterfaceList.Capacity Property

Specifies the list capacity.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

Use Capacity to determine the list capacity. Before adding many interfaces to the list, you can improve performance by setting Capacity to the final number of interfaces. This prevents the interface list from having to reallocate the list every time an interface is added.

See Also

Count (see page 2865)

Add (see page 2858)

Items (see page 2866)

Expand (see page 2859)

23.1.35.5.2 TInterfaceList.Count Property

Specifies the number of interfaces in the list.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of interfaces in the list.

See Also

Capacity (see page 2865)

Add (see page 2858)

Items (see page 2866)

Delete (see page 2859)

23.1.35.5.3 TInterfaceList.Items Property

Provides direct access to an interface in the list.

Pascal

```
property Items [Index: Integer]: IInterface;
```

C++

```
__property IInterface Items[int Index];
```

Description

Use Items to directly access an interface in the list. Index identifies each interface by its position in the list.

Note: In Delphi, Items is the default property of TInterfaceList (see page 2855). That means you can omit the property name. Thus, instead of writing

Note: InterfaceList1.Items[i]

Note: you can write

Note: InterfaceList1[i]

See Also

Count (see page 2865)

Add (see page 2858)

Delete (see page 2859)

operator_sb

23.1.36 TInterfaceListEnumerator Class

Enumerates through the IInterfaces in a TInterfaceList (see page 2855).

Class Hierarchy

Classes.TInterfaceListEnumerator

Pascal

```
TInterfaceListEnumerator = class;
```

C++

```
class TInterfaceListEnumerator;
```

File

Classes

Description

TInterfaceListEnumerator provides an enumerator for TInterfaceLists.

23.1.36.1 TInterfaceListEnumerator Members

The following tables list the members exposed by TInterfaceListEnumerator.

Public Methods

	Name	Description
	Create (see page 2867)	Creates a TInterfaceList (see page 2855) enumerator.
	GetCurrent (see page 2867)	Gets the current IInterface.
	MoveNext (see page 2868)	Moves the enumerator to the next IInterface in the collection.

Public Properties

	Name	Description
R	Current (see page 2868)	The current IInterface.

23.1.36.2 TInterfaceListEnumerator.Create Constructor

Creates a TInterfaceList (see page 2855) enumerator.

Pascal

```
constructor Create(AInterfaceList: TInterfaceList);
```

C++

```
__fastcall TInterfaceListEnumerator(TInterfaceList AInterfaceList);
```

Description

Creates an instance of TInterfaceListEnumerator (see page 2866).

23.1.36.3 TInterfaceListEnumerator Methods

The methods of the TInterfaceListEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 2867)	Gets the current IInterface.
	MoveNext (see page 2868)	Moves the enumerator to the next IInterface in the collection.

23.1.36.3.1 TInterfaceListEnumerator.GetCurrent Method

Gets the current IInterface.

Pascal

```
function GetCurrent: IInterface;
```

C++

```
__fastcall IInterface GetCurrent();
```

Description

Use GetCurrent to get the current IInterface of the TInterfaceList (see page 2855) object being enumerated.

23.1.36.3.2 TInterfaceListEnumerator.MoveNext Method

Moves the enumerator to the next IInterface in the collection.

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

Use MoveNext to move the TInterfaceListEnumerator (see page 2866) to the next IInterface in the TInterfaceList (see page 2855) object.

23.1.36.4 TInterfaceListEnumerator Properties

The properties of the TInterfaceListEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 2868)	The current IInterface.

23.1.36.4.1 TInterfaceListEnumerator.Current Property

The current IInterface.

Pascal

```
property Current: IInterface;
```

C++

```
__property IInterface Current;
```

Description

Current contains the current IInterface in the TInterfaceList (see page 2855) object being enumerated.

23.1.37 TList Class

TList stores an array of pointers.

Class Hierarchy

Pascal

```
TList = class(TObject);
```

C++

```
class TList : public TObject;
```

File

Classes

Description

TList, which stores an array of pointers, is often used to maintain lists of objects. TList introduces properties and methods to

Add (see page 2871) or delete the objects in the list.

Rearrange the objects in the list.

Locate and access objects in the list.

Sort (see page 2892) the objects in the list.

See Also

TCollection (see page 2731)

TStrings (see page 3029)

TComponent (see page 2762)

TObjectList (see page 5677)

TComponentList (see page 5653)

TClassList (see page 5646)

TStack (see page 5701)

Working with Lists

23.1.37.1 TList Members

The following tables list the members exposed by TList.

Protected Methods

	Name	Description
	Get (see page 2878)	This is Get, a member of class TList.
V	Grow (see page 2879)	This is Grow, a member of class TList.
V	Notify (see page 2884)	Responds when items are added, removed, or extracted from the list.
	Put (see page 2887)	This is Put, a member of class TList.
	SetCapacity (see page 2891)	This is SetCapacity, a member of class TList.
	SetCount (see page 2892)	This is SetCount, a member of class TList.

Public Methods

	Name	Description
	Add (see page 2871)	Inserts a new item at the end of the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2874)	Copies elements of one list to another.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 2874)	Deletes all items from the list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.

	Delete (see page 2874)	Removes the item at the position given by the Index parameter.
V	Destroy (see page 2870)	Destroys an instance of TList (see page 2868).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Error (see page 2875)	This is the overview for the Error method overload.
	Exchange (see page 2876)	Swaps the position of two items in the Items (see page 2898) array.
	Expand (see page 2877)	Increases the Capacity (see page 2895) of the list.
	Extract (see page 2877)	Removes a specified item from the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	First (see page 2878)	Returns Items (see page 2898)[0].
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2878)	Returns a TList (see page 2868) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 2879)	Returns the index of the first entry in the Items (see page 2898) array with a specified value.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2882)	Adds an object to the Items (see page 2898) array at the position specified by Index.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Last (see page 2882)	Returns Items (see page 2898)[Count (see page 2896) - 1].
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 2884)	Changes the position of an item in the Items (see page 2898) array.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pack (see page 2885)	Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.
	Remove (see page 2887)	Deletes the first reference to the Item parameter from the Items (see page 2898) array.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Sort (see page 2892)	Performs a QuickSort on the list based on the comparison function Compare.

Public Properties

	Name	Description
	Capacity (see page 2895)	Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.
	Count (see page 2896)	Indicates the number of entries in the list that are in use.
	Items (see page 2898)	Lists the object references.
R	List (see page 2900)	Specifies the array of pointers that make up the Items (see page 2898) array.

23.1.37.2 TList.Destroy Destructor

Destroys an instance of TList (see page 2868).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TList();
```

Description

Do not call Destroy directly. Instead, call Free. Free verifies that the TList (see page 2868) reference is not nil, and only then calls Destroy.

Destroy frees the memory used to store the list of items.

Note: Destroy does not free the memory pointed to by the elements of the list.

See Also

Free (see page 22300)

23.1.37.3 TList Methods

The methods of the TList class are listed here.

Protected Methods

	Name	Description
	Get (see page 2878)	This is Get, a member of class TList.
V	Grow (see page 2879)	This is Grow, a member of class TList.
V	Notify (see page 2884)	Responds when items are added, removed, or extracted from the list.
	Put (see page 2887)	This is Put, a member of class TList.
	SetCapacity (see page 2891)	This is SetCapacity, a member of class TList.
	SetCount (see page 2892)	This is SetCount, a member of class TList.

Public Methods

	Name	Description
	Add (see page 2871)	Inserts a new item at the end of the list.
	Assign (see page 2874)	Copies elements of one list to another.
V	Clear (see page 2874)	Deletes all items from the list.
	Delete (see page 2874)	Removes the item at the position given by the Index parameter.
	Error (see page 2875)	This is the overview for the Error method overload.
	Exchange (see page 2876)	Swaps the position of two items in the Items (see page 2898) array.
	Expand (see page 2877)	Increases the Capacity (see page 2895) of the list.
	Extract (see page 2877)	Removes a specified item from the list.
	First (see page 2878)	Returns Items (see page 2898)[0].
	GetEnumerator (see page 2878)	Returns a TList (see page 2868) enumerator.
	IndexOf (see page 2879)	Returns the index of the first entry in the Items (see page 2898) array with a specified value.
	Insert (see page 2882)	Adds an object to the Items (see page 2898) array at the position specified by Index.
	Last (see page 2882)	Returns Items (see page 2898)[Count (see page 2896) - 1].
	Move (see page 2884)	Changes the position of an item in the Items (see page 2898) array.
	Pack (see page 2885)	Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.
	Remove (see page 2887)	Deletes the first reference to the Item parameter from the Items (see page 2898) array.
	Sort (see page 2892)	Performs a QuickSort on the list based on the comparison function Compare.

23.1.37.3.1 TList.Add Method

Inserts a new item at the end of the list.

Pascal

```
function Add(Item: Pointer): Integer;
```

C++

```
__fastcall int Add(void * Item);
```

Description

Call Add to insert a new object at the end of the Items (see page 2898) array. Add returns the index of the new item, where the first item in the list has an index of 0.

Add increments Count (see page 2896) and, if necessary, allocates memory by increasing the value of Capacity (see page 2895).

Note: Add always inserts the Item pointer at the end of the Items (see page 2898) array, even if the Items (see page 2898) array contains nil (Delphi) or NULL (C++) pointers.

C++ Examples:

```
/*
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
*/

typedef struct AList
{
  int I;
  char C;
} TAList;

typedef TAList* PAList;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PAList AStruct;
  TList *MyList = new TList;
  // fill the TList
  AStruct = new TAList;
  AStruct->I = 100;
  AStruct->C = 'Z';
  MyList->Add(AStruct);
  AStruct = new TAList;
  AStruct->I = 200;
  AStruct->C = 'X';
  MyList->Add(AStruct);

  // Go through the list, writing the elements to the
  // canvas of a paintbox component.
  int Y = 10; // position on canvas
  for (int i = 0; i < MyList->Count; i++)
  {
    AStruct = (PAList) MyList->Items[i];
    PaintBox1->Canvas->TextOut(10, Y, IntToStr(AStruct->I));
    Y += 30;  // Increment Y Value again
    PaintBox1->Canvas->TextOut(10, Y, AStruct->C);
    Y += 30;  //Increment Y Value
  }

  // Clean up - must free memory for the items as well as the list
  for (int i = 0; i < MyList->Count; i++)
  {
    AStruct = (PAList) MyList->Items[i];
    delete AStruct;
  }
  delete MyList;
```

```
}
```

Delphi Examples:

```
{
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
}
procedure TForm1.Button1Click(Sender: TObject);
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  MyList: TList;
  ARecord: PMyList;
  B: Byte;
  Y: Word;
begin
  MyList := TList.Create;
  try
    New(ARecord);
    ARecord^.I := 100;
    ARecord^.C := 'Z';
    MyList.Add(ARecord); {Add integer 100 and character Z to list}
    New(ARecord);
    ARecord^.I := 200;
    ARecord^.C := 'X';
    MyList.Add(ARecord); {Add integer 200 and character X to list}

    { Now paint the items onto the paintbox}
    Y := 10;             {Variable used in TextOut function}
    for B := 0 to (MyList.Count - 1) do
    begin
      ARecord := MyList.Items[B];
      Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
      Y := Y + 30;  {Increment Y Value again}
      Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
      Y := Y + 30;  {Increment Y Value}
    end;

    { Cleanup: must free the list items as well as the list }
   for B := 0 to (MyList.Count - 1) do
   begin
     ARecord := MyList.Items[B];
     Dispose(ARecord);
   end;
  finally
    MyList.Free;
  end;
end;
```

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 2882)

Items (see page 2898)

Remove (see page 2887)

23.1.37.3.2 TList.Assign Method

Copies elements of one list to another.

Pascal

```
procedure Assign(ListA: TList; AOperator: TListAssignOp = laCopy; ListB: TList = nil);
```

C++

```
__fastcall Assign(TList ListA, TListAssignOp AOperator = laCopy, TList ListB = nil);
```

Description

Call Assign to assign the elements of another list to this one. Assign combines the source list with this one using the logical operator specified by the AOperator parameter.

If the ListB parameter is specified (Delphi) or not NULL (C++), then Assign first replaces all the elements of this list with those in ListA, and then merges ListB into this list using the operator specified by AOperator.

If the ListB parameter is not specified (Delphi) or NULL (C++), then Assign merges ListA into this list using the operator specified by AOperator.

See Also

Items (see page 2898)

23.1.37.3.3 TList.Clear Method

Deletes all items from the list.

Pascal

```
procedure Clear; virtual;
```

C++

```
virtual __fastcall Clear();
```

Description

Call Clear to empty the Items (see page 2898) array and set the Count (see page 2896) to 0. Clear also frees the memory used to store the Items (see page 2898) array and sets the Capacity (see page 2895) to 0.

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 2898)

Remove (see page 2887)

23.1.37.3.4 TList.Delete Method

Removes the item at the position given by the Index parameter.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Call Delete to remove the item at a specific position from the list. The index is zero-based, so the first item has an Index value of 0, the second item has an Index value of 1, and so on. Calling Delete moves up all items in the Items (see page 2898) array that follow the deleted item, and reduces the Count (see page 2896).

To remove the reference to an item without deleting the entry from the Items (see page 2898) array and changing the Count (see page 2896), set the Items (see page 2898) property for Index to nil (Delphi) or NULL (C++).

Note: Delete does not free any memory associated with the item. To free the memory that was used to store a deleted item, set the Capacity (see page 2895) property.

See Also

Add (see page 2871)

Capacity (see page 2895)

Clear (see page 2874)

Count (see page 2896)

Insert (see page 2882)

Items (see page 2898)

Remove (see page 2887)

Extract (see page 2877)

TObjectList (see page 5677)

TComponentList (see page 5653)

23.1.37.3.5 Error Method

This is the overview for the Error method overload.

Overload List

	Name	Description
	TList.Error (PResStringRec, Integer) (see page 2875)	Raises an EListError (see page 2701) exception.
	TList.Error (string, Integer) (see page 2875)	Raises an EListError (see page 2701) exception.

23.1.37.3.5.1 TList.Error Method (PResStringRec, Integer)

Raises an EListError (see page 2701) exception.

Pascal

```
class procedure Error(const Msg: string; Data: Integer); virtual; overload;
class procedure Error(Msg: PResStringRec; Data: Integer); overload;
```

C++

```
virtual __fastcall Error(const AnsiString Msg, int Data);
__fastcall Error(PResStringRec Msg, int Data);
```

Description

Call Error to raise an exception when an error occurs working with a TList (see page 2868) object. Error assembles an error message from the format string (or resource string) passed as the Msg parameter and the data value passed as the Data parameter, and then raises an EListError (see page 2701) exception.

Call Error rather than adding a line such as

Note: raise EListError.CreateFmt(MyMsg, iBadValue);

Note: or

Note: resourcestring sBadValueMessage = '%s not a valid list value';

Note: ...

Note: EListError.Create(@sBadValueMessage, iBadValue);

Note: throw EListError (see page 2701)(MyMsg, iBadValue);

to reduce the code size of an application.

See Also

EListError (see page 2701)

Create (see page 22752)

CreateFmt (see page 22754)

23.1.37.3.6 TList.Exchange Method

Swaps the position of two items in the Items (see page 2898) array.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer);
```

C++

```
__fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to swap the positions of the items at positions Index1 and Index2 of the Items (see page 2898) array. The indexes are zero-based, so the first item in the list has an index value of 0, the second item has an index value of 1, and so on.

Items (see page 2898)

Move (see page 2884)

23.1.37.3.7 TList.Expand Method

Increases the Capacity (see page 2895) of the list.

Pascal

```
function Expand: TList;
```

C++

```
__fastcall TList Expand();
```

Description

Call Expand to create more space for adding new items to the list. Expand does nothing if the list is not already filled to Capacity (see page 2895).

If Count (see page 2896) = Capacity (see page 2895), Expand increases the Capacity (see page 2895) of the list as follows. If the value of Capacity (see page 2895) is greater than 8, Expand increases the Capacity (see page 2895) of the list by 16. If the value of Capacity (see page 2895) is greater than 4, but less than 9, the Capacity (see page 2895) of the list increases by 8. If the value of Capacity (see page 2895) is less than 4, the Capacity (see page 2895) of the list grows by 4.

The returned value is the expanded list object.

See Also

Capacity (see page 2895)

Count (see page 2896)

23.1.37.3.8 TList.Extract Method

Removes a specified item from the list.

Pascal

```
function Extract(Item: Pointer): Pointer;
```

C++

```
__fastcall void * Extract(void * Item);
```

Description

Call Extract to remove an item from the list. After the item is removed, all the objects that follow it are moved up in index position and Count (see page 2896) is decremented.

To remove the reference to an item without deleting the entry from the Items (see page 2898) array and changing the Count (see page 2896), set the Items (see page 2898) property for Index to nil (Delphi) or NULL (C++).

See Also

Add (see page 2871)

Capacity (see page 2895)

Clear (see page 2874)

Count (see page 2896)

Insert (see page 2882)

Items (see page 2898)

Remove (see page 2887)

Delete (see page 2874)

TObjectList (see page 5677)

TComponentList (see page 5653)

23.1.37.3.9 TList.First Method

Returns Items (see page 2898)[0].

Pascal

```
function First: Pointer;
```

C++

```
__fastcall void * First();
```

Description

Call First to get the first pointer in the Items (see page 2898) array.

See Also

Items (see page 2898)

Last (see page 2882)

23.1.37.3.10 TList.Get Method

Pascal

```
function Get(Index: Integer): Pointer;
```

C++

```
__fastcall void * Get(int Index);
```

Description

This is Get, a member of class TList.

23.1.37.3.11 TList.GetEnumerator Method

Returns a TList (see page 2868) enumerator.

Pascal

```
function GetEnumerator: TListEnumerator;
```

C++

```
__fastcall TListEnumerator GetEnumerator();
```

Description

GetEnumerator returns a TListEnumerator (see page 2900) reference, which enumerates all items in the list.

To do so, call the TListEnumerator (see page 2900) GetCurrent method within a While MoveNext do loop.

See Also

TListEnumerator (see page 2900)

23.1.37.3.12 TList.Grow Method

Pascal

```
procedure Grow; virtual;
```

C++

```
virtual __fastcall Grow();
```

Description

This is Grow, a member of class TList.

23.1.37.3.13 TList.IndexOf Method

Returns the index of the first entry in the Items (see page 2898) array with a specified value.

Pascal

```
function IndexOf(Item: Pointer): Integer;
```

C++

```
__fastcall int IndexOf(void * Item);
```

Description

Call IndexOf to get the index for a pointer in the Items (see page 2898) array. Specify the pointer as the Item parameter.

The first item in the array has index 0, the second item has index 1, and so on. If an item is not in the list, IndexOf returns -1. If a pointer appears more than once in the array, IndexOf returns the index of the first appearance.

C++ Examples:

```
/*
The following code adds an object to MyList if it isn't
already in the list.
*/
typedef struct AList
{
  int I;
  char C;
} TAList;

typedef AList* PAList;

TList *MyList;
PAList ARecord1, ARecord2;

void __fastcall DisplayTList(TList *theList)
{
  PAList AStruct;
  // Go through the list, writing the elements to the
  // canvas of a paintbox component.
  int Y = 10; // position on canvas
  for (int i = 0; i < theList->Count; i++)
  {
    AStruct = (PAList) theList->Items[i];
    Form1->PaintBox1->Canvas->TextOut(10, Y, IntToStr(AStruct->I));
    Y += 30;  // Increment Y Value again
    Form1->PaintBox1->Canvas->TextOut(10, Y, AStruct->C);
    Y += 30;  //Increment Y Value
  }
}
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (MyList->IndexOf(ARecord1) == -1) MyList->Add(ARecord1);
  DisplayTList(MyList);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (MyList->IndexOf(ARecord2) == -1) MyList->Add(ARecord2);
  DisplayTList(MyList);
}

void __fastcall TForm1::Button3Click(TObject *Sender)
{
  if (MyList->Count != 0)
  {
    for (int B = MyList->Count - 1; B >= 0; B--)
    {
      PAList ARecord;
      ARecord = PAList(MyList->Items[B]);
      MyList->Remove(ARecord);
    }
  }
  Form1->PaintBox1->Repaint();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TList;
  ARecord1 = new TAList;
  ARecord1->I = 100;
  ARecord1->C = 'Z';
  ARecord2 = new TAList;
  ARecord2->I = 200;
  ARecord2->C = 'X';
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  // Clean up - must free memory for the items as well as the list
  for (int i = 0; i < MyList->Count; i++)
  {
    PAList ARecord = (PAList) MyList->Items[i];
    delete ARecord;
  }
  delete MyList;

}
```

Delphi Examples:

```
{
The following code adds an object to MyList if it isn't
already in the list.
}
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  Form1: TForm1;
  MyList: TList;
  ARecord1, ARecord2: PMyList;

implementation
```

```
{$R *.dfm}

procedure DisplayTList(TheList: TList);
var
  ARecord: PMyList;
  B: Byte;
  Y: Word;
begin
    { Now paint the items onto the paintbox}
    Y := 10;             {Variable used in TextOut function}
    for B := 0 to (TheList.Count - 1) do
    begin
      ARecord := TheList.Items[B];
      Form1.PaintBox1.Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
      Y := Y + 30;  {Increment Y Value again}
      Form1.PaintBox1.Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
      Y := Y + 30;  {Increment Y Value}
    end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  if (MyList.IndexOf(ARecord1) = -1) then MyList.Add(ARecord1);
  DisplayTList(MyList);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  if (MyList.IndexOf(ARecord2) = -1) then MyList.Add(ARecord2);
  DisplayTList(MyList);
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  ARecord: PMyList;
  B: Integer;
begin
  if (MyList.Count <> 0) then
  begin
    for B := (MyList.Count - 1) downto 0 do
    begin
      ARecord := MyList.Items[B];
      MyList.Remove(ARecord);
    end;
  end;
  Form1.PaintBox1.Repaint;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TList.Create;
  New(ARecord1);
  ARecord1^.I := 100;
  ARecord1^.C := 'Z';
  New(ARecord2);
  ARecord2^.I := 200;
  ARecord2^.C := 'X';
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(ARecord1);
  Dispose(ARecord2);
  MyList.Free;
end;
```

Delete (see page 2874)

Items (see page 2898)

23.1.37.3.14 TList.Insert Method

Adds an object to the Items (see page 2898) array at the position specified by Index.

Pascal

```
procedure Insert(Index: Integer; Item: Pointer);
```

C++

```
__fastcall Insert(int Index, void * Item);
```

Description

Call Insert to add Item to the middle of the Items (see page 2898) array. The Index parameter is a zero-based index, so the first position in the array has an index of 0. Insert adds the item at the indicated position, shifting the item that previously occupied that position, and all subsequent items, up. Insert increments Count (see page 2896) and, if necessary, allocates memory by increasing the value of Capacity (see page 2895).

To replace a nil (Delphi) or NULL (C++) pointer in the array with a new item, without growing the Items (see page 2898) array, set the Items (see page 2898) property.

See Also

Add (see page 2871)

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 2898)

Remove (see page 2887)

23.1.37.3.15 TList.Last Method

Returns Items (see page 2898)[Count (see page 2896) - 1].

Pascal

```
function Last: Pointer;
```

C++

```
__fastcall void * Last();
```

Description

Call Last to retrieve the last pointer in the Items (see page 2898) array.

C++ Examples:

```
/*
This example inserts two records into a list object and
displays the contents of the last record in the list on the form:
*/
typedef struct AList
{
```

```
  int I;
  char C;
} TAList;

typedef AList* PAList;

TList *MyList;
PAList ARecord1, ARecord2;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PAList ARecord = (AList *)(MyList->Last());
  PaintBox1->Canvas->TextOut(10, 10, IntToStr(ARecord->I)); // Display I
  PaintBox1->Canvas->TextOut(10, 40, ARecord->C); // Display C
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Refresh();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TList;
  ARecord1 = new TAList;
  ARecord1->I = 100;
  ARecord1->C = 'Z';
  MyList->Add(ARecord1);
  ARecord2 = new TAList;
  ARecord2->I = 200;
  ARecord2->C = 'X';
  MyList->Add(ARecord2);
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  // Clean up - must free memory for the items as well as the list
  for (int i = 0; i < MyList->Count; i++)
  {
    PAList ARecord = (PAList) MyList->Items[i];
    delete ARecord;
  }
  delete MyList;
}
```

Delphi Examples:

```
{
This example inserts two records into a list object and
displays the contents of the last record in the list on the form:
}
procedure TForm1.Button1Click(Sender: TObject);
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  MyList: TList;
  ARecord: PMyList;
  I: integer;
begin
  MyList := TList.Create;
  New(ARecord);
  ARecord^.I := 100;
  ARecord^.C := 'Z';
```

```
    MyList.Add(ARecord); {Add integer 100 and character Z to list}
    New(ARecord);
    ARecord^.I := 200;
    ARecord^.C := 'X';
    MyList.Add(ARecord); {Add integer 200 and character X to list}
    ARecord := MyList.Last;
    Canvas.TextOut(10, 10, IntToStr(ARecord^.I)); {Display I}
    Canvas.TextOut(10, 40, ARecord^.C);  {Display C}
    { Cleanup: must free the list items as well as the list }
    for I := 0 to (MyList.Count - 1) do
    begin
      ARecord := MyList.Items[I];
      Dispose(ARecord);
    end;
    MyList.Free;
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    Refresh;
  end;
```

See Also

Count (see page 2896)

First (see page 2878)

Items (see page 2898)

23.1.37.3.16 TList.Move Method

Changes the position of an item in the Items (see page 2898) array.

Pascal

```
procedure Move(CurIndex: Integer; NewIndex: Integer);
```

C++

```
__fastcall Move(int CurIndex, int NewIndex);
```

Description

Call Move to move the item at the position CurIndex so that it occupies the position NewIndex. CurIndex and NewIndex are zero-based indexes into the Items (see page 2898) array.

See Also

Exchange (see page 2876)

IndexOf (see page 2879)

Items (see page 2898)

23.1.37.3.17 TList.Notify Method

Responds when items are added, removed, or extracted from the list.

Pascal

```
procedure Notify(Ptr: Pointer; Action: TListNotification); virtual;
```

C++

```
virtual __fastcall Notify(void * Ptr, TListNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Ptr points to item affected by the change.

Action indicates the change.

As implemented in TList (see page 2868), Notify does nothing. Descendant classes can override Notify in order to implement an appropriate response to the change notification.

23.1.37.3.18 TList.Pack Method

Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.

Pascal

```
procedure Pack;
```

C++

```
__fastcall Pack();
```

Description

Call Pack to move all non-nil (Delphi) or non-NULL (C++) items to the front of the Items (see page 2898) array and reduce the Count (see page 2896) property to the number of items actually used. Pack does not free up the memory used to store the nil (Delphi) or NULL (C++) pointers. To free up the memory for the unused entries removed by Pack, set the Capacity (see page 2895) property to the new value of Count (see page 2896).

C++ Examples:

```
/*
This example requires two edit box controls and a button on
the form. The code creates a list object and adds some
strings to it. The forth string in the list is a null string.
The code counts the number of strings in the list and
displays the number in the Edit1 control. The code then
packs the list, removing the nil string, and counts the
strings in the list again. The second count displays in the
Edit2 control:
*/
void __fastcall  DisplayTList(TList *TheList)
{
    // Now paint the items onto the paintbox}
    short Y = 10;             // Variable used in TextOut function
    for (byte B = 0; B < TheList->Count; B++)
    {
      AnsiString str = PChar(TheList->Items[B]);
      Form1->Canvas->TextOut(10, Y, str);
      Y = Y + 30;  // Increment Y Value again
    }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TList; // Create a list
  MyList->Add(PChar("A string")); // Add a string
  MyList->Add(PChar("")); // Add an empty string
  MyList->Add(PChar("A third string")); // Add a string
  MyList->Add(NULL);              // Add nil
  MyList->Add(PChar("A fifth string")); // Add a string
  MyList->Add(PChar("")); // Add another empty string
  MyList->Add(PChar("A seventh string")); // Add a string
  Edit1->Text = IntToStr(MyList->Count); // Put count into Edit1
```

```
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MyList->Pack();                          // Pack the list.
  Edit2->Text = IntToStr(MyList->Count); // Put count into Edit2
  Repaint();
}

void __fastcall TForm1::FormPaint(TObject *Sender)
{
  DisplayTList(MyList);
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete MyList;                          // Free memory for list
}
```

Delphi Examples:

```
{
This example requires two edit box controls and a button on
the form. The code creates a list object and adds some
strings to it. The second string in the list is a nil string.
The code counts the number of strings in the list and
displays the number in the Edit1 control. The code then
packs the list, removing the nil string, and counts the
strings in the list again. The second count displays in the
Edit2 control:
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  MyList := TList.Create;              {Create a list }
  MyList.Add(PChar('A string')); {Add a string}
  MyList.Add(PChar('')); { Add an empty string }
  MyList.Add(PChar('A third string')); {Add a string}
  MyList.Add(nil);              {Add nil }
  MyList.Add(PChar('A fifth string')); {Add a string}
  MyList.Add(PChar('')); { Add another empty string }
  MyList.Add(PChar('A seventh string')); {Add a string}
  Edit1.Text := IntToStr(MyList.Count); {Put count into Edit1}
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MyList.Pack;                         {Pack the list.}
  Edit2.Text := IntToStr(MyList.Count); {Put count into Edit2}
  Repaint;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  MyList.Free;                         {Free memory for list}
end;

procedure TForm1.FormPaint(Sender: TObject);
begin
  DisplayTList(MyList);
end;
```

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 2898)

23.1.37.3.19 TList.Put Method

Pascal

```
procedure Put(Index: Integer; Item: Pointer);
```

C++

```
__fastcall Put(int Index, void * Item);
```

Description

This is Put, a member of class TList.

23.1.37.3.20 TList.Remove Method

Deletes the first reference to the Item parameter from the Items (see page 2898) array.

Pascal

```
function Remove(Item: Pointer): Integer;
```

C++

```
__fastcall int Remove(void * Item);
```

Description

Call Remove to remove a specific item from the Items (see page 2898) array when its index is unknown. The value returned is the index of the item in the Items (see page 2898) array before it was removed. After an item is removed, all the items that follow it are moved up in index position and the Count (see page 2896) is reduced by one.

If the Items (see page 2898) array contains more than one copy of the pointer, only the first copy is deleted.

C++ Examples:

```
/*
The following code adds an object to MyList if it isn't
already in the list.
*/
typedef struct AList
{
  int I;
  char C;
} TAList;

typedef AList* PAList;

TList *MyList;
PAList ARecord1, ARecord2;

void __fastcall DisplayTList(TList *theList)
{
  PAList AStruct;
  // Go through the list, writing the elements to the
  // canvas of a paintbox component.
  int Y = 10; // position on canvas
  for (int i = 0; i < theList->Count; i++)
  {
    AStruct = (PAList) theList->Items[i];
```

```
      Form1->PaintBox1->Canvas->TextOut(10, Y, IntToStr(AStruct->I));
      Y += 30;  // Increment Y Value again
      Form1->PaintBox1->Canvas->TextOut(10, Y, AStruct->C);
      Y += 30;  //Increment Y Value
    }
  }

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    if (MyList->IndexOf(ARecord1) == -1) MyList->Add(ARecord1);
    DisplayTList(MyList);
  }

  void __fastcall TForm1::Button2Click(TObject *Sender)
  {
    if (MyList->IndexOf(ARecord2) == -1) MyList->Add(ARecord2);
    DisplayTList(MyList);
  }

  void __fastcall TForm1::Button3Click(TObject *Sender)
  {
    if (MyList->Count != 0)
    {
      for (int B = MyList->Count - 1; B >= 0; B--)
      {
        PAList ARecord;
        ARecord = PAList(MyList->Items[B]);
        MyList->Remove(ARecord);
      }
    }
    Form1->PaintBox1->Repaint();
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    MyList = new TList;
    ARecord1 = new TAList;
    ARecord1->I = 100;
    ARecord1->C = 'Z';
    ARecord2 = new TAList;
    ARecord2->I = 200;
    ARecord2->C = 'X';
  }

  void __fastcall TForm1::FormDestroy(TObject *Sender)
  {
    // Clean up - must free memory for the items as well as the list
    for (int i = 0; i < MyList->Count; i++)
    {
      PAList ARecord = (PAList) MyList->Items[i];
      delete ARecord;
    }
    delete MyList;

  }
  /*
  The following code adds a new object to a list in a list
  object and then removes it:
  */
  class TMyClass : public TComponent
  {
  __published:    // IDE-managed Components
  private:    // User declarations
  public:     // User declarations
    AnsiString MyString;
      __fastcall TMyClass(TComponent* Owner, AnsiString mystr);
```

```
};

__fastcall TMyClass::TMyClass(TComponent* Owner, AnsiString mystr)
    : TComponent(Owner)
{
  MyString = mystr;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TList *list = new TList();
  TMyClass *TheObject = new TMyClass(Form1, "This is an object.");
  try
  {
    list->Add(TheObject); // add AnsiString instance to list
    MessageDlg("The list has " + IntToStr(list->Count) + " objects",
               mtInformation, TMsgDlgButtons() << mbOK, 0);
    list->Remove(TheObject);
    MessageDlg("The list has " + IntToStr(list->Count) + " objects",
               mtInformation, TMsgDlgButtons() << mbOK, 0);
  }
  __finally
  {
    delete list;
  }
}
```

Delphi Examples:

```
{
The following code adds an object to MyList if it isn't
already in the list.
}
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  Form1: TForm1;
  MyList: TList;
  ARecord1, ARecord2: PMyList;

implementation

{$R *.dfm}

procedure DisplayTList(TheList: TList);
var
  ARecord: PMyList;
  B: Byte;
  Y: Word;
begin
    { Now paint the items onto the paintbox}
    Y := 10;             {Variable used in TextOut function}
    for B := 0 to (TheList.Count - 1) do
    begin
      ARecord := TheList.Items[B];
      Form1.PaintBox1.Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
      Y := Y + 30;  {Increment Y Value again}
      Form1.PaintBox1.Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
      Y := Y + 30;  {Increment Y Value}
    end;
end;

procedure TForm1.Button1Click(Sender: TObject);
```

```
begin

23.1.37.3.21 TList.SetCapacity Method

Pascal

```
procedure SetCapacity(NewCapacity: Integer);
```

C++

```
__fastcall SetCapacity(int NewCapacity);
```

Description

This is SetCapacity, a member of class TList.

23.1.37.3.22 TList.SetCount Method

Pascal

```
procedure SetCount(NewCount: Integer);
```

C++

```
__fastcall SetCount(int NewCount);
```

Description

This is SetCount, a member of class TList.

23.1.37.3.23 TList.Sort Method

Performs a QuickSort on the list based on the comparison function Compare.

Pascal

```
procedure Sort(Compare: TListSortCompare);
```

C++

```
__fastcall Sort(TListSortCompare Compare);
```

Description

Call Sort to sort the items in the Items (see page 2898) array. Compare is a comparison function that indicates how the items are to be ordered.

C++ Examples:

```
/*
The following code sorts the objects in a list in
alphabetical order based on their names. It assumes that the
list contains only TMyClass references.  The CompareNames
function performs the comparisons between objects in the list.
The list is sorted when the user clicks a button.
*/
class TMyClass : public TObject
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
  AnsiString MyString;
    __fastcall TMyClass(AnsiString mystr);
};

__fastcall TMyClass::TMyClass(AnsiString mystr)
    : TObject()
{
  MyString = mystr;
}

void __fastcall  DisplayTList(TList *TheList)
{
    // Now paint the items onto the paintbox}
```

```
    short Y = 10;             // Variable used in TextOut function
    for (byte B = 0; B < TheList->Count; B++)
    {
      TMyClass *temp = (TMyClass *)(TheList->Items[B]);
      Form1->Canvas->TextOut(10, Y, temp->MyString);
      Y = Y + 30;  // Increment Y Value again
    }
}

int __fastcall CompareNames(void *Item1, void *Item2)
{
  return CompareText(((TMyClass *)Item1)->MyString, ((TMyClass *)Item2)->MyString);
}
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MyList->Sort(CompareNames);
  Refresh();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TList;           // Create a list
  for (int I = 0; I < ComponentCount; I++)
  {
    TMyClass *MyObject = new TMyClass(Components[I]->Name);  // create a class instance
    MyList->Add(MyObject);      // add instance to list
  }
}

void __fastcall TForm1::FormPaint(TObject *Sender)
{
  DisplayTList(MyList);
}
```

Delphi Examples:

```
{
The following code sorts the objects in a list in
alphabetical order based on their names. It assumes that the
list contains only TMyClass references.  The CompareNames
function performs the comparisons between objects in the list.
The list is sorted when the user clicks a button.

23.1.37.4 TList Properties

The properties of the TList class are listed here.

Public Properties

	Name	Description
	Capacity (see page 2895)	Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.
	Count (see page 2896)	Indicates the number of entries in the list that are in use.
	Items (see page 2898)	Lists the object references.
R	List (see page 2900)	Specifies the array of pointers that make up the Items (see page 2898) array.

23.1.37.4.1 TList.Capacity Property

Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

Set Capacity to the number of pointers the list will need to contain. When setting the Capacity property, an EOutOfMemory exception occurs if there is not enough memory to expand the list to its new size.

Read Capacity to learn number of objects the list can hold without reallocating memory. Do not confuse Capacity with the Count (see page 2896) property, which is the number of entries in the list that are in use. The value of Capacity is always greater than or equal to the value of Count (see page 2896). When Capacity is greater than Count (see page 2896), the unused memory can be reclaimed by setting Capacity to Count (see page 2896).

When an object is added to a list that is already filled to capacity, the Capacity property is automatically increased. Setting Capacity before adding objects can reduce the number of memory reallocations and thereby improve performance. For example,

Note: Delphi example:

```
List.Clear;
List.Capacity := Count;
for I := 1 to Count do List.Add(...);
```

Note: C++ example:

```
List->Clear();
List->Capacity = Count;
for (int I = 0; I < Count; I++)
  List->Add(...);
```

The assignment to Capacity before the for loop ensures that each of the following Add (see page 2871) operations doesn't cause the list to be reallocated. Avoiding reallocations on the calls to Add (see page 2871) improves performance and ensures that the Add (see page 2871) operations never raise an exception.

See Also

Add (see page 2871)

Count (see page 2896)

Expand (see page 2877)

Pack (see page 2885)

23.1.37.4.2 TList.Count Property

Indicates the number of entries in the list that are in use.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read Count to determine the number of entries in the Items (see page 2898) array.

Increasing the size of Count will add the necessary number of nil (Delphi) or NULL (C++) pointers to the end of the Items (see page 2898) array. Decreasing the size of Count will remove the necessary number of entries from the end of the Items (see page 2898) array.

Count is not always the same as the number of objects referenced in the list. Some of the entries in the Items (see page 2898) array may contain nil (Delphi) or NULL (C++) pointers. To remove the nil (Delphi) or NULL (C++) pointers and set Count to the number of entries that contain references to objects, call the Pack (see page 2885) method.

C++ Examples:

```
/*
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
*/

typedef struct AList
{
  int I;
  char C;
} TAList;

typedef TAList* PAList;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PAList AStruct;
  TList *MyList = new TList;
  // fill the TList
  AStruct = new TAList;
  AStruct->I = 100;
  AStruct->C = 'Z';
  MyList->Add(AStruct);
  AStruct = new TAList;
  AStruct->I = 200;
  AStruct->C = 'X';
  MyList->Add(AStruct);

  // Go through the list, writing the elements to the
  // canvas of a paintbox component.
  int Y = 10; // position on canvas
  for (int i = 0; i < MyList->Count; i++)
  {
```

```
    AStruct = (PAList) MyList->Items[i];
    PaintBox1->Canvas->TextOut(10, Y, IntToStr(AStruct->I));
    Y += 30;  // Increment Y Value again
    PaintBox1->Canvas->TextOut(10, Y, AStruct->C);
    Y += 30;  //Increment Y Value
  }

  // Clean up - must free memory for the items as well as the list
  for (int i = 0; i < MyList->Count; i++)
  {
    AStruct = (PAList) MyList->Items[i];
    delete AStruct;
  }
  delete MyList;

}
```

Delphi Examples:

```
{
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
}
procedure TForm1.Button1Click(Sender: TObject);
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  MyList: TList;
  ARecord: PMyList;
  B: Byte;
  Y: Word;
begin
  MyList := TList.Create;
  try
    New(ARecord);
    ARecord^.I := 100;
    ARecord^.C := 'Z';
    MyList.Add(ARecord); {Add integer 100 and character Z to list}
    New(ARecord);
    ARecord^.I := 200;
    ARecord^.C := 'X';
    MyList.Add(ARecord); {Add integer 200 and character X to list}

    { Now paint the items onto the paintbox}
    Y := 10;             {Variable used in TextOut function}
    for B := 0 to (MyList.Count - 1) do
    begin
      ARecord := MyList.Items[B];
      Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
      Y := Y + 30;  {Increment Y Value again}
      Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
      Y := Y + 30;  {Increment Y Value}
    end;

    { Cleanup: must free the list items as well as the list }
   for B := 0 to (MyList.Count - 1) do
   begin
     ARecord := MyList.Items[B];
     Dispose(ARecord);
   end;
  finally
    MyList.Free;
```

```
  end;
end;
```

See Also

Capacity (see page 2895)

Items (see page 2898)

Pack (see page 2885)

23.1.37.4.3 TList.Items Property

Lists the object references.

Pascal

```
property Items [Index: Integer]: Pointer;
```

C++

```
__property void * Items[int Index];
```

Description

Use Items to obtain a pointer to a specific object in the array. The Index parameter indicates the index of the object, where 0 is the index of the first object, 1 is the index of the second object, and so on. Set Items to change the reference at a specific location.

Use Items with the Count (see page 2896) property to iterate through all of the objects in the list.

Not all of the entries in the Items array need to contain references to objects. Some of the entries may be nil (Delphi) or NULL (C++) pointers. To remove the nil (Delphi) or NULL (C++) pointers and reduce the size of the Items array to the number of objects, call the Pack (see page 2885) method.

Note: Items is the default property for TList (see page 2868). This means you can omit the property name. Thus, instead of

Note: MyList.Items[i]

Note: you can write

Note: MyList[i]

C++ Examples:

```
/*
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
*/

typedef struct AList
{
  int I;
  char C;
} TAList;

typedef TAList* PAList;
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PAList AStruct;
  TList *MyList = new TList;
  // fill the TList
  AStruct = new TAList;
  AStruct->I = 100;
  AStruct->C = 'Z';
  MyList->Add(AStruct);
  AStruct = new TAList;
  AStruct->I = 200;
  AStruct->C = 'X';
  MyList->Add(AStruct);

  // Go through the list, writing the elements to the
  // canvas of a paintbox component.
  int Y = 10; // position on canvas
  for (int i = 0; i < MyList->Count; i++)
  {
    AStruct = (PAList) MyList->Items[i];
    PaintBox1->Canvas->TextOut(10, Y, IntToStr(AStruct->I));
    Y += 30;  // Increment Y Value again
    PaintBox1->Canvas->TextOut(10, Y, AStruct->C);
    Y += 30;  //Increment Y Value
  }

  // Clean up - must free memory for the items as well as the list
  for (int i = 0; i < MyList->Count; i++)
  {
    AStruct = (PAList) MyList->Items[i];
    delete AStruct;
  }
  delete MyList;

}
```

Delphi Examples:

```
{
This example creates a list object and inserts two records
into it. The value of the record fields are written on a
paintbox:
}
procedure TForm1.Button1Click(Sender: TObject);
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  MyList: TList;
  ARecord: PMyList;
  B: Byte;
  Y: Word;
begin
  MyList := TList.Create;
  try
    New(ARecord);
    ARecord^.I := 100;
    ARecord^.C := 'Z';
    MyList.Add(ARecord); {Add integer 100 and character Z to list}
    New(ARecord);
    ARecord^.I := 200;
    ARecord^.C := 'X';
    MyList.Add(ARecord); {Add integer 200 and character X to list}
```

```
      { Now paint the items onto the paintbox}
      Y := 10;             {Variable used in TextOut function}
      for B := 0 to (MyList.Count - 1) do
      begin
        ARecord := MyList.Items[B];
        Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
        Y := Y + 30;  {Increment Y Value again}
        Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
        Y := Y + 30;  {Increment Y Value}
      end;

      { Cleanup: must free the list items as well as the list }
     for B := 0 to (MyList.Count - 1) do
     begin
       ARecord := MyList.Items[B];
       Dispose(ARecord);
     end;
    finally
      MyList.Free;
    end;
  end;
```

23.1.37.4.4 TList.List Property

Specifies the array of pointers that make up the Items (see page 2898) array.

Pascal

```
property List: PPointerList;
```

C++

```
__property PPointerList List;
```

Description

Use List to gain direct access to the Items (see page 2898) array.

See Also

Items (see page 2898)

23.1.38 TListEnumerator Class

Enumerates through the objects in a TList (see page 2868).

Class Hierarchy

Classes.TListEnumerator

Pascal

```
TListEnumerator = class;
```

C++

```
class TListEnumerator;
```

File

Classes

Description

TListEnumerator provides an enumerator for TList (see page 2868) objects.

23.1.38.1 TListEnumerator Members

The following tables list the members exposed by TListEnumerator.

Public Methods

	Name	Description
	Create (see page 2901)	Creates a TList (see page 2868) enumerator.
	GetCurrent (see page 2901)	Gets the current object.
	MoveNext (see page 2902)	Moves the enumerator to the next TList (see page 2868) item in the collection.

Public Properties

	Name	Description
R	Current (see page 2902)	The current TList (see page 2868) object.

23.1.38.2 TListEnumerator.Create Constructor

Creates a TList (see page 2868) enumerator.

Pascal

```
constructor Create(AList: TList);
```

C++

```
__fastcall TListEnumerator(TList AList);
```

Description

Creates an instance of TListEnumerator (see page 2900).

23.1.38.3 TListEnumerator Methods

The methods of the TListEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 2901)	Gets the current object.
	MoveNext (see page 2902)	Moves the enumerator to the next TList (see page 2868) item in the collection.

23.1.38.3.1 TListEnumerator.GetCurrent Method

Gets the current object.

Pascal

```
function GetCurrent: Pointer;
```

C++

```
__fastcall void * GetCurrent();
```

Description

Use GetCurrent to get the current object in the TList (see page 2868) being enumerated.

23.1.38.3.2 TListEnumerator.MoveNext Method

Moves the enumerator to the next TList (see page 2868) item in the collection.

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

Use MoveNext to move the TListEnumerator (see page 2900) to the next object in the TList (see page 2868).

23.1.38.4 TListEnumerator Properties

The properties of the TListEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 2902)	The current TList (see page 2868) object.

23.1.38.4.1 TListEnumerator.Current Property

The current TList (see page 2868) object.

Pascal

```
property Current: Pointer;
```

C++

```
__property void * Current;
```

Description

Current contains the current object in the TList (see page 2868) that is being enumerated.

23.1.39 TMemoryStream Class

TMemoryStream is a stream that stores its data in dynamic memory.

Class Hierarchy

Pascal

```
TMemoryStream = class(TCustomMemoryStream);
```

C++

```
class TMemoryStream : public TCustomMemoryStream;
```

File

Classes

Description

Use TMemoryStream to store data in a dynamic memory buffer that is enhanced with file-like access capabilities. TMemoryStream provides the general I/O capabilities of a stream object while introducing methods and properties to manage a dynamic memory buffer.

Memory (see page 2823) streams are useful as intermediary objects that can hold information as well as read it from or write it to another storage medium. They provide a useful format for comparing the contents of streams, or for manipulating data that is stored in a less accessible medium.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
```

```
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}

23.1.39.1 TMemoryStream Members

The following tables list the members exposed by TMemoryStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	Realloc (see page 2910)	This is Realloc, a member of class TMemoryStream.
	SetPointer (see page 2823)	Replaces the memory buffer associated with the memory stream.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Protected Properties

	Name	Description
	Capacity (see page 2912)	This is Capacity, a member of class TMemoryStream.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2909)	Frees the memory buffer, discarding all data associated with the memory stream.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2908)	Destroys an instance of TMemoryStream (see page 2902).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadFromFile (see page 2909)	Loads the entire contents of a file into the memory buffer.
	LoadFromStream (see page 2909)	Loads the entire contents of a stream into the memory buffer.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Read (see page 2817)	Reads up to Count bytes from the memory stream into Buffer and advances the current position of the stream by the number of bytes read.
A	Read (see page 2982)	Introduces an abstract or pure virtual method responsible for reading from the stream.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 2818)	Writes the entire contents of the memory stream to the file with a given file name.
	SaveToStream (see page 2818)	Writes the entire contents of the memory stream to the stream object specified by Stream.
V	Seek (see page 2819)	Moves the current position of the stream by Offset bytes, relative to the origin specified by Origin.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
V	SetSize (see page 2910)	Sets the Size (see page 2997) property of the memory stream.
V	Write (see page 2911)	Writes Count bytes from Buffer to the current position in the memory buffer and updates the current position by Count bytes.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.

	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
R	Memory (see page 2823)	Provides direct access to the memory pool allocated for the memory stream.
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.39.2 TMemoryStream.Destroy Destructor

Destroys an instance of TMemoryStream (see page 2902).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMemoryStream();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TMemoryStream (see page 2902) reference is not nil, and only then calls Destroy.

Destroy a TMemoryStream (see page 2902) object when it is no longer needed to store or write data. Destroy calls Clear (see page 2909) to free the memory buffer before calling the inherited destructor.

See Also

Clear (see page 2909)

Free (see page 22300)

23.1.39.3 TMemoryStream Methods

The methods of the TMemoryStream class are listed here.

Protected Methods

	Name	Description
V	Realloc (see page 2910)	This is Realloc, a member of class TMemoryStream.

Public Methods

	Name	Description
	Clear (see page 2909)	Frees the memory buffer, discarding all data associated with the memory stream.
	LoadFromFile (see page 2909)	Loads the entire contents of a file into the memory buffer.
	LoadFromStream (see page 2909)	Loads the entire contents of a stream into the memory buffer.
V	SetSize (see page 2910)	Sets the Size (see page 2997) property of the memory stream.
V	Write (see page 2911)	Writes Count bytes from Buffer to the current position in the memory buffer and updates the current position by Count bytes.

23.1.39.3.1 TMemoryStream.Clear Method

Frees the memory buffer, discarding all data associated with the memory stream.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Use Clear to empty the memory buffer for the memory stream and free all associated memory. In addition to freeing the memory associated with the memory buffer, Clear

Sets the Memory (see page 2823) property to nil (Delphi) or NULL (C++).

Sets the Position (see page 2996) property to 0.

Sets the Size (see page 2997) property to 0.

See Also

Memory (see page 2823)

Position (see page 2996)

Size (see page 2997)

23.1.39.3.2 TMemoryStream.LoadFromFile Method

Loads the entire contents of a file into the memory buffer.

Pascal

```
procedure LoadFromFile(const FileName: string);
```

C++

```
__fastcall LoadFromFile(const AnsiString FileName);
```

Description

Use LoadFromFile to fill the memory stream with the contents of a file. Pass the name of the file as the FileName parameter. LoadFromFile allows an application to read the contents of a file into the memory stream without having to explicitly create and free a file stream object.

LoadFromFile reallocates the memory buffer so that the contents of the file will exactly fit. It sets the Size (see page 2997) property accordingly, and then reads the entire contents of the file into the memory buffer. Thus, LoadFromFile will discard any pre-existing data stored in the memory stream.

See Also

LoadFromStream (see page 2909)

Memory (see page 2823)

Size (see page 2997)

23.1.39.3.3 TMemoryStream.LoadFromStream Method

Loads the entire contents of a stream into the memory buffer.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to fill the memory stream with the contents of the stream specified by the Stream parameter. LoadFromStream always sets the Position (see page 2996) of the source stream to 0, before streaming in the number of bytes indicated by the source stream's Size (see page 2997) property.

LoadFromStream reallocates the memory buffer so that the contents of the source stream will exactly fit. It sets the Size (see page 2997) property accordingly, and then reads the entire contents of the source stream into the memory buffer. Thus, LoadFromStream will discard any pre-existing data stored in the memory stream.

If the source stream is a TFileStream (see page 2841) object, LoadFromStream does the same thing as LoadFromFile (see page 2909), except that the application must create and free the TFileStream (see page 2841) object. LoadFromStream also allows applications to fill a memory stream object from other types of stream objects.

See Also

LoadFromFile (see page 2909)

Memory (see page 2823)

TFileStream (see page 2841)

Position (see page 2996)

Size (see page 2997)

23.1.39.3.4 TMemoryStream.Realloc Method

Pascal

```
function Realloc(var NewCapacity: Longint): Pointer; virtual;
```

C++

```
virtual __fastcall void * Realloc(Longint NewCapacity);
```

Description

This is Realloc, a member of class TMemoryStream.

23.1.39.3.5 TMemoryStream.SetSize Method

Sets the Size (see page 2997) property of the memory stream.

Pascal

```
procedure SetSize(NewSize: Longint); override;
```

C++

```
virtual __fastcall SetSize(Longint NewSize);
```

Description

Use SetSize to set the Size (see page 2997) of a memory stream before filling it with data. SetSize allocates the memory buffer to hold NewSize bytes, preserving as much of the existing data as possible.

Use SetSize before filling the memory buffer with data from various sources, or from a portion of another stream. If the intended

contents of the memory stream is exactly the same as the contents of another stream or file, use LoadFromStream (see page 2909) or LoadFromFile (see page 2909) instead.

See Also

LoadFromFile (see page 2909)

LoadFromStream (see page 2909)

Memory (see page 2823)

Size (see page 2997)

23.1.39.3.6 TMemoryStream.Write Method

Writes Count bytes from Buffer to the current position in the memory buffer and updates the current position by Count bytes.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count);
```

Description

Use Write to insert Count bytes into the memory buffer of the memory stream, starting at the current position. Write will increase the size of the memory buffer, if necessary, to accommodate the data being written in. If the current position is not the end of the memory buffer, Write will overwrite the data following the current position.

Write updates the Size (see page 2997) property to Position (see page 2996) + Count, and sets the Position (see page 2996) property to the new value of Size (see page 2997). Thus, any data that was stored in the memory stream in the Count bytes after the current position is lost when calling Write.

Write always writes the Count bytes in the Buffer, unless there is a memory failure. Thus, for TMemoryStream (see page 2902), Write is equivalent to the WriteBuffer (see page 2990) method.

All other data-writing methods of a memory stream (WriteBuffer (see page 2990), WriteComponent (see page 2990)) call Write to do the actual writing.

See Also

Memory (see page 2823)

Position (see page 2996)

Size (see page 2997)

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

23.1.39.4 TMemoryStream Properties

The properties of the TMemoryStream class are listed here.

Protected Properties

	Name	Description
	Capacity (see page 2912)	This is Capacity, a member of class TMemoryStream.

23.1.39.4.1 TMemoryStream.Capacity Property

Pascal

```
property Capacity: Longint;
```

C++

```
__property Longint Capacity;
```

Description

This is Capacity, a member of class TMemoryStream.

23.1.40 TOwnedCollection Class

TOwnedCollection is a collection that maintains information about its owner.

Class Hierarchy

Pascal

```
TOwnedCollection = class(TCollection);
```

C++

```
class TOwnedCollection : public TCollection;
```

File

Classes

Description

By maintaining information about its owner, TOwnedCollection lets the Object Inspector display the collection's name at design time.

Note: This information is not part of TOwnedCollection's public interface.

New collection classes should descend from TOwnedCollection. By descending from TOwnedCollection, the derived class does not need to add anything in order to appear in the Object Inspector. Classes (see page 2685) that descend directly from TCollection (see page 2731) must implement a GetOwner (see page 2915) method if they are to appear in the Object Inspector.

See Also

TCollection (see page 2731)

TCollectionItem (see page 2755)

TPersistent (see page 2928)

TPersistent (see page 2928)

23.1.40.1 TOwnedCollection Members

The following tables list the members exposed by TOwnedCollection.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 2915)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 2747)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 2736)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 2914)	Creates and initializes a TOwnedCollection (see page 2912) instance.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 2751)	Lists the items in the collection.

23.1.40.2 TOwnedCollection.Create Constructor

Creates and initializes a TOwnedCollection (see page 2912) instance.

Pascal

```
constructor Create(AOwner: TPersistent; ItemClass: TCollectionItemClass);
```

C++

```
__fastcall TOwnedCollection(TPersistent * AOwner, TCollectionItemClass ItemClass);
```

Description

The Create method takes two parameters: the name of an instance object descended from TPersistent (see page 2928) and the name of a TCollectionItem (see page 2755) descendant class. The first parameter is the owner of the TOwnedCollection (see page 2912) instance. The second parameter determines the class of the items created by the Add (see page 2736) method.

See Also

Add (see page 2736)

23.1.40.3 TOwnedCollection Methods

The methods of the TOwnedCollection class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 2915)	Returns the owner of an object.

23.1.40.3.1 TOwnedCollection.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

23.1.41 TParser Class

TParser allows DFM files to be parsed.

Class Hierarchy

Pascal

```
TParser = class(TObject);
```

C++

```
class TParser : public TObject;
```

File

Classes

Description

The TParser is principally used internally in RAD Studio to parse (tokenise) VCL Form files (which have a .dfm extension on Win32, and .nfm on .NET). However, it can potentially be used as a more general parser.

A VCL form file contains the description of the properties of the form and the components it owns. Each form file represents a single form, which usually corresponds to a window or dialog box in an application.

The parsing dissects the form text into a set of symbol strings, and value strings. Values may be string representations of strings, widestrings, integers, or floating point numbers.

Navigation is performed by repeatedly using the NextToken (see page 2922) method to retrieve a sequence of tokens (symobols and values). The value of each retrieved token is obtained using the TParser methods :

Method	Returns	Token (see page 2926)(s)
TokenFloat (see page 2923)	Float	toFloat (see page 3322)
TokenInteger	Integer	toInteger (see page 3322)
TokenString (see page 2924)	String	toFloat (see page 3322), toInteger (see page 3322), toString (see page 3323), toSymbol (see page 3324)
TokenWideString (see page 2925)	WideString	toWString (see page 3324)

toEOF (see page 3321) is the token returned when the form navigation is complete.

See Also

TForm (see page 13992)

23.1.41.1 TParser Members

The following tables list the members exposed by TParser.

Protected Methods

	Name	Description
	GetLinePos (see page 2921)	This is GetLinePos, a member of class TParser.

Public Events

	Name	Description
	OnError (see page 2927)	Occurs when a parse error is encountered.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	CheckToken (see page 2919)	Checks if the current token in the file is a specific type.
	CheckTokenSymbol (see page 2919)	Checks if the current token in the file is a symbol with a specific value.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2917)	Creates a TParser (see page 2915) class instance.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2917)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Error (see page 2920)	Raise an EParseError error.
	ErrorFmt (see page 2920)	Raise an EParseError error with a specified error message.
	ErrorStr (see page 2921)	Raise an EParseError error with a specific message.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	HexToBinary (see page 2921)	Converts a sequence of hex values into binary.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NextToken (see page 2922)	Moves to the next token in the file.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SourcePos (see page 2922)	Returns the position in the file being parsed.
	TokenComponentIdent (see page 2923)	Checks if the current token in the file is a valid component symbol.
	TokenFloat (see page 2923)	Returns a toFloat (see page 3322) token as a float.
	TokenInt (see page 2923)	Returns a toInteger (see page 3322) token as a float.
	TokenString (see page 2924)	Returns a string representation of the current token.
	TokenSymbolIs (see page 2924)	Checks if the next token in the file is a symbol with a specific value.
	TokenWideString (see page 2925)	Returns a toWString (see page 3324) token as a wide string value.

Public Properties

	Name	Description
R	FloatType (see page 2925)	Gives the type of floating pointer number.
R	LinePos (see page 2926)	Gives the position in the line currently being parsed.
R	SourceLine (see page 2926)	Gives the number of the line currently being parsed.
R	Token (see page 2926)	Gives the type of token at the current file position.

23.1.41.2 TParser.Create Constructor

Creates a TParser (see page 2915) class instance.

Pascal

```
constructor Create(Stream: TStream; AOnError: TParserErrorEvent = nil);
```

C++

```
__fastcall TParser(TStream Stream, TParserErrorEvent AOnError = nil);
```

Description

Call Create to instantiate a TParser (see page 2915) object at runtime.

The file to be parsed is defined by **Stream**. **AOnError** optionally defines an object method to be called when a parsing error is encountered. After this method returns, an Exception is raised anyway.

23.1.41.3 TParser.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TParser();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

23.1.41.4 TParser Methods

The methods of the TParser class are listed here.

Protected Methods

	Name	Description
	GetLinePos (see page 2921)	This is GetLinePos, a member of class TParser.

Public Methods

	Name	Description
	CheckToken (see page 2919)	Checks if the current token in the file is a specific type.
	CheckTokenSymbol (see page 2919)	Checks if the current token in the file is a symbol with a specific value.
	Error (see page 2920)	Raise an EParseError error.
	ErrorFmt (see page 2920)	Raise an EParseError error with a specified error message.
	ErrorStr (see page 2921)	Raise an EParseError error with a specific message.
	HexToBinary (see page 2921)	Converts a sequence of hex values into binary.
	NextToken (see page 2922)	Moves to the next token in the file.
	SourcePos (see page 2922)	Returns the position in the file being parsed.
	TokenComponentIdent (see page 2923)	Checks if the current token in the file is a valid component symbol.
	TokenFloat (see page 2923)	Returns a toFloat (see page 3322) token as a float.
	TokenInt (see page 2923)	Returns a toInteger (see page 3322) token as a float.
	TokenString (see page 2924)	Returns a string representation of the current token.
	TokenSymbolIs (see page 2924)	Checks if the next token in the file is a symbol with a specific value.
	TokenWideString (see page 2925)	Returns a toWString (see page 3324) token as a wide string value.

23.1.41.4.1 TParser.CheckToken Method

Checks if the current token in the file is a specific type.

Pascal

```
procedure CheckToken(T: Char);
```

C++

```
__fastcall CheckToken(Char T);
```

Description

Call CheckToken to check if the current token in the file is a specific type. If the token is not the specified type, then the EParseError exception is raised, otherwise, processing continues. You can respond to this error by specifying the OnError (see page 2927) event.

You pass the token type in the **T** value, passing one of the following values :

T value	Meaning
toEOF (see page 3321)	End of file has been reached
toFloat (see page 3322)	The next token is a floating (decimal) pointing value
toInteger (see page 3322)	The next token is an integer value
toString (see page 3323)	The next token is a text value
toSymbol (see page 3324)	The next token is a symbol
toWString (see page 3324)	The next token is a wide string value

See Also

CheckTokenSymbol (see page 2919)

EParseError

OnError

toEOF (see page 3321)

toFloat (see page 3322)

toInteger (see page 3322)

toString (see page 3323)

toSymbol (see page 3324)

toWString (see page 3324)

23.1.41.4.2 TParser.CheckTokenSymbol Method

Checks if the current token in the file is a symbol with a specific value.

Pascal

```
procedure CheckTokenSymbol(const S: string);
```

C++

```
__fastcall CheckTokenSymbol(const AnsiString S);
```

Description

Call CheckTokenSymbol to check if the current token in the file is symbol named **S**. If the token is not a symbol, or not a symbol with the specified value, then the EParseError exception is raised, otherwise, processing continues. You can respond to this error by specifying the OnError (see page 2927) event.

Note: Use TokenSymbolIs (see page 2924) if you want to perform this check without raising an exception

See Also

CheckToken (see page 2919)

EParseError

OnError

TokenSymbolIs (see page 2924)

toSymbol (see page 3324)

23.1.41.4.3 TParser.Error Method

Raise an EParseError error.

Pascal

```
procedure Error(const Ident: string);
```

C++

```
__fastcall Error(const AnsiString Ident);
```

Description

Call Error to force the raising of an EParseError exception. Use this to simulate an error encountered in the parsing of a file.

See Also

EParseError

ErrorFmt

ErrorStr

OnError

23.1.41.4.4 TParser.ErrorFmt Method

Raise an EParseError error with a specified error message.

Pascal

```
procedure ErrorFmt(const Ident: string; const Args: array of const);
```

C++

```
__fastcall ErrorFmt(const AnsiString Ident, const array of const Args);
```

Description

Call ErrorFmt to force the raising of an EParseError exception. **Ident** specifies the exception error message string. **Args** specify an array of constants that can be incorporated into the error message string - the Format routine is called to replace placeholder characters in the error message string with these values.

Use this to simulate an error encountered in the parsing of a file.

See Also

EParseError

ErrorFmt

ErrorStr

Format (see page 22897)

OnError

23.1.41.4.5 TParser.ErrorStr Method

Raise an EParseError error with a specific message.

Pascal

```
procedure ErrorStr(const Message: string);
```

C++

```
__fastcall ErrorStr(const AnsiString Message);
```

Description

Call ErrorStr to force the raising of an EParseError exception with an error message specified by **S**.

Use this to simulate an error encountered in the parsing of a file.

See Also

EParseError

Error

ErrorFmt

OnError

23.1.41.4.6 TParser.GetLinePos Method

Pascal

```
function GetLinePos: Integer;
```

C++

```
__fastcall int GetLinePos();
```

Description

This is GetLinePos, a member of class TParser.

23.1.41.4.7 TParser.HexToBinary Method

Converts a sequence of hex values into binary.

Pascal

```
procedure HexToBinary(Stream: TStream);
```

C++

```
__fastcall HexToBinary(TStream Stream);
```

Description

Call HexToBinary to convert a hex string value in a file to its binary equivalent. **Stream** specifies a writeable stream for the binary values to be written to.

It is principally used internally by TParser (see page 2915)

23.1.41.4.8 TParser.NextToken Method

Moves to the next token in the file.

Pascal

```
function NextToken: Char;
```

C++

```
__fastcall Char NextToken();
```

Description

Call NextToken to move to the next token in the file being parsed. This is normally called in a loop as the file is parsed, terminating when toEOF (see page 3321) is encountered. Use Token (see page 2926) to retrieve the type of the current token.

See Also

toEOF (see page 3321)

Token (see page 2926)

TokenFloat

TokenInt

TokenString

TokenSymbolIs

TokenSymbol

23.1.41.4.9 TParser.SourcePos Method

Returns the position in the file being parsed.

Pascal

```
function SourcePos: Longint;
```

C++

```
__fastcall Longint SourcePos();
```

Description

Call SourcePos to get the character position in the file being parsed..

See Also

LinePos (see page 2926)

SourceLine (see page 2926)

23.1.41.4.10 TParser.TokenComponentIdent Method

Checks if the current token in the file is a valid component symbol.

Pascal

```
function TokenComponentIdent: string;
```

C++

```
__fastcall AnsiString TokenComponentIdent();
```

Description

Call TokenComponentIdent to check if the current token in the file is symbol that legitimately represents a component. Namely, that it must start with a letter or number, and only contain alphanumeric and underscore characters. If it is valid, the string value of the token is returned. If not, a EParseError exception is raised.

See Also

EParseError

OnError

toSymbol (see page 3324)

23.1.41.4.11 TParser.TokenFloat Method

Returns a toFloat (see page 3322) token as a float.

Pascal

```
function TokenFloat: Extended;
```

C++

```
__fastcall Extended TokenFloat();
```

Description

Call TokenFloat to retrieve the current token value as a floating point number value. An exception will be raised of the token string value fails to convert to a floating point value.

See Also

EParseError

toFloat (see page 3322)

TokenInt (see page 2923)

TokenString (see page 2924)

TokenWideString (see page 2925)

23.1.41.4.12 TParser.TokenInt Method

Returns a toInteger (see page 3322) token as a float.

Pascal

```
function TokenInt: Int64;
```

C++

```
__fastcall Int64 TokenInt();
```

Description

Call TokenInt to retrieve the current token value as an integer number value. An exception will be raised of the token string value fails to convert to an integer value.

See Also

EParseError

TokenFloat (see page 2923)

TokenString (see page 2924)

TokenWideString (see page 2925)

toInteger (see page 3322)

23.1.41.4.13 TParser.TokenString Method

Returns a string representation of the current token.

Pascal

```
function TokenString: string;
```

C++

```
__fastcall AnsiString TokenString();
```

Description

Call TokenString to retrieve the current token value as a string, regardless of its type.

See Also

EParseError

TokenFloat (see page 2923)

TokenInt (see page 2923)

TokenWideString (see page 2925)

23.1.41.4.14 TParser.TokenSymbolIs Method

Checks if the next token in the file is a symbol with a specific value.

Pascal

```
function TokenSymbolIs(const S: string): Boolean;
```

C++

```
__fastcall Boolean TokenSymbolIs(const AnsiString S);
```

Description

Call TokenSymbolIs to check if the current token in the file is symbol named **S**. If the token is not a symbol, or not a symbol with the specified value, then false is returned, otherwise, true is returned.

See Also

CheckToken (see page 2919)

CheckTokenSymbol (see page 2919)

toSymbol (see page 3324)

23.1.41.4.15 TParser.TokenWideString Method

Returns a toWString (see page 3324) token as a wide string value.

Pascal

```
function TokenWideString: WideString;
```

C++

```
__fastcall BSTR TokenWideString();
```

Description

Call TokenWideString to retrieve the current token value as a wide string value.

See Also

EParseError

TokenFloat (see page 2923)

TokenInt (see page 2923)

TokenString (see page 2924)

toWString (see page 3324)

23.1.41.5 TParser Properties

The properties of the TParser class are listed here.

Public Properties

	Name	Description
R	FloatType (see page 2925)	Gives the type of floating pointer number.
R	LinePos (see page 2926)	Gives the position in the line currently being parsed.
R	SourceLine (see page 2926)	Gives the number of the line currently being parsed.
R	Token (see page 2926)	Gives the type of token at the current file position.

23.1.41.5.1 TParser.FloatType Property

Gives the type of floating pointer number.

Pascal

```
property FloatType: Char;
```

C++

```
__property Char FloatType;
```

Description

This read only property gives the type of floating point number for the current token. If the file value read for this token ends in one of : 'c', 'C', 'd', 'D', 's', 'S', then this is the value returned. Otherwise, #0 is returned.

See Also

TokenFloat (see page 2923)

toFloat (see page 3322)

23.1.41.5.2 TParser.LinePos Property

Gives the position in the line currently being parsed.

Pascal

```
property LinePos: Integer;
```

C++

```
__property int LinePos;
```

Description

This read only property gives the character position in the current line being parsed. The position in the file is determined by the NextToken (see page 2922) method.

See Also

NextToken (see page 2922)

SourceLine (see page 2926)

SourcePos (see page 2922)

23.1.41.5.3 TParser.SourceLine Property

Gives the number of the line currently being parsed.

Pascal

```
property SourceLine: Integer;
```

C++

```
__property int SourceLine;
```

Description

This read only property gives the line number of the current line being parsed. Lines start at 0. The position in the file is determined by the NextToken (see page 2922) method.

See Also

LinePos (see page 2926)

NextToken (see page 2922)

SourcePos (see page 2922)

23.1.41.5.4 TParser.Token Property

Gives the type of token at the current file position.

Pascal

```
property Token: Char;
```

C++

```
__property Char Token;
```

Description

Token is a read only property that describes the type of token at current file parse position. The NextToken (see page 2922) method is used to navigate through the file tokens. Token can then be used to determine what to do with each token

encountered.

The token character can have one of the following values :

Value	Meaning
toEOF (see page 3321)	End of file has been reached
toFloat (see page 3322)	The next token is a floating (decimal) pointing value
toInteger (see page 3322)	The next token is an integer value
toString (see page 3323)	The next token is a text value
toSymbol (see page 3324)	The next token is a symbol
toWString (see page 3324)	The next token is a wide string value

See Also

NextToken (see page 2922)

toEOF (see page 3321)

toFloat (see page 3322)

toInteger (see page 3322)

toString (see page 3323)

toSymbol (see page 3324)

toWString (see page 3324)

23.1.41.6 TParser Events

The events of the TParser class are listed here.

Public Events

	Name	Description
	OnError (see page 2927)	Occurs when a parse error is encountered.

23.1.41.6.1 TParser.OnError Event

Occurs when a parse error is encountered.

Pascal

```
property OnError: TParserErrorEvent;
```

C++

```
__property TParserErrorEvent OnError;
```

Description

OnError is used internally by TParser (see page 2915) to report errors.

See Also

TParseErrorEvent

23.1.42 TPersistent Class

TPersistent is the ancestor for all objects that have assignment and streaming capabilities.

Class Hierarchy

Pascal

```
TPersistent = class(TObject);
```

C++

```
class TPersistent : public TObject;
```

File

Classes

Description

TPersistent encapsulates the behavior common to all objects that can be assigned to other objects, and that can read and write their properties to and from a form file (.xfm or .dfm file). For this purpose TPersistent introduces methods that can be overridden to:

Define the procedure for loading and storing unpublished data to a stream.

Provide the means to assign values to properties.

Provide the means to assign the contents of one object to another.

Do not create instances of TPersistent. Use TPersistent as a base class when declaring objects that are not components, but that need to be saved to a stream or have their properties assigned to other objects.

See Also

TComponent (see page 2762)

TFiler (see page 2834)

TReader (see page 2933)

TStream (see page 2973)

TWriter (see page 3175)

TPersistent Branch

23.1.42.1 TPersistent Members

The following tables list the members exposed by TPersistent.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

23.1.42.2 TPersistent.Destroy Destructor

Destroys the TPersistent (see page 2928) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TPersistent();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Destroy (see page 22287)

23.1.42.3 TPersistent Methods

The methods of the TPersistent class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Public Methods

	Name	Description
	Assign (see page 2930)	Copies the contents of another, similar object.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.

23.1.42.3.1 TPersistent.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); virtual;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent (see page 2928) calls the source object's AssignTo (see page 2931) method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

See Also

AssignTo (see page 2931)

EConvertError (see page 22724)

23.1.42.3.2 TPersistent.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); virtual;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign (see page 2930) method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign (see page 2930) method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign (see page 2930) method of TPersistent (see page 2928) calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent (see page 2928) raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent (see page 2928) version of Assign (see page 2930), which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent (see page 2928) raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

23.1.42.3.3 TPersistent.DefineProperties Method

Provides an interface for a method that reads and writes otherwise unpublished data.

Pascal

```
procedure DefineProperties(Filer: TFiler); virtual;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

Descendants of TPersistent (see page 2928) override DefineProperties to designate a method for storing the object's unpublished data to a stream such as a form file. By default, writing an object to a stream writes the values of all its published properties, and reading the object in reads those values and assigns them to the properties. Objects can also specify methods

that read and write data other than published properties by overriding the DefineProperties method.

When overriding DefineProperties, consider including some or all of the following:

A call to the inherited method

Calls to the filer object's DefineProperty method

Calls to the filer object's DefineBinaryProperty method

DefineProperties is virtual, so descendant classes can override it as necessary but are not required to do so.

See Also

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

23.1.42.3.4 TPersistent.GetNamePath Method

Returns the name of the object as it appears in the Object Inspector.

Pascal

```
function GetNamePath: string; dynamic;
```

C++

```
__fastcall AnsiString GetNamePath();
```

Description

GetNamePath is for internal use only. It determines the text that the Object Inspector displays for the name of the object being edited. GetNamePath is introduced in TPersistent (see page 2928) so descendants such as collections can appear in the Object Inspector. Do not call GetNamePath directly.

For components, GetNamePath returns the component name. For TCollectionItem (see page 2755) objects it returns the name of the hosting component, the name of the property, and the index into the collection surrounded by brackets.

See Also

GetOwner (see page 2932)

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

23.1.42.3.5 TPersistent.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; dynamic;
```

C++

```
__fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath (see page 2932) method to find the owner of a persistent object. GetNamePath (see page 2932) and GetOwner are introduced in TPersistent (see page 2928) so descendants such as collections can appear

in the Object Inspector. As implemented in TPersistent (see page 2928), GetOwner returns nil (Delphi) or NULL (C++).

For TCollection (see page 2731), GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent (see page 2762) it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

23.1.43 TReader Class

TReader is a specialized filer that reads component data from an associated stream.

Class Hierarchy

Pascal

```
TReader = class(TFiler);
```

C++

```
class TReader : public TFiler;
```

File

Classes

Description

TReader is used internally by the component streaming system to restore the state of a component that has been written to a stream. It handles the mechanics of reading the data associated with a component from the stream. The reader object, rather than the stream object, is responsible for handling the complexities of streaming components. These include methods for:

Creating component instances from class names read from the stream.

Assigning stream data to published component properties.

Enabling an object to store hidden or complex data as if they were published properties of the object.

Resolving references between components, such as when a property refers to another component.

Other methods and properties of TReader trigger the reader object's events and interaction with the stream.

Applications do not directly create reader objects. Readers are automatically created in a stream object's methods or in global routines that initiate the component streaming process. These include:

the global routine ObjectBinaryToText (see page 3235) procedure, which directly creates a reader object.

the global ReadComponentResFile (see page 3247) function, which creates a file stream that creates a reader object.

the ReadComponent (see page 2945) method of a stream object, which creates a reader object.

Once the streaming process is underway applications do not need to directly manipulate reader objects. The interaction between the reader, component, and stream objects happens automatically in methods of these objects that make calls to each other.

TComponent (see page 2762)

TStream (see page 2973)

TWriter (see page 3175)

Using Streams to Read or Write Data

23.1.43.1 TReader Members

The following tables list the members exposed by TReader.

Protected Methods

	Name	Description
V	Error (see page 2942)	This is Error, a member of class TReader.
V	FindAncestorComponent (see page 2942)	This is FindAncestorComponent, a member of class TReader.
V	FindMethod (see page 2942)	This is FindMethod, a member of class TReader.
V	FindMethodInstance (see page 2942)	This is FindMethodInstance, a member of class TReader.
	PropertyError (see page 2944)	This is PropertyError, a member of class TReader.
	ReadData (see page 2947)	This is ReadData, a member of class TReader.
	ReadProperty (see page 2951)	This is ReadProperty, a member of class TReader.
	ReadPropValue (see page 2952)	This is ReadPropValue, a member of class TReader.
	ReadSet (see page 2952)	This is ReadSet, a member of class TReader.
V	ReferenceName (see page 2956)	This is ReferenceName, a member of class TReader.
V	SetName (see page 2956)	This is SetName, a member of class TReader.
	SetPosition (see page 2957)	This is SetPosition, a member of class TReader.
V	SetRoot (see page 2838)	This is SetRoot, a member of class TFiler.
	SkipBytes (see page 2957)	This is SkipBytes, a member of class TReader.
	SkipComponent (see page 2957)	This is SkipComponent, a member of class TReader.
	SkipProperty (see page 2957)	This is SkipProperty, a member of class TReader.
	SkipSetBody (see page 2958)	This is SkipSetBody, a member of class TReader.

Protected Properties

	Name	Description
R	CanHandleExceptions (see page 2958)	This is CanHandleExceptions, a member of class TReader.
R	PropName (see page 2960)	This is PropName, a member of class TReader.

Public Events

	Name	Description
	OnAncestorNotFound (see page 2961)	Occurs when the object from which a streamed object is derived cannot be found.
	OnCreateComponent (see page 2961)	Occurs when the reader has read a component's class but has not yet instantiated the component.
	OnError (see page 2961)	Occurs when a reader object encounters an error reading its data, such as reading the name of an undeclared property or an illegal value.
	OnFindComponentClass (see page 2962)	Occurs when a reader first reads the name of a component class.
	OnFindComponentInstance (see page 2962)	This is OnFindComponentInstance, a member of class TReader.
	OnFindMethod (see page 2962)	Occurs each time the reader object reads an event, which is a method-pointer property, for an object.
	OnFindMethodInstance (see page 2963)	This is OnFindMethodInstance, a member of class TReader.
	OnReferenceName (see page 2963)	Occurs when resolving references to other objects such as when one object is the property value of another.

	OnSetName (see page 2963)	Occurs just before the reader object sets the Name property of a component it reads from its stream.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginReferences (see page 2938)	Starts a block of commands that read components that might contain references to other components.
	CheckValue (see page 2939)	Checks that the next value to be read from the stream is of a specified type.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyValue (see page 2939)	Copies data while reading components.
	Create (see page 2836)	Creates a filer object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefineBinaryProperty (see page 2939)	Defines binary data the reader object reads as if the data were a published property.
	DefineProperty (see page 2940)	Defines data the reader object reads as if it were a published property.
	Destroy (see page 2936)	Moves the current position of the stream back to the beginning before calling the inherited destructor.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndOfList (see page 2941)	Indicates the end of a group of items that are sequentially read from the stream.
	EndReferences (see page 2941)	Terminates a block of code that reads components from the reader object's stream that might contain references to each other.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupReferences (see page 2942)	Resolves references when streaming properties that are represented by another component.
	FlushBuffer (see page 2943)	Synchronizes the reader's buffer with its stream's buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NextValue (see page 2943)	Returns the type of the next item in the reader object's stream without moving the position of the stream.
	Read (see page 2944)	Reads data from the associated stream.
	ReadBoolean (see page 2944)	Reads a boolean from the reader object's stream and returns that boolean value.
	ReadChar (see page 2945)	Reads a character from the reader object's stream and returns that character value.
	ReadCollection (see page 2945)	Reads a collection from the reader object's stream and returns that character value.

	ReadComponent (see page 2945)	Reads the component specified by Instance from the stream and returns the component.
	ReadComponents (see page 2946)	Reads a list of owned components from the reader object's associated stream.
	ReadCurrency (see page 2946)	Reads a Currency value from the reader object's stream and returns its value.
	ReadDate (see page 2947)	Reads a TDateTime value from the reader object's stream and returns its value.
	ReadDouble (see page 2947)	Reads a double type floating point number from the reader object's stream and returns its value.
	ReadFloat (see page 2948)	Reads a floating-point number from the reader object's stream and returns its value.
	ReadIdent (see page 2948)	Reads an identifier from the reader object's stream and returns the identifier.
	ReadInt64 (see page 2949)	Reads an 64-bit integer from the reader object's stream and returns its value.
	ReadInteger (see page 2949)	Reads an integer-type number from the reader object's stream and returns its value.
	ReadListBegin (see page 2950)	Reads a start-of-list marker from the reader object's associated stream.
	ReadListEnd (see page 2950)	Reads an end-of-list marker from the reader object's associated stream.
V	ReadPrefix (see page 2951)	Reads preliminary information concerning form inheritance for a component.
	ReadRootComponent (see page 2952)	Reads a component and all its owned components from the reader object's stream.
	ReadSignature (see page 2953)	Reads the filer signature from the reader object's associated stream.
	ReadSingle (see page 2953)	Reads a float value from the reader object's stream and returns its value.
	ReadStr (see page 2953)	Reads one character from the reader object's stream and returns its contents.
	ReadString (see page 2954)	Reads a tagged string value written by WriteString from the reader object's stream and returns its contents.
	ReadValue (see page 2954)	Reads the type of the next item on the reader object's stream and returns with the stream positioned after the value-type indicator.
	ReadVariant (see page 2955)	Reads a Variant value from the reader object's stream and returns its value.
	ReadWideChar (see page 2955)	Reads a wide character from the reader object's stream and returns that character value.
	ReadWideString (see page 2956)	Reads a tagged wide string value from the reader object's stream and returns its contents.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SkipValue (see page 2958)	Skips the next value read from the stream.

Public Properties

	Name	Description
	Ancestor (see page 2839)	Determines whether to write the properties of inherited components.
	IgnoreChildren (see page 2839)	Enables a writer object to save a component without saving the components it owns.
R	LookupRoot (see page 2840)	Specifies the root component for resolving names while loading and saving components.
	Owner (see page 2959)	Stores the component that is assigned as the Owner property of components read from the reader object's stream.
	Parent (see page 2959)	Stores the component that is assigned as the Parent property of controls read from the reader's stream.
	Position (see page 2960)	Represents the current reading position in the associated stream.
	Root (see page 2840)	Indicates which object is the root, or ultimate owner, of the objects read or written by the filer.

23.1.43.2 TReader.Destroy Destructor

Moves the current position of the stream back to the beginning before calling the inherited destructor.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TReader();
```

Description

Do not call Destroy directly. Reader objects are created indirectly through the methods or routines that use them. These methods and routines handle freeing the TReader (see page 2933) object.

See Also

Free (see page 22300)

23.1.43.3 TReader Methods

The methods of the TReader class are listed here.

Protected Methods

	Name	Description
	Error (see page 2942)	This is Error, a member of class TReader.
	FindAncestorComponent (see page 2942)	This is FindAncestorComponent, a member of class TReader.
	FindMethod (see page 2942)	This is FindMethod, a member of class TReader.
	FindMethodInstance (see page 2942)	This is FindMethodInstance, a member of class TReader.
	PropertyError (see page 2944)	This is PropertyError, a member of class TReader.
	ReadData (see page 2947)	This is ReadData, a member of class TReader.
	ReadProperty (see page 2951)	This is ReadProperty, a member of class TReader.
	ReadPropValue (see page 2952)	This is ReadPropValue, a member of class TReader.
	ReadSet (see page 2952)	This is ReadSet, a member of class TReader.
	ReferenceName (see page 2956)	This is ReferenceName, a member of class TReader.
	SetName (see page 2956)	This is SetName, a member of class TReader.
	SetPosition (see page 2957)	This is SetPosition, a member of class TReader.
	SkipBytes (see page 2957)	This is SkipBytes, a member of class TReader.
	SkipComponent (see page 2957)	This is SkipComponent, a member of class TReader.
	SkipProperty (see page 2957)	This is SkipProperty, a member of class TReader.
	SkipSetBody (see page 2958)	This is SkipSetBody, a member of class TReader.

Public Methods

	Name	Description
	BeginReferences (see page 2938)	Starts a block of commands that read components that might contain references to other components.
	CheckValue (see page 2939)	Checks that the next value to be read from the stream is of a specified type.
	CopyValue (see page 2939)	Copies data while reading components.
	DefineBinaryProperty (see page 2939)	Defines binary data the reader object reads as if the data were a published property.
	DefineProperty (see page 2940)	Defines data the reader object reads as if it were a published property.
	EndOfList (see page 2941)	Indicates the end of a group of items that are sequentially read from the stream.
	EndReferences (see page 2941)	Terminates a block of code that reads components from the reader object's stream that might contain references to each other.
	FixupReferences (see page 2942)	Resolves references when streaming properties that are represented by another component.
	FlushBuffer (see page 2943)	Synchronizes the reader's buffer with its stream's buffer.
	NextValue (see page 2943)	Returns the type of the next item in the reader object's stream without moving the position of the stream.
	Read (see page 2944)	Reads data from the associated stream.
	ReadBoolean (see page 2944)	Reads a boolean from the reader object's stream and returns that boolean value.
	ReadChar (see page 2945)	Reads a character from the reader object's stream and returns that character value.
	ReadCollection (see page 2945)	Reads a collection from the reader object's stream and returns that character value.
	ReadComponent (see page 2945)	Reads the component specified by Instance from the stream and returns the component.

	ReadComponents (see page 2946)	Reads a list of owned components from the reader object's associated stream.
	ReadCurrency (see page 2946)	Reads a Currency value from the reader object's stream and returns its value.
	ReadDate (see page 2947)	Reads a TDateTime value from the reader object's stream and returns its value.
	ReadDouble (see page 2947)	Reads a double type floating point number from the reader object's stream and returns its value.
	ReadFloat (see page 2948)	Reads a floating-point number from the reader object's stream and returns its value.
	ReadIdent (see page 2948)	Reads an identifier from the reader object's stream and returns the identifier.
	ReadInt64 (see page 2949)	Reads an 64-bit integer from the reader object's stream and returns its value.
	ReadInteger (see page 2949)	Reads an integer-type number from the reader object's stream and returns its value.
	ReadListBegin (see page 2950)	Reads a start-of-list marker from the reader object's associated stream.
	ReadListEnd (see page 2950)	Reads an end-of-list marker from the reader object's associated stream.
V	ReadPrefix (see page 2951)	Reads preliminary information concerning form inheritance for a component.
	ReadRootComponent (see page 2952)	Reads a component and all its owned components from the reader object's stream.
	ReadSignature (see page 2953)	Reads the filer signature from the reader object's associated stream.
	ReadSingle (see page 2953)	Reads a float value from the reader object's stream and returns its value.
	ReadStr (see page 2953)	Reads one character from the reader object's stream and returns its contents.
	ReadString (see page 2954)	Reads a tagged string value written by WriteString from the reader object's stream and returns its contents.
	ReadValue (see page 2954)	Reads the type of the next item on the reader object's stream and returns with the stream positioned after the value-type indicator.
	ReadVariant (see page 2955)	Reads a Variant value from the reader object's stream and returns its value.
	ReadWideChar (see page 2955)	Reads a wide character from the reader object's stream and returns that character value.
	ReadWideString (see page 2956)	Reads a tagged wide string value from the reader object's stream and returns its contents.
	SkipValue (see page 2958)	Skips the next value read from the stream.

23.1.43.3.1 TReader.BeginReferences Method

Starts a block of commands that read components that might contain references to other components.

Pascal

```
procedure BeginReferences;
```

C++

```
__fastcall BeginReferences();
```

Description

Do not call BeginReferences directly. BeginReferences is used internally for streaming properties that reference other components.

Following the call to BeginReferences, the reader object creates a list of all the objects read and their names. After all of the interdependent objects are read, FixupReferences (see page 2942) is called to resolve the named references from the stream into instance references. Finally, call EndReferences (see page 2941) to dispose of the fixup list.

BeginReferences is always used together with FixupReferences (see page 2942) and EndReferences (see page 2941) in a try...finally (Delphi) or try...__finally (C++) block.

See Also

EndReferences (see page 2941)

FixupReferences (see page 2942)

23.1.43.3.2 TReader.CheckValue Method

Checks that the next value to be read from the stream is of a specified type.

Pascal

```
procedure CheckValue(Value: TValueType);
```

C++

```
__fastcall CheckValue(TValueType Value);
```

Description

CheckValue ascertains that the next value to be read from the stream is of the type specified by Value. If it is not, CheckValue skips over that value, positioning the stream on the following value, and raises an EReadError (see page 2703) exception.

See Also

EReadError (see page 2703)

Position (see page 2960)

23.1.43.3.3 TReader.CopyValue Method

Copies data while reading components.

Pascal

```
procedure CopyValue(Writer: TWriter);
```

C++

```
__fastcall CopyValue(TWriter Writer);
```

Description

Do not call CopyValue, it is used internally.

23.1.43.3.4 TReader.DefineBinaryProperty Method

Defines binary data the reader object reads as if the data were a published property.

Pascal

```
procedure DefineBinaryProperty(const Name: string; ReadData: TStreamProc; WriteData:
TStreamProc; HasData: Boolean); override;
```

C++

```
virtual __fastcall DefineBinaryProperty(const AnsiString Name, TStreamProc ReadData,
TStreamProc WriteData, Boolean HasData);
```

Description

DefineBinaryProperty is called internally by the DefineProperties method of an object that has data it needs to store. Applications can call DefineBinaryProperty directly when overriding the DefineProperties method of a component with large custom data (like a bitmap). This is the only context in which DefineBinaryProperty (or DefineProperty (see page 2940)) should be used.

DefineProperties takes a generic filer object as its parameter. For reading binary data, DefineProperties takes a TReader (see page 2933) object and calls its DefineBinaryProperty method. DefineBinaryProperty then reads the property's name data and passes the data to the indicated ReadData (see page 2947) method.

The Name parameter specifies the name of the "fake" property to be read from the stream. A "fake" property is a property that is not published, and that exists only in the code for the DefineBinaryProperty method. The Top and Left properties of a non-visual

component are examples of "fake" properties. These are also called "defined properties" or "custom defined properties."

The ReadData (see page 2947) and WriteData parameters point to a procedure (defined in the component object) that reads or writes a binary representation of the object's data directly to or from the stream passed to them in the Stream parameter. For TReader (see page 2933) the WriteData parameter is ignored.

The HasData parameter determines at run time whether the "fake" property has data to store (write). For TReader (see page 2933) the HasData parameter is ignored.

Defined binary properties are rare. More commonly, objects use the DefineProperty (see page 2940) method. The difference between DefineBinaryProperty and DefineProperty (see page 2940) is that when using DefineBinaryProperty, the component reads the binary property directly from a memory stream, rather than going through the filer object. Binary data is also harder to edit as text.

Note: Streamable objects that are descended from TPersistent (see page 2928) inherit a DefineProperties method, however DefineProperties does nothing until TComponent (see page 2762). Therefore, it is a component's DefineProperties method that calls the reader's DefineBinaryProperty when reading binary data.

See Also

DefineProperty (see page 2940)

DefineProperties (see page 2771)

23.1.43.3.5 TReader.DefineProperty Method

Defines data the reader object reads as if it were a published property.

Pascal

```
procedure DefineProperty(const Name: string; ReadData: TReaderProc; WriteData: TWriterProc;
HasData: Boolean); override;
```

C++

```
virtual __fastcall DefineProperty(const AnsiString Name, TReaderProc ReadData, TWriterProc
WriteData, Boolean HasData);
```

Description

DefineProperty is called internally by the DefineProperties method of an object that has data it needs to store. DefineProperties takes a generic filer object as its parameter. For reading data DefineProperties takes a TReader (see page 2933) object and then calls the DefineProperties method of the reader object. DefineProperty then reads the property's name and its data.

The Name parameter specifies the name of the "fake" property to be read from the stream.

The ReadData (see page 2947) parameter points to a procedure (defined in the storing object) that reads the object's data which represents a property value to the reader object. For TReader (see page 2933) the WriteData parameter is ignored.

The HasData parameter determines at run time whether the "fake" property has data to store (write). For TReader (see page 2933) the HasData parameter is ignored.

The difference between DefineBinaryProperty (see page 2939) and DefineProperty is that the binary property is read directly from a stream, rather than going through a filer object, and binary data is harder to edit as text.

See Also

Ancestor (see page 2839)

DefineBinaryProperty (see page 2939)

DefineProperties (see page 2771)

23.1.43.3.6 TReader.EndOfList Method

Indicates the end of a group of items that are sequentially read from the stream.

Pascal

```
function EndOfList: Boolean;
```

C++

```
__fastcall Boolean EndOfList();
```

Description

EndOfList is used by other methods that iterate through a list of items when reading in data. It checks for a value type that signals the end of that type of data. EndOfList returns true if the reader object has read to the end of a list of items.

When reading a list of items, the reader object calls ReadListBegin (see page 2950) method, then the items are repeatedly read until EndOfList returns true. Finally, the reader calls ReadListEnd (see page 2950).

Note: Component writers can use this in their defined property ReadData (see page 2947) methods, as, for example, with TStrings (see page 3029).

See Also

ReadListBegin (see page 2950)

ReadListEnd (see page 2950)

DefineProperty (see page 2838)

23.1.43.3.7 TReader.EndReferences Method

Terminates a block of code that reads components from the reader object's stream that might contain references to each other.

Pascal

```
procedure EndReferences;
```

C++

```
__fastcall EndReferences();
```

Description

EndReferences is used for streaming properties that reference another component. Programmers should not need to call EndReferences directly.

The reader object calls EndReferences and creates a list of all the objects read and their names. After all the interdependent objects are read, FixupReferences (see page 2942) is called to resolve the named references from the stream into instance references. Finally, call EndReferences to dispose of the fixup list.

EndReferences is always used in the finally part of a try...finally (Delphi) or try...__finally (C++) block that also includes calls to BeginReferences (see page 2938) and FixupReferences (see page 2942).

See Also

BeginReferences (see page 2938)

FixupReferences (see page 2942)

23.1.43.3.8 TReader.Error Method

Pascal

```
function Error(const Message: string): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Error(const AnsiString Message);
```

Description

This is Error, a member of class TReader.

23.1.43.3.9 TReader.FindAncestorComponent Method

Pascal

```
function FindAncestorComponent(const Name: string; ComponentClass: TPersistentClass):
TComponent; virtual;
```

C++

```
virtual __fastcall TComponent * FindAncestorComponent(const AnsiString Name, TPersistentClass
ComponentClass);
```

Description

This is FindAncestorComponent, a member of class TReader.

23.1.43.3.10 TReader.FindMethod Method

Pascal

```
function FindMethod(Root: TComponent; const MethodName: string): Pointer; virtual;
```

C++

```
virtual __fastcall void * FindMethod(TComponent * Root, const AnsiString MethodName);
```

Description

This is FindMethod, a member of class TReader.

23.1.43.3.11 TReader.FindMethodInstance Method

Pascal

```
function FindMethodInstance(Root: TComponent; const MethodName: string): TMethod; virtual;
```

C++

```
virtual __fastcall TMethod FindMethodInstance(TComponent * Root, const AnsiString MethodName);
```

Description

This is FindMethodInstance, a member of class TReader.

23.1.43.3.12 TReader.FixupReferences Method

Resolves references when streaming properties that are represented by another component.

Pascal

```
procedure FixupReferences;
```

C++

```
__fastcall FixupReferences();
```

Description

FixupReferences is used internally by the streaming system to resolve the named references from the stream into instance references. Users would never need to call this method.

The reader object calls BeginReferences (see page 2938) and creates a list of all the objects read and their names. After all the interdependent objects are read, FixupReferences is called to resolve the references among various mutually dependent components read from the reader object's stream after all of the objects have been read. Finally, call EndReferences (see page 2941) to dispose of the fixup list.

FixupReferences is always used inside a try...finally (Delphi) or try...__finally (C++) block between calls to BeginReferences (see page 2938) and EndReferences (see page 2941).

See Also

BeginReferences (see page 2938)

EndReferences (see page 2941)

23.1.43.3.13 TReader.FlushBuffer Method

Synchronizes the reader's buffer with its stream's buffer.

Pascal

```
procedure FlushBuffer; override;
```

C++

```
virtual __fastcall FlushBuffer();
```

Description

FlushBuffer synchronizes the reader's buffer with the associated stream by setting the stream's Position (see page 2960) to match the reader's Position (see page 2960).

See Also

BeginReferences (see page 2938)

EndReferences (see page 2941)

23.1.43.3.14 TReader.NextValue Method

Returns the type of the next item in the reader object's stream without moving the position of the stream.

Pascal

```
function NextValue: TValueType;
```

C++

```
__fastcall TValueType NextValue();
```

Description

NextValue is used internally by reader methods to query the type of the next item in the stream. After identifying the type of the next item, NextValue returns with the stream position still before the value-type indicator.

See Also

ReadValue (see page 2954)

23.1.43.3.15 TReader.PropertyError Method

Pascal

```
procedure PropertyError(const Name: string);
```

C++

```
__fastcall PropertyError(const AnsiString Name);
```

Description

This is PropertyError, a member of class TReader.

23.1.43.3.16 TReader.Read Method

Reads data from the associated stream.

Pascal

```
procedure Read(var Buf; Count: Longint);
```

C++

```
__fastcall Read( Buf, Longint Count);
```

Description

Do not call read directly. Read is used internally to read data from the stream. Many other writer methods call Read, usually after setting pertinent values or verifying data types.

See Also

ReadChar (see page 2945)

ReadIdent (see page 2948)

ReadInteger (see page 2949)

ReadStr (see page 2953)

ReadString (see page 2954)

23.1.43.3.17 TReader.ReadBoolean Method

Reads a boolean from the reader object's stream and returns that boolean value.

Pascal

```
function ReadBoolean: Boolean;
```

C++

```
__fastcall Boolean ReadBoolean();
```

Description

ReadBoolean is a helper method used by other reader methods to read a tagged boolean value at the current reader Position (see page 2960). ReadBoolean uses ReadValue (see page 2954) to check the type for a vaTrue value and returns that result. Note that ReadBoolean will not verify that the value being read is a boolean, only whether or not the value is true.

See Also

ReadValue (see page 2954)

TValueType

23.1.43.3.18 TReader.ReadChar Method

Reads a character from the reader object's stream and returns that character value.

Pascal

```
function ReadChar: Char;
```

C++

```
__fastcall Char ReadChar();
```

Description

ReadChar is a helper method used by other reader methods to read a tagged character value at the current reader Position (see page 2960). ReadChar first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaString, ReadString (see page 2954) checks the length. If the length indicates that the value is a char, it calls Read (see page 2944) and returns the character. Otherwise a EReadError (see page 2703) exception is raised.

Note: If the tagged data is a string with length = 1, it is char compatible. If length > 1, it is an error, however, the rest of the string data must be read to keep the reader in a consistent state. Each action that processes tagged data must leave the reader Position (see page 2960) at the start of the next unread tag.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

TValueType

23.1.43.3.19 TReader.ReadCollection Method

Reads a collection from the reader object's stream and returns that character value.

Pascal

```
procedure ReadCollection(Collection: TCollection);
```

C++

```
__fastcall ReadCollection(TCollection Collection);
```

Description

ReadCollection is a helper method used by other reader methods to read a tagged collection value at the current reader Position (see page 2960). ReadCollection iterates through items in a collection so that each item in a collection property has an opportunity to stream out its properties. This method does not write out the number of items and the collection indices, because a user can add or delete items.

23.1.43.3.20 TReader.ReadComponent Method

Reads the component specified by Instance from the stream and returns the component.

Pascal

```
function ReadComponent(Component: TComponent): TComponent;
```

C++

```
__fastcall TComponent * ReadComponent(TComponent * Component);
```

Description

ReadComponent is called by ReadRootComponent (see page 2952) to read each of the components owned by Root (see page 2840). Users would not need to call ReadComponent directly.

ReadComponent handles the loading and initialization process for each component. After loading all the components in the list, ReadComponents (see page 2946) calls the Loaded method of each loaded component in the order it read them. ReadComponent manages the complexities of reading the component from the stream through calls to other reader methods and to the component's methods.

See Also

ReadComponents (see page 2946)

ReadRootComponent (see page 2952)

23.1.43.3.21 TReader.ReadComponents Method

Reads a list of owned components from the reader object's associated stream.

Pascal

```
procedure ReadComponents(AOwner: TComponent; AParent: TComponent; Proc: TReadComponentsProc);
```

C++

```
__fastcall ReadComponents(TComponent * AOwner, TComponent * AParent, TReadComponentsProc Proc);
```

Description

ReadComponents is used internally by the IDE for design-time streaming. Do not call ReadComponents directly.

ReadComponents first sets the reader object's Root (see page 2840) and Owner (see page 2959) properties to the component passed in the AOwner parameter and sets its Parent (see page 2959) property to AParent. Next ReadComponents reads components by calling the ReadComponent (see page 2945) method, passing each returned component to the method passed in Proc.

Note: ReadComponents is used at design-time for clipboard cut and paste of multiple components.

23.1.43.3.22 TReader.ReadCurrency Method

Reads a Currency value from the reader object's stream and returns its value.

Pascal

```
function ReadCurrency: Currency;
```

C++

```
__fastcall Currency ReadCurrency();
```

Description

ReadCurrency is a helper method used by other reader methods to read a tagged Currency data value at the current reader Position (see page 2960). ReadCurrency first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaCurrency ReadCurrency calls Read (see page 2944) and returns the value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

23.1.43.3.23 TReader.ReadData Method

Pascal

```
procedure ReadData(Instance: TComponent);
```

C++

```
__fastcall ReadData(TComponent * Instance);
```

Description

This is ReadData, a member of class TReader.

23.1.43.3.24 TReader.ReadDate Method

Reads a TDateTime value from the reader object's stream and returns its value.

Pascal

```
function ReadDate: TDateTime;
```

C++

```
__fastcall TDateTime ReadDate();
```

Description

ReadDate is a helper method used by other reader methods to read a tagged TDateTime data value at the current reader Position (see page 2960). ReadDate first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaDate ReadDate calls Read (see page 2944) and returns the value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

23.1.43.3.25 TReader.ReadDouble Method

Reads a double type floating point number from the reader object's stream and returns its value.

Pascal

```
function ReadDouble: Double;
```

C++

```
__fastcall Double ReadDouble();
```

Description

ReadDouble is a helper method used by other reader methods to read a tagged double type floating-point data value at the current reader Position (see page 2960). ReadFloat (see page 2948) first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaDouble ReadDouble calls Read (see page 2944) and returns the double value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

23.1.43.3.26 TReader.ReadFloat Method

Reads a floating-point number from the reader object's stream and returns its value.

Pascal

```
function ReadFloat: Extended;
```

C++

```
__fastcall Extended ReadFloat();
```

Description

ReadFloat is a helper method used by other reader methods to read a tagged floating-point data value at the current reader Position (see page 2960). ReadFloat first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaExtended ReadFloat calls Read (see page 2944) and returns the float value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

23.1.43.3.27 TReader.ReadIdent Method

Reads an identifier from the reader object's stream and returns the identifier.

Pascal

```
function ReadIdent: string;
```

C++

```
__fastcall AnsiString ReadIdent();
```

Description

ReadIndent is a helper method used by other reader methods to read an identifying type at the current reader Position (see page 2960). ReadIndent first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is:

A vaIdent type, ReadIndent calls Read (see page 2944) and returns the identifier string value.

A vaFalse type, ReadIdent returns the string 'False.'

A vaTrue type, ReadIdent returns the string 'True.'

A vaNil type, ReadIdent returns the string 'Nil.'

Otherwise it raises an EReadError (see page 2703) exception.

Note: The strings returned for vaFalse, vaTrue, and vaNil correspond to Delphi reserved words.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

ReadValue (see page 2954)

TValueType

23.1.43.3.28 TReader.ReadInt64 Method

Reads an 64-bit integer from the reader object's stream and returns its value.

Pascal

```
function ReadInt64: Int64;
```

C++

```
__fastcall Int64 ReadInt64();
```

Description

ReadInt64 is a helper method used by other reader methods to read a tagged 64-bit integer value at the current reader Position (see page 2960). ReadInt64 first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaInt64, ReadInt64 calls Read (see page 2944) and returns the integer value. Otherwise it calls ReadInteger (see page 2949), in case the value was saved in another integer format.

See Also

Position (see page 2960)

Read (see page 2944)

ReadValue (see page 2954)

TValueType

ReadInteger (see page 2949)

23.1.43.3.29 TReader.ReadInteger Method

Reads an integer-type number from the reader object's stream and returns its value.

Pascal

```
function ReadInteger: Longint;
```

C++

```
__fastcall Longint ReadInteger();
```

Description

ReadInteger is a helper method used by other reader methods to read a tagged integer value at the current reader Position (see page 2960). ReadInteger first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaString or a vaInt8, vaInt16 or vaInt32 type, ReadInteger calls Read (see page 2944) and returns the integer value. Otherwise it raises an EReadError (see page 2703) exception.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

ReadValue (see page 2954)

TValueType

23.1.43.3.30 TReader.ReadListBegin Method

Reads a start-of-list marker from the reader object's associated stream.

Pascal

```
procedure ReadListBegin;
```

C++

```
__fastcall ReadListBegin();
```

Description

ReadListBegin is used by other methods that iterate through a list of items to ensure that the type about to be read is a list. ReadListBegin is also used by component writers in defined property ReadData (see page 2947) methods.

If the next item in the stream is not a start-of list marker as written by the WriteListBegin method, ReadListBegin raises an EReadError (see page 2703) exception.

A call to ReadListBegin is generally followed by a reading loop that terminates when the EndOfList (see page 2941) method returns true, indicating that an end-of-list marker is next on the stream, at which point a call to ReadListEnd (see page 2950) is required.

See Also

EndOfList (see page 2941)

EReadError (see page 2703)

ReadListEnd (see page 2950)

WriteListBegin (see page 3187)

23.1.43.3.31 TReader.ReadListEnd Method

Reads an end-of-list marker from the reader object's associated stream.

Pascal

```
procedure ReadListEnd;
```

C++

```
__fastcall ReadListEnd();
```

Description

ReadListEnd is used by other methods that iterate through a list of items to signal the end of a group of items being read. ReadListEnd is also used by component writers in defined property ReadData (see page 2947) methods.

A call to ReadListEnd is generally preceded by a reading loop that terminates when the EndOfList (see page 2941) method returns true, indicating that an end-of-list marker is next on the stream.

If the item read is not an end-of-list marker, ReadListEnd raises an EReadError (see page 2703) exception. A call to ReadListEnd must correspond to a preceding call to ReadListBegin (see page 2950).

See Also

EndOfList (see page 2941)

EReadError (see page 2703)

ReadListBegin (see page 2950)

WriteListEnd (see page 3187)

23.1.43.3.32 TReader.ReadPrefix Method

Reads preliminary information concerning form inheritance for a component.

Pascal

```
procedure ReadPrefix(var Flags: TFilerFlags; var AChildPos: Integer); virtual;
```

C++

```
virtual __fastcall ReadPrefix(TFilerFlags Flags, int AChildPos);
```

Description

ReadPrefix is used internally by the component streaming system. It is called automatically by ReadComponent (see page 2945) to read flags that determine whether a component in an inherited form (ffInherited), whether its creation order in the form is important (ffChildPos), and whether it is a top-level component such as a form or data module (ffInline). It also reads the component's position in the ancestor form's creation order if the ffChildPos flag is set. When a writer object writes a component to its stream, it prefixes the component with these flags.

See Also

ReadComponent (see page 2945)

23.1.43.3.33 TReader.ReadProperty Method

Pascal

```
procedure ReadProperty(AInstance: TPersistent);
```

C++

```
__fastcall ReadProperty(TPersistent * AInstance);
```

Description

This is ReadProperty, a member of class TReader.

23.1.43.3.34 TReader.ReadPropValue Method

Pascal

```
procedure ReadPropValue(Instance: TPersistent; PropInfo: Pointer);
```

C++

```
__fastcall ReadPropValue(TPersistent * Instance, void * PropInfo);
```

Description

This is ReadPropValue, a member of class TReader.

23.1.43.3.35 TReader.ReadRootComponent Method

Reads a component and all its owned components from the reader object's stream.

Pascal

```
function ReadRootComponent(Root: TComponent): TComponent;
```

C++

```
__fastcall TComponent * ReadRootComponent(TComponent * Root);
```

Description

Do not call ReadRootComponent directly. It is used internally by the component streaming system. When the reader object is created by its stream in the stream's ReadComponent (see page 2945) method, it immediately calls the ReadRootComponent method, which initiates the streaming sequence of restoring an object.

ReadRootComponent first calls the ReadSignature (see page 2953) method to ensure that it is reading a proper component. ReadRootComponent also handles initializations and fixup references. For example, the component passed in Root (see page 2840) becomes the value of the Root (see page 2840) property for the reader object.

ReadRootComponent calls the component's ReadState method, which calls back to the reader's ReadData (see page 2947) method. The ReadState method of TComponent (see page 2762) is virtual, which allows component classes to override ReadState to prepare themselves for being loaded with the new data from the stream.

See Also

FixupReferences (see page 2942)

ReadComponents (see page 2946)

Read (see page 2944)

ReadSignature (see page 2953)

ReadState (see page 2784)

23.1.43.3.36 TReader.ReadSet Method

Pascal

```
function ReadSet(SetType: Pointer): Integer;
```

C++

```
__fastcall int ReadSet(void * SetType);
```

Description

This is ReadSet, a member of class TReader.

23.1.43.3.37 TReader.ReadSignature Method

Reads the filer signature from the reader object's associated stream.

Pascal

```
procedure ReadSignature;
```

C++

```
__fastcall ReadSignature();
```

Description

ReadSignature is used by several routines to ensure that the file about to be read is a valid component stream. For example, ReadRootComponent (see page 2952), calls ReadSignature before reading its component from the stream. By checking for the signature before loading objects, the reader object can guard against inadvertently reading invalid or corrupted data.

The signature is a four-character sequence.

See Also

ReadComponents (see page 2946)

ReadRootComponent (see page 2952)

23.1.43.3.38 TReader.ReadSingle Method

Reads a float value from the reader object's stream and returns its value.

Pascal

```
function ReadSingle: Single;
```

C++

```
__fastcall Single ReadSingle();
```

Description

ReadSingle is a helper method used by other reader methods to read a tagged Delphi Single data value at the current reader Position (see page 2960). (The Single data type corresponds to float in C++.) ReadSingle first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaSingle, ReadSingle calls Read (see page 2944) and returns the value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

23.1.43.3.39 TReader.ReadStr Method

Reads one character from the reader object's stream and returns its contents.

Pascal

```
function ReadStr: string;
```

C++

```
__fastcall AnsiString ReadStr();
```

Description

ReadStr is a helper method used by other reader methods to read one character from a string at the current reader Position (see page 2960). Unlike ReadChar (see page 2945), ReadStr will not throw an exception if the tagged value is not a single character.

Warning: This method is for Delphi internal use only.

See Also

EReadError (see page 2703)

Position (see page 2960)

ReadChar (see page 2945)

ReadString (see page 2954)

23.1.43.3.40 TReader.ReadString Method

Reads a tagged string value written by WriteString from the reader object's stream and returns its contents.

Pascal

```
function ReadString: string;
```

C++

```
__fastcall AnsiString ReadString();
```

Description

ReadString is a helper method used by other reader methods to read a string at the current reader Position (see page 2960). ReadString first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaString or a vaLString type ReadString calls Read (see page 2944) and returns the string. Otherwise it raises an EReadError (see page 2703) exception.

Warning: Always use ReadString for reading component strings to streams.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

ReadValue (see page 2954)

TValueType

23.1.43.3.41 TReader.ReadValue Method

Reads the type of the next item on the reader object's stream and returns with the stream positioned after the value-type indicator.

Pascal

```
function ReadValue: TValueType;
```

C++

```
__fastcall TValueType ReadValue();
```

Description

ReadValue is used by other reader methods when the subsequent processing depends upon a type check of the data about to be read.

See Also

NextValue (see page 2943)

23.1.43.3.42 TReader.ReadVariant Method

Reads a Variant value from the reader object's stream and returns its value.

Pascal

```
function ReadVariant: Variant;
```

C++

```
__fastcall Variant ReadVariant();
```

Description

ReadVariant is a helper method used by other reader methods to read a tagged Variant data value at the current reader Position (see page 2960). ReadVariant first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaVariant ReadVariant calls Read (see page 2944) and returns the value. Otherwise it calls ReadInteger (see page 2949).

See Also

Position (see page 2960)

Read (see page 2944)

ReadInteger (see page 2949)

ReadValue (see page 2954)

TValueType

WriteVariant (see page 3190)

23.1.43.3.43 TReader.ReadWideChar Method

Reads a wide character from the reader object's stream and returns that character value.

Pascal

```
function ReadWideChar: WideChar;
```

C++

```
__fastcall WideChar ReadWideChar();
```

Description

ReadWideChar is a helper method used by other reader methods to read a tagged wide character value at the current reader Position (see page 2960). ReadWideChar invokes the ReadWideString (see page 2956), and return that string if it is 1 character long. Otherwise, an exception is thrown.

Note: If the tagged data is a widestring with length = 1, it is widechar compatible. If length > 1, it is an error, however, the rest of

the string data must be read to keep the reader in a consistent state. Each action that processes tagged data must leave the reader Position (see page 2960) at the start of the next unread tag.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

ReadWideString (see page 2956)

TValueType

23.1.43.3.44 TReader.ReadWideString Method

Reads a tagged wide string value from the reader object's stream and returns its contents.

Pascal

```
function ReadWideString: WideString;
```

C++

```
__fastcall BSTR ReadWideString();
```

Description

ReadWideString is a helper method used by other reader methods to read a wide string at the current reader Position (see page 2960). ReadWideString first checks the value type (TValueType (see page 3279)) by calling the ReadValue (see page 2954) method. If the item is a vaWString type, ReadWideString calls Read (see page 2944) and returns the string. Otherwise it raises an EReadError (see page 2703) exception.

See Also

EReadError (see page 2703)

Position (see page 2960)

Read (see page 2944)

ReadValue (see page 2954)

TValueType

23.1.43.3.45 TReader.ReferenceName Method

Pascal

```
procedure ReferenceName(var Name: string); virtual;
```

C++

```
virtual __fastcall ReferenceName(AnsiString Name);
```

Description

This is ReferenceName, a member of class TReader.

23.1.43.3.46 TReader.SetName Method

Pascal

```
procedure SetName(Component: TComponent; var Name: string); virtual;
```

C++

```
virtual __fastcall SetName(TComponent * Component, AnsiString Name);
```

Description

This is SetName, a member of class TReader.

23.1.43.3.47 TReader.SetPosition Method

Pascal

```
procedure SetPosition(Value: Longint);
```

C++

```
__fastcall SetPosition(Longint Value);
```

Description

This is SetPosition, a member of class TReader.

23.1.43.3.48 TReader.SkipBytes Method

Pascal

```
procedure SkipBytes(Count: Integer);
```

C++

```
__fastcall SkipBytes(int Count);
```

Description

This is SkipBytes, a member of class TReader.

23.1.43.3.49 TReader.SkipComponent Method

Pascal

```
procedure SkipComponent(SkipHeader: Boolean);
```

C++

```
__fastcall SkipComponent(Boolean SkipHeader);
```

Description

This is SkipComponent, a member of class TReader.

23.1.43.3.50 TReader.SkipProperty Method

Pascal

```
procedure SkipProperty;
```

C++

```
__fastcall SkipProperty();
```

Description

This is SkipProperty, a member of class TReader.

23.1.43.3.51 TReader.SkipSetBody Method

Pascal

```
procedure SkipSetBody;
```

C++

```
__fastcall SkipSetBody();
```

Description

This is SkipSetBody, a member of class TReader.

23.1.43.3.52 TReader.SkipValue Method

Skips the next value read from the stream.

Pascal

```
procedure SkipValue;
```

C++

```
__fastcall SkipValue();
```

Description

Use SkipValue to skip over a value, positioning the stream on the following value.

See Also

EReadError (see page 2703)

Position (see page 2960)

23.1.43.4 TReader Properties

The properties of the TReader class are listed here.

Protected Properties

	Name	Description
R	CanHandleExceptions (see page 2958)	This is CanHandleExceptions, a member of class TReader.
R	PropName (see page 2960)	This is PropName, a member of class TReader.

Public Properties

	Name	Description
	Owner (see page 2959)	Stores the component that is assigned as the Owner property of components read from the reader object's stream.
	Parent (see page 2959)	Stores the component that is assigned as the Parent property of controls read from the reader's stream.
	Position (see page 2960)	Represents the current reading position in the associated stream.

23.1.43.4.1 TReader.CanHandleExceptions Property

Pascal

```
property CanHandleExceptions: Boolean;
```

C++

```
__property Boolean CanHandleExceptions;
```

Description

This is CanHandleExceptions, a member of class TReader.

23.1.43.4.2 TReader.Owner Property

Stores the component that is assigned as the Owner property of components read from the reader object's stream.

Pascal

```
property Owner: TComponent;
```

C++

```
__property TComponent * Owner;
```

Description

Owner is used internally by the component streaming system to determine which components to stream. The streaming process handles all components owned by the Root (see page 2840) component.

Owner is the Owner property of the component read from the stream. The component's Owner property is assigned its value from the reader's Owner property. If the value of the reader's Owner property is nil (Delphi) or NULL (C++), then the Root (see page 2840) property is assigned as the component's Owner property.

For most components, Owner is nil (Delphi) or NULL (C++). For components that can contain subcomponents that are not owned by the Root (see page 2840) form, such as the nodes of a tree view component, the Owner is not the same as the Root (see page 2840). The GetChildOwner method of the component determines the Owner.

See Also

Root (see page 2840)

Owner (see page 2807)

GetChildOwner (see page 2776)

Parent (see page 2959)

23.1.43.4.3 TReader.Parent Property

Stores the component that is assigned as the Parent property of controls read from the reader's stream.

Pascal

```
property Parent: TComponent;
```

C++

```
__property TComponent * Parent;
```

Description

Parent is used internally by the component streaming system. The value of the Parent property is determined by the order that components are read from the stream. The Parent relationship determines the visual containment of components.

See Also

GetChildren (see page 2777)

GetChildren (see page 6153)

GetChildren

Owner (see page 2959)

Parent (see page 5832)

23.1.43.4.4 TReader.Position Property

Represents the current reading position in the associated stream.

Pascal

```
property Position: Longint;
```

C++

```
__property Longint Position;
```

Description

Position is used to track the reader's position within the stream. The value of Position will always be inside the most recent buffer block read. Thus, for reading, Position will always be less than the stream's Position.

See Also

FlushBuffer (see page 2943)

Position (see page 2996)

23.1.43.4.5 TReader.PropName Property

Pascal

```
property PropName: string;
```

C++

```
__property AnsiString PropName;
```

Description

This is PropName, a member of class TReader.

23.1.43.5 TReader Events

The events of the TReader class are listed here.

Public Events

	Name	Description
	OnAncestorNotFound (see page 2961)	Occurs when the object from which a streamed object is derived cannot be found.
	OnCreateComponent (see page 2961)	Occurs when the reader has read a component's class but has not yet instantiated the component.
	OnError (see page 2961)	Occurs when a reader object encounters an error reading its data, such as reading the name of an undeclared property or an illegal value.
	OnFindComponentClass (see page 2962)	Occurs when a reader first reads the name of a component class.
	OnFindComponentInstance (see page 2962)	This is OnFindComponentInstance, a member of class TReader.
	OnFindMethod (see page 2962)	Occurs each time the reader object reads an event, which is a method-pointer property, for an object.
	OnFindMethodInstance (see page 2963)	This is OnFindMethodInstance, a member of class TReader.
	OnReferenceName (see page 2963)	Occurs when resolving references to other objects such as when one object is the property value of another.

	OnSetName (see page 2963)	Occurs just before the reader object sets the Name property of a component it reads from its stream.

23.1.43.5.1 TReader.OnAncestorNotFound Event

Occurs when the object from which a streamed object is derived cannot be found.

Pascal

```
property OnAncestorNotFound: TAncestorNotFoundEvent;
```

C++

```
__property TAncestorNotFoundEvent OnAncestorNotFound;
```

Description

OnAncestorNotFound is for internal use.

See Also

Ancestor (see page 2839)

23.1.43.5.2 TReader.OnCreateComponent Event

Occurs when the reader has read a component's class but has not yet instantiated the component.

Pascal

```
property OnCreateComponent: TCreateComponentEvent;
```

C++

```
__property TCreateComponentEvent OnCreateComponent;
```

Description

OnCreateComponent is used internally to provide an alternate mechanism for instantiating components. If OnCreateComponent returns a component as the value of the Component parameter, the Reader uses that instance instead of calling the component's constructor.

See Also

ReadComponent (see page 2945)

OnFindComponentClass (see page 2962)

23.1.43.5.3 TReader.OnError Event

Occurs when a reader object encounters an error reading its data, such as reading the name of an undeclared property or an illegal value.

Pascal

```
property OnError: TReaderError;
```

C++

```
__property TReaderError OnError;
```

Description

OnError is used internally by the IDE to report errors. It can also be used to write an event handler to selectively choose to process or ignore errors.

The last parameter passed to the OnError event handler, Handled, is passed by reference. By default, the Error (see page

2942) method passes false in Handled, but a handler that corrects the error or chooses to ignore the error can set Handled to true, which prevents further processing of the error. If the event handler returns with Handler still set to false, the reader object raises an EReadError (see page 2703) exception.

See Also

EReadError (see page 2703)

23.1.43.5.4 TReader.OnFindComponentClass Event

Occurs when a reader first reads the name of a component class.

Pascal

```
property OnFindComponentClass: TFindComponentClassEvent;
```

C++

```
__property TFindComponentClassEvent OnFindComponentClass;
```

Description

The ReadComponent (see page 2945) method generates an OnFindComponentClass event when it reads the class name for the component it is loading. An OnFindComponentClass event handler can replace the class reference with a different class to change the type of component that gets loaded.

See Also

ReadComponent (see page 2945)

OnCreateComponent (see page 2961)

23.1.43.5.5 TReader.OnFindComponentInstance Event

Pascal

```
property OnFindComponentInstance: TFindComponentInstanceEvent;
```

C++

```
__property TFindComponentInstanceEvent OnFindComponentInstance;
```

Description

This is OnFindComponentInstance, a member of class TReader.

23.1.43.5.6 TReader.OnFindMethod Event

Occurs each time the reader object reads an event, which is a method-pointer property, for an object.

Pascal

```
property OnFindMethod: TFindMethodEvent;
```

C++

```
__property TFindMethodEvent OnFindMethod;
```

Description

OnFindMethod is used internally by the IDE for reading events. It can also be used to write a handler to ask the user how to handle missing methods.

If the reader cannot locate the named method assigned to the method pointer, it sets the Error (see page 2942) parameter of the OnFindMethod handler to true. The handler can set Error (see page 2942) to false, which prevents FindMethod (see

page 2942) from raising an exception when the handler returns.

See Also

EReadError (see page 2703)

23.1.43.5.7 TReader.OnFindMethodInstance Event

Pascal

```
property OnFindMethodInstance: TFindMethodInstanceEvent;
```

C++

```
__property TFindMethodInstanceEvent OnFindMethodInstance;
```

Description

This is OnFindMethodInstance, a member of class TReader.

23.1.43.5.8 TReader.OnReferenceName Event

Occurs when resolving references to other objects such as when one object is the property value of another.

Pascal

```
property OnReferenceName: TReferenceNameEvent;
```

C++

```
__property TReferenceNameEvent OnReferenceName;
```

Description

OnReferenceName is for internal use only.

See Also

Name (see page 2805)

23.1.43.5.9 TReader.OnSetName Event

Occurs just before the reader object sets the Name property of a component it reads from its stream.

Pascal

```
property OnSetName: TSetNameEvent;
```

C++

```
__property TSetNameEvent OnSetName;
```

Description

OnSetName is used by internally by the IDE to handle duplicate names of components and forms. It can also be used to write an event handler to perform special processing just before the Name property is set for the component which has just been created and is about to have its properties read from the stream.

The Name parameter to the OnSetName event handler passed by reference, so the handler can change the name before the reader assigns it to the component. For example, OnSetName is useful for filtering all the component names in a form, to add or change part of the string.

See Also

Name (see page 2805)

23.1.44 TRecall Class

TRecall stores the properties of a persistent object so that they can be restored at a later time.

Class Hierarchy

Pascal

```
TRecall = class(TObject);
```

C++

```
class TRecall : public TObject;
```

File

Classes

Description

TRecall acts as a temporary repository for the properties of a persistent object. To use TRecall

1. Create (see page 2965) an instance of TRecall, assigning an object to use for storing property values (the storage object), and an object whose property values it represents (the reference object). When you create an instance of TRecall, it automatically stores the current properties of the reference object.
2. Call the Store (see page 2967) method at any time to take a snapshot of the reference object's properties. TRecall updates the storage object so that it reflects only the property settings from the last time you called the Store (see page 2967) method (or, if Store (see page 2967) was never called, from the point when the TRecall object was created).
3. Delete the TRecall object to restore the reference object to the set of properties it had when you last called the Store (see page 2967) method.

If you do not want the TRecall object to restore the properties it is saving, call the Forget (see page 2967) method. After you call Forget (see page 2967), the TRecall object can't be used. It does not update the reference object when destroyed and can't save any more properties.

You can use TRecall to save the properties of any persistent object, using any explicitly specified storage object. In addition, TRecall has several descendants with their own built-in storage objects that work only with a specific class of reference object. These include TFontRecall, TPenRecall, and TBrushRecall.

See Also

TPersistent (see page 2928)

TBrushRecall (see page 14439)

TFontRecall (see page 14514)

TPenRecall (see page 14582)

23.1.44.1 TRecall Members

The following tables list the members exposed by TRecall.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2965)	Creates an instance of a TRecall (see page 2964) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2966)	Destroys the TRecall (see page 2964) instance, assigning the stored properties to the reference object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Forget (see page 2967)	Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Store (see page 2967)	Saves the current property settings of the reference object.

Public Properties

	Name	Description
R	Reference (see page 2968)	Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

23.1.44.2 TRecall.Create Constructor

Creates an instance of a TRecall (see page 2964) object.

Pascal

```
constructor Create(AStorage: TPersistent; AReference: TPersistent);
```

C++

```
__fastcall TRecall(TPersistent * AStorage, TPersistent * AReference);
```

Description

Note: Call Create to instantiate a TRecall (see page 2964) object to save the properties of a specific reference object.

AStorage is an object that saves the properties of the reference object. Once you create the TRecall (see page 2964) instance, it is responsible for the memory of AStorage, and frees AStorage when it is destroyed. Do not free AStorage yourself after creating the TRecall (see page 2964) object.

AReference is the object whose properties are saved when you create the TRecall (see page 2964) object and, subsequently, any time you call the Store (see page 2967) method.

AStorage and AReference do not need to be the same type of object. However, TRecall (see page 2964) can only save and restore those properties that can be assigned from the reference object to the storage object and back again. That is, TRecall (see page 2964) only handles those properties that are copied by the Assign method of AStorage and AReference.

See Also

Destroy (see page 2966)

Reference (see page 2968)

Store (see page 2967)

Assign (see page 2930)

23.1.44.3 TRecall.Destroy Destructor

Destroys the TRecall (see page 2964) instance, assigning the stored properties to the reference object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TRecall();
```

Description

Destroy a TRecall (see page 2964) instance to restore the properties of the reference object to the last values saved to the TRecall (see page 2964) object. The properties of the reference object are saved to the TRecall (see page 2964) instance when you first create it, and subsequently any time you call the Store (see page 2967) method. The TRecall (see page 2964) destructor assigns the currently saved property values to the reference object by calling the reference object's Assign method.

If you do not want to restore the currently saved property values, call the Forget (see page 2967) method before freeing the TRecall (see page 2964) object. Once you call Forget (see page 2967), TRecall (see page 2964) ceases to store any property information, and destroying the TRecall (see page 2964) leaves the properties of the reference object unchanged.

Note: Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Reference (see page 2968)

Store (see page 2967)

Forget (see page 2967)

Assign (see page 2930)

23.1.44.4 TRecall Methods

The methods of the TRecall class are listed here.

Public Methods

	Name	Description
	Forget (see page 2967)	Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.
	Store (see page 2967)	Saves the current property settings of the reference object.

23.1.44.4.1 TRecall.Forget Method

Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.

Pascal

```
procedure Forget;
```

C++

```
__fastcall Forget();
```

Description

By default, the TRecall (see page 2964) destructor updates the reference object, assigning the most recently saved property values. To prevent this from happening, call Forget before destroying the TRecall (see page 2964) object.

Once you have called Forget, the TRecall (see page 2964) instance can not do anything. It ignores any further attempts to store property settings because it can't use them to update the reference object when it is destroyed.

See Also

Reference (see page 2968)

Destroy (see page 2966)

23.1.44.4.2 TRecall.Store Method

Saves the current property settings of the reference object.

Pascal

```
procedure Store;
```

C++

```
__fastcall Store();
```

Description

Call Store to update the TRecall (see page 2964) object's saved property values so that they reflect the current property values of the reference object. Each call to Store completely supersedes the previously stored property values.

When you destroy the TRecall (see page 2964) object, it assigns the most recently stored property values to the reference object.

See Also

Forget (see page 2967)

Reference (see page 2968)

Create (see page 2965)

23.1.44.5 TRecall Properties

The properties of the TRecall class are listed here.

Public Properties

	Name	Description
R	Reference (see page 2968)	Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

23.1.44.5.1 TRecall.Reference Property

Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

Pascal

```
property Reference: TPersistent;
```

C++

```
__property TPersistent * Reference;
```

Description

Read Reference to determine the object that TRecall (see page 2964) updates when it is destroyed. The value of this read-only property is assigned in the constructor.

See Also

Destroy (see page 2966)

23.1.45 TResourceStream Class

TResourceStream is a memory stream that provides access to the compiled resources in an application.

Class Hierarchy

Pascal

```
TResourceStream = class(TCustomMemoryStream);
```

C++

```
class TResourceStream : public TCustomMemoryStream;
```

File

Classes

Description

Use TResourceStream to read the resources of an application. An instance of TResourceStream holds the value of a single resource in a memory buffer where it is accessible to the application.

The global ReadComponentRes (see page 3245) function uses TResourceStream to access the compiled resources used by the application.

See Also

ReadComponentRes (see page 3245)

TStream (see page 2973)

23.1.45.1 TResourceStream Members

The following tables list the members exposed by TResourceStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	SetPointer (see page 2823)	Replaces the memory buffer associated with the memory stream.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 2970)	Creates an instance of TResourceStream (see page 2968) associated with a particular resource name and type.
	CreateFromID (see page 2971)	Creates an instance of TResourceStream (see page 2968) associated with a particular resource ID and type.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2972)	Destroys an instance of TResourceStream (see page 2968).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Read (see page 2817)	Reads up to Count bytes from the memory stream into Buffer and advances the current position of the stream by the number of bytes read.
	Read (see page 2982)	Introduces an abstract or pure virtual method responsible for reading from the stream.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.

	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 2818)	Writes the entire contents of the memory stream to the file with a given file name.
	SaveToStream (see page 2818)	Writes the entire contents of the memory stream to the stream object specified by Stream.
V	Seek (see page 2819)	Moves the current position of the stream by Offset bytes, relative to the origin specified by Origin.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
V	Write (see page 2973)	Overrides the inherited method to raise an exception when an attempt is made to write the resource back to the application.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
R	Memory (see page 2823)	Provides direct access to the memory pool allocated for the memory stream.
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.45.2 TResourceStream.Create Constructor

Creates an instance of TResourceStream (see page 2968) associated with a particular resource name and type.

Pascal

```
constructor Create(Instance: THandle; const ResName: string; ResType: PChar);
```

C++

```
__fastcall TResourceStream(THandle Instance, const AnsiString ResName, const char * ResType);
```

Description

Call Create to instantiate a TResourceStream (see page 2968), passing in parameters that identify the resource in a specified instance. TResourceStream (see page 2968) finds the resource data and loads it into the Memory (see page 2823) buffer for the TResourceStream (see page 2968).

The Instance parameter is the instance handle associated with the executable or shared library that contains the resource.

In the first constructor syntax, the ResName is the string associated with the resource in the .rc file that was compiled with the application. If the resource is associated with an integer ID rather than a string, use the string representation of the integer after a pound sign. Thus, for example, a resource with an integer identifier of 128 be identified by a ResName of #128.

Note: Specifying resources by ID requires less memory than specifying resources by name.

The ResType parameter is a string identifying the type of the resource. Applications can define their own resource types and identify them by name in the .rc file. In addition, there are a number of predefined resource types (which reflect Windows resource types). To identify a resource that is one of the predefined resource types, set ResType to the appropriate value from the following table:

ResType	Type of resource
RT_ACCELERATOR	Accelerator table

RT_BITMAP	Bitmap resource
RT_DIALOG	Dialog box
RT_FONT	Font resource
RT_FONTDIR	Font directory resource
RT_MENU	Menu resource
RT_RCDATA	Application-defined resource (raw data)
RT_STRING	String-table entry
RT_MESSAGETABLE	Message-table entry
RT_CURSOR	Hardware-dependent cursor resource
RT_GROUP_CURSOR	Hardware-independent cursor resource
RT_ICON	Hardware-dependent icon resource
RT_GROUP_ICON	Hardware-independent icon resource
RT_VERSION	Version resource

CreateFromID (see page 2971)

Memory (see page 2823)

23.1.45.3 TResourceStream.CreateFromID Constructor

Creates an instance of TResourceStream (see page 2968) associated with a particular resource ID and type.

Pascal

```
constructor CreateFromID(Instance: THandle; ResID: Integer; ResType: PChar);
```

C++

```
__fastcall TResourceStream(THandle Instance, int ResID, const char * ResType);
```

Description

Call CreateFromID to instantiate a TResourceStream (see page 2968) for a resource in the indicated instance that can be identified by an integer ID. Create (see page 2970) finds the resource data and loads it into the Memory (see page 2823) buffer for the TResourceStream (see page 2968).

The Instance parameter is the instance handle associated with the executable or shared library that contains the resource.

The ResID is the integer ID associated with the resource in the .rc file that was compiled with the application. If the Resource was identified by a string rather than an ID number, use the Create (see page 2970) method instead.

The ResType parameter is a string identifying the type of the resource. Applications can define their own resource types and identify them by name in the .rc file. In addition, there are a number of predefined resource types (which reflect Windows resource types). To identify a resource that is one of the predefined resource types, set ResType to the appropriate value from the following table:

ResType	Type of resource
RT_ACCELERATOR	Accelerator table
RT_BITMAP	Bitmap resource
RT_DIALOG	Dialog box

RT_FONT	Font resource
RT_FONTDIR	Font directory resource
RT_MENU	Menu resource
RT_RCDATA	Application-defined resource (raw data)
RT_STRING	String-table entry
RT_MESSAGETABLE	Message-table entry
RT_CURSOR	Hardware-dependent cursor resource
RT_GROUP_CURSOR	Hardware-independent cursor resource
RT_ICON	Hardware-dependent icon resource
RT_GROUP_ICON	Hardware-independent icon resource
RT_VERSION	Version resource

Note: Specifying resources by ID requires less memory than specifying resources by name.

Create (see page 2970)

Memory (see page 2823)

23.1.45.4 TResourceStream.Destroy Destructor

Destroys an instance of TResourceStream (see page 2968).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TResourceStream();
```

Description

Do not call Destroy directly in an application to destroy an instance of TResourceStream (see page 2968). Instead, call Free. Free verifies that the TResourceStream (see page 2968) reference is not nil, and only then calls Destroy.

Destroy frees the memory buffer that stores the resource before calling the inherited destructor.

Create (see page 2970)

Free (see page 22300)

Memory (see page 2823)

23.1.45.5 TResourceStream Methods

The methods of the TResourceStream class are listed here.

Public Methods

	Name	Description
	Write (see page 2973)	Overrides the inherited method to raise an exception when an attempt is made to write the resource back to the application.

23.1.45.5.1 TResourceStream.Write Method

Overrides the inherited method to raise an exception when an attempt is made to write the resource back to the application.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count);
```

Description

Applications should not use a TResourceStream (see page 2968) to write the resources of the running application. Write overrides the inherited method to raise an EStreamError (see page 2704) exception when an application tries to write to the application's resources.

As all other data-writing methods of TResourceStream (see page 2968) (WriteBuffer (see page 2990), WriteComponent (see page 2990)) call Write to do the actual writing, calling any of the data-writing methods of TResourceStream (see page 2968) will raise an exception.

See Also

EStreamError (see page 2704)

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

23.1.46 TStream Class

TStream is the base class type for stream objects that can read from or write to various kinds of storage media, such as disk files, dynamic memory, and so on.

Class Hierarchy

Pascal

```
TStream = class(TObject);
```

C++

```
class TStream : public TObject;
```

File

Classes

Description

Use specialized stream objects to read from, write to, or copy information stored in a particular medium. Each descendant of TStream implements methods for transferring information to and from a particular storage medium, such as a disk file, dynamic memory, and so on. In addition to methods for reading, writing, and copying bytes to and from the stream, stream objects permit

applications to seek to an arbitrary position in the stream. Properties of TStream provide information about the stream, such as its size and the current position in the stream.

TStream also introduces methods that work in conjunction with components and filers for loading and saving components in simple and inherited forms. These methods are called automatically by global routines that initiate component streaming. They can also be called directly to initiate the streaming process. Note, however, that component streaming always involves two additional objects:

A component object that is passed as a parameter to the stream's methods.

A filer object that is automatically created by the stream, and associated with the stream.

TStream is an abstract or, in C++ terminology, pure virtual class. It should not be instantiated; it relies on abstract or pure virtual methods that must be overridden in descendant classes. Descendant stream objects, such as memory and file streams used for component streaming, are created automatically by the global functions ReadComponentRes (see page 2987) and WriteComponentRes (see page 2994). For streaming other kinds of information, choose a descendant class according to the specific data and storage needs. These include

TFileStream (see page 2841) (for working with files)

TStringStream (see page 3088) (for manipulating in-memory strings)

TMemoryStream (see page 2902) (for working with a memory buffer)

TBlobStream (for working with BLOB fields)

TWinSocketStream (for reading and writing over a socket connection)

TOleStream (for using a COM interface to read and write)

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
```

```
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)

{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
```

```
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type

Using Streams

Using Streams to Read or Write Data

23.1.46.1 TStream Members

The following tables list the members exposed by TStream.

Protected Methods

	Name	Description
V	GetSize (see page 2982)	This is GetSize, a member of class TStream.
V	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
A	Read (see page 2982)	Introduces an abstract or pure virtual method responsible for reading from the stream.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
A	Write (see page 2989)	Introduces a pure virtual method for writing to the stream.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.

	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.46.2 TStream Methods

The methods of the TStream class are listed here.

Protected Methods

	Name	Description
V	GetSize (see page 2982)	This is GetSize, a member of class TStream.
V	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
A	Read (see page 2982)	Introduces an abstract or pure virtual method responsible for reading from the stream.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
A	Write (see page 2989)	Introduces a pure virtual method for writing to the stream.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

23.1.46.2.1 TStream.CopyFrom Method

Copies a specified number of bytes from one stream to another.

Pascal

```
function CopyFrom(Source: TStream; Count: Int64): Int64;
```

C++

```
__fastcall Int64 CopyFrom(TStream Source, Int64 Count);
```

Description

Use CopyFrom to copy data to the stream from a different stream. Using CopyFrom eliminates the need for the user to create, read into, write from, and free a buffer when copying data.

CopyFrom copies Count bytes from the stream specified by Source into the stream. It then moves the current position by Count bytes, and returns the number of bytes copied.

If Count is 0, CopyFrom sets Source position to 0 before reading and then copies the entire contents of Source into the stream. If Count is greater than or less than 0, CopyFrom reads from the current position in Source.

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
*/
void __fastcall TForm1::Save1Click(TObject *Sender)
{
  AnsiString NewFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit1->Text);
  AnsiString OldFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit2->Text);
  AnsiString Msg = Format("Copy %s to %s", ARRAYOFCONST((OldFileName, NewFileName)));
  if (MessageDlg(Msg, mtCustom, TMsgDlgButtons() << mbOK << mbCancel, 0) == mrOk)
  {
    TFileStream *OldFile = new TFileStream(OldFileName, fmOpenRead);
    try
    {
      TFileStream *NewFile = new TFileStream(NewFileName, fmCreate);
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      }
    }
    __finally
    {
      FreeAndNil(&OldFile);
    }
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label3->Caption = "Current directory: " + ExtractFilePath(Application->ExeName);
}
```

Delphi Examples:

```
{
The following example copies the data in the Notes field of
Table1 or SQLDataSet1 to the Remarks field of ClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Stream1: TBlobStream;
  Stream2: TStream;
  blobType : TBlobType;
begin
  blobType := Table1Notes.BlobType;
  Stream1 := TBlobStream.Create(Table1Notes, bmRead);
  try
```

```
      CDS2.Edit;
      { here's a different way to create a blob stream }
      Stream2 := CDS2.CreateBlobStream(CDS2.FieldByName('Remarks'), bmReadWrite);
      try
        Stream2.CopyFrom(Stream1, Stream1.Size);
//      CDS2.Post;
//      CDS2.Active := True;
      finally
        Stream2.Free;
      end;
    finally
      Stream1.Free;
    end;
  end;
  {
  This example copies a specified old file to a new file.  Add
  a TSaveDialog to the form.  Also add two TEdits, two TLabels
  and a TButton with the OnClick event named Save1Click. Files
  can be saved to and from the app directory by using relative
  paths.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Label3.Caption:= 'Current directory: ' + ExtractFilePath(Application.ExeName);
  end;

  procedure TForm1.Save1Click(Sender: TObject);
  var
    NewFileName, OldFileName: string;
    Msg: string;
    NewFile: TFileStream;
    OldFile: TFileStream;
  begin
    NewFileName :=
      ExtractFilePath(Application.ExeName) +
      ExtractFileName(Edit1.Text);
    OldFileName :=
      ExtractFilePath(Application.ExeName) +
      ExtractFileName(Edit2.Text);
    Msg := Format('Copy %s to %s?', [OldFileName, NewFileName]);
    if MessageDlg(Msg, mtCustom, mbOKCancel, 0) = mrOK then
    begin
      OldFile := TFileStream.Create(
        OldFileName, fmOpenRead or fmShareDenyWrite);
      try
        NewFile := TFileStream.Create(
          NewFileName, fmCreate or fmShareDenyRead);
        try
          NewFile.CopyFrom(OldFile, OldFile.Size);
        finally
          FreeAndNil(NewFile);
        end;
      finally
        FreeAndNil(OldFile);
      end;
    end;
  end;
```

23.1.46.2.2 TStream.FixupResourceHeader Method

Patches the resource header for a resource that has been written to the stream.

Pascal

```
procedure FixupResourceHeader(FixupInfo: Integer);
```

C++

```
__fastcall FixupResourceHeader(int FixupInfo);
```

Description

Do not call FixupResourceHeader, it is used internally. The WriteDescendentRes (see page 2995) method calls FixupResourceHeader after writing a component to the stream. This method then uses the current position to determine the size of the resource just written and adjust the resource header accordingly.

The FixupInfo parameter is the value returned by WriteResourceHeader (see page 2995) when it writes the resource header (before WriteDescendentRes (see page 2995) streams out the component).

See Also

WriteResourceHeader (see page 2995)

WriteDescendentRes (see page 2995)

Position (see page 2996)

23.1.46.2.3 TStream.GetSize Method

Pascal

```
function GetSize: Int64; virtual;
```

C++

```
virtual __fastcall Int64 GetSize();
```

Description

This is GetSize, a member of class TStream.

23.1.46.2.4 TStream.Read Method

Introduces an abstract or pure virtual method responsible for reading from the stream.

Pascal

```
function Read(var Buffer; Count: Longint): Longint; virtual; abstract;
```

C++

```
virtual __fastcall Longint Read( Buffer, Longint Count) = 0;
```

Description

Each descendant stream object defines a Read method that reads data from its particular storage medium (such as memory or a disk file).

Read is used in cases where the number of bytes to read from the stream is not necessarily fixed. It attempts to read up to Count bytes into buffer and returns the number of bytes actually read.

All the other data-reading methods of a stream (ReadBuffer (see page 2983), ReadComponent (see page 2983)) call Read to do their actual reading.

See Also

EReadError (see page 2703)

ReadBuffer (see page 2983)

ReadComponent (see page 2983)

23.1.46.2.5 TStream.ReadBuffer Method

Reads bytes from the stream into Buffer.

Pascal

```
procedure ReadBuffer(var Buffer; Count: Longint);
```

C++

```
__fastcall ReadBuffer( Buffer, Longint Count);
```

Description

Use ReadBuffer to read Count bytes from the stream into a buffer in cases where the number of bytes is known and fixed, for example when reading in structures. ReadBuffer is used internally for loading from a stream and copying from a stream.

ReadBuffer calls Read (see page 2982) to do the actual reading. If Count bytes cannot be read from the stream, an EReadError (see page 2703) exception is raised.

See Also

EReadError (see page 2703)

Read (see page 2982)

23.1.46.2.6 TStream.ReadComponent Method

Initiates streaming of components and their properties.

Pascal

```
function ReadComponent(Instance: TComponent): TComponent;
```

C++

```
__fastcall TComponent * ReadComponent(TComponent * Instance);
```

Description

ReadComponent is called indirectly by the global routine ReadComponentRes (see page 2987), by the ReadComponentRes (see page 2987) method, or it can be called directly to initiate component streaming.

ReadComponent reads data values from the stream and assigns them to Instance's properties. It then constructs a reader object and calls the reader's ReadRootComponent method to read Instance's property values and construct child objects defined in the stream as children of the Instance. ReadComponent returns the component.

If Instance is nil (Delphi) or NULL (C++), ReadComponent constructs a component based on the type information in the stream and returns the newly-constructed component.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};
```

```
__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)

{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
```

```
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)

ReadRootComponent (see page 2952)

WriteComponent (see page 2990)

Using Streams to Read or Write Data

23.1.46.2.7 TStream.ReadComponentRes Method

Reads components and their properties from a stream in a resource file format.

Pascal

```
function ReadComponentRes(Instance: TComponent): TComponent;
```

C++

```
__fastcall TComponent * ReadComponentRes(TComponent * Instance);
```

Description

ReadComponentRes is called automatically by the global routine ReadComponentResFile (see page 3247). It can also be called directly if the current position of the stream points to a component written using the WriteComponentRes (see page 2994) method.

ReadComponentResFile (see page 3247) creates a file stream object, which then calls its ReadComponentRes method.

ReadComponentRes first calls the ReadResHeader (see page 2987) method to read a resource header from the stream. If the stream does not contain a resource header at the current position, ReadResHeader (see page 2987) will raise an EInvalidImage (see page 2699) exception. ReadComponentRes then calls ReadComponent (see page 2983) to read the properties that must be set on Instance.

See Also

EInvalidImage (see page 2699)

ReadComponentResFile

ReadResHeader (see page 2987)

TResourceStream (see page 2968)

WriteComponentRes (see page 2994)

23.1.46.2.8 TStream.ReadResHeader Method

Reads a resource-file header from the stream.

Pascal

```
procedure ReadResHeader;
```

C++

```
__fastcall ReadResHeader();
```

Description

Do not call ReadResHeader directly. It is called automatically by ReadComponentRes (see page 2987) before reading a component from a resource file.

After reading the resource-file header, ReadResHeader moves the current position of the stream to just beyond the header. If the stream does not contain a valid resource-file header, ReadResHeader raises an EInvalidImage (see page 2699) exception.

See Also

EInvalidImage (see page 2699)

ReadComponentRes (see page 2987)

23.1.46.2.9 Seek Method

This is the overview for the Seek method overload.

Overload List

	Name	Description
	TStream.Seek (Int64, TSeekOrigin) (see page 2988)	Moves to a specified position in the streamed resource.
	TStream.Seek (Longint, Word) (see page 2988)	Moves to a specified position in the streamed resource.

23.1.46.2.9.1 TStream.Seek Method (Int64, TSeekOrigin)

Moves to a specified position in the streamed resource.

Pascal

```
function Seek(Offset: Longint; Origin: Word): Longint; virtual; overload;
function Seek(const Offset: Int64; Origin: TSeekOrigin): Int64; virtual; overload;
```

C++

```
virtual __fastcall Longint Seek(Longint Offset, Word Origin);
virtual __fastcall Int64 Seek(const Int64 Offset, TSeekOrigin Origin);
```

Description

Call Seek to move the current position of the stream in its particular storage medium (such as memory or a disk file).

The Origin parameter indicates how to interpret the Offset parameter. Origin should be one of the following values:

Value	Meaning
soBeginning	Offset is from the beginning of the resource. Seek moves to the position Offset. Offset must be >= 0.
soCurrent	Offset is from the current position in the resource. Seek moves to Position (see page 2996) + Offset.
soEnd	Offset is from the end of the resource. Offset must be <= 0 to indicate a number of bytes before the end of the file.

Seek returns the new value of the Position (see page 2996) property.

Seek is called by the Position (see page 2996) and Size (see page 2997) properties.

Note: As implemented in TStream (see page 2973), the two versions (the 32-bit or 64-bit syntax) call each other. Descendant

stream classes must override at least one of these versions, and the override must not call the inherited default implementation.

See Also

Position (see page 2996)

23.1.46.2.10 SetSize Method

This is the overview for the SetSize method overload.

Overload List

	Name	Description
	TStream.SetSize (Int64) (see page 2989)	Provides a placeholder for a method to change the size of the streamed resource.
	TStream.SetSize (Longint) (see page 2989)	Provides a placeholder for a method to change the size of the streamed resource.

23.1.46.2.10.1 TStream.SetSize Method (Int64)

Provides a placeholder for a method to change the size of the streamed resource.

Pascal

```
procedure SetSize(NewSize: Longint); virtual; overload;
procedure SetSize(const NewSize: Int64); virtual; overload;
```

C++

```
virtual __fastcall SetSize(Longint NewSize);
virtual __fastcall SetSize(const Int64 NewSize);
```

Description

SetSize does nothing in TStream (see page 2973). Descendant stream classes can override this method to set the Size (see page 2997) property of their objects. SetSize is the write procedure for the Size (see page 2997) property.

Note: SetSize is introduced in TStream (see page 2973), even though it does nothing, because it is not possible to change the definition of a property in a descendant class. SetSize must therefore be introduced when Size (see page 2997) is introduced.

23.1.46.2.11 TStream.Write Method

Introduces a pure virtual method for writing to the stream.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; virtual; abstract;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count) = 0;
```

Description

Each descendant stream object defines a Write method that writes data to its particular storage medium (such as memory or a disk file). Write attempts to write up to Count bytes from Buffer, and returns the number of bytes actually written.

All the other data-writing methods of a stream (WriteBuffer (see page 2990), WriteComponent (see page 2990)) call Write to do their actual writing.

See Also

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

23.1.46.2.12 TStream.WriteBuffer Method

Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.

Pascal

```
procedure WriteBuffer(const Buffer; Count: Longint);
```

C++

```
__fastcall WriteBuffer(const  Buffer, Longint Count);
```

Description

Use WriteBuffer to save data to a stream. WriteBuffer and ReadBuffer (see page 2983) are used in cases where the number of bytes is known and required, for example when reading in structures. Use WriteBuffer for standard file I/O streaming.

WriteBuffer is used internally for writing to a stream and copying from a stream. It is used by other objects, such as strings and lists, for writing strings stored in a buffer.

WriteBuffer calls Write (see page 2989) to handle the actual writing. If the stream fails to write all the requested bytes, an EWriteError (see page 2706) exception is raised.

See Also

EWriteError (see page 2706)

ReadBuffer (see page 2983)

Write (see page 2989)

23.1.46.2.13 TStream.WriteComponent Method

Initiates the writing of components and their properties to a stream.

Pascal

```
procedure WriteComponent(Instance: TComponent);
```

C++

```
__fastcall WriteComponent(TComponent * Instance);
```

Description

WriteComponent is used internally in the component streaming system, but can also be called directly when writing components to memory streams or database blobs.

WriteComponent constructs a writer object and calls its WriteRootComponent method to write the component specified by Instance, and its owned objects, to the stream.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
```

```
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();

Write (see page 2989)

WriteComponentRes (see page 2994)

WriteRootComponent (see page 3188)

WriteComponentResFile

Using Streams to Read or Write Data

23.1.46.2.14 TStream.WriteComponentRes Method

Writes components and their properties to a stream from a resource file format.

Pascal

```
procedure WriteComponentRes(const ResName: string; Instance: TComponent);
```

C++

```
__fastcall WriteComponentRes(const AnsiString ResName, TComponent * Instance);
```

Description

WriteComponentRes is used internally in the streaming system, but can also be called directly when sending data to other applications on disk. WriteComponentRes is used for streaming components that need data, such as a bitmap or icon to be stored in a resource-file format.

WriteComponentRes calls WriteDescendentRes (see page 2995), passing in nil (Delphi) or NULL (C++) as the Ancestor. Therefore, WriteDescendentRes (see page 2995) initiates the remainder of the streaming process for a component that, in this case, is not a descendant.

To read a component written with WriteComponentRes, call the ReadComponentRes (see page 2987) method.

See Also

Ancestor (see page 2839)

ReadComponentRes (see page 2987)

WriteComponent (see page 2990)

WriteDescendentRes (see page 2995)

23.1.46.2.15 TStream.WriteDescendent Method

Streams components and their properties in inherited forms.

Pascal

```
procedure WriteDescendent(Instance: TComponent; Ancestor: TComponent);
```

C++

```
__fastcall WriteDescendent(TComponent * Instance, TComponent * Ancestor);
```

Description

Do not call WriteDescendent directly. WriteDescendent is called automatically by WriteComponent (see page 2990).

WriteDescendent constructs a writer object, then calls the writer object's WriteDescendent method to write the component passed in Instance to the stream. Instance is either an inherited form descended from Ancestor or nil (Delphi) or NULL (C++). However, WriteDescendent is never used to write owned components, only to initiate streaming on the root component.

See Also

Ancestor (see page 2839)

23.1.46.2.16 TStream.WriteDescendentRes Method

Streams components and their properties in inherited forms.

Pascal

```
procedure WriteDescendentRes(const ResName: string; Instance: TComponent; Ancestor:
TComponent);
```

C++

```
__fastcall WriteDescendentRes(const AnsiString ResName, TComponent * Instance, TComponent *
Ancestor);
```

Description

Do not call WriteDescendentRes directly. WriteDescendentRes is called automatically by WriteComponentRes (see page 2994).

WriteDescendentRes writes a resource-file header to the stream, using the resource name passed in ResName as the name of the resource. It then calls WriteDescendent (see page 2994) to write Instance to the stream as a descendant of Ancestor.

See Also

Ancestor (see page 2839)

23.1.46.2.17 TStream.WriteResourceHeader Method

Writes a resource-file header to the stream.

Pascal

```
procedure WriteResourceHeader(const ResName: string; out FixupInfo: Integer);
```

C++

```
__fastcall WriteResourceHeader(const AnsiString ResName, int FixupInfo);
```

Description

Do not call WriteResourceHeader, it is used internally. The WriteDescendentRes (see page 2995) method calls WriteResourceHeader before writing a component to the stream. This method writes the resource-file header, using the value passed as ResName for the name of the resource. It returns a position in FixupInfo that must be used to adjust the header after the size of the resource is known. WriteDescendentRes (see page 2995) calls FixupResourceHeader (see page 2981) with the value returned as FixupInfo after streaming out the component.

See Also

FixupResourceHeader (see page 2981)

WriteDescendentRes (see page 2995)

23.1.46.3 TStream Properties

The properties of the TStream class are listed here.

Public Properties

	Name	Description
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.46.3.1 TStream.Position Property

Indicates the current offset into the stream for reading and writing.

Pascal

```
property Position: Int64;
```

C++

```
__property Int64 Position;
```

Description

Use Position to obtain the current position of the stream. This is the number of bytes from the beginning of the streamed data.

C++ Examples:

```
/*
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemoryStream* pms = new TMemoryStream();
  ListBox1->Items->SaveToStream(pms); // write list box contents to the
                                      // stream.
  pms->Position = 0;                  // reset to the beginning of the stream.
  RichEdit1->Lines->LoadFromStream(pms); // load stream contents into rich
                                         // edit control.
  delete pms;
}
```

Delphi Examples:

```
{
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TempStream : TMemoryStream;
begin
  TempStream := TMemoryStream.Create;
  ListBox1.Items.SaveToStream(TempStream);  // write list box contents to the
                                            // stream
  TempStream.Position := 0;      // reset to the beginning of the stream
```

```
    RichEdit1.Lines.LoadFromStream( TempStream); // load stream contents into rich
                                                 // edit control
    TempStream.Free;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Apples');
    ListBox1.Items.Add('Oranges');
    ListBox1.Items.Add('Pears');
  end;
```

See Also

Seek (see page 2988)

Position (see page 2960)

Position (see page 3192)

23.1.46.3.2 TStream.Size Property

Indicates the size in bytes of the stream.

Pascal

```
property Size: Int64;
```

C++

```
__property Int64 Size;
```

Description

Use Size to find the size of the stream. Size is used internally in routines that read and write to and from the stream. Setting the Size property of TStream (see page 2973) does nothing. Some descendants of TStream (see page 2973) override this property to allow applications to change the size of the resource accessed using the stream.

See Also

Seek (see page 2988)

23.1.47 TStreamAdapter Class

TStreamAdapter implements the IStream interface on a TStream (see page 2973) object.

Class Hierarchy

Pascal

```
TStreamAdapter = class(TInterfacedObject, IStream);
```

C++

```
class TStreamAdapter : public TInterfacedObject, public IStream;
```

File

Classes

Description

DescriptionTStreamAdapter is an interfaced object that implements the IStream interface. It is associated with a TStream (see page 2973) object in the constructor, which it uses to implement the IStream methods.

Note: On Windows, TStreamAdapter allows a TStream (see page 2973) object to be used as a COM-based IStream interface.

See Also

TCustomAdapter

TFontAdapter (see page 1583)

TPictureAdapter (see page 1599)

TOleStream (see page 1595)

IStream

23.1.47.1 TStreamAdapter Members

The following tables list the members exposed by TStreamAdapter.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clone (see page 3000)	Implements the IStream Clone method.
V	Commit (see page 3001)	Implements the IStream Commit method.
V	CopyTo (see page 3001)	Implements the IStream CopyTo method.
	Create (see page 2999)	Creates an instance of a TStreamAdapter (see page 2997) object.

	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 3000)	Frees the instance of TStreamAdapter (see page 2997).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LockRegion (see page 3002)	Implements the IStream LockRegion method.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Read (see page 3002)	Implements the IStream Read method.
	Revert (see page 3002)	Implements the IStream Revert method.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Seek (see page 3003)	Implements the IStream Seek method.
	SetSize (see page 3003)	Implements the IStream SetSize method.
	Stat (see page 3004)	Implements the IStream Stat method.
	UnlockRegion (see page 3004)	Implements the IStream UnlockRegion method.
	Write (see page 3004)	Implements the IStream Write method.

Public Properties

	Name	Description
	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.
	Stream (see page 3005)	Identifies the associated TStream (see page 2973) object that TStreamAdapter (see page 2997) uses to implement the IStream interface.
	StreamOwnership (see page 3005)	Specifies whether the TStreamAdapter (see page 2997) should act as the Owner of the associated stream object.

23.1.47.2 TStreamAdapter.Create Constructor

Creates an instance of a TStreamAdapter (see page 2997) object.

Pascal

```
constructor Create(Stream: TStream; Ownership: TStreamOwnership = soReference);
```

C++

```
__fastcall TStreamAdapter(TStream Stream, TStreamOwnership Ownership = soReference);
```

Description

Call Create to instantiate a TStreamAdapter (see page 2997) object that implements the IStream interface using the stream object specified by Stream (see page 3005). Ownership initializes the StreamOwnership (see page 3005) property, indicating whether the TStreamAdapter (see page 2997) object is responsible for freeing the stream specified by Stream (see page 3005) from its own destructor.

See Also

Stream (see page 3005)

StreamOwnership (see page 3005)

23.1.47.3 TStreamAdapter.Destroy Destructor

Frees the instance of TStreamAdapter (see page 2997).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TStreamAdapter();
```

Description

Most applications do not need to explicitly free the TStreamAdapter (see page 2997) instance. Instead, it is freed automatically when its reference count drops to 0.

If you must explicitly destroy a TStreamAdapter (see page 2997) instance, use the Free method instead of Destoy. Free checks that the TStreamAdapter (see page 2997) reference is not nil before calling Destroy.

Destroy frees the associated stream object (Stream (see page 3005) property) if its StreamOwnership (see page 3005) property is True.

See Also

Stream (see page 3005)

StreamOwnership (see page 3005)

Free (see page 22300)

23.1.47.4 TStreamAdapter Methods

The methods of the TStreamAdapter class are listed here.

Public Methods

	Name	Description
	Clone (see page 3000)	Implements the IStream Clone method.
	Commit (see page 3001)	Implements the IStream Commit method.
	CopyTo (see page 3001)	Implements the IStream CopyTo method.
	LockRegion (see page 3002)	Implements the IStream LockRegion method.
	Read (see page 3002)	Implements the IStream Read method.
	Revert (see page 3002)	Implements the IStream Revert method.
	Seek (see page 3003)	Implements the IStream Seek method.
	SetSize (see page 3003)	Implements the IStream SetSize method.
	Stat (see page 3004)	Implements the IStream Stat method.
	UnlockRegion (see page 3004)	Implements the IStream UnlockRegion method.
	Write (see page 3004)	Implements the IStream Write method.

23.1.47.4.1 TStreamAdapter.Clone Method

Implements the IStream Clone method.

Pascal

```
function Clone(out stm: IStream): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Clone(IStream stm);
```

Description

The Clone method defined by IStream returns a second IStream interface that accesses the same bytes as this IStream interface, but which operates independently (can have its own position).

TStreamAdapter (see page 2997) returns E_NOTIMPL to indicate that it does not support the Clone method.

23.1.47.4.2 TStreamAdapter.Commit Method

Implements the IStream Commit method.

Pascal

```
function Commit(grfCommitFlags: Longint): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Commit(Longint grfCommitFlags);
```

Description

The Commit method defined by IStream commits any changes written to a stream that is participating in a transaction.

TStreamAdapter (see page 2997) does not implement any transaction support, but operates in direct mode. Because of this, Commit returns S_OK to indicate that all changes are already written, but does nothing else.

See Also

Revert (see page 3002)

23.1.47.4.3 TStreamAdapter.CopyTo Method

Implements the IStream CopyTo method.

Pascal

```
function CopyTo(stm: IStream; cb: Largeint; out cbRead: Largeint; out cbWritten: Largeint):
HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT CopyTo(IStream stm, Largeint cb, Largeint cbRead,
Largeint cbWritten);
```

Description

CopyTo copies up to cb bytes from the current position in the stream to the stream specified by stm. cbRead returns the number of bytes successfully read from the associated stream. cbWritten returns the number of bytes successfully written to stm.

CopyTo returns S_OK if it successfully copied all the bytes read from Stream (see page 3005) to the interface specified by stm. It returns E_FAIL if it could not write all the bytes read from Stream (see page 3005) to stm. It returns E_UNEXPECTED if it encountered an exception while attempting to perform the copy operation.

See Also

Stream (see page 3005)

CopyFrom (see page 2979)

Read (see page 3002)

23.1.47.4.4 TStreamAdapter.LockRegion Method

Implements the IStream LockRegion method.

Pascal

```
function LockRegion(libOffset: Largeint; cb: Largeint; dwLockType: Longint): HResult; virtual;
stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT LockRegion(Largeint libOffset, Largeint cb, Longint
dwLockType);
```

Description

The LockRegion method defined by IStream restricts access in the associated stream from the position specified by libOffset to the position specified by cb. dwLockType indicates the type of restriction imposed.

TStreamAdapter (see page 2997) does not support locking of regions, so LockRegion returns STG_E_INVALIDFUNCTION.

See Also

UnlockRegion (see page 3004)

23.1.47.4.5 TStreamAdapter.Read Method

Implements the IStream Read method.

Pascal

```
function Read(pv: Pointer; cb: Longint; pcbRead: PLongint): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Read(void * pv, Longint cb, PLongint pcbRead);
```

Description

Read reads up to cb bytes from the current position in the stream into the buffer pointed to by pv. pcbRead returns the number of bytes actually read.

Read returns S_OK if it successfully reads pcbRead bytes into the buffer. It returns STG_E_INVALIDPOINTER it can't read because pv is nil (Delphi) or NULL (C++). It returns S_FALSE if the read operation fails for any other reason.

See Also

Write (see page 3004)

Read (see page 2982)

CopyTo (see page 3001)

23.1.47.4.6 TStreamAdapter.Revert Method

Implements the IStream Revert method.

Pascal

```
function Revert: HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Revert();
```

Description

The Revert method defined by IStream rolls back any changes written to a stream that is participating in a transaction.

TStreamAdapter (see page 2997) does not implement any transaction support, but operates in direct mode. Because of this, Revert returns STG_E_REVERTED, but does nothing else.

See Also

Commit (see page 3001)

23.1.47.4.7 TStreamAdapter.Seek Method

Implements the IStream Seek method.

Pascal

```
function Seek(dlibMove: Largeint; dwOrigin: Longint; out libNewPosition: Largeint): HResult;
virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Seek(Largeint dlibMove, Longint dwOrigin, Largeint
libNewPosition);
```

Description

Seek moves the current position of the stream to the position specified by dlibMove and dwOrigin. The dlibMove parameter indicates a number of bytes, and dwOrigin indicates from where the bytes are measured to locate the new position. The libNewPosition parameter returns the new position of the stream.

Seek returns S_OK if it successfully Seeks to the specified position. It returns STG_E_INVALIDFUNCTION if dlibMove is STREAM_SEEK_SET or STREAM_SEEK_END, because these types of seek operations are not supported by the TStream.Seek method. It returns STG_E_INVALIDPOINTER if the seek operation fails for any other reason.

See Also

Seek (see page 2988)

Stream (see page 3005)

23.1.47.4.8 TStreamAdapter.SetSize Method

Implements the IStream SetSize method.

Pascal

```
function SetSize(libNewSize: Largeint): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT SetSize(Largeint libNewSize);
```

Description

SetSize sets the size of the stream to the number of bytes specified by libNewSize.

SetSize returns S_OK if it successfully resizes the stream to libNewSize. It returns E_FAIL if it could not resize the stream and the current size of the stream is not libNewSize on exit. It returns E_UNEXPECTED if SetSize encounters an exception while trying to set the size of the stream.

See Also

Size (see page 2997)

Stream (see page 3005)

23.1.47.4.9 TStreamAdapter.Stat Method

Implements the IStream Stat method.

Pascal

```
function Stat(out statstg: TStatStg; grfStatFlag: Longint): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Stat(TStatStg statstg, Longint grfStatFlag);
```

Description

Stat fills out a TStatStg record with information about the stream object The grfStatFlag parameter indicates what information in the record, if any, is not needed.

Stat ignores the grfStatFlag parameter. It always sets dwType to STGTY_STREAM, grfLocksSupported to LOCK_WRITE, and all of the TFileTime parameters to 0. It sets cbSize to the size of the stream, and leaves the remaining fields unchanged.

Stat returns S_OK if it does not encounter any exceptions filling out statstg, E_UNEXPECTED otherwise.

See Also

Size (see page 2997)

Stream (see page 3005)

23.1.47.4.10 TStreamAdapter.UnlockRegion Method

Implements the IStream UnlockRegion method.

Pascal

```
function UnlockRegion(libOffset: Largeint; cb: Largeint; dwLockType: Longint): HResult;
virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT UnlockRegion(Largeint libOffset, Largeint cb, Longint
dwLockType);
```

Description

The UnlockRegion method defined by IStream re-enables access in the associated stream that was previously restricted by a call to LockRegion (see page 3002). The region runs from the position specified by libOffset to the position specified by cb. dwLockType indicates the type of restriction to be released.

TStreamAdapter (see page 2997) does not support locking of regions, so UnlockRegion returns STG_E_INVALIDFUNCTION.

See Also

LockRegion (see page 3002)

23.1.47.4.11 TStreamAdapter.Write Method

Implements the IStream Write method.

Pascal

```
function Write(pv: Pointer; cb: Longint; pcbWritten: PLongint): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Write(void * pv, Longint cb, PLongint pcbWritten);
```

Description

Write writes up to cb bytes from the buffer pointed to by pv into the stream, starting at the current position. pcbWritten returns the number of bytes actually written.

Write returns S_OK if it successfully writes pcbWritten bytes into the stream. It returns STG_E_INVALIDPOINTER it can't write because pv is nil. It returns STG_E_CANTSAVE if the write operation fails for any other reason.

See Also

Read (see page 3002)

Write (see page 2989)

23.1.47.5 TStreamAdapter Properties

The properties of the TStreamAdapter class are listed here.

Public Properties

	Name	Description
R	Stream (see page 3005)	Identifies the associated TStream (see page 2973) object that TStreamAdapter (see page 2997) uses to implement the IStream interface.
	StreamOwnership (see page 3005)	Specifies whether the TStreamAdapter (see page 2997) should act as the Owner of the associated stream object.

23.1.47.5.1 TStreamAdapter.Stream Property

Identifies the associated TStream (see page 2973) object that TStreamAdapter (see page 2997) uses to implement the IStream interface.

Pascal

```
property Stream: TStream;
```

C++

```
__property TStream Stream;
```

Description

Read (see page 3002) Stream to directly access the TStream (see page 2973) object that the stream adapter represents. This object is associated with the TStream (see page 2973) object in the TStreamAdapter (see page 2997) constructor.

See Also

Create (see page 2999)

StreamOwnership (see page 3005)

23.1.47.5.2 TStreamAdapter.StreamOwnership Property

Specifies whether the TStreamAdapter (see page 2997) should act as the Owner of the associated stream object.

Pascal

```
property StreamOwnership: TStreamOwnership;
```

C++

```
__property TStreamOwnership StreamOwnership;
```

Description

StreamOwnership indicates whether the TStreamAdapter (see page 2997) is responsible for freeing the associated stream object.

See Also

Create (see page 2999)

Stream (see page 3005)

Destroy (see page 3000)

23.1.48 TStringList Class

TStringList maintains a list of strings.

Class Hierarchy

Pascal

```
TStringList = class(TStrings);
```

C++

```
class TStringList : public TStrings;
```

File

Classes

Description

Use a string list object to store and manipulate a list of strings. TStringList implements the abstract properties and methods introduced by TStrings (see page 3029), and introduces new properties, events, and methods to

Sort (see page 3023) the strings in the list.

Prohibit duplicate strings in sorted lists.

Respond to changes in the contents of the list.

Control whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.

See Also

TCollection (see page 2731)

TList (see page 2868)

Adding Graphical Objects to a String List

Adding Images to a String List

List Controls

Working with Lists

23.1.48.1 TStringList Members

The following tables list the members exposed by TStringList.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 3013)	This is Changed, a member of class TStringList.
	Changing (see page 3013)	This is Changing, a member of class TStringList.
	CompareStrings (see page 3014)	Compares two strings.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
	Get (see page 3017)	Returns a string given its index.
	GetCapacity (see page 3017)	Returns the currently allocated size of the list of strings.
	GetCount (see page 3018)	Returns the number of strings in the list
	GetObject (see page 3018)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
	InsertItem (see page 3020)	This is InsertItem, a member of class TStringList.
	Put (see page 3022)	Changes the value of the string with a specified index.
	PutObject (see page 3022)	Changes the object associated with the string at a specified index.
	SetCapacity (see page 3022)	Changes the amount of memory allocated to hold strings in the list.
	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
	SetUpdateState (see page 3023)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Events

	Name	Description
	OnChange (see page 3028)	Occurs immediately after the list of strings changes.
	OnChanging (see page 3028)	Occurs immediately before the list of strings changes.

Public Methods

	Name	Description
	Add (see page 3010)	Adds a new string to the list.
	AddObject (see page 3012)	Adds a string to the list, and associates an object with the string.
	AddStrings (see page 3039)	Adds a group of strings to the list.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 3041)	Adds a string to the list.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 3043)	Sets the strings in the list, and possibly associated objects, from a source object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.

	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 3013)	Deletes all the strings from the list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	CustomSort (see page 3014)	Sorts the strings in the list in a customized order.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Delete (see page 3015)	Removes the string specified by the Index parameter.
V	Destroy (see page 3009)	Destroys an instance of TStringList (see page 3006).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
V	Exchange (see page 3015)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
V	Find (see page 3016)	Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3019)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Insert (see page 3019)	Inserts a string to the list at the position specified by Index.
V	InsertObject (see page 3020)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	Move (see page 3063)	Changes the position of a string in the list.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.
V	Sort (see page 3023)	Sorts the strings in the list in ascending order.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.

	CaseSensitive (see page 3025)	Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	Duplicates (see page 3025)	Specifies whether duplicate strings can be added to sorted lists.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	Sorted (see page 3026)	Specifies whether the strings in the list should be automatically sorted.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

23.1.48.2 TStringList.Destroy Destructor

Destroys an instance of TStringList (see page 3006).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TStringList();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TStringList (see page 3006) reference is not nil and only then calls Destroy.

Destroy frees the memory allocated to hold the list of strings and object references before calling the inherited destructor.

See Also

Free (see page 22300)

23.1.48.3 TStringList Methods

The methods of the TStringList class are listed here.

Protected Methods

	Name	Description
V	Changed (see page 3013)	This is Changed, a member of class TStringList.
V	Changing (see page 3013)	This is Changing, a member of class TStringList.

	CompareStrings (see page 3014)	Compares two strings.
	Get (see page 3017)	Returns a string given its index.
	GetCapacity (see page 3017)	Returns the currently allocated size of the list of strings.
	GetCount (see page 3018)	Returns the number of strings in the list
	GetObject (see page 3018)	Returns the object associated with the string at a specified index.
	InsertItem (see page 3020)	This is InsertItem, a member of class TStringList.
	Put (see page 3022)	Changes the value of the string with a specified index.
	PutObject (see page 3022)	Changes the object associated with the string at a specified index.
	SetCapacity (see page 3022)	Changes the amount of memory allocated to hold strings in the list.
	SetUpdateState (see page 3023)	Performs internal adjustments before or after a series of updates.

Public Methods

	Name	Description
	Add (see page 3010)	Adds a new string to the list.
	AddObject (see page 3012)	Adds a string to the list, and associates an object with the string.
	Clear (see page 3013)	Deletes all the strings from the list.
	CustomSort (see page 3014)	Sorts the strings in the list in a customized order.
	Delete (see page 3015)	Removes the string specified by the Index parameter.
	Exchange (see page 3015)	Swaps the position of two strings in the list.
	Find (see page 3016)	Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.
	IndexOf (see page 3019)	Returns the position of a string in the list.
	Insert (see page 3019)	Inserts a string to the list at the position specified by Index.
	InsertObject (see page 3020)	Inserts a string into the list at the specified position, and associates it with an object.
	Sort (see page 3023)	Sorts the strings in the list in ascending order.

23.1.48.3.1 TStringList.Add Method

Adds a new string to the list.

Pascal

```
function Add(const S: string): Integer; override;
```

C++

```
virtual __fastcall int Add(const AnsiString S);
```

Description

Call Add to add the string S to the list. If the list is sorted, S is added to the appropriate position in the sort order. If the list is not sorted, S is added to the end of the list. Add returns the position of the item in the list, where the first item in the list has a value of 0.

Note: For sorted lists, Add will raise an EListError (see page 2701) exception if the string S already appears in the list and Duplicates (see page 3025) is set to dupError. If Duplicates (see page 3025) is set to dupIgnore, trying to add a duplicate string causes Add to return the index of the existing entry.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
```

```
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TStrings *StringList = new TStringList();
  try
  {
    StringList->Add("This example uses A string List. ");
    StringList->Add("It is the easiest way to add strings");
    StringList->Add("to a combobox's list of strings. ");
    StringList->Add("Always remember TStrings is abstract,");
    StringList->Add("So create a TStringList instead.");
    ComboBox1->Width = 210;
    ComboBox1->Items->Assign(StringList);
    ComboBox1->ItemIndex = 0;
  }
  __finally
  {
    delete StringList;
  }
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
```

```
      MyList.Sort;   { Find will only work on sorted lists! }
      if MyList.Find('Flowers', Index) then
      begin
        ListBox1.Items.AddStrings(MyList);
        Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
      end;
    finally
      MyList.Free;
    end;
  end;
  {
  This example creates a stringlist, adds elements to it and
  assigns the strings to items of a combo box.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    StringList: TStringList;
  begin
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('This example uses A string List.');
        Add('It is the easiest way to add strings');
        Add('to a combobox''s list of strings.');
        Add('Always remember TStrings.Create method');
        Add('is abstract; So use TStringList.Create');
        Add('method instead.');
      end;
      with ComboBox1 do begin
        Width := 210;
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

Duplicates (see page 3025)

Insert (see page 3019)

Sorted (see page 3026)

23.1.48.3.2 TStringList.AddObject Method

Adds a string to the list, and associates an object with the string.

Pascal

```
function AddObject(const S: string; AObject: TObject): Integer; override;
```

C++

```
virtual __fastcall int AddObject(const AnsiString S, TObject * AObject);
```

Description

Call AddObject to add a string and its associated object to the list. AddObject returns the index of the new string and object.

Note: The TStringList (see page 3006) object does not own the objects you add this way. Objects (see page 3077) added to the TStringList (see page 3006) object still exist even if the TStringList (see page 3006) instance is destroyed. They must be explicitly destroyed by the application.

Note: For sorted lists, AddObject raises an EListError (see page 2701) exception if the string S already appears in the list and Duplicates (see page 3025) is set to dupError. If Duplicates (see page 3025) is set to dupIgnore, trying to add a duplicate string causes AddObject to return the index of the existing entry.

See Also

Add (see page 3010)

AddStrings (see page 3039)

23.1.48.3.3 TStringList.Changed Method

Pascal

```
procedure Changed; virtual;
```

C++

```
virtual __fastcall Changed();
```

Description

This is Changed, a member of class TStringList.

23.1.48.3.4 TStringList.Changing Method

Pascal

```
procedure Changing; virtual;
```

C++

```
virtual __fastcall Changing();
```

Description

This is Changing, a member of class TStringList.

23.1.48.3.5 TStringList.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 3015)

Objects

Strings

23.1.48.3.6 TStringList.CompareStrings Method

Compares two strings.

Pascal

```
function CompareStrings(const S1: string; const S2: string): Integer; override;
```

C++

```
virtual __fastcall int CompareStrings(const AnsiString S1, const AnsiString S2);
```

Description

TStrings uses CompareStrings internally to compare the values of strings that appear in the list. For example, the IndexOf and IndexOfName methods use CompareStrings to compare a specified string with the strings in the list.

S1 and S2 are the strings to compare.

CompareStrings returns a value less than 0 if S1 < S2, 0 if S1 == S2, and a value greater than 0 if S1 > S2.

As implemented in TStrings, CompareStrings uses the global AnsiCompareText function, which compares strings case insensitively. Some descendant classes override this method to change the way strings are compared (for example, to introduce case sensitivity).

See Also

AnsiCompareText (see page 22790)

IndexOf (see page 3056)

IndexOfName (see page 3057)

23.1.48.3.7 TStringList.CustomSort Method

Sorts the strings in the list in a customized order.

Pascal

```
procedure CustomSort(Compare: TStringListSortCompare); virtual;
```

C++

```
virtual __fastcall CustomSort(TStringListSortCompare Compare);
```

Description

Use CustomSort to sort the strings in the list, where the sort order is defined by the Compare parameter.

Supply a value for the Compare function that compares two strings in the string list. The List parameter provides access to the string list, while the Index1 and Index2 parameters identify the strings to be compared.

Do not pass nil (Delphi) or NULL (C++) as the value of the Compare parameter.

Note: You must explicitly call the CustomSort method. Setting the Sorted (see page 3026) property only sorts strings using ANSI (Windows) or UTF-8 (Linux) order, as implemented in the Sort (see page 3023) method.

See Also

Sort (see page 3023)

Strings

Sorted (see page 3026)

23.1.48.3.8 TStringList.Delete Method

Removes the string specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add (see page 3010)

AddObject (see page 3012)

Clear (see page 3013)

IndexOf (see page 3019)

InsertObject (see page 3060)

Objects

Strings

23.1.48.3.9 TStringList.Exchange Method

Swaps the position of two strings in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer); override;
```

C++

```
virtual __fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to rearrange the strings in the list. The strings are specified by their index values in the Index1 and Index2 parameters. Indexes are zero-based, so the first string in the list has an index value of 0, the second has an index value of 1, and so on.

If either string has an associated object, Exchange changes the index of the object as well.

Warning: Do not call Exchange on a sorted list except to swap two identical strings with different associated objects. Exchange does not check whether the list is sorted, and can destroy the sort order of a sorted list.

Move (see page 3063)

Objects

Sorted (see page 3026)

Strings

23.1.48.3.10 TStringList.Find Method

Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.

Pascal

```
function Find(const S: string; var Index: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Find(const AnsiString S, int Index);
```

Description

Use Find to obtain the index in a sorted list where the string S should be added. If the string S, or a string that differs from S only in case when CaseSensitive (see page 3025) is false, already exists in the list, Find returns true. If the list does not contain a string that matches S, Find returns false. The index where S should go is returned in the Index parameter. The value of Index is zero-based, where the first string has the index 0, the second string has the index 1, and so on.

Note: Only use Find with sorted lists. For unsorted lists, use the IndexOf (see page 3019) method instead.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
```

```
  added to the list box, and the index value of the 'Flowers'
  string appears in the caption of the label control.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    MyList: TStringList;
    Index: Integer;
  begin
    MyList := TStringList.Create;
    try
      MyList.Add('Animals');
      MyList.Add('Flowers');
      MyList.Add('Cars');
      MyList.Sort;   { Find will only work on sorted lists! }
      if MyList.Find('Flowers', Index) then
      begin
        ListBox1.Items.AddStrings(MyList);
        Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
      end;
    finally
      MyList.Free;
    end;
  end;
```

Duplicates (see page 3025)

IndexOf (see page 3019)

Sorted (see page 3026)

Strings

23.1.48.3.11 TStringList.Get Method

Returns a string given its index.

Pascal

```
function Get(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString Get(int Index);
```

Description

Get is the protected read implementation of the Strings property.

In TStrings Get is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the string with the specified index.

See Also

Strings (see page 3080)

23.1.48.3.12 TStringList.GetCapacity Method

Returns the currently allocated size of the list of strings.

Pascal

```
function GetCapacity: Integer; override;
```

C++

```
virtual __fastcall int GetCapacity();
```

Description

GetCapacity is the protected read implementation of the Capacity property. In TStrings, GetCapacity returns the value of the Count property. Descendants of TStrings can override this property to let a string list allocate memory for entries that have not been added to the list.

See Also

Capacity (see page 3070)

Count (see page 3071)

23.1.48.3.13 TStringList.GetCount Method

Returns the number of strings in the list

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count property.

In TStrings GetCount is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the number of strings that have been added to the list.

See Also

Count (see page 3071)

23.1.48.3.14 TStringList.GetObject Method

Returns the object associated with the string at a specified index.

Pascal

```
function GetObject(Index: Integer): TObject; override;
```

C++

```
virtual __fastcall TObject * GetObject(int Index);
```

Description

GetObject is the protected read implementation of the Objects property.

Index is the index of the string with which the object is associated.

In TStrings, GetObject always returns nil (Delphi) or NULL (C++). This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override GetObject to return the specified object.

See Also

Objects (see page 3077)

23.1.48.3.15 TStringList.IndexOf Method

Returns the position of a string in the list.

Pascal

```
function IndexOf(const S: string): Integer; override;
```

C++

```
virtual __fastcall int IndexOf(const AnsiString S);
```

Description

Call IndexOf to obtain the position of the first occurrence of a string that matches S. A string matches S if it is identical to S or, if CaseSensitive (see page 3025) is false, if it differs only in case.

IndexOf returns the 0-based index of the string. Thus, if S matches the first string in the list, IndexOf returns 0, if S is the second string, IndexOf returns 1, and so on. If the string does not have a match in the string list, IndexOf returns -1.

IndexOfObject (see page 3059)

Strings

23.1.48.3.16 TStringList.Insert Method

Inserts a string to the list at the position specified by Index.

Pascal

```
procedure Insert(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Insert(int Index, const AnsiString S);
```

Description

Call Insert to add the string S to the list at the position specified by Index. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

If the string has an associated object, use the InsertObject (see page 3020) method instead.

Note: If the list is sorted, calling Insert or InsertObject (see page 3020) will raise an EListError (see page 2701) exception. Use Add (see page 3010) or AddObject (see page 3012) with sorted lists.

See Also

Add (see page 3010)

AddObject (see page 3012)

EListError (see page 2701)

InsertObject (see page 3020)

Sorted (see page 3026)

Strings

23.1.48.3.17 TStringList.InsertItem Method

Pascal

```
procedure InsertItem(Index: Integer; const S: string; AObject: TObject); virtual;
```

C++

```
virtual __fastcall InsertItem(int Index, const AnsiString S, TObject * AObject);
```

Description

This is InsertItem, a member of class TStringList.

23.1.48.3.18 TStringList.InsertObject Method

Inserts a string into the list at the specified position, and associates it with an object.

Pascal

```
procedure InsertObject(Index: Integer; const S: string; AObject: TObject); override;
```

C++

```
virtual __fastcall InsertObject(int Index, const AnsiString S, TObject * AObject);
```

Description

Call InsertObject to insert the string S into the list at the position identified by Index, and associate it with the object AObject. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

C++ Examples:

```
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < ComponentCount; i++)
    ListBox1->Items->InsertObject(0,
                                  Components[i]->Name,
                                  (TObject *)Components[i]);
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  if (Button == mbRight)
  {
    TClass ClassRef;
    int Index = ListBox1->ItemAtPos(Point(X,Y), true);
    // only components that are controls have a position
    // make sure the component is a control
```

```
    for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
         ClassRef != NULL;
         ClassRef = ClassRef->ClassParent())
      if (String(ClassRef->ClassName()) == "TControl")
      {
        TControl *TheObject = (TControl *)ListBox1->Items->Objects[Index];
        StatusBar1->SimpleText =
          TheObject->Name + " is at (" +
          IntToStr(TheObject->Left) + ", " +
          IntToStr(TheObject->Top) + ")";
         break;
      }
    if (ClassRef == NULL) // if it wasn't a control
      MessageBeep(0);
  }
}
```

Delphi Examples:

```
{
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Form1.ComponentCount-1 do
    ListBox1.Items.InsertObject(
      0, Form1.Components[I].Name,
      Form1.Components[I] as TObject);
end;

procedure TForm1.ListBox1MouseUp(
  Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X,Y: integer);
var
  APoint: TPoint;
  Index: integer;
  TheObject: TControl;
begin
  if Button = mbRight then
  begin
  APoint.X := X;
  APoint.Y := Y;
  Index := ListBox1.ItemAtPos(APoint, True);
  if (ListBox1.Items.Objects[Index] is TControl) then
  begin
    TheObject :=
      (ListBox1.Items.Objects[Index] as TControl);
    StatusBar1.SimpleText := TheObject.Name + ' is at (' +
                             IntToStr(TheObject.Left) + ', ' +
                             IntToStr(TheObject.Top) + ') ';
  end
  else
    Beep;
```

```
  end;
end;
```

See Also

Insert (see page 3019)

Objects (see page 3077)

23.1.48.3.19 TStringList.Put Method

Changes the value of the string with a specified index.

Pascal

```
procedure Put(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Put(int Index, const AnsiString S);
```

Description

Put is the protected write implementation of the Strings property.

Put changes the value of the string with the index specified by Index to S. Put does not change the object at the specified position. That is, any object associated with the previous string becomes associated with the new string.

See Also

Strings (see page 3080)

Objects (see page 3077)

23.1.48.3.20 TStringList.PutObject Method

Changes the object associated with the string at a specified index.

Pascal

```
procedure PutObject(Index: Integer; AObject: TObject); override;
```

C++

```
virtual __fastcall PutObject(int Index, TObject * AObject);
```

Description

PutObject is the protected write implementation of the Objects property.

As implemented in TStrings, PutObject does nothing. This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override PutObject to change the specified object.

See Also

Objects (see page 3077)

23.1.48.3.21 TStringList.SetCapacity Method

Changes the amount of memory allocated to hold strings in the list.

Pascal

```
procedure SetCapacity(NewCapacity: Integer); override;
```

C++

```
virtual __fastcall SetCapacity(int NewCapacity);
```

Description

SetCapacity is the protected read implementation of the Capacity property.

Integer is the number of strings the list can hold after the capacity has changed.

In TStrings, SetCapacity does nothing. Descendant classes override this method to change the number of strings that the list can hold. For descendant classes that implement SetCapacity, assigning a value smaller than Count removes strings from the end of the list. Assigning a value greater than Count allocates space for more strings to be added.

See Also

Capacity (see page 3070)

Count (see page 3071)

23.1.48.3.22 TStringList.SetUpdateState Method

Performs internal adjustments before or after a series of updates.

Pascal

```
procedure SetUpdateState(Updating: Boolean); override;
```

C++

```
virtual __fastcall SetUpdateState(Boolean Updating);
```

Description

SetUpdateState is called at the beginning or end of a series of updates. When the BeginUpdate method is first called and the TStrings object is not already in the middle of an update, TStrings calls SetUpdateState internally, with Updating set to true. When the EndUpdate method is called and it cancels out the last unmatched call to BeginUpdate, TStrings calls SetUpdateState internally, with Updating set to false.

As implemented in TStrings, SetUpdateState does nothing. Descendant classes can override this method to optimize the response to updates.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

23.1.48.3.23 TStringList.Sort Method

Sorts the strings in the list in ascending order.

Pascal

```
procedure Sort; virtual;
```

C++

```
virtual __fastcall Sort();
```

Description

Call Sort to sort the strings in a list that has the Sorted (see page 3026) property set to false. String lists with the Sorted (see page 3026) property set to true are automatically sorted.

Note: Sort uses AnsiCompareStr to sort the strings when CaseSensitive (see page 3025) is true and AnsiCompareText when CaseSensitive (see page 3025) is false. To provide your own comparison operator instead, use the CustomSort (see page 3014) method.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
```

```
    finally
      MyList.Free;
    end;
  end;
```

CustomSort (see page 3014)

AnsiCompareText (see page 22790)

23.1.48.4 TStringList Properties

The properties of the TStringList class are listed here.

Public Properties

	Name	Description
	CaseSensitive (see page 3025)	Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.
	Duplicates (see page 3025)	Specifies whether duplicate strings can be added to sorted lists.
	Sorted (see page 3026)	Specifies whether the strings in the list should be automatically sorted.

23.1.48.4.1 TStringList.CaseSensitive Property

Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.

Pascal

```
property CaseSensitive: Boolean;
```

C++

```
__property Boolean CaseSensitive;
```

Description

Use CaseSensitive to indicate whether strings in the list should be compared in a case-sensitive or case-insensitive manner. Set CaseSensitive to true to make the string list locate, check for duplicates, and sort its strings in a case-sensitive manner. Set CaseSensitive to false to make the string list perform these operations case-insensitively.

See Also

CustomSort (see page 3014)

Sort (see page 3023)

23.1.48.4.2 TStringList.Duplicates Property

Specifies whether duplicate strings can be added to sorted lists.

Pascal

```
property Duplicates: TDuplicates;
```

C++

```
__property TDuplicates Duplicates;
```

Description

Set Duplicates to specify what should happen when an attempt is made to add a duplicate string to a sorted list. The CaseSensitive (see page 3025) property controls whether two strings are considered duplicates if they are identical except for differences in case.

The value of Duplicates should be one of the following.

Value	Meaning
dupIgnore	Ignore attempts to add duplicate strings to the list.
dupError	raise an EStringListError (see page 2705) exception when an attempt is made to add duplicate strings to the sorted list.
dupAccept	Permit duplicate strings in the sorted list.

Set Duplicates before adding any strings to the list. Setting Duplicates to dupIgnore or dupError does nothing about duplicate strings that are already in the list.

Note: Duplicates does nothing if the list is not sorted.

See Also

Add (see page 3010)

EStringListError (see page 2705)

Sorted (see page 3026)

CaseSensitive (see page 3025)

23.1.48.4.3 TStringList.Sorted Property

Specifies whether the strings in the list should be automatically sorted.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Set Sorted to true to cause the strings in the list to be automatically sorted in ascending order. Set Sorted to false to allow strings to remain where they are inserted. When Sorted is false, the strings in the list can be put in ascending order at any time by calling the Sort (see page 3023) method.

When Sorted is true, do not use Insert (see page 3019) to add strings to the list. Instead, use Add (see page 3010), which will insert the new strings in the appropriate position. When Sorted is false, use Insert (see page 3019) to add strings to an arbitrary position in the list, or Add (see page 3010) to add strings to the end of the list.

Note: The CaseSensitive (see page 3025) property controls whether the strings in the list are sorted based on a case-sensitive or case-insensitive comparison. The sort order takes into account the locale of the system on which the application is running.

C++ Examples:

```
/*
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TStringList *list = new TStringList();
  list->Add("Plants");
  list->Add("Animals");
  list->Add("Minerals");
  list->Sorted = true;
  ListBox1->Items->AddStrings(list);
  delete list;
}
```

Delphi Examples:

```
{
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
begin
  MyList := TStringList.Create;
  MyList.Add('Plants');
  MyList.Add('Animals');
  MyList.Add('Minerals');
  MyList.Sorted := True;
  ListBox1.Items.AddStrings(MyList);
  MyList.Free;
end;
```

See Also

Add (see page 3010)

Duplicates (see page 3025)

Insert (see page 3019)

Sort (see page 3023)

AnsiCompareStr (see page 22789)

CaseSensitive (see page 3025)

23.1.48.5 TStringList Events

The events of the TStringList class are listed here.

Public Events

	Name	Description
	OnChange (see page 3028)	Occurs immediately after the list of strings changes.
	OnChanging (see page 3028)	Occurs immediately before the list of strings changes.

23.1.48.5.1 TStringList.OnChange Event

Occurs immediately after the list of strings changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to respond to changes in the list of strings. For example, if the string list is associated with a control, the OnChange event handler could tell the control to repaint itself whenever the content of the list changes.

Whenever strings in the list are added, deleted, moved, or modified, the following events take place:

1An OnChanging (see page 3028) event occurs before the change.

2The strings are added, deleted, moved, or modified.

3An OnChange event occurs.

Note: OnChange occurs for every change made to the list, regardless of whether the application calls BeginUpdate (see page 3045) and EndUpdate (see page 3050) around a series of changes.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

OnChanging (see page 3028)

23.1.48.5.2 TStringList.OnChanging Event

Occurs immediately before the list of strings changes.

Pascal

```
property OnChanging: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChanging;
```

Description

Write an OnChanging event handler to prepare for changes in the list of strings. For example, if the string list is associated with a control, the OnChanging event handler could tell the control to disable repaints until the OnChange (see page 3028) event when the list has finished changing.

Whenever strings in the list are added, deleted, moved, or modified, the following events take place:

1An OnChanging event occurs.

2The strings are added, deleted, moved, or modified.

3An OnChange (see page 3028) event occurs after the changes are complete.

Note: OnChanging occurs for every change made to the list, regardless of whether the application calls BeginUpdate (see page 3045) and EndUpdate (see page 3050) around a series of changes.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

OnChange (see page 3028)

23.1.49 TStrings Class

TStrings is the base class for objects that represent a list of strings.

Class Hierarchy

Pascal

```
TStrings = class(TPersistent);
```

C++

```
class TStrings : public TPersistent;
```

File

Classes

Description

Derive a class from TStrings to store and manipulate a list of strings. TStrings contains abstract or, in C++ terminology, pure virtual methods and should not be directly instantiated.

Descendants of TStrings can represent several individual strings, such as the individual lines that appear in a list box. Some objects use descendants of TStrings to represent one long body of text so that it can be manipulated in smaller chunks.

TStrings introduces many properties and methods to

Add (see page 3033) or delete strings at specified positions in the list.

Rearrange the strings in the list.

Access the string at a particular location.

Read the strings from or write the strings to a file or stream.

Associate an object with each string in the list.

Store and retrieve strings as name-value pairs.

For an explanation of name-value pairs, refer to the NameValueSeparator (see page 3077) property.

Specifying the HTML Template

23.1.49.1 TStrings Members

The following tables list the members exposed by TStrings.

Protected Methods

	Name	Description
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	CompareStrings (see page 3048)	Compares two strings.
V	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
A	Get (see page 3053)	Returns a string given its index.
V	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
A	GetCount (see page 3054)	Returns the number of strings in the list
V	GetObject (see page 3055)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
V	Put (see page 3064)	Changes the value of the string with a specified index.
V	PutObject (see page 3065)	Changes the object associated with the string at a specified index.
V	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
V	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
V	SetUpdateState (see page 3069)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
R	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Methods

	Name	Description
V	Add (see page 3033)	Adds a string at the end of the list.
V	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
V	AddStrings (see page 3039)	Adds a group of strings to the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 3041)	Adds a string to the list.
V	Assign (see page 3043)	Sets the strings in the list, and possibly associated objects, from a source object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 3047)	Introduces an abstract (Delphi) or pure virtual (C++) method to empty the list and any associated objects.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	Delete (see page 3049)	Introduces an abstract (Delphi) or pure virtual (C++) method to delete a specified string from the list.
V	Destroy (see page 3032)	Destroys the TPersistent instance and frees its memory.

V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
V	Exchange (see page 3053)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3056)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
A	Insert (see page 3059)	Introduces abstract (Delphi) or pure virtual (C++) method to insert a string at a specified position.
V	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	Move (see page 3063)	Changes the position of a string in the list.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.

	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

23.1.49.2 TStrings.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TStrings();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Destroy (see page 22287)

23.1.49.3 TStrings Methods

The methods of the TStrings class are listed here.

Protected Methods

	Name	Description
	CompareStrings (see page 3048)	Compares two strings.
	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
	Get (see page 3053)	Returns a string given its index.
	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
	GetCount (see page 3054)	Returns the number of strings in the list
	GetObject (see page 3055)	Returns the object associated with the string at a specified index.
	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
	Put (see page 3064)	Changes the value of the string with a specified index.
	PutObject (see page 3065)	Changes the object associated with the string at a specified index.
	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
	SetUpdateState (see page 3069)	Performs internal adjustments before or after a series of updates.

Public Methods

	Name	Description
	Add (see page 3033)	Adds a string at the end of the list.
	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
	AddStrings (see page 3039)	Adds a group of strings to the list.

	Append (see page 3041)	Adds a string to the list.
V	Assign (see page 3043)	Sets the strings in the list, and possibly associated objects, from a source object.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
A	Clear (see page 3047)	Introduces an abstract (Delphi) or pure virtual (C++) method to empty the list and any associated objects.
A	Delete (see page 3049)	Introduces an abstract (Delphi) or pure virtual (C++) method to delete a specified string from the list.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
V	Exchange (see page 3053)	Swaps the position of two strings in the list.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3056)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
A	Insert (see page 3059)	Introduces abstract (Delphi) or pure virtual (C++) method to insert a string at a specified position.
V	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
V	Move (see page 3063)	Changes the position of a string in the list.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.

23.1.49.3.1 TStrings.Add Method

Adds a string at the end of the list.

Pascal

```
function Add(const S: string): Integer; virtual;
```

C++

```
virtual __fastcall int Add(const AnsiString S);
```

Description

Call Add to add a string to the end of the list. Add returns the index of the new string.

C++ Examples:

```
/*
This example adds text to a TRichEdit and to a StatusBar.
This example requires no additional controls. All controls are
created dynamically within the form's OnCreate event handler.
Note: Be sure to add ComCtrls to your uses clause to support
TRichEdit.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TStatusBar *status = new TStatusBar(this);
  // Display the StatusBar control on the surface
  // of the form.
  status->Parent = this;
```

```
  // Allow a single line of text -- no panels.
  status->SimplePanel = true;
  // Provide sample text.
  // Create a new instance of TRichEdit, set its
  // properties, and display on the form.
  TRichEdit *rich = new TRichEdit(this);
  // Display the RichEdit control on the surface
  // of the form.
  rich->Parent = this;
  // The RichText control takes all space left
  // over from the StatusBar.
  rich->Align = alClient;
  // Add 50 lines to the RichText
  for (int i = 1; i <= 50; i++)
    rich->Lines->Add(AnsiString("This is line ") + IntToStr(i));
  rich->SelStart = 0; // set text cursor to first character
  status->SimpleText = IntToStr(rich->Lines->Count) + " Lines loaded";
}
/*
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
*/
void __fastcall TForm1::Add_a_fileClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    int index = TabControl1->Tabs->Add(OpenDialog1->FileName);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[index]);
  }
}

void __fastcall TForm1::Assign_filesClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TabControl1->Tabs->Assign(OpenDialog1->Files);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[TabControl1->TabIndex]);
  }
}
/*
Place the following code in the tab control’s OnChange event
handler:
*/
void __fastcall TForm1::TabControl1Change(TObject *Sender)
{
    Memo1->Lines->LoadFromFile(
      TabControl1->Tabs->Strings[TabControl1->TabIndex]);
}
```

Delphi Examples:

```
{
This example adds text to a TRichEdit and to a StatusBar.
This example requires no additional controls. All controls are
created dynamically within the form's OnCreate event handler.
Note: Be sure to add ComCtrls to your uses clause to support
TRichEdit.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  with TStatusBar.Create(Self) do
  begin
    // Display the StatusBar control on the surface
    // of the form.
    Parent := Self;
    // Allow a single line of text -- no panels.
    SimplePanel := True;
    // Provide sample text.
    // Create a new instance of TRichEdit, set its
    // properties, and display on the form.
    with TRichEdit.Create(Self) do

23.1.49.3.2 TStrings.AddObject Method

Adds a string to the list, and associates an object with the string.

Pascal

```
function AddObject(const S: string; AObject: TObject): Integer; virtual;
```

C++

```
virtual __fastcall int AddObject(const AnsiString S, TObject * AObject);
```

Description

Call AddObject to add a string and its associated object to the list. AddObject returns the index of the new string and object.

Note: The TStrings (see page 3029) object does not own the objects you add this way. Objects (see page 3077) added to the TStrings (see page 3029) object still exist even if the TStrings (see page 3029) instance is destroyed. They must be explicitly destroyed by the application.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
```

```
  if (pCB)
    PageControl1->ActivePage = (TTabSheet *)(pCB->Items->Objects[pCB->ItemIndex]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
    ComboBox1->Items->AddObject(PageControl1->Pages[i]->Name, PageControl1->Pages[i]);
    ComboBox1->ItemIndex = 0;
  }
}
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
  ComboBox1->Items->AddObject("vsIcon", (TObject *)vsIcon);
  ComboBox1->Items->AddObject("vsList", (TObject *)vsList);
  ComboBox1->Items->AddObject("vsReport", (TObject *)vsReport);
  ComboBox1->Items->AddObject("vsSmallIcon", (TObject *)vsSmallIcon);
  // Display first item in the Combo Box
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
```

```
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
}
```

Delphi Examples:

```
{
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to PageControl1.PageCount - 1 do
    ComboBox1.Items.AddObject(PageControl1.Pages[i].Name,
      PageControl1.Pages[i]);
  ComboBox1.ItemIndex := 0;
end;

procedure TForm1.ComboBox1Change(Sender: TObject);
begin
  if (Sender is TComboBox) then
    with (Sender as TComboBox) do
      PageControl1.ActivePage := TTabSheet(Items.Objects[ItemIndex]);
end;
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
```

```
      for I := 0 to ImageList1.Count - 1 do
      begin
        ListItem := Items.Add;
        Listitem.Caption := 'Image' + IntToStr(I);
        ListItem.ImageIndex := I;
        Listitem.SubItems.Add(Col2Array[I]);
      end;
      // Create two columns to show during viewing as vsReport
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 1';
      NewColumn.Width := 200;
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 2';
      NewColumn.Width := 200;
      // Add View styles and constants to the Combo Box
      ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
      ComboBox1.Items.AddObject('vsList', TObject(vsList));
      ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
      ComboBox1.Items.AddObject(
        'vsSmallIcon', TObject(vsSmallIcon));
      // Display first item in the Combo Box
      ComboBox1.ItemIndex := 0;
    end;
  end;

  procedure TComboForm.ComboBox1Click(Sender: TObject);
  begin
    with ComboBox1 do
      ListView1.ViewStyle := TViewStyle(Items.Objects[ItemIndex]);

  end;
```

Count (see page 3071)

IndexOfObject (see page 3059)

Objects (see page 3077)

23.1.49.3.3 TStrings.AddStrings Method

Adds a group of strings to the list.

Pascal

```
procedure AddStrings(Strings: TStrings); virtual;
```

C++

```
virtual __fastcall AddStrings(TStrings Strings);
```

Description

Call AddStrings to add the strings from another TStrings (see page 3029) object to the list. If both the source and destination TStrings (see page 3029) objects support objects associated with their strings, references to the associated objects will be added as well.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
```

```
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
/*
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TStringList *list = new TStringList();
  list->Add("Plants");
  list->Add("Animals");
  list->Add("Minerals");
  list->Sorted = true;
  ListBox1->Items->AddStrings(list);
  delete list;
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
```

```
      begin
        ListBox1.Items.AddStrings(MyList);
        Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
      end;
    finally
      MyList.Free;
    end;
  end;
  {
  This example uses a list box on a form. When the application
  runs, a string list object is created and three strings are
  added to it. The strings are sorted and added to the list
  box, where they appear in their sorted order:
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    MyList: TStringList;
  begin
    MyList := TStringList.Create;
    MyList.Add('Plants');
    MyList.Add('Animals');
    MyList.Add('Minerals');
    MyList.Sorted := True;
    ListBox1.Items.AddStrings(MyList);
    MyList.Free;
  end;
```

Objects (see page 3077)

23.1.49.3.4 TStrings.Append Method

Adds a string to the list.

Pascal

```
procedure Append(const S: string);
```

C++

```
__fastcall Append(const AnsiString S);
```

Description

Append is the same as the Add (see page 3033) method, except that it does not return a value. Use Append when there is no need to know the index of the string after it has been added, or with descendants of TStrings (see page 3029) for which the index returned is not meaningful.

For example, the TStrings (see page 3029) descendant used by memo objects uses an index to determine where to insert a string, but the inserted string does not necessarily end up as a single string in the list. Part of the inserted text may become part of the previous string, and part may be broken off into a subsequent string. The index returned by Add (see page 3033) is not meaningful in this case.

Use Append rather than Add (see page 3033) as a parameter for a function requiring a TGetStrProc (see page 3294).

C++ Examples:

```
/*
This example uses an Open dialog box, a memo, and a button
on a form. When the user clicks the button, the Open dialog
box appears. When the user selects files in the dialog box
and chooses the OK button, the first line from each of the
files is added to the memo. Choose multiple files using the
CNTL key or the SHIFT key.
*/

#include <stdio.h>     // for FILE

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FILE *stream;
  char FirstLine[512];

  OpenDialog1->Options.Clear();
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist;
  OpenDialog1->Filter = "Text files (*.txt)|*.txt|All files (*.*)|*.*";
  OpenDialog1->FilterIndex = 2; // start the dialog showing all files
  if (OpenDialog1->Execute())
  {
    for (int I = 0; I < OpenDialog1->Files->Count; I ++)
    {
      stream = fopen(OpenDialog1->Files->Strings[I].c_str(), "r");
      if (stream)
      {
        // read the first line from the file
        fgets(FirstLine, sizeof(FirstLine), stream);
        Memo1->Lines->Append(FirstLine);
        fclose(stream);
      }
    }
  }
}
```

Delphi Examples:

```
{
This example uses an Open dialog box, a memo, and a button
on a form. When the user clicks the button, the Open dialog
box appears. When the user selects files in the dialog box
and chooses the OK button, the first line from each of the
files is added to the memo. Choose multiple files using the
CNTL key or the SHIFT key.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: integer;
  F: TextFile;
  FirstLine: string;
begin
  OpenDialog1.Options := [ofAllowMultiSelect, ofFileMustExist];
  OpenDialog1.Filter := 'Text files (*.txt)|*.txt|All files (*.*)|*.*';
  OpenDialog1.FilterIndex := 2; { start the dialog showing all files }
  if OpenDialog1.Execute then
    with OpenDialog1.Files do
      for I := 0 to Count - 1 do
      begin
        AssignFile(F, Strings[I]);  { next file in Files property }
        Reset(F);
        Readln(F, FirstLine);  { Read the first line out of the file }
        Memo1.Lines.Append(FirstLine);  { Add the line to the memo }
        CloseFile(F);
      end;
end;
```

23.1.49.3.5 TStrings.Assign Method

Sets the strings in the list, and possibly associated objects, from a source object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to set the value of the TStrings (see page 3029) object from another object. If Source is of type TStrings (see page 3029), the list is set to the list of the source TStrings (see page 3029) object, and if associated objects are supported, any associated objects are copied from the Source as well.

If Source is not of type TStrings (see page 3029), the inherited Assign will set the value of the list from any object that supports TStrings (see page 3029) in its AssignTo (see page 2931) method.

C++ Examples:

```
/*
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
*/
void __fastcall TForm1::Add_a_fileClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    int index = TabControl1->Tabs->Add(OpenDialog1->FileName);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[index]);
  }
}

void __fastcall TForm1::Assign_filesClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TabControl1->Tabs->Assign(OpenDialog1->Files);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[TabControl1->TabIndex]);
  }
}
/*
Place the following code in the tab control's OnChange event
handler:
```

```
*/
void __fastcall TForm1::TabControl1Change(TObject *Sender)
{
    Memo1->Lines->LoadFromFile(
      TabControl1->Tabs->Strings[TabControl1->TabIndex]);
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TStrings *StringList = new TStringList();
  try
  {
    StringList->Add("This example uses A string List. ");
    StringList->Add("It is the easiest way to add strings");
    StringList->Add("to a combobox's list of strings. ");
    StringList->Add("Always remember TStrings is abstract,");
    StringList->Add("So create a TStringList instead.");
    ComboBox1->Width = 210;
    ComboBox1->Items->Assign(StringList);
    ComboBox1->ItemIndex = 0;
  }
  __finally
  {
    delete StringList;
  }
}
```

Delphi Examples:

```
{
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
}
procedure TForm1.Add_a_fileClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
    index:= TabControl1.Tabs.Add(OpenDialog1.FileName);
    Memo1.Lines.LoadFromFile(TabControl1.Tabs[index]);
  end;
end;

procedure TForm1.Assign_filesClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
    TabControl1.Tabs.Assign(OpenDialog1.Files);
    Memo1.Lines.LoadFromFile(
      TabControl1.Tabs[TabControl1.TabIndex]);
  end;
```

```
end;

{
Place the following code in the tab control's OnChange event
handler:
}
procedure TForm1.TabControl1Change(Sender: TObject);
begin
  with TabControl1 do
    Memo1.Lines.LoadFromFile(Tabs[TabIndex]);
end;
{
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  StringList: TStringList;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
      Add('This example uses A string List.');
      Add('It is the easiest way to add strings');
      Add('to a combobox''s list of strings.');
      Add('Always remember TStrings.Create method');
      Add('is abstract; So use TStringList.Create');
      Add('method instead.');
    end;
    with ComboBox1 do begin
      Width := 210;
      Items.Assign(StringList);
      ItemIndex := 0;
    end;
  finally
    StringList.free;
  end;
end;
```

23.1.49.3.6 TStrings.BeginUpdate Method

Enables the TStrings (see page 3029) object to track when the list of strings is changing.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

BeginUpdate is called automatically by any property or method that changes the list of strings. Once the changes are complete, the property or method calls EndUpdate (see page 3050). Call BeginUpdate before directly modifying the strings in the list, and EndUpdate (see page 3050) after. When implementing properties or methods that change the list in descendants of

TStrings (see page 3029), call BeginUpdate before the changes are made, and EndUpdate (see page 3050) when the changes are complete.

TStrings (see page 3029) simply keeps track of when the list of strings is being changed. Some descendants of TStrings (see page 3029) use this information to perform certain actions, such as telling a control to repaint, when updates are complete.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if (((TForm1 *)Screen->CustomForms[i])->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
```

```
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

EndUpdate (see page 3050)

UpdateCount (see page 3085)

23.1.49.3.7 TStrings.Clear Method

Introduces an abstract (Delphi) or pure virtual (C++) method to empty the list and any associated objects.

Pascal

```
procedure Clear; virtual; abstract;
```

C++

```
virtual __fastcall Clear() = 0;
```

Description

Descendants of TStrings (see page 3029) implement a Clear method to delete all the strings in the list, and to remove any references to associated objects.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if (((TForm1 *)Screen->CustomForms[i])->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
```

```
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

See Also

Delete (see page 3049)

Objects (see page 3077)

Strings (see page 3080)

23.1.49.3.8 TStrings.CompareStrings Method

Compares two strings.

Pascal

```
function CompareStrings(const S1: string; const S2: string): Integer; virtual;
```

C++

```
virtual __fastcall int CompareStrings(const AnsiString S1, const AnsiString S2);
```

Description

TStrings (see page 3029) uses CompareStrings internally to compare the values of strings that appear in the list. For example, the IndexOf (see page 3056) and IndexOfName (see page 3057) methods use CompareStrings to compare a specified string with the strings in the list.

S1 and S2 are the strings to compare.

CompareStrings returns a value less than 0 if S1 < S2, 0 if S1 == S2, and a value greater than 0 if S1 > S2.

As implemented in TStrings (see page 3029), CompareStrings uses the global AnsiCompareText function, which compares strings case insensitively. Some descendant classes override this method to change the way strings are compared (for example, to introduce case sensitivity).

See Also

AnsiCompareText (see page 22790)

IndexOf (see page 3056)

IndexOfName (see page 3057)

23.1.49.3.9 TStrings.DefineProperties Method

Reads and writes the Strings (see page 3080) property as if it were published.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TStrings (see page 3029) overrides DefineProperties so that the strings in the list can be loaded and saved with a form file as if the Strings (see page 3080) property were published.

See Also

DefineProperties (see page 2931)

Strings (see page 3080)

23.1.49.3.10 TStrings.Delete Method

Introduces an abstract (Delphi) or pure virtual (C++) method to delete a specified string from the list.

Pascal

```
procedure Delete(Index: Integer); virtual; abstract;
```

C++

```
virtual __fastcall Delete(int Index) = 0;
```

Description

Descendants of TStrings (see page 3029) implement a Delete method to remove a specified string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

AddObject (see page 3036)

Clear (see page 3047)

IndexOf (see page 3056)

InsertObject (see page 3060)

Objects (see page 3077)

Strings (see page 3080)

23.1.49.3.11 TStrings.EndUpdate Method

Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

EndUpdate is called automatically by any property or method that changes the list of strings. Call BeginUpdate (see page 3045) before directly modifying the strings in the list, and EndUpdate after. When implementing properties or methods that change the list in descendants of TStrings (see page 3029), call BeginUpdate (see page 3045) before the changes are made, and EndUpdate when the changes are complete.

TStrings (see page 3029) simply keeps track of when the list of strings is being changed. Some descendants of TStrings (see page 3029) use this information to perform certain actions, such as telling a control to repaint, when updates are complete.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if (((TForm1 *)Screen->CustomForms[i])->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

See Also

BeginUpdate (see page 3045)

UpdateCount (see page 3085)

23.1.49.3.12 TStrings.Equals Method

Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.

Pascal

```
function Equals(Strings: TStrings): Boolean;
```

C++

```
__fastcall Boolean Equals(TStrings Strings);
```

Description

Call Equals to compare the lists in two TStrings (see page 3029) objects. Equals compares only the strings, not any references to associated objects. Equals returns true if the lists for both TStrings (see page 3029) objects have the same number of strings and the strings in each list match. Equals returns false if the lists are different in length, if they contain different strings, or if the order of the strings in the two lists differ.

Note: The Equals method uses an overridden Get (see page 3053) method to perform the compare, thus it does not provide a context-insensitive option.

See Also

Count (see page 3071)

Strings (see page 3080)

CompareStrings (see page 3048)

23.1.49.3.13 Error Method

This is the overview for the Error method overload.

Overload List

	Name	Description
	TStrings.Error (PResStringRec, Integer) (see page 3052)	raises an EStringListError (see page 2705) exception.
	TStrings.Error (string, Integer) (see page 3052)	raises an EStringListError (see page 2705) exception.

23.1.49.3.13.1 TStrings.Error Method (PResStringRec, Integer)

raises an EStringListError (see page 2705) exception.

Pascal

```
procedure Error(const Msg: string; Data: Integer); overload;
procedure Error(Msg: PResStringRec; Data: Integer); overload;
```

C++

```
__fastcall Error(const AnsiString Msg, int Data);
__fastcall Error(PResStringRec Msg, int Data);
```

Description

TStrings (see page 3029) calls Error internally to raise an EStringListError (see page 2705) exception when it encounters a problem.

Msg specifies the string with a single format specifier for an integer, that appears in the exception message box. It can be either a string, or a pointer to a record structure that indicates the module and resource identifier for a string.

Data is an integer value that is inserted into Msg.

See Also

EStringListError (see page 2705)

23.1.49.3.14 TStrings.Exchange Method

Swaps the position of two strings in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer); virtual;
```

C++

```
virtual __fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to rearrange the strings in the list. The strings are specified by their index values in the Index1 and Index2 parameters. Indexes are zero-based, so the first string in the list has an index value of 0, the second has an index value of 1, and so on.

If either string has an associated object, Exchange changes the position of the object as well.

See Also

Move (see page 3063)

Objects (see page 3077)

Strings (see page 3080)

23.1.49.3.15 TStrings.ExtractName Method

Returns the name portion of a string that is a name value pair.

Pascal

```
function ExtractName(const S: string): string;
```

C++

```
__fastcall AnsiString ExtractName(const AnsiString S);
```

Description

TStrings (see page 3029) calls ExtractName internally to parse strings that are name-value pairs and return the name portion.

S is the string to parse.

If S is a name-value pair, ExtractName returns the name portion. Otherwise, ExtractName returns an empty string.

See Also

Names (see page 3075)

23.1.49.3.16 TStrings.Get Method

Returns a string given its index.

Pascal

```
function Get(Index: Integer): string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString Get(int Index) = 0;
```

Description

Get is the protected read implementation of the Strings (see page 3080) property.

In TStrings (see page 3029) Get is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the string with the specified index.

See Also

Strings (see page 3080)

23.1.49.3.17 TStrings.GetCapacity Method

Returns the currently allocated size of the list of strings.

Pascal

```
function GetCapacity: Integer; virtual;
```

C++

```
virtual __fastcall int GetCapacity();
```

Description

GetCapacity is the protected read implementation of the Capacity (see page 3070) property. In TStrings (see page 3029), GetCapacity returns the value of the Count (see page 3071) property. Descendants of TStrings (see page 3029) can override this property to let a string list allocate memory for entries that have not been added to the list.

See Also

Capacity (see page 3070)

Count (see page 3071)

23.1.49.3.18 TStrings.GetCount Method

Returns the number of strings in the list

Pascal

```
function GetCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetCount() = 0;
```

Description

GetCount is the protected read implementation of the Count (see page 3071) property.

In TStrings (see page 3029) GetCount is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the number of strings that have been added to the list.

See Also

Count (see page 3071)

23.1.49.3.19 TStrings.GetEnumerator Method

Returns a TStrings (see page 3029) enumerator.

Pascal

```
function GetEnumerator: TStringsEnumerator;
```

C++

```
__fastcall TStringsEnumerator GetEnumerator();
```

Description

GetEnumerator returns a TStringsEnumerator (see page 3086) reference, which enumerates the strings in a TStrings (see page 3029) object.

To process all these strings, call the TStringsEnumerator (see page 3086) GetCurrent method within a While MoveNext do loop.

See Also

TStringsEnumerator (see page 3086)

23.1.49.3.20 TStrings.GetObject Method

Returns the object associated with the string at a specified index.

Pascal

```
function GetObject(Index: Integer): TObject; virtual;
```

C++

```
virtual __fastcall TObject * GetObject(int Index);
```

Description

GetObject is the protected read implementation of the Objects (see page 3077) property.

Index is the index of the string with which the object is associated.

In TStrings (see page 3029), GetObject always returns nil (Delphi) or NULL (C++). This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override GetObject to return the specified object.

See Also

Objects (see page 3077)

23.1.49.3.21 TStrings.GetText Method

Allocates a text buffer and fills it with the value of the Text (see page 3084) property.

Pascal

```
function GetText: PChar; virtual;
```

C++

```
virtual __fastcall const char * GetText();
```

Description

Call GetText to obtain a dynamically allocated character buffer containing all of the strings in the list. Individual strings are separated by a carriage return and (on Windows) line feed. The caller is responsible for freeing the returned value using the StrDispose procedure.

See Also

SetText (see page 3068)

Strings (see page 3080)

Text (see page 3084)

StrDispose (see page 22947)

23.1.49.3.22 TStrings.GetTextStr Method

Returns the value of the Text (see page 3084) property.

Pascal

```
function GetTextStr: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetTextStr();
```

Description

GetTextStr is the protected read implementation of the Text (see page 3084) property. It returns a string that lists all the strings in the list, with individual strings separated by a carriage return and (on Windows) line feed.

See Also

GetText (see page 3055)

Text (see page 3084)

23.1.49.3.23 TStrings.IndexOf Method

Returns the position of a string in the list.

Pascal

```
function IndexOf(const S: string): Integer; virtual;
```

C++

```
virtual __fastcall int IndexOf(const AnsiString S);
```

Description

Call IndexOf to obtain the position of the first occurrence of the string S, or of a string that differs from S only by case. IndexOf returns the 0-based index of the string. Thus, if S matches the first string in the list, IndexOf returns 0, if S is the second string, IndexOf returns 1, and so on. If the string is not in the string list, IndexOf returns -1.

Note: If the string appears in the list more than once, IndexOf returns the position of the first occurrence.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
```

```
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

See Also

IndexOfName (see page 3057)

IndexOfObject (see page 3059)

Strings (see page 3080)

23.1.49.3.24 TStrings.IndexOfName Method

Returns the position of the first name-value pair with the specified name.

Pascal

```
function IndexOfName(const Name: string): Integer; virtual;
```

C++

```
virtual __fastcall int IndexOfName(const AnsiString Name);
```

Description

Call IndexOfName to locate the first occurrence of a name-value pair where the name part is equal to the Name parameter or differs only in case. IndexOfName returns the 0-based index of the string. If no string in the list has the indicated name, IndexOfName returns -1.

Note: If there is more than one name-value pair with a name portion matching the Name parameter, IndexOfName returns the position of the first such string.

C++ Examples:

```
/*
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
```

```
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.  TStrings Values are referenced using the
name AnsiString as an index.
*/
void MergeStrings(TStrings *Dest, TStrings *Source)
{
  for (int i = 0; i < Source->Count; i++)
  {
    if (Source->Strings[i].Pos("=") > 1)
    {
      int DI = Dest->IndexOfName(Source->Names[i]);
      if (DI > -1)
        Dest->Values[Source->Names[i]] = Source->Values[Source->Names[i]];
    }
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MergeStrings(ListBox1->Items,ListBox2->Items);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Plants = 10");
  ListBox1->Items->Add("Animals = 20");
  ListBox1->Items->Add("Minerals = 15");
  ListBox2->Items->Add("Animals = 4");
  ListBox2->Items->Add("Plants = 3");
  ListBox2->Items->Add("Minerals = 78");
}
```

Delphi Examples:

```
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
  begin
  for I := 0 to Source.Count - 1 do
  begin
    if Pos ('=', Source[I]) > 1 then
    begin
      DI := Dest.IndexOfName(Source.Names[I]);
      if DI > -1 then Dest[DI] := Source[I];
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MergeStrings(ListBox1.Items, ListBox2.Items);
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  ListBox1.Items.Add('Plants = 10');
  ListBox1.Items.Add('Animals = 20');
  ListBox1.Items.Add('Minerals = 15');
  ListBox2.Items.Add('Animals = 4');
  ListBox2.Items.Add('Plants = 3');
  ListBox2.Items.Add('Minerals = 78');
end;
```

Values (see page 3086)

23.1.49.3.25 TStrings.IndexOfObject Method

Returns the index of the first string in the list associated with a given object.

Pascal

```
function IndexOfObject(AObject: TObject): Integer; virtual;
```

C++

```
virtual __fastcall int IndexOfObject(TObject * AObject);
```

Description

Call IndexOfObject to locate the first string in the list associated with the object AObject. Specify the object you want to locate as the value of the AObject parameter. IndexOfObject returns the 0-based index of the string and object. If the object is not associated with any of the strings, IndexOfObject returns -1.

See Also

IndexOf (see page 3056)

Objects (see page 3077)

23.1.49.3.26 TStrings.Insert Method

Introduces abstract (Delphi) or pure virtual (C++) method to insert a string at a specified position.

Pascal

```
procedure Insert(Index: Integer; const S: string); virtual; abstract;
```

C++

```
virtual __fastcall Insert(int Index, const AnsiString S) = 0;
```

Description

Descendants of TStrings (see page 3029) implement an Insert method to add the string S to the list at the position specified by Index. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

All methods that add strings to the list use the Insert method to add the string.

If the string has an associated object, use the InsertObject (see page 3060) method instead.

See Also

Add (see page 3033)

AddObject (see page 3036)

AddStrings (see page 3039)

Append (see page 3041)

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

InsertObject (see page 3060)

Strings (see page 3080)

23.1.49.3.27 TStrings.InsertObject Method

Inserts a string into the list at the specified position, and associates it with an object.

Pascal

```
procedure InsertObject(Index: Integer; const S: string; AObject: TObject); virtual;
```

C++

```
virtual __fastcall InsertObject(int Index, const AnsiString S, TObject * AObject);
```

Description

Call InsertObject to insert the string S into the list at the position identified by Index, and associate it with the object AObject. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

C++ Examples:

```
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < ComponentCount; i++)
    ListBox1->Items->InsertObject(0,
                                  Components[i]->Name,
                                  (TObject *)Components[i]);
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  if (Button == mbRight)
  {
    TClass ClassRef;
    int Index = ListBox1->ItemAtPos(Point(X,Y), true);
    // only components that are controls have a position
    // make sure the component is a control
```

```
    for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
         ClassRef != NULL;
         ClassRef = ClassRef->ClassParent())
      if (String(ClassRef->ClassName()) == "TControl")
      {
        TControl *TheObject = (TControl *)ListBox1->Items->Objects[Index];
        StatusBar1->SimpleText =
          TheObject->Name + " is at (" +
          IntToStr(TheObject->Left) + ", " +
          IntToStr(TheObject->Top) + ")";
         break;
      }
    if (ClassRef == NULL) // if it wasn't a control
      MessageBeep(0);
  }
}
```

See Also

Insert (see page 3059)

Objects (see page 3077)

23.1.49.3.28 TStrings.LoadFromFile Method

Fills the list with the lines of text in a specified file.

Pascal

```
procedure LoadFromFile(const FileName: string); virtual;
```

C++

```
virtual __fastcall LoadFromFile(const AnsiString FileName);
```

Description

Call LoadFromFile to fill the list of the TStrings (see page 3029) object from the file specified by FileName. LoadFromFile first clears any strings already in the list. Then, each line in the file, as indicated by carriage return or linefeed characters, is appended as a string in the list.

Note: LoadFromFile uses the Add (see page 3033) method to add the strings that are read from the file.

C++ Examples:

```
/*
This example requires two TRichEdit controls placed on the
form.  When the form becomes visible, the first Rich Edit
control will display the rich text in its raw form, including
formatting characters. The second will show the rich text in
its intended format.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
// you may need to change this path to suit your environment
  char const *Path = "..\\OVERVIEW.RTF";
  RichEdit1->PlainText = true;
  RichEdit1->Lines->LoadFromFile(Path);
  RichEdit2->PlainText = false;
  RichEdit2->Lines->LoadFromFile(Path);
}
```

Delphi Examples:

```
{
```

```
This example requires two TRichEdit controls placed on the
form.  When the form becomes visible, the first Rich Edit
control will display the rich text in its raw form, including
formatting characters. The second will show the rich text in
its intended format.
}

procedure TForm1.FormCreate(Sender: TObject);
const
  // you may need to change this path to suit your environment
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := True;
  RichEdit1.Lines.LoadFromFile(Path);
  RichEdit1.ScrollBars := ssVertical;
  RichEdit2.PlainText := False;
  RichEdit2.Lines.LoadFromFile(Path);
  RichEdit2.ScrollBars := ssVertical;
end;
```

Add (see page 3033)

LoadFromStream (see page 3062)

SaveToFile (see page 3065)

Strings (see page 3080)

Text (see page 3084)

23.1.49.3.29 TStrings.LoadFromStream Method

Fills the list with lines of text read from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); virtual;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream);
```

Description

Call LoadFromStream to fill the list of the TStrings (see page 3029) object from the stream specified by Stream. The text read from the stream is parsed into strings separated by carriage return or linefeed characters. Thus, LoadFromStream reads the value of the Text (see page 3084) property.

If the stream is a file stream, LoadFromStream does the same thing as LoadFromFile (see page 3061), except the application must create and destroy the file stream.

C++ Examples:

```
/*
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemoryStream* pms = new TMemoryStream();
  ListBox1->Items->SaveToStream(pms); // write list box contents to the
                                      // stream.
```

```
  pms->Position = 0;                  // reset to the beginning of the stream.
  RichEdit1->Lines->LoadFromStream(pms); // load stream contents into rich
                                         // edit control.
  delete pms;
}
```

Delphi Examples:

```
{
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TempStream : TMemoryStream;
begin
  TempStream := TMemoryStream.Create;
  ListBox1.Items.SaveToStream(TempStream);  // write list box contents to the
                                            // stream
  TempStream.Position := 0;      // reset to the beginning of the stream
  RichEdit1.Lines.LoadFromStream( TempStream); // load stream contents into rich
                                               // edit control
  TempStream.Free;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Apples');
  ListBox1.Items.Add('Oranges');
  ListBox1.Items.Add('Pears');
end;
```

See Also

Add (see page 3033)

LoadFromFile (see page 3061)

SaveToStream (see page 3067)

Text (see page 3084)

23.1.49.3.30 TStrings.Move Method

Changes the position of a string in the list.

Pascal

```
procedure Move(CurIndex: Integer; NewIndex: Integer); virtual;
```

C++

```
virtual __fastcall Move(int CurIndex, int NewIndex);
```

Description

Use Move to move the string at position CurIndex so that it occupies the position NewIndex. The positions are specified as 0-based indexes. For example, the following lines of code move the string in the first position to the last position.

```
MyStringsObject.Move(0, MyStringsObject.Count
MyStringsObject->Move(0, MyStringsObject->Count - 1);
```

If the string has an associated object, the object remains associated with the string in its new position.

C++ Examples:

```
/*
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
clicks the button, the selected item in the list box is
moved to the top of the list box:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->MultiSelect = false;
  Button1->Caption = "Move to Top";
  for (int i = 1; i <= 10; i++)
    ListBox1->Items->Add("Item " + IntToStr(i));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ListBox1->ItemIndex >= 0 && ListBox1->ItemIndex <= 9)
    ListBox1->Items->Move(ListBox1->ItemIndex, 0);
}
```

Delphi Examples:

```
{
This example uses a list box and a button on a form. The
list box contains items when the form appears. When the user
clicks the button, the selected item in the list box is
moved to the top of the list box:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (ListBox1.ItemIndex in [0..9]) then
    ListBox1.Items.Move(ListBox1.ItemIndex, 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  ListBox1.MultiSelect := False;
  Button1.Caption := 'Move to Top';
  for I := 1 to 10 do
    ListBox1.Items.Add('Item ' + IntToStr(I));
end;
```

See Also

Count (see page 3071)

Objects (see page 3077)

Strings (see page 3080)

23.1.49.3.31 TStrings.Put Method

Changes the value of the string with a specified index.

Pascal

```
procedure Put(Index: Integer; const S: string); virtual;
```

C++

```
virtual __fastcall Put(int Index, const AnsiString S);
```

Description

Put is the protected write implementation of the Strings (see page 3080) property.

Put changes the value of the string with the index specified by Index to S. Put does not change the object at the specified position. That is, any object associated with the previous string becomes associated with the new string.

See Also

Strings (see page 3080)

Objects (see page 3077)

23.1.49.3.32 TStrings.PutObject Method

Changes the object associated with the string at a specified index.

Pascal

```
procedure PutObject(Index: Integer; AObject: TObject); virtual;
```

C++

```
virtual __fastcall PutObject(int Index, TObject * AObject);
```

Description

PutObject is the protected write implementation of the Objects (see page 3077) property.

As implemented in TStrings (see page 3029), PutObject does nothing. This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override PutObject to change the specified object.

See Also

Objects (see page 3077)

23.1.49.3.33 TStrings.SaveToFile Method

Saves the strings in the list to the specified file.

Pascal

```
procedure SaveToFile(const FileName: string); virtual;
```

C++

```
virtual __fastcall SaveToFile(const AnsiString FileName);
```

Description

Call SaveToFile to save the strings in the list to the file specified by FileName. Each string in the list is written to a separate line in the file.

Note: In Linux, SaveToFile saves the strings as they appear in the list. If the last string does not have an end-of-line marker, the resulting file may be considered incomplete by some editors.

C++ Examples:

```
/*
This example displays a print dialog box with a Print to
File check box, and then prints the contents of a rich edit
control to the indicated destination:
Verify that the file is saved by the SaveDialog.
*/
void __fastcall TForm1::BitBtn1Click(TObject *Sender)
{
  PrintDialog1->Options << poPrintToFile;
```

```
    PrintDialog1->PrintToFile = true;
    if (PrintDialog1->Execute())
    {
      if (PrintDialog1->PrintToFile)
      {
        SaveDialog1->Title = "Print to File:";
        if (SaveDialog1->Execute())
          RichEdit1->Lines->SaveToFile(SaveDialog1->FileName);
        else
          RichEdit1->Print("");
      }
    }
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
  // you may need to change this path to suit your environment
    char const *Path = "..\\overview.rtf";
    RichEdit1->PlainText = false;
    RichEdit1->Lines->LoadFromFile(Path);
    RichEdit1->ScrollBars = ssVertical;
  }
```

Delphi Examples:

```
  {
  This example displays a print dialog box with a Print to
  File check box, and then prints the contents of a rich edit
  control to the indicated destination:
  Verify that the file is saved by the SaveDialog.
  }
  procedure TForm1.BitBtn1Click(Sender: TObject);
  begin
  with PrintDialog1 do
    begin
    Options := [poPrintToFile];
    PrintToFile := True;
    if Execute then
      begin
      if PrintToFile then
        begin
        SaveDialog1.Title := 'Print to File: ';
        if SaveDialog1.Execute then
          RichEdit1.Lines.SaveToFile(SaveDialog1.FileName);
        end
      else
        RichEdit1.Print('');
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const
    // you may need to change this path to suit your environment
    Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
```

SaveToStream (see page 3067)

Strings (see page 3080)

Text (see page 3084)

23.1.49.3.34 TStrings.SaveToStream Method

Writes the value of the Text (see page 3084) property to a stream object.

Pascal

```
procedure SaveToStream(Stream: TStream); virtual;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream);
```

Description

Call SaveToStream to save the strings in the list to the stream specified by the Stream parameter. SaveToStream writes the strings delimited by carriage return, line feed pairs. If the stream is a file stream, SaveToStream does the same thing as SaveToFile (see page 3065), except the application must create and destroy the file stream.

C++ Examples:

```
/*
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemoryStream* pms = new TMemoryStream();
  ListBox1->Items->SaveToStream(pms); // write list box contents to the
                                      // stream.
  pms->Position = 0;                  // reset to the beginning of the stream.
  RichEdit1->Lines->LoadFromStream(pms); // load stream contents into rich
                                         // edit control.
  delete pms;
}
```

Delphi Examples:

```
{
This example requires TListBox, TMemo, TRichEdit, and
TButton controls placed on the form. The list box should
contain one or more items.  When the form becomes visible,
click on the button and the contents of the list box will be
transferred to a stream and then to the rich edit control.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TempStream : TMemoryStream;
begin
  TempStream := TMemoryStream.Create;
  ListBox1.Items.SaveToStream(TempStream);  // write list box contents to the
                                            // stream
  TempStream.Position := 0;      // reset to the beginning of the stream
  RichEdit1.Lines.LoadFromStream( TempStream); // load stream contents into rich
                                               // edit control
  TempStream.Free;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
  ListBox1.Items.Add('Apples');
  ListBox1.Items.Add('Oranges');
  ListBox1.Items.Add('Pears');
end;
```

Text (see page 3084)

23.1.49.3.35 TStrings.SetCapacity Method

Changes the amount of memory allocated to hold strings in the list.

Pascal

```
procedure SetCapacity(NewCapacity: Integer); virtual;
```

C++

```
virtual __fastcall SetCapacity(int NewCapacity);
```

Description

SetCapacity is the protected read implementation of the Capacity (see page 3070) property.

Integer is the number of strings the list can hold after the capacity has changed.

In TStrings (see page 3029), SetCapacity does nothing. Descendant classes override this method to change the number of strings that the list can hold. For descendant classes that implement SetCapacity, assigning a value smaller than Count (see page 3071) removes strings from the end of the list. Assigning a value greater than Count (see page 3071) allocates space for more strings to be added.

See Also

Capacity (see page 3070)

Count (see page 3071)

23.1.49.3.36 TStrings.SetText Method

Sets the Text (see page 3084) property.

Pascal

```
procedure SetText(Text: PChar); virtual;
```

C++

```
virtual __fastcall SetText(const char * Text);
```

Description

Call SetText to replace the list with the strings specified by the Text (see page 3084) parameter. SetText adds strings one at a time to the list, using the carriage returns or linefeed characters in Text (see page 3084) as delimiters indicating when to add a new string.

See Also

Add (see page 3033)

Text (see page 3084)

23.1.49.3.37 TStrings.SetTextStr Method

Sets the Text (see page 3084) property.

Pascal

```
procedure SetTextStr(const Value: string); virtual;
```

C++

```
virtual __fastcall SetTextStr(const AnsiString Value);
```

Description

GetTextStr (see page 3056) is the protected write implementation of the Text (see page 3084) property. It replaces the list with the strings specified by the Value parameter. SetTextStr adds strings one at a time to the list, using the carriage returns or linefeed characters in Value as delimiters indicating when to add a new string.

See Also

SetText (see page 3068)

Text (see page 3084)

23.1.49.3.38 TStrings.SetUpdateState Method

Performs internal adjustments before or after a series of updates.

Pascal

```
procedure SetUpdateState(Updating: Boolean); virtual;
```

C++

```
virtual __fastcall SetUpdateState(Boolean Updating);
```

Description

SetUpdateState is called at the beginning or end of a series of updates. When the BeginUpdate (see page 3045) method is first called and the TStrings (see page 3029) object is not already in the middle of an update, TStrings (see page 3029) calls SetUpdateState internally, with Updating set to true. When the EndUpdate (see page 3050) method is called and it cancels out the last unmatched call to BeginUpdate (see page 3045), TStrings (see page 3029) calls SetUpdateState internally, with Updating set to false.

As implemented in TStrings (see page 3029), SetUpdateState does nothing. Descendant classes can override this method to optimize the response to updates.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

23.1.49.4 TStrings Properties

The properties of the TStrings class are listed here.

Protected Properties

	Name	Description
R	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

23.1.49.4.1 TStrings.Capacity Property

Indicates the number of strings the TStrings (see page 3029) object can hold.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

Read Capacity to determine the currently allocated size of the string list. For the TStrings (see page 3029) object, reading Capacity returns the Count (see page 3071) property, and setting Capacity does nothing. Descendants of TStrings (see page 3029) can override this property to allow a string list to allocate memory for entries that have not been added to the list.

See Also

Count (see page 3071)

23.1.49.4.2 TStrings.CommaText Property

Lists the strings in the TStrings (see page 3029) object in system data format (SDF).

Pascal

```
property CommaText: string;
```

C++

```
__property AnsiString CommaText;
```

Description

Use CommaText to get or set all the strings in the TStrings (see page 3029) object in a single comma-delimited string.

When retrieving CommaText, any string in the list that include spaces, commas or quotes will be contained in double quotes, and any double quotes in a string will be repeated. For example, if the list contains the following strings:

```
Stri,ng 1
Stri"ng 2
String 3
String4
```

CommaText will return:

```
"Stri,ng 1","Stri""ng 2","String 3",String4
```

When assigning CommaText, the value is parsed as SDF formatted text. For SDF format, strings are separated by commas or spaces, and optionally enclosed in double quotes. Double quote marks that are part of the string are repeated to distinguish them from the quotes that surround the string. Spaces and commas that are not contained within double quote marks are delimiters. Two commas next to each other will indicate an empty string, but spaces that appear next to another delimiter are ignored. For example, suppose CommaText is set to:

```
"Stri,ng 1", "Stri""ng 2" , String 3,String4
```

The list will then contain:

```
Stri,ng 1
Stri"ng 2
String
3
String4
```

Note: CommaText is the same as the DelimitedText (see page 3074) property with a delimiter of ',' and a quote character of "".

Including a trailing comma in the source string causes a blank item to be included in the string list. For example, if CommaText is set to

```
"String1, String 2, String 3,"
```

the string list will contain

```
String1
String2
String3
<Blank>
```

See Also

Add (see page 3033)

Strings (see page 3080)

Text (see page 3084)

DelimitedText (see page 3074)

23.1.49.4.3 TStrings.Count Property

Introduces an abstract property to represent the number of strings in the list.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Descendants of TStrings (see page 3029) implement a Count property to indicate the number of strings in the list.

Use the Count property when iterating over all the strings in the list, or when trying to locate the position of a string relative to the last string in the list.

C++ Examples:

```
/*
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.  TStrings Values are referenced using the
name AnsiString as an index.
*/
void MergeStrings(TStrings *Dest, TStrings *Source)
{
  for (int i = 0; i < Source->Count; i++)
  {
    if (Source->Strings[i].Pos("=") > 1)
    {
      int DI = Dest->IndexOfName(Source->Names[i]);
      if (DI > -1)
        Dest->Values[Source->Names[i]] = Source->Values[Source->Names[i]];
    }
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MergeStrings(ListBox1->Items,ListBox2->Items);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Plants = 10");
  ListBox1->Items->Add("Animals = 20");
  ListBox1->Items->Add("Minerals = 15");
  ListBox2->Items->Add("Animals = 4");
  ListBox2->Items->Add("Plants = 3");
  ListBox2->Items->Add("Minerals = 78");
}
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
```

```
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
  begin
  for I := 0 to Source.Count - 1 do
  begin
    if Pos ('=', Source[I]) > 1 then
    begin
      DI := Dest.IndexOfName(Source.Names[I]);
      if DI > -1 then Dest[DI] := Source[I];
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MergeStrings(ListBox1.Items, ListBox2.Items);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Plants = 10');
  ListBox1.Items.Add('Animals = 20');
  ListBox1.Items.Add('Minerals = 15');
  ListBox2.Items.Add('Animals = 4');
  ListBox2.Items.Add('Plants = 3');
  ListBox2.Items.Add('Minerals = 78');
end;
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

IndexOf (see page 3056)

Strings (see page 3080)

23.1.49.4.4 TStrings.DelimitedText Property

Represents all the strings in the TStrings (see page 3029) object as a single delimited string.

Pascal

```
property DelimitedText: string;
```

C++

```
__property AnsiString DelimitedText;
```

Description

Use DelimitedText to get or set all the strings in the TStrings (see page 3029) object in a single string.

When retrieving DelimitedText, the resulting value delimits individual strings in two ways: each string is surrounded (before and after) by the quote character specified by the QuoteChar (see page 3080) property. In addition, individual strings are separated by the character specified by the Delimiter (see page 3074) property.

When assigning DelimitedText, individual strings must be separated using QuoteChar (see page 3080) at both ends, using Delimiter (see page 3074) as a separator, or using both these methods.

A space is always interpreted as a delimiter, regardless of the value of Delimiter (see page 3074), unless the space occurs between quote characters.

Note: CommaText (see page 3070) is the same as the DelimitedText property when Delimiter (see page 3074) is ',' and QuoteChar (see page 3080) is "".

See Also

CommaText (see page 3070)

Delimiter (see page 3074)

Text (see page 3084)

QuoteChar (see page 3080)

23.1.49.4.5 TStrings.Delimiter Property

Specifies the delimiter used by the DelimitedText (see page 3074) property.

Pascal

```
property Delimiter: Char;
```

C++

```
__property Char Delimiter;
```

Description

Use Delimiter to get or set the delimiter used by the DelimitedText (see page 3074) property. DelimitedText (see page 3074) represents all of the strings in the TStrings (see page 3029) object as a single string, with individual strings separated by the character that is the value of Delimiter.

See Also

DelimitedText (see page 3074)

QuoteChar (see page 3080)

23.1.49.4.6 TStrings.LineBreak Property

Defines the line break character(s).

Pascal

```
property LineBreak: string;
```

C++

```
__property AnsiString LineBreak;
```

Description

LineBreak can be read and set. It is used internally in TStrings (see page 3029) to terminate strings in multi-string output operations.

For example, the GetText (see page 3055) method returns a long string containing all TStrings (see page 3029) strings, each of which is terminated by the LineBreak value.

Note: In Windows, the default LineBreak value is a carriage return and line feed combination (#13#10), whereas on Linux, it is just a carriage return (#13).

See Also

GetText (see page 3055)

23.1.49.4.7 TStrings.Names Property

Indicates the name part of strings that are name-value pairs.

Pascal

```
property Names [Index: Integer]: string;
```

C++

```
__property AnsiString Names[int Index];
```

Description

When the list of strings for the TStrings (see page 3029) object includes strings that are name-value pairs, read Names to access the name part of a string. Names is the name part of the string at Index, where 0 is the first string, 1 is the second string, and so on. If the string is not a name-value pair, Names contains an empty string.

C++ Examples:

```
/*
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.  TStrings Values are referenced using the
name AnsiString as an index.
*/
void MergeStrings(TStrings *Dest, TStrings *Source)
```

```
{
  for (int i = 0; i < Source->Count; i++)
  {
    if (Source->Strings[i].Pos("=") > 1)
    {
      int DI = Dest->IndexOfName(Source->Names[i]);
      if (DI > -1)
        Dest->Values[Source->Names[i]] = Source->Values[Source->Names[i]];
    }
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MergeStrings(ListBox1->Items,ListBox2->Items);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Plants = 10");
  ListBox1->Items->Add("Animals = 20");
  ListBox1->Items->Add("Minerals = 15");
  ListBox2->Items->Add("Animals = 4");
  ListBox2->Items->Add("Plants = 3");
  ListBox2->Items->Add("Minerals = 78");
}
```

Delphi Examples:

```
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
  begin
  for I := 0 to Source.Count - 1 do
  begin
    if Pos ('=', Source[I]) > 1 then
    begin
      DI := Dest.IndexOfName(Source.Names[I]);
      if DI > -1 then Dest[DI] := Source[I];
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MergeStrings(ListBox1.Items, ListBox2.Items);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Plants = 10');
  ListBox1.Items.Add('Animals = 20');
  ListBox1.Items.Add('Minerals = 15');
  ListBox2.Items.Add('Animals = 4');
  ListBox2.Items.Add('Plants = 3');
  ListBox2.Items.Add('Minerals = 78');
end;
```

See Also

NameValueSeparator (see page 3077)

IndexOfName (see page 3057)

Strings (see page 3080)

Values (see page 3086)

23.1.49.4.8 TStrings.NameValueSeparator Property

Indicates the character used to separate names from values.

Pascal

```
property NameValueSeparator: Char;
```

C++

```
__property Char NameValueSeparator;
```

Description

Strings (see page 3080) that contain the NameValueSeparator character are considered name-value pairs. NameValueSeparator defaults to the equal sign (=). TStrings (see page 3029) defines various methods for accessing names and values and for searching for specific names.

Strings (see page 3080) that are name-value pairs consist of a name part, the separator character, and a value part. Any spaces around the separator character are part of the name or value. This convention corresponds to the format used in many initialization files. For example:

```
DisplayGrid=1
SnapToGrid=1
GridSizeX=8
GridSizeY=8
```

See Also

ValueFromIndex (see page 3085)

Names (see page 3075)

IndexOfName (see page 3057)

Strings (see page 3080)

Values (see page 3086)

23.1.49.4.9 TStrings.Objects Property

Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.

Pascal

```
property Objects [Index: Integer]: TObject;
```

C++

```
__property TObject * Objects[int Index];
```

Description

Setting the Objects property for TStrings (see page 3029) does nothing. Reading the Objects property for TStrings (see page 3029) returns nil (Delphi) or NULL (C++). Descendant classes can associate objects with the strings in the set by

implementing the Objects property.

Use the Objects property of a descendant of TStrings (see page 3029) to get or set the object associated with the string at the position indicated by Index. Index gives the position of the string associated with the object, where 0 is the first string, 1 is the second string, and so on. If a descendant of TStrings (see page 3029) does not support the Objects property, reading this property returns nil (Delphi) or NULL (C++)

Note: The TStrings (see page 3029) object does not own the objects in the Objects array. Objects added to the Objects array still exist even if the TStrings (see page 3029) object is destroyed. They must be explicitly destroyed by the application.

C++ Examples:

```
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
  ComboBox1->Items->AddObject("vsIcon", (TObject *)vsIcon);
  ComboBox1->Items->AddObject("vsList", (TObject *)vsList);
  ComboBox1->Items->AddObject("vsReport", (TObject *)vsReport);
  ComboBox1->Items->AddObject("vsSmallIcon", (TObject *)vsSmallIcon);
  // Display first item in the Combo Box
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
```

```
}
```

Delphi Examples:

```
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
    for I := 0 to ImageList1.Count - 1 do
    begin
      ListItem := Items.Add;
      Listitem.Caption := 'Image' + IntToStr(I);
      ListItem.ImageIndex := I;
      Listitem.SubItems.Add(Col2Array[I]);
    end;
    // Create two columns to show during viewing as vsReport
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 1';
    NewColumn.Width := 200;
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 2';
    NewColumn.Width := 200;
    // Add View styles and constants to the Combo Box
    ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
    ComboBox1.Items.AddObject('vsList', TObject(vsList));
    ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
    ComboBox1.Items.AddObject(
      'vsSmallIcon', TObject(vsSmallIcon));
    // Display first item in the Combo Box
    ComboBox1.ItemIndex := 0;
  end;
end;

procedure TComboForm.ComboBox1Click(Sender: TObject);
begin
  with ComboBox1 do
    ListView1.ViewStyle := TViewStyle(Items.Objects[ItemIndex]);

end;
```

23.1.49.4.10 TStrings.QuoteChar Property

Specifies the quote character used by the DelimitedText (see page 3074) property.

Pascal

```
property QuoteChar: Char;
```

C++

```
__property Char QuoteChar;
```

Description

Use QuoteChar to get or set the quote character that is used to enclose individual strings in the DelimitedText (see page 3074) property.

DelimitedText (see page 3074)

CommaText (see page 3070)

23.1.49.4.11 TStrings.StrictDelimiter Property

Determines how the Delimiter (see page 3074) property is used.

Pascal

```
property StrictDelimiter: Boolean;
```

C++

```
__property Boolean StrictDelimiter;
```

Description

Use this property to specify whether the Delimiter (see page 3074) is the only value used within the DelimitedText (see page 3074) property. If set to True, individual strings in DelimitedText (see page 3074) are separated only by the character that is the value of Delimiter (see page 3074). If set to False, individual strings in DelimitedText (see page 3074) can be separated by a space, a non-printable character, or the character that is the value of Delimiter (see page 3074).

23.1.49.4.12 TStrings.Strings Property

References the strings in the list by their positions.

Pascal

```
property Strings [Index: Integer]: string;
```

C++

```
__property AnsiString Strings[int Index];
```

Description

Descendants of TStrings (see page 3029) must implement an accessor function for the Strings property to return the string at the position indicated by Index. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

Use the Strings property to get or set the string at a particular position.

To store a string as a name-value pair, assign Strings a value that includes the NameValueSeparator (see page 3077) character. The name and value will then be accessible separately using the Names (see page 3075) and Values (see page 3086) properties.

Note: In Delphi, Strings is the default property of TStrings (see page 3029) objects. The Strings identifier can be omitted when accessing the Strings property of a descendant of TStrings (see page 3029). For example, the following two lines of code are both acceptable and do the same thing:

MyStrings.Strings[0] := 'This is the first string';

MyStrings[0] := 'This is the first string';

C++ Examples:

```
/*
This example uses an Open dialog box, a memo, and a button
on a form. When the user clicks the button, the Open dialog
box appears. When the user selects files in the dialog box
and chooses the OK button, the first line from each of the
files is added to the memo. Choose multiple files using the
CNTL key or the SHIFT key.
*/

#include <stdio.h>     // for FILE

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FILE *stream;
  char FirstLine[512];

  OpenDialog1->Options.Clear();
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist;
  OpenDialog1->Filter = "Text files (*.txt)|*.txt|All files (*.*)|*.*";
  OpenDialog1->FilterIndex = 2; // start the dialog showing all files
  if (OpenDialog1->Execute())
  {
    for (int I = 0; I < OpenDialog1->Files->Count; I ++)
    {
      stream = fopen(OpenDialog1->Files->Strings[I].c_str(), "r");
      if (stream)
      {
        // read the first line from the file
        fgets(FirstLine, sizeof(FirstLine), stream);
        Memo1->Lines->Append(FirstLine);
        fclose(stream);
      }
    }
  }
}
/*
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.  TStrings Values are referenced using the
```

```
name AnsiString as an index.
*/
void MergeStrings(TStrings *Dest, TStrings *Source)
{
  for (int i = 0; i < Source->Count; i++)
  {
    if (Source->Strings[i].Pos("=") > 1)
    {
      int DI = Dest->IndexOfName(Source->Names[i]);
      if (DI > -1)
        Dest->Values[Source->Names[i]] = Source->Values[Source->Names[i]];
    }
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MergeStrings(ListBox1->Items,ListBox2->Items);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Plants = 10");
  ListBox1->Items->Add("Animals = 20");
  ListBox1->Items->Add("Minerals = 15");
  ListBox2->Items->Add("Animals = 4");
  ListBox2->Items->Add("Plants = 3");
  ListBox2->Items->Add("Minerals = 78");
}
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses an Open dialog box, a memo, and a button
on a form. When the user clicks the button, the Open dialog
box appears. When the user selects files in the dialog box
and chooses the OK button, the first line from each of the
files is added to the memo. Choose multiple files using the
CNTL key or the SHIFT key.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: integer;
  F: TextFile;
  FirstLine: string;
begin
  OpenDialog1.Options := [ofAllowMultiSelect, ofFileMustExist];
  OpenDialog1.Filter := 'Text files (*.txt)|*.txt|All files (*.*)|*.*';
  OpenDialog1.FilterIndex := 2; { start the dialog showing all files }
  if OpenDialog1.Execute then
    with OpenDialog1.Files do
      for I := 0 to Count - 1 do
      begin
        AssignFile(F, Strings[I]);  { next file in Files property }
        Reset(F);
        Readln(F, FirstLine);  { Read the first line out of the file }
```

```
        Memo1.Lines.Append(FirstLine);  { Add the line to the memo }
        CloseFile(F);
      end;
end;
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
  begin
  for I := 0 to Source.Count - 1 do
  begin
    if Pos ('=', Source[I]) > 1 then
    begin
      DI := Dest.IndexOfName(Source.Names[I]);
      if DI > -1 then Dest[DI] := Source[I];
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MergeStrings(ListBox1.Items, ListBox2.Items);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Plants = 10');
  ListBox1.Items.Add('Animals = 20');
  ListBox1.Items.Add('Minerals = 15');
  ListBox2.Items.Add('Animals = 4');
  ListBox2.Items.Add('Plants = 3');
  ListBox2.Items.Add('Minerals = 78');
end;
```

23.1.49.4.13 TStrings.StringsAdapter Property

Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.

Pascal

```
property StringsAdapter: IStringsAdapter;
```

C++

```
__property IStringsAdapter StringsAdapter;
```

Description

Do not use the StringsAdapter property. StringsAdapter is used internally.

See Also

TStringsAdapter (see page 1696)

23.1.49.4.14 TStrings.Text Property

Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.

Pascal

```
property Text: string;
```

C++

```
__property AnsiString Text;
```

Description

Use Text to get or set all the strings in the TStrings (see page 3029) object in a single string delimited by carriage return, line feed pairs.

When reading Text, the strings in the list will be separated by carriage return and (on Windows) line feed. If any of the strings in the list contain a carriage return (and line feed), the resulting value of Text will appear to contain more strings than is indicated by the Count (see page 3071) property.

When setting Text, the value will be parsed by separating into substrings whenever a carriage return or linefeed is encountered. (The two do not need to form pairs).

If the strings in the list contain carriage return or linefeed characters, a less ambiguous format for the strings is available through the CommaText (see page 3070) or DelimitedText (see page 3074) property.

SetText (see page 3068)

DelimitedText (see page 3074)

23.1.49.4.15 TStrings.UpdateCount Property

Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Pascal

```
property UpdateCount: Integer;
```

C++

```
__property int UpdateCount;
```

Description

TStrings (see page 3029) uses UpdateCount to keep track of calls to the BeginUpdate (see page 3045) and EndUpdate (see page 3050) methods. Every time a call is made to BeginUpdate (see page 3045), TStrings (see page 3029) increments the value of UpdateCount. Every call to EndUpdate (see page 3050) causes TStrings (see page 3029) to decrement UpdateCount.

When UpdateCount changes from 0 to 1, TStrings (see page 3029) calls the SetUpdateState (see page 3069) method with a parameter of true. When UpdateCount changes from 1 to 0, TStrings (see page 3029) calls the SetUpdateState (see page 3069) method with a parameter of false. This allows descendant classes to perform optimizations when handling multiple updates.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

SetUpdateState (see page 3069)

23.1.49.4.16 TStrings.ValueFromIndex Property

Represents the value part of a string with a given index, on strings that are name-value pairs.

Pascal

```
property ValueFromIndex [Index: Integer]: string;
```

C++

```
__property AnsiString ValueFromIndex[int Index];
```

Description

When the list of strings for the TStrings (see page 3029) object includes strings that are name-value pairs, use ValueFromIndex to get or set the value part of a string associated with an index.

For more information on name-value pairs, refer to the NameValueSeparator (see page 3077) property.

See Also

NameValueSeparator (see page 3077)

IndexOfName (see page 3057)

Strings (see page 3080)

Values (see page 3086)

23.1.49.4.17 TStrings.Values Property

Represents the value part of a string associated with a given name, on strings that are name-value pairs.

Pascal

```
property Values [const Name: string]: string;
```

C++

```
__property AnsiString Values[AnsiString const Name];
```

Description

When the list of strings for the TStrings (see page 3029) object includes strings that are name-value pairs, use Values to get or set the value part of a string associated with a specific name part.

For more information on name-value pairs, refer to the NameValueSeparator (see page 3077) property.

Note: The Name index is case-insensitive. That is, Values is the value part for the first occurrence of Name or an equivalent string that differs only in case.

Strings (see page 3080)

23.1.50 TStringsEnumerator Class

Enumerates through the strings of a TStrings (see page 3029) object.

Class Hierarchy

Pascal

```
TStringsEnumerator = class;
```

C++

```
class TStringsEnumerator;
```

File

Classes

Description

TStringsEnumerator provides an enumerator for TStrings (see page 3029) objects.

23.1.50.1 TStringsEnumerator Members

The following tables list the members exposed by TStringsEnumerator.

Public Methods

	Name	Description
	Create (see page 3087)	Creates a TStrings (see page 3029) enumerator.
	GetCurrent (see page 3087)	Gets the current string.
	MoveNext (see page 3087)	Moves the enumerator to the next string in the TStrings (see page 3029) collection.

Public Properties

	Name	Description
R	Current (see page 3088)	The current string.

23.1.50.2 TStringsEnumerator.Create Constructor

Creates a TStrings (see page 3029) enumerator.

Pascal

```
constructor Create(AStrings: TStrings);
```

C++

```
__fastcall TStringsEnumerator(TStrings AStrings);
```

Description

Creates an instance of TStringsEnumerator (see page 3086).

23.1.50.3 TStringsEnumerator Methods

The methods of the TStringsEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 3087)	Gets the current string.
	MoveNext (see page 3087)	Moves the enumerator to the next string in the TStrings (see page 3029) collection.

23.1.50.3.1 TStringsEnumerator.GetCurrent Method

Gets the current string.

Pascal

```
function GetCurrent: string;
```

C++

```
__fastcall AnsiString GetCurrent();
```

Description

Use GetCurrent to get the current string in the TStrings (see page 3029) object being enumerated.

23.1.50.3.2 TStringsEnumerator.MoveNext Method

Moves the enumerator to the next string in the TStrings (see page 3029) collection.

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

Use MoveNext to move the TStringsEnumerator (see page 3086) to the next string in the TStrings (see page 3029) object being enumerated.

23.1.50.4 TStringsEnumerator Properties

The properties of the TStringsEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 3088)	The current string.

23.1.50.4.1 TStringsEnumerator.Current Property

The current string.

Pascal

```
property Current: string;
```

C++

```
__property AnsiString Current;
```

Description

Current contains the current string in the TStrings (see page 3029) object being enumerated.

23.1.51 TStringStream Class

TStringStream provides file-like access to information stored as a long string.

Class Hierarchy

Pascal

```
TStringStream = class(TStream);
```

C++

```
class TStringStream : public TStream;
```

File

Classes

Description

Use TStringStream to store data as a long string enhanced with I/O capabilities. TStringStream is useful as an intermediary object that can hold text as well as read it from or write it to another storage medium. TStringStream provides a mechanism for

manipulating text that is obtained from a less accessible medium.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)
```

```
{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)
    Memo1: TMemo;
    Button1: TButton;
    Button2: TButton;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
```

```
    MyScrollBar = class(TScrollBar)
    end;

  var
    Form1: TForm1;
    ScrollBar1: MyScrollBar;

23.1.51.1 TStringStream Members

The following tables list the members exposed by TStringStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	SetSize (see page 3102)	This is SetSize, a member of class TStringStream.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 3093)	Creates an instance of TStringStream (see page 3088).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Read (see page 3097)	Reads up to Count bytes from the string stream into Buffer, and advances the current position of the stream by the number of bytes read.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
	ReadString (see page 3098)	Returns a string that consists of up to Count bytes from the current position in the string stream, and advances the current position of the stream by the number of bytes read.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Seek (see page 3098)	Moves the current position in the stream by Offset bytes, relative to a specified origin.
V	Seek (see page 2988)	This is the overview for the Seek method overload.
V	Write (see page 3103)	Write writes Count bytes from Buffer to the current position in the string stream and updates the current position by Count bytes.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.
	WriteString (see page 3103)	Concatenates a specified string to the current position in the string stream, and updates the current position accordingly.

Public Properties

	Name	Description
R	DataString (see page 3104)	Provides direct access to the string that stores the text represented by the TStringStream (see page 3088) object.
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

23.1.51.2 TStringStream.Create Constructor

Creates an instance of TStringStream (see page 3088).

Pascal

```
constructor Create(const AString: string);
```

C++

```
__fastcall TStringStream(const AnsiString AString);
```

Description

Call Create to instantiate a TStringStream (see page 3088) object. Create initializes the DataString (see page 3104)

property to the AString parameter.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)
```

```
{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)
    Memo1: TMemo;
    Button1: TButton;
    Button2: TButton;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
```

```
    MyScrollBar = class(TScrollBar)
    end;

  var
    Form1: TForm1;
    ScrollBar1: MyScrollBar;

23.1.51.3 TStringStream Methods

The methods of the TStringStream class are listed here.

Protected Methods

	Name	Description
	SetSize (see page 3102)	This is SetSize, a member of class TStringStream.

Public Methods

	Name	Description
	Read (see page 3097)	Reads up to Count bytes from the string stream into Buffer, and advances the current position of the stream by the number of bytes read.
	ReadString (see page 3098)	Returns a string that consists of up to Count bytes from the current position in the string stream, and advances the current position of the stream by the number of bytes read.
	Seek (see page 3098)	Moves the current position in the stream by Offset bytes, relative to a specified origin.
	Write (see page 3103)	Write writes Count bytes from Buffer to the current position in the string stream and updates the current position by Count bytes.
	WriteString (see page 3103)	Concatenates a specified string to the current position in the string stream, and updates the current position accordingly.

23.1.51.3.1 TStringStream.Read Method

Reads up to Count bytes from the string stream into Buffer, and advances the current position of the stream by the number of bytes read.

Pascal

```
function Read(var Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( Buffer, Longint Count);
```

Description

Use Read to read the contents of the string stream into a buffer, starting at the current position. If Count extends beyond the end of the DataString (see page 3104), Read will only transfer the characters up to the end of the DataString (see page 3104), and advances the current position accordingly. If the return value is less than Count, it means that the end of the string was read.

The ReadBuffer (see page 2983) method and ReadComponent (see page 2983) method call Read to do the actual reading.

Note: Read treats Count as an upper bound. The ReadBuffer (see page 2983) method, by contrast, raises an exception if Count bytes cannot be read.

See Also

DataString (see page 3104)

Position (see page 2996)

ReadBuffer (see page 2983)

ReadComponent (see page 2983)

ReadString (see page 3098)

Write (see page 3103)

23.1.51.3.2 TStringStream.ReadString Method

Returns a string that consists of up to Count bytes from the current position in the string stream, and advances the current position of the stream by the number of bytes read.

Pascal

```
function ReadString(Count: Longint): string;
```

C++

```
__fastcall AnsiString ReadString(Longint Count);
```

Description

Use Read (see page 3097) to read the contents of the string stream into a string, starting at the current position. If Count extends beyond the end of the DataString (see page 3104), the returned string will only contain the characters up to the end of DataString (see page 3104), and the current position is advanced accordingly.

Note: ReadString does the same thing as Read (see page 3097), except that it returns a string rather than filling a buffer.

See Also

DataString (see page 3104)

Position (see page 2996)

Read (see page 3097)

WriteString (see page 3103)

23.1.51.3.3 TStringStream.Seek Method

Moves the current position in the stream by Offset bytes, relative to a specified origin.

Pascal

```
function Seek(Offset: Longint; Origin: Word): Longint; override;
```

C++

```
virtual __fastcall Longint Seek(Longint Offset, Word Origin);
```

Description

Use Seek to move the current position within the string stream by the indicated offset. Seek allows an application to read from or write to a particular location within the DataString (see page 3104).

If Offset is a negative number, the seek is backwards from the specified origin. The following table shows the different values of Origin and their meanings for seeking.

Value	Meaning
soFromBeginning (see page 3319)	Offset is from the beginning of DataString (see page 3104). Seek moves to the position Offset. Offset must be >= 0.
soFromCurrent (see page 3320)	Offset is from the current position. Seek moves to Position (see page 2996) + Offset.
soFromEnd (see page 3320)	Offset is from the end of Memory. Offset must be <= 0 to indicate a number of bytes before the end of the DataString (see page 3104).

Seek returns the new value of the Position (see page 2996) property.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
```

```
  try
  {
     pms->WriteComponent(c);
     pms->Seek(0, soFromBeginning);
     ObjectBinaryToText(pms, pss);
     pss->Seek(0, soFromBeginning);
     as = pss->DataString;
  }
  catch(...)
  {
     ShowMessage("Streaming error.");
  }

  delete pms;
  delete pss;
  return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)

{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}
```

```
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)
    Memo1: TMemo;

23.1.51.3.4 TStringStream.SetSize Method

Pascal

```
procedure SetSize(NewSize: Longint); override;
```

C++

```
virtual __fastcall SetSize(Longint NewSize);
```

Description

This is SetSize, a member of class TStringStream.

23.1.51.3.5 TStringStream.Write Method

Write writes Count bytes from Buffer to the current position in the string stream and updates the current position by Count bytes.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count);
```

Description

Use Write to replace the end of the string from the current position on with the first Count bytes of Buffer. Write will change the Size (see page 2997) property to reflect the new length of the DataString (see page 3104).

Write always writes Count bytes from Buffer, even if a null character is included as one of the Count bytes. Thus, Write is equivalent to the WriteBuffer (see page 2990) method.

See Also

DataString (see page 3104)

Position (see page 2996)

Read (see page 3097)

Size

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

WriteString (see page 3103)

23.1.51.3.6 TStringStream.WriteString Method

Concatenates a specified string to the current position in the string stream, and updates the current position accordingly.

Pascal

```
procedure WriteString(const AString: string);
```

C++

```
__fastcall WriteString(const AnsiString AString);
```

Description

Use WriteString to replace the end of the string from the current position on with the string specified by the AString parameter. WriteString changes the Size (see page 2997) property to reflect the new length of the DataString (see page 3104).

See Also

DataString (see page 3104)

Position (see page 2996)

ReadString (see page 3098)

Size (see page 2997)

Write (see page 3103)

23.1.51.4 TStringStream Properties

The properties of the TStringStream class are listed here.

Public Properties

	Name	Description
	DataString (see page 3104)	Provides direct access to the string that stores the text represented by the TStringStream (see page 3088) object.

23.1.51.4.1 TStringStream.DataString Property

Provides direct access to the string that stores the text represented by the TStringStream (see page 3088) object.

Pascal

```
property DataString: string;
```

C++

```
__property AnsiString DataString;
```

Description

Use DataString to get access to the text of the stream. The text represents the information that is being transferred by means of the string stream. Size (see page 2997) is the number of bytes in the string, and Position (see page 2996) is the current position within DataString.

Note: DataString is a read-only property. DataString can be used to change the contents of the string, but applications can't change the DataString itself.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components

23.1.52 TThread Class

TThread is an abstract class that enables creation of separate threads of execution in an application.

Class Hierarchy

Classes.TThread

Pascal

```
TThread = class;
```

C++

```
class TThread;
```

File

Classes

Description

Create (see page 3110) a descendant of TThread to represent an execution thread in a multi-threaded application. Each new instance of a TThread descendant is a new thread of execution. Multiple instances of a TThread derived class make an application multi-threaded.

When an application is run, it is loaded into memory ready for execution. At this point it becomes a process containing one or more threads that contain the data, code and other system resources for the program. A thread executes one part of an application and is allocated CPU time by the operating system. All threads of a process share the same address space and can access the process's global variables.

Use threads to improve application performance by

- Managing input from several communication devices.
- Distinguishing among tasks of varying priority. For example, a high priority thread handles time critical tasks, and a low priority thread performs other tasks.

Following are issues and recommendations to be aware of when using threads:

- Keeping track of too many threads consumes CPU time; the recommended limit is 16 active threads per process on single processor systems.
- When multiple threads update the same resources, they must be synchronized to avoid conflicts.
- Most methods that access an object and update a form must only be called from within the main thread or use a synchronization object such as TMultiReadExclusiveWriteSynchronizer.

Define the thread object's Execute (see page 3115) method by inserting the code that should execute when the thread is executed.

Note: See the Threads demo for multi-threading program samples.

Defining Thread Objects

23.1.52.1 TThread Members

The following tables list the members exposed by TThread.

Protected Methods

	Name	Description
	CheckThreadError (see page 3114)	This is the overview for the CheckThreadError method overload.
V	DoTerminate (see page 3115)	Generates an OnTerminate (see page 3148) event.
A	Execute (see page 3115)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Protected Properties

	Name	Description
	ReturnValue (see page 3141)	Specifies the value returned to other waiting threads when the thread finishes executing.
R	Terminated (see page 3142)	Indicates whether the thread has been asked to terminate.

Public Events

	Name	Description
	OnTerminate (see page 3148)	Occurs after the thread's Execute (see page 3115) method has returned and before the thread is destroyed.

Public Methods

	Name	Description
V	AfterConstruction (see page 3114)	Executes the thread when the thread is created with CreateSuspended set to false.
	Create (see page 3110)	Creates an instance of a thread object.
V	Destroy (see page 3113)	Destroys the thread object and releases the memory allocated to it.
	Queue (see page 3119)	This is the overview for the Queue method overload.
	RemoveQueuedEvents (see page 3120)	Remove queued method calls.
	Resume (see page 3120)	Restarts the execution of a suspended thread.
	StaticQueue (see page 3124)	Asynchronously executes a method call within the main thread.
	StaticSynchronize (see page 3125)	Executes a method call within the main thread.
	Suspend (see page 3125)	Pauses a running thread.
	Synchronize (see page 3126)	This is the overview for the Synchronize method overload.
	Terminate (see page 3126)	Signals the thread to terminate by setting the Terminated (see page 3142) property to true.
	WaitFor (see page 3132)	Waits for the thread to terminate and then returns the value of the ReturnValue (see page 3141) property.

Public Properties

	Name	Description
R	FatalException (see page 3133)	Determines whether the thread object is automatically destroyed when the thread terminates.
	FreeOnTerminate (see page 3134)	Determines whether the thread object is automatically destroyed when the thread terminates.
R	Handle (see page 3137)	Indicates the thread's handle (Windows only).
	Priority (see page 3138)	Determines the thread's scheduling priority relative to other threads in the process.
	Suspended (see page 3142)	Indicates whether a thread is suspended.
R	ThreadID (see page 3148)	Identifies the thread throughout the system.

23.1.52.2 TThread.Create Constructor

Creates an instance of a thread object.

Pascal

```
constructor Create(CreateSuspended: Boolean);
```

C++

```
__fastcall TThread(Boolean CreateSuspended);
```

Description

Call Create to create a thread in an application. If CreateSuspended is False, Execute (see page 3115) is called immediately. If CreateSuspended is True, Execute (see page 3115) won't be called until after Resume (see page 3120) is called.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

__fastcall TYouThread::TYouThread(bool suspended)
    : TThread(suspended)
{
}

void __fastcall TMyThread::Execute()
{
  Form1->Memo1->Lines->Add("Process has been running for this many seconds:");
  for (int I = 0; I <= 10; I++)
  {
```

```
    Form1->Memo1->Lines->Add("Low priority process " + IntToStr(I));
    Sleep(1000);
  }
  mythreadRunning = FALSE;
}

void __fastcall TYouThread::Execute()
{
  Form1->Memo3->Lines->Add("Second low priority process has been running for this many
seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo3->Lines->Add("Second low priority process " + IntToStr(I));
    Sleep(1000);
  }
  youthreadRunning = FALSE;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMyThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (mythreadRunning == FALSE)
  {
    mythreadRunning = TRUE;
    SecondProcess = new TMyThread(True); // create suspended – secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form1->Memo2->Lines->Add("Do some work in the main process for 10 seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo2->Lines->Add("Main process " + IntToStr(I));
    Sleep(1000);
  }
}

void __fastcall TForm1::Button3Click(TObject *Sender)
{
  TYouThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (youthreadRunning == FALSE)
  {
    youthreadRunning = TRUE;
    SecondProcess = new TYouThread(True); // create suspended – secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  mythreadRunning = FALSE;
  youthreadRunning = FALSE;
}
```

Delphi Examples:

```
{
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes.  The
Execute procedure must be overridden in the extension class
of TThread or an "Abstract Error" will result. To create the
extension choose the File | New | Other | Thread Object menu.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (mythreadRunning = FALSE) then
  begin
    mythreadRunning:= TRUE;
    MyProcess := TMyThread.Create(True); { create suspended - secondprocess does not run yet }
    MyProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    MyProcess.Priority := tpLower;  // set the priority to lower than normal
    MyProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  if mythreadRunning then MyProcess.Terminate();
end;

procedure TMyThread.Execute;
var I: Integer;
begin
  Form1.Memo1.Lines.Add('Process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo1.Lines.Add('Low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
  mythreadRunning:= FALSE;
end;

procedure TYouThread.Execute;
var I: Integer;
begin
  Form1.Memo3.Lines.Add('Second low priority process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo3.Lines.Add('Second low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
    youthreadRunning:= FALSE;
end;

procedure TForm1.Button2Click(Sender: TObject);
var   I: Integer;
begin
  Form1.Memo2.Lines.Add('Do some work in the main process for 10 seconds:');
  for I := 0 to 10 do
  begin
    Form1.Memo2.Lines.Add('Main process ' + InttoStr(I));
    Sleep(1000);
  end;
end;
```

```
procedure TForm1.Button3Click(Sender: TObject);
begin
  if (youthreadRunning = FALSE) then
  begin
    youthreadRunning:= TRUE;
    YouProcess := TYouThread.Create(True); { create suspended – secondprocess does not run yet
}
    YouProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    YouProcess.Priority := tpLower;  // set the priority to lower than normal
    YouProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  if youthreadRunning then YouProcess.Terminate();
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  mythreadRunning:= FALSE;
  youthreadRunning:= FALSE;
end;
```

See Also

Destroy (see page 3113)

Execute (see page 3115)

FreeOnTerminate (see page 3134)

23.1.52.3 TThread.Destroy Destructor

Destroys the thread object and releases the memory allocated to it.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TThread();
```

Description

Do not call Destroy in an application. Instead, use Free to destroy a thread when FreeOnTerminate (see page 3134) is False.

Destroy signals the thread to terminate and then waits for the thread to return before calling the inherited Destroy method.

See Also

Create (see page 3110)

Terminate (see page 3126)

WaitFor (see page 3132)

FreeOnTerminate (see page 3134)

Free (see page 22300)

23.1.52.4 TThread Methods

The methods of the TThread class are listed here.

Protected Methods

	Name	Description
	CheckThreadError (see page 3114)	This is the overview for the CheckThreadError method overload.
V	DoTerminate (see page 3115)	Generates an OnTerminate (see page 3148) event.
A	Execute (see page 3115)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
V	AfterConstruction (see page 3114)	Executes the thread when the thread is created with CreateSuspended set to false.
	Queue (see page 3119)	This is the overview for the Queue method overload.
	RemoveQueuedEvents (see page 3120)	Remove queued method calls.
	Resume (see page 3120)	Restarts the execution of a suspended thread.
	StaticQueue (see page 3124)	Asynchronously executes a method call within the main thread.
	StaticSynchronize (see page 3125)	Executes a method call within the main thread.
	Suspend (see page 3125)	Pauses a running thread.
	Synchronize (see page 3126)	This is the overview for the Synchronize method overload.
	Terminate (see page 3126)	Signals the thread to terminate by setting the Terminated (see page 3142) property to true.
	WaitFor (see page 3132)	Waits for the thread to terminate and then returns the value of the ReturnValue (see page 3141) property.

23.1.52.4.1 TThread.AfterConstruction Method

Executes the thread when the thread is created with CreateSuspended set to false.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction launches the Execute (see page 3115) method when the thread is not created in a suspended state. By calling Execute (see page 3115) from the AfterConstruction method rather than the constructor, TThread (see page 3108) avoids a race condition where the thread may free itself after Execute (see page 3115) finishes but before the main thread calls AfterConstruction.

See Also

Create (see page 3110)

Execute (see page 3115)

23.1.52.4.2 CheckThreadError Method

This is the overview for the CheckThreadError method overload.

Overload List

	Name	Description
	TThread.CheckThreadError (Boolean) (see page 3115)	This is CheckThreadError, a member of class TThread.
	TThread.CheckThreadError (Integer) (see page 3115)	This is CheckThreadError, a member of class TThread.

23.1.52.4.2.1 TThread.CheckThreadError Method (Boolean)

Pascal

```
procedure CheckThreadError(Success: Boolean); overload;
```

C++

```
__fastcall CheckThreadError(Boolean Success);
```

Description

This is CheckThreadError, a member of class TThread.

23.1.52.4.2.2 TThread.CheckThreadError Method (Integer)

Pascal

```
procedure CheckThreadError(ErrCode: Integer); overload;
```

C++

```
__fastcall CheckThreadError(int ErrCode);
```

Description

This is CheckThreadError, a member of class TThread.

23.1.52.4.3 TThread.DoTerminate Method

Generates an OnTerminate (see page 3148) event.

Pascal

```
procedure DoTerminate; virtual;
```

C++

```
virtual __fastcall DoTerminate();
```

Description

DoTerminate calls the OnTerminate (see page 3148) event handler, but does not terminate the thread.

See Also

OnTerminate (see page 3148)

23.1.52.4.4 TThread.Execute Method

Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Pascal

```
procedure Execute; virtual; abstract;
```

C++

```
virtual __fastcall Execute() = 0;
```

Description

Override Execute and insert the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated (see page 3142) property to determine if the thread needs to exit.

A thread executes when Create (see page 3110) is called if CreateSuspended set to false, or when Resume (see page 3120) is first called after the thread is created if CreateSuspended set to true.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize (see page 3126) method.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

23.1.52.4.5 Queue Method

This is the overview for the Queue method overload.

Overload List

	Name	Description
	TThread.Queue (TThread, TThreadMethod) (see page 3119)	Asynchronously executes a method call within the main thread.
	TThread.Queue (TThreadMethod) (see page 3119)	Asynchronously executes a method call within the main thread.

23.1.52.4.5.1 TThread.Queue Method (TThread, TThreadMethod)

Asynchronously executes a method call within the main thread.

Pascal

```
procedure Queue(AMethod: TThreadMethod); overload;
class procedure Queue(AThread: TThread; AMethod: TThreadMethod); overload;
```

C++

```
__fastcall Queue(TThreadMethod AMethod);
__fastcall Queue(TThread AThread, TThreadMethod AMethod);
```

Description

Queue causes the call specified by **AMethod** to be executed using the main thread, thereby avoiding multi-thread conflicts. The current thread is passed in the **AThread** parameter.

If you are unsure whether a method call is thread-safe, call it from within the Synchronize (see page 3126) or Queue methods to ensure that it executes in the main thread.

Unlike Synchronize (see page 3126), execution of the current thread is allowed to continue. The main thread will eventually process all queued methods.

Warning: Do not call Queue from within the main thread. This can cause an infinite loop.

Note: You can also protect unsafe methods using critical sections or the multi-read exclusive-write synchronizer.

See Also

Execute (see page 3115)

Synchronize (see page 3126)

23.1.52.4.6 TThread.RemoveQueuedEvents Method

Remove queued method calls.

Pascal

```
class procedure RemoveQueuedEvents(AThread: TThread; AMethod: TThreadMethod);
```

C++

```
__fastcall RemoveQueuedEvents(TThread AThread, TThreadMethod AMethod);
```

Description

The Queue (see page 3119) method is used by a thread to queue a request for the main thread to execute a method. This is mostly done where the safety of the main thread is important.

RemoveQueuedEvents removes queued method calls. The operation proceeds in one of two ways. If **AThread** is specified, then all method calls queued by this thread are removed. If **AThread** is nil, then all calls to the specified **AMethod** method are removed, regardless of the thread that queued the call.

See Also

Queue (see page 3119)

23.1.52.4.7 TThread.Resume Method

Restarts the execution of a suspended thread.

Pascal

```
procedure Resume;
```

C++

```
__fastcall Resume();
```

Description

Call Resume to cause a suspended thread to start running again. Calls to Suspend (see page 3125) can be nested; Resume must be called the same number of times Suspend (see page 3125) was called before the thread will resume execution.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

}
```

Delphi Examples:

```
{
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread’s FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes.  The
Execute procedure must be overridden in the extension class
of TThread or an "Abstract Error" will result. To create the
extension choose the File | New | Other | Thread Object menu.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (mythreadRunning = FALSE) then
```

```
  begin
    mythreadRunning:= TRUE;
    MyProcess := TMyThread.Create(True); { create suspended - secondprocess does not run yet }
    MyProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    MyProcess.Priority := tpLower;  // set the priority to lower than normal
    MyProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',

Executing Thread Objects

Starting and Stopping Threads

23.1.52.4.8 TThread.StaticQueue Method

Asynchronously executes a method call within the main thread.

Pascal

```
class procedure StaticQueue(AThread: TThread; AMethod: TThreadMethod);
```

C++

```
__fastcall StaticQueue(TThread AThread, TThreadMethod AMethod);
```

Description

StaticQueue causes the call specified by **AMethod** to be executed using the main thread, thereby avoiding multi-thread conflicts. The current thread is passed in the **AThread** parameter.

If you are unsure whether a method call is thread-safe, call it from within the Synchronize (see page 3126) or StaticQueue methods to ensure that it executes in the main thread.

Unlike Synchronize (see page 3126), execution of the current thread is allowed to continue. The main thread will eventually process all queued methods.

Warning: Do not call StaticQueue from within the main thread. This can cause an infinite loop.

Note: StaticQueue simply calls Queue (see page 3119) with the same parameters.

Note: You can also protect unsafe methods using critical sections or the multi-read exclusive-write synchronizer.

See Also

Execute (see page 3115)

Queue (see page 3119)

Synchronize (see page 3126)

23.1.52.4.9 TThread.StaticSynchronize Method

Executes a method call within the main thread.

Pascal

```
class procedure StaticSynchronize(AThread: TThread; AMethod: TThreadMethod);
```

C++

```
__fastcall StaticSynchronize(TThread AThread, TThreadMethod AMethod);
```

Description

StaticSynchronize causes the call specified by **AMethod** to be executed using the main thread, thereby avoiding multi-thread conflicts. The current thread is passed in the **AThread** parameter.

If you are unsure whether a method call is thread-safe, call it from within the StaticSynchronize method to ensure that it executes in the main thread.

Execution of the current thread is suspended while Method executes in the main thread.

Warning: Do not call StaticSynchronize from within the main thread. This can cause an infinite loop.

Note: StaticSynchronize simply invokes Synchronize (see page 3126) with the same parameters.

Note: You can also protect unsafe methods using critical sections or the multi-read exclusive-write synchronizer.

CheckSynchronize

Using the Main VCL

23.1.52.4.10 TThread.Suspend Method

Pauses a running thread.

Pascal

```
procedure Suspend;
```

C++

```
__fastcall Suspend();
```

Description

Call Suspend to temporarily halt execution of the thread. To resume execution after a call to Suspend, call Resume (see page 3120). Calls to Suspend can be nested; Resume (see page 3120) must be called the same number of times Suspend was called before the thread will resume execution.

See Also

Resume (see page 3120)

Starting and Stopping Threads

23.1.52.4.11 Synchronize Method

This is the overview for the Synchronize method overload.

Overload List

	Name	Description
	TThread.Synchronize (TThread, TThreadMethod) (see page 3126)	This is Synchronize, a member of class TThread.
	TThread.Synchronize (TThreadMethod) (see page 3126)	This is Synchronize, a member of class TThread.

23.1.52.4.11.1 TThread.Synchronize Method (TThread, TThreadMethod)

Pascal

```
class procedure Synchronize(AThread: TThread; AMethod: TThreadMethod); overload;
```

C++

```
__fastcall Synchronize(TThread AThread, TThreadMethod AMethod);
```

Description

This is Synchronize, a member of class TThread.

23.1.52.4.11.2 TThread.Synchronize Method (TThreadMethod)

Pascal

```
procedure Synchronize(AMethod: TThreadMethod); overload;
```

C++

```
__fastcall Synchronize(TThreadMethod AMethod);
```

Description

This is Synchronize, a member of class TThread.

23.1.52.4.12 TThread.Terminate Method

Signals the thread to terminate by setting the Terminated (see page 3142) property to true.

Pascal

```
procedure Terminate;
```

C++

```
__fastcall Terminate();
```

Description

Terminate sets the thread's Terminated (see page 3142) property to true, signaling that the thread should be terminated as soon as possible.

For Terminate to work, the thread's Execute (see page 3115) method and any methods that Execute (see page 3115) calls should check Terminated (see page 3142) periodically and exit when it's true.

Note: Unlike the Windows API TerminateThread, which forces the thread to terminate immediately, the Terminate method merely requests that the thread terminate. This allows the thread to perform any cleanup before it shuts down.

C++ Examples:

```
/*
The following example shows how to use the LockList and
UnlockList methods to access a thread-safe version  of a
TList object:
*/
class TMyThread : public TThread
{
__published:    // IDE-managed Components

        threadList1->Remove(Temp);
      }
    }
    __finally
    {
      threadList1->UnlockList();
    }
    if (Terminated)
      MessageDlg("youThread has been asked to terminate, but is still running!",
```

```
        mtInformation, TMsgDlgButtons() << mbOK, 0);
    Sleep(3000);
  }
  youthreadRunning = FALSE;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (listthreadRunning == FALSE)
  {
    listthreadRunning = TRUE;
    listProcess = new TListThread(True); // create suspended – secondprocess does not run yet
    listProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    listProcess->Priority = tpLower;  // set the priority to lower than normal
    listProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TListThread::Execute()
{
  while(True)
  {
    if (Terminated) break;
    Form1->ListBox1->Clear();
    TList *myList = threadList1->LockList();
    try
    {
      for (int I = 0; I < myList->Count; I++)
      {
        TControl *Temp = (TControl *)myList->Items[I];
        Form1->ListBox1->Items->Add(Temp->Name);
      }
    }
    __finally
    {
      threadList1->UnlockList();
    }
    Sleep(1000);
  }
}

void __fastcall TForm1::Button4Click(TObject *Sender)
{
  if (listProcess != NULL)
    listProcess->Terminate();
  if (secondProcess != NULL)
    secondProcess->Terminate();
  if (otherSecondProcess != NULL)
    otherSecondProcess->Terminate();
}
```

Delphi Examples:

```
{
The following example shows how to use the LockList and
UnlockList methods to access a thread-safe version  of a
TList object:
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button3: TButton;
    ListBox1: TListBox;
    Button2: TButton;
```

```
    Button4: TButton;
    procedure Button1Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button4Click(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  TListThread = class(TThread)
  protected
    procedure Execute; override;
  end;
  TMyThread = class(TThread)
  protected
    procedure Execute; override;
  end;
  TYouThread = class(TThread)
  protected
    procedure Execute; override;
  end;

var

Execute (see page 3115)

Terminated (see page 3142)

Checking for Termination by Other Threads

Starting and Stopping Threads

23.1.52.4.13 TThread.WaitFor Method

Waits for the thread to terminate and then returns the value of the ReturnValue (see page 3141) property.

Pascal

```
function WaitFor: LongWord;
```

C++

```
__fastcall LongWord WaitFor();
```

Description

Call WaitFor to obtain the value of ReturnValue (see page 3141) when the thread finishes executing. WaitFor doesn't return until the thread terminates, so the thread must exit either by finishing the Execute (see page 3115) method or by exiting when

the Terminated (see page 3142) property is true.

See Also

TThread (see page 3108)

Execute (see page 3115)

ReturnValue (see page 3141)

Synchronize (see page 3126)

Waiting for a Thread to Finish Executing

23.1.52.5 TThread Properties

The properties of the TThread class are listed here.

Protected Properties

	Name	Description
	ReturnValue (see page 3141)	Specifies the value returned to other waiting threads when the thread finishes executing.
R	Terminated (see page 3142)	Indicates whether the thread has been asked to terminate.

Public Properties

	Name	Description
R	FatalException (see page 3133)	Determines whether the thread object is automatically destroyed when the thread terminates.
	FreeOnTerminate (see page 3134)	Determines whether the thread object is automatically destroyed when the thread terminates.
R	Handle (see page 3137)	Indicates the thread's handle (Windows only).
	Priority (see page 3138)	Determines the thread's scheduling priority relative to other threads in the process.
	Suspended (see page 3142)	Indicates whether a thread is suspended.
R	ThreadID (see page 3148)	Identifies the thread throughout the system.

23.1.52.5.1 TThread.FatalException Property

Determines whether the thread object is automatically destroyed when the thread terminates.

Pascal

```
property FatalException: TObject;
```

C++

```
__property TObject * FatalException;
```

Description

If the Execute (see page 3115) method raises an exception that is not caught and handled within that method, the thread terminates and sets FatalException to the exception object for that exception. Applications can check FatalException from an OnTerminate (see page 3148) event handler to determine whether the thread terminated due to an exception.

See Also

ReturnValue (see page 3141)

OnTerminate (see page 3148)

Exception (see page 22750)

Execute (see page 3115)

23.1.52.5.2 TThread.FreeOnTerminate Property

Determines whether the thread object is automatically destroyed when the thread terminates.

Pascal

```
property FreeOnTerminate: Boolean;
```

C++

```
__property Boolean FreeOnTerminate;
```

Description

Set FreeOnTerminate to true if you don't want to explicitly destroy threads after they finish executing. When FreeOnTerminate is false, the thread object must be explicitly destroyed in application code.

Warning: When FreeOnTerminate is true, the Execute (see page 3115) method may run and then free the thread before your application can execute the next line of code. Thus, you should not call any methods of the thread object when FreeOnTerminate is true unless you create the thread in a suspended state.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/

Initializing the Thread

23.1.52.5.3 TThread.Handle Property

Indicates the thread's handle (Windows only).

Pascal

```
property Handle: THandle;
```

C++

```
__property THandle Handle;
```

Description

On Windows, use Handle for calling Win32 API functions for thread manipulation.

The Handle property is not available on Linux.

See Also

ThreadID (see page 3148)

23.1.52.5.4 TThread.Priority Property

Determines the thread's scheduling priority relative to other threads in the process.

Pascal

```
property Priority: TThreadPriority;
```

C++

```
__property TThreadPriority Priority;
```

Description

Priority indicates the priority used when scheduling the thread. Adjust the priority higher or lower as needed.

On Win32, Priority is a TThread (see page 3108) Priority value. The possible values are listed in a table within the topic “Initializing the Thread” (see the link at the end of this topic). The system schedules CPU cycles to each thread based on a priority scale; the Priority property adjusts a thread's priority higher or lower on the scale.

On Linux, Priority is an integer value. A higher value (numerically) implies that the thread has greater priority. The possible values for priority depend on the value of the Policy property.

Warning: Boosting the thread priority of a CPU intensive operation may "starve" the other threads in the application. Only apply priority boosts to threads that spend most of their time waiting for external events.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread’s FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.

Execute (see page 3115)

Policy

Initializing the Thread

23.1.52.5.5 TThread.ReturnValue Property

Specifies the value returned to other waiting threads when the thread finishes executing.

Pascal

```
property ReturnValue: Integer;
```

C++

```
__property int ReturnValue;
```

Description

Use ReturnValue to indicate success/failure or numeric result/output of the thread to the application or other threads. The WaitFor (see page 3132) method returns the value stored in ReturnValue.

See Also

Execute (see page 3115)

WaitFor (see page 3132)

Waiting for a Thread to Finish Executing

23.1.52.5.6 TThread.Suspended Property

Indicates whether a thread is suspended.

Pascal

```
property Suspended: Boolean;
```

C++

```
__property Boolean Suspended;
```

Description

Set Suspended to true to suspend a thread; set it to false to resume it. Suspended threads do not continue execution until they are resumed.

See Also

Resume (see page 3120)

Suspend (see page 3125)

23.1.52.5.7 TThread.Terminated Property

Indicates whether the thread has been asked to terminate.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

The thread's Execute (see page 3115) method and any methods that Execute (see page 3115) calls should check Terminated periodically and exit when it's true. The Terminate (see page 3126) method sets the Terminated property to true.

The Terminate (see page 3126) method is the polite way to abort the execution of a thread, but it requires cooperation from the thread's Execute (see page 3115) code. Using Terminate (see page 3126) is recommended over the TerminateThread Win32 API call.

C++ Examples:

```
/*

Starting and Stopping Threads

23.1.52.5.8 TThread.ThreadID Property

Identifies the thread throughout the system.

Pascal

```
property ThreadID: THandle;
```

C++

```
__property THandle ThreadID;
```

Description

Use ThreadID, during debugging, to identify the thread in the Threads status box. On Win32, ThreadID is also useful when calling Win32 API functions for manipulating the thread.

ThreadID is different than the thread's handle in the Handle (see page 3137) property.

See Also

Handle (see page 3137)

23.1.52.6 TThread Events

The events of the TThread class are listed here.

Public Events

	Name	Description
	OnTerminate (see page 3148)	Occurs after the thread's Execute (see page 3115) method has returned and before the thread is destroyed.

23.1.52.6.1 TThread.OnTerminate Event

Occurs after the thread's Execute (see page 3115) method has returned and before the thread is destroyed.

Pascal

```
property OnTerminate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTerminate;
```

Description

Write an OnTerminate event handler to execute code after the thread finishes executing. The OnTerminate event handler is called in the context of the main thread, which means methods and properties can be called freely.

23.1.53 TThreadList Class

TThreadList represents a thread-safe list.

Class Hierarchy

Classes.TThreadList

Pascal

```
TThreadList = class;
```

C++

```
class TThreadList;
```

File

Classes

Description

A TThreadList object is a thread-safe list. Each TThreadList maintains a private TList (see page 2868) (a list of pointers to objects). You can add or remove items in a TThreadList from multiple threads without explicit locks.

To access the actual TList (see page 2868) object managed by the thread list, first lock the list by calling the LockList (see page 3157) method. Unlock the list by calling the Unlock method when done.

Tip: By default, TThreadList ignores attempts to add duplicate entries to the list. If the list is large, this default is computationally expensive. For better performance, you may want to change the Duplicates (see page 3175) property to dupAccept where possible.

Locking Objects

Using the Main VCL

23.1.53.1 TThreadList Members

The following tables list the members exposed by TThreadList.

Public Methods

	Name	Description
	Add (see page 3151)	Adds an item to the list.
	Clear (see page 3157)	Deletes all items from the list.
	Create (see page 3150)	Creates and initializes a TThreadList (see page 3149) instance.
V	Destroy (see page 3150)	Destroys the TThreadList (see page 3149) and frees its memory.
	LockList (see page 3157)	Locks the thread-safe list and returns a TList (see page 2868) object.
	Remove (see page 3163)	Removes an item from the list.
	UnlockList (see page 3169)	Unlocks the thread-safe list.

Public Properties

	Name	Description
	Duplicates (see page 3175)	Indicates whether the thread list allows duplicate entries.

23.1.53.2 TThreadList.Create Constructor

Creates and initializes a TThreadList (see page 3149) instance.

Pascal

```
constructor Create;
```

C++

```
__fastcall TThreadList();
```

Description

The Create method generates a TThreadList (see page 3149) object.

23.1.53.3 TThreadList.Destroy Destructor

Destroys the TThreadList (see page 3149) and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TThreadList();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the thread list is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

23.1.53.4 TThreadList Methods

The methods of the TThreadList class are listed here.

Public Methods

	Name	Description
	Add (see page 3151)	Adds an item to the list.
	Clear (see page 3157)	Deletes all items from the list.
	LockList (see page 3157)	Locks the thread-safe list and returns a TList (see page 2868) object.
	Remove (see page 3163)	Removes an item from the list.
	UnlockList (see page 3169)	Unlocks the thread-safe list.

23.1.53.4.1 TThreadList.Add Method

Adds an item to the list.

Pascal

```
procedure Add(Item: Pointer);
```

C++

```
__fastcall Add(void * Item);
```

Description

Call Add to insert a new object at the end of the thread-safe list.

C++ Examples:

```
/*
The following example shows how to use the LockList and
UnlockList methods to access a thread-safe version  of a
TList object:
*/
class TMyThread : public TThread
{
__published:    // IDE-managed Components

    Sleep(3000);
  end;
  youthreadRunning:= FALSE;
end;
```

23.1.53.4.2 TThreadList.Clear Method

Deletes all items from the list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Clear locks the list, calls the Clear method in TList (see page 2868), then unlocks the list.

See Also

Clear (see page 2874)

23.1.53.4.3 TThreadList.LockList Method

Locks the thread-safe list and returns a TList (see page 2868) object.

Pascal

```
function LockList: TList;
```

C++

```
__fastcall TList LockList();
```

Description

Note: In Windows, LockList calls the Windows EnterCriticalSection function to lock the thread-safe list. It then returns the TList (see page 2868) object that contains the list.

Note: In Linux, LockList returns the TList (see page 2868) object that contains the list, after locking out all other threads.

C++ Examples:

```
/*
The following example shows how to use the LockList and
UnlockList methods to access a thread-safe version  of a
TList object:
*/
class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
```

```
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

Locking Objects

23.1.53.4.4 TThreadList.Remove Method

Removes an item from the list.

Pascal

```
procedure Remove(Item: Pointer);
```

C++

```
__fastcall Remove(void * Item);
```

Description

Call Remove to remove a specific item from the list without having to determine its index. Remove locks the list, calls the Remove method in TList (see page 2868), then unlocks the list.

C++ Examples:

```
/*
The following example shows how to use the LockList and
UnlockList methods to access a thread-safe version  of a
TList object:
*/
class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};
```

```

23.1.53.5 TThreadList Properties

The properties of the TThreadList class are listed here.

Public Properties

	Name	Description
	Duplicates (see page 3175)	Indicates whether the thread list allows duplicate entries.

23.1.53.5.1 TThreadList.Duplicates Property

Indicates whether the thread list allows duplicate entries.

Pascal

```
property Duplicates: TDuplicates;
```

C++

```
__property TDuplicates Duplicates;
```

Description

Set Duplicates to specify what should happen when an attempt is made to add a duplicate item to the list. The value of Duplicates should be one of the following.

Value	Meaning
dupIgnore	Ignore attempts to add duplicate items to the list.
dupError	raise an EListError (see page 2701) exception when an attempt is made to add duplicate items to the list.
dupAccept	Permit duplicate items in the list.

Set Duplicates before adding any items to the list. Setting Duplicates to dupIgnore or dupError does nothing about duplicates that are already in the list.

Note: Setting duplicates to dupIgnore (the default) or dupError can be computationally expensive if the list has many items.

23.1.54 TWriter Class

TWriter is a specialized filer object that writes data to its associated stream.

Class Hierarchy

Pascal

```
TWriter = class(TFiler);
```

C++

```
class TWriter : public TFiler;
```

File

Classes

Description

TWriter is used internally by the component streaming system to write information associated with a component, such as

published properties of components or custom property data, to a stream. TWriter handles the mechanics of writing the data associated with a component to a stream. It is the writer object, rather than the stream, that is responsible for handling the complexities of streaming components. These include methods for:

Writing different kinds of items to the associated stream.

Writing property deltas used for streaming inherited forms and properties with default values.

Writing nested groups of items or collections to the stream.

Other methods and properties of TWriter are used for interacting with stream and component objects.

Do not directly create writer objects. Writers are automatically created in stream object methods or in global routines that initiate the streaming process. These include:

the global routine ObjectTextToBinary (see page 3240) procedure, which directly creates a writer.

the global WriteComponentResFile (see page 3266) function, which creates a file stream that creates a writer.

the WriteDescendent (see page 3184) method of TStream (see page 2973), which creates a writer object.

Once the streaming process is underway, programs do not need to directly manipulate writer objects. The interaction between the writer, component, and stream objects happens automatically in methods of these objects that make calls to each other.

23.1.54.1 TWriter Members

The following tables list the members exposed by TWriter.

Protected Methods

	Name	Description
	FindMethodName (see page 3181)	This is FindMethodName, a member of class TWriter.
	SetRoot (see page 3181)	This is SetRoot, a member of class TWriter.
	WriteBinary (see page 3182)	This is WriteBinary, a member of class TWriter.
	WritePrefix (see page 3187)	This is WritePrefix, a member of class TWriter.
	WriteProperties (see page 3188)	This is WriteProperties, a member of class TWriter.
	WriteProperty (see page 3188)	This is WriteProperty, a member of class TWriter.
	WritePropName (see page 3188)	This is WritePropName, a member of class TWriter.
	WriteValue (see page 3190)	This is WriteValue, a member of class TWriter.

Public Events

	Name	Description
	OnFindAncestor (see page 3193)	Occurs when a component is about to be written to a stream.
	OnFindMethodName (see page 3194)	This is OnFindMethodName, a member of class TWriter.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2836)	Creates a filer object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefineBinaryProperty (see page 3179)	Treats unformatted data as if it were the value of a published property, and writes it directly to a memory stream.
	DefineProperty (see page 3180)	Defines data the writer object writes as if the data were a property.
	Destroy (see page 3178)	Destroys of an instance of a writer.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FlushBuffer (see page 3181)	Synchronizes the writer's buffer with the associated stream by writing the current buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Write (see page 3181)	Writes Count bytes from Buf to the writer object's associated stream.
	WriteBoolean (see page 3182)	Writes the Boolean value passed in Value to the writer object's stream.
	WriteChar (see page 3182)	Writes the character passed in Value to the writer object's stream.
	WriteCollection (see page 3183)	Writes the collection of objects passed in Value to the writer object's stream.
	WriteComponent (see page 3183)	Writes the component specified by Component to a stream.
	WriteCurrency (see page 3184)	Writes a currency value to the writer's stream.
	WriteDate (see page 3184)	Writes a datetime value to the writer's stream.
	WriteDescendent (see page 3184)	Triggers the writing of descendant components in inherited forms.
	WriteDouble (see page 3185)	Writes a value of type Double to the writer object’s stream.
	WriteFloat (see page 3185)	Writes the floating-point value passed in Value to the writer object's stream.
	WriteIdent (see page 3186)	Writes the identifier passed in Ident to the writer object's stream.
	WriteInteger (see page 3186)	This is the overview for the WriteInteger method overload.
	WriteListBegin (see page 3187)	Writes a start-of-list marker to the writer object's associated stream.
	WriteListEnd (see page 3187)	Writes an end-of-list marker to the writer object's associated stream.
	WriteRootComponent (see page 3188)	Calls the WriteDescendent (see page 3184) method.
	WriteSignature (see page 3189)	Writes a filer signature to the writer object's associated stream.

	WriteSingle (see page 3189)	Writes a value of type Single (Delphi) or float (C++) to the writer's stream.
	WriteStr (see page 3189)	Writes raw data to the writer object's stream.
	WriteString (see page 3190)	Writes tagged data to the writer object's stream.
	WriteVariant (see page 3190)	Writes a Variant value to the writer's stream.
	WriteWideChar (see page 3191)	Writes the wide character passed in Value to the writer object's stream.
	WriteWideString (see page 3191)	WriteWideString writes a wide string to the writer's stream.

Public Properties

	Name	Description
	Ancestor (see page 2839)	Determines whether to write the properties of inherited components.
	IgnoreChildren (see page 2839)	Enables a writer object to save a component without saving the components it owns.
R	LookupRoot (see page 2840)	Specifies the root component for resolving names while loading and saving components.
	Position (see page 3192)	Represents the current writing position in the associated stream.
	Root (see page 2840)	Indicates which object is the root, or ultimate owner, of the objects read or written by the filer.
	RootAncestor (see page 3192)	Represents the ancestor of the component in the Root (see page 2840) property.
	UseQualifiedNames (see page 3193)	Indicates whether all class names should be qualified by the name of the unit in which they are defined.

23.1.54.2 TWriter.Destroy Destructor

Destroys of an instance of a writer.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWriter();
```

Description

Do not call Destroy directly in an application. Writers are created indirectly by the global routines or stream methods that use them. When these routines are finished, they handle disposing of the writer.

Destroy writes the buffer before calling the inherited Destroy, which frees the buffer.

See Also

Destroy (see page 2837)

Free (see page 22300)

23.1.54.3 TWriter Methods

The methods of the TWriter class are listed here.

Protected Methods

	Name	Description
V	FindMethodName (see page 3181)	This is FindMethodName, a member of class TWriter.
V	SetRoot (see page 3181)	This is SetRoot, a member of class TWriter.
	WriteBinary (see page 3182)	This is WriteBinary, a member of class TWriter.
	WritePrefix (see page 3187)	This is WritePrefix, a member of class TWriter.
	WriteProperties (see page 3188)	This is WriteProperties, a member of class TWriter.
	WriteProperty (see page 3188)	This is WriteProperty, a member of class TWriter.

	WritePropName (see page 3188)	This is WritePropName, a member of class TWriter.
	WriteValue (see page 3190)	This is WriteValue, a member of class TWriter.

Public Methods

	Name	Description
	DefineBinaryProperty (see page 3179)	Treats unformatted data as if it were the value of a published property, and writes it directly to a memory stream.
	DefineProperty (see page 3180)	Defines data the writer object writes as if the data were a property.
	FlushBuffer (see page 3181)	Synchronizes the writer's buffer with the associated stream by writing the current buffer.
	Write (see page 3181)	Writes Count bytes from Buf to the writer object's associated stream.
	WriteBoolean (see page 3182)	Writes the Boolean value passed in Value to the writer object's stream.
	WriteChar (see page 3182)	Writes the character passed in Value to the writer object's stream.
	WriteCollection (see page 3183)	Writes the collection of objects passed in Value to the writer object's stream.
	WriteComponent (see page 3183)	Writes the component specified by Component to a stream.
	WriteCurrency (see page 3184)	Writes a currency value to the writer's stream.
	WriteDate (see page 3184)	Writes a datetime value to the writer's stream.
	WriteDescendent (see page 3184)	Triggers the writing of descendant components in inherited forms.
	WriteDouble (see page 3185)	Writes a value of type Double to the writer object's stream.
	WriteFloat (see page 3185)	Writes the floating-point value passed in Value to the writer object's stream.
	WriteIdent (see page 3186)	Writes the identifier passed in Ident to the writer object's stream.
	WriteInteger (see page 3186)	This is the overview for the WriteInteger method overload.
	WriteListBegin (see page 3187)	Writes a start-of-list marker to the writer object's associated stream.
	WriteListEnd (see page 3187)	Writes an end-of-list marker to the writer object's associated stream.
	WriteRootComponent (see page 3188)	Calls the WriteDescendent (see page 3184) method.
	WriteSignature (see page 3189)	Writes a filer signature to the writer object's associated stream.
	WriteSingle (see page 3189)	Writes a value of type Single (Delphi) or float (C++) to the writer's stream.
	WriteStr (see page 3189)	Writes raw data to the writer object's stream.
	WriteString (see page 3190)	Writes tagged data to the writer object's stream.
	WriteVariant (see page 3190)	Writes a Variant value to the writer's stream.
	WriteWideChar (see page 3191)	Writes the wide character passed in Value to the writer object's stream.
	WriteWideString (see page 3191)	WriteWideString writes a wide string to the writer's stream.

23.1.54.3.1 TWriter.DefineBinaryProperty Method

Treats unformatted data as if it were the value of a published property, and writes it directly to a memory stream.

Pascal

```
procedure DefineBinaryProperty(const Name: string; ReadData: TStreamProc; WriteData:
TStreamProc; HasData: Boolean); override;
```

C++

```
virtual __fastcall DefineBinaryProperty(const AnsiString Name, TStreamProc ReadData,
TStreamProc WriteData, Boolean HasData);
```

Description

DefineBinaryProperty is called internally by the DefineProperties method of an object that has data it needs to store. DefineProperties takes a generic filer object as its parameter.

For writing binary data DefineProperties takes a TWriter (see page 3175) object and then calls its DefineBinaryProperty method. DefineBinaryProperty writes the property's name and it's data, but only if the HasData parameter is true. Otherwise it does nothing.

The Name parameter specifies the name of the "fake" property to be written to the stream. A "fake" property is a property that is not published, and that exists only in the code for the DefineBinaryProperty method. The Top and Left properties of a non-visual component are examples of "fake" properties. These are also called "defined properties" or "custom defined properties."

The TStreamProc (see page 3304) type is the type of the ReadData and WriteData parameters. It is the method-pointer type that points to a procedure (defined in the storing object) that reads or writes a binary representation of the object's data directly to or from the stream passed as its Stream parameter. For TWriter (see page 3175) the ReadData parameter is ignored.

The HasData parameter determines at run time whether the "fake" property has data to store (write).

Defined binary properties are quite rare. Persistent objects that store graphics as binary data are the most common use of filer objects to store and retrieve that data. More commonly, objects use the DefineProperty (see page 3180) method. The difference between DefineBinaryProperty and DefineProperty (see page 3180) is that with DefineBinaryProperty the component reads or writes the binary property directly to or from a memory stream, rather than going through a filer object.

Note: Streamable objects that are descended from TPersistent (see page 2928) inherit a DefineProperties method, however DefineProperties does not do anything until TComponent (see page 2762). It is TComponent (see page 2762)'s DefineProperties method that calls the writer's DefineBinaryProperty when writing out binary data.

See Also

DefineProperty (see page 3180)

DefineProperties (see page 2771)

23.1.54.3.2 TWriter.DefineProperty Method

Defines data the writer object writes as if the data were a property.

Pascal

```
procedure DefineProperty(const Name: string; ReadData: TReaderProc; WriteData: TWriterProc;
HasData: Boolean); override;
```

C++

```
virtual __fastcall DefineProperty(const AnsiString Name, TReaderProc ReadData, TWriterProc
WriteData, Boolean HasData);
```

Description

DefineProperty is called internally by the DefineProperties method of an object that has data it needs to store. DefineProperties takes a generic filer object as its parameter. For writing data, DefineProperties takes a TWriter (see page 3175) object and calls its DefineProperty method. DefineProperty then writes the property's name and its data, but only if the HasData parameter is true. Otherwise it does nothing.

The Name parameter specifies the name of the "fake" property to be written to the stream.

The WriteData parameter points to a procedure (defined in the component object) that writes the object's data, which represents a property value, to the writer object. For TWriter (see page 3175) the ReadData parameter is ignored.

The HasData parameter determines at run time whether the "fake" property has data to store (write). Thus, writer objects only use HasData when writing data.

The difference between DefineBinaryProperty (see page 3179) and DefineProperty is that with DefineBinaryProperty (see page 3179), the binary data is written directly to a stream object, rather than going through a filer object.

When writing a component that has special (large) data storage requirements, the component's DefineProperties can be overridden. For each special or "fake" property item, call DefineProperty or DefineBinaryProperty (see page 3179). For the ReadData and WriteData parameters, pass in methods of the component that know how to handle that special data type. When reading, ReadData is called. When writing, WriteData is called.

Note: When defining properties, a component should be aware of the Ancestor (see page 2839) property, which, if non-nil (Delphi) or non-NULL (C++) indicates that the component should only write the values of properties that differ from those inherited from Ancestor (see page 2839).

Ancestor (see page 2839)

DefineBinaryProperty (see page 3179)

DefineProperties (see page 2771)

23.1.54.3.3 TWriter.FindMethodName Method

Pascal

```
function FindMethodName(Method: TMethod): string; virtual;
```

C++

```
virtual __fastcall AnsiString FindMethodName(TMethod Method);
```

Description

This is FindMethodName, a member of class TWriter.

23.1.54.3.4 TWriter.FlushBuffer Method

Synchronizes the writer's buffer with the associated stream by writing the current buffer.

Pascal

```
procedure FlushBuffer; override;
```

C++

```
virtual __fastcall FlushBuffer();
```

Description

FlushBuffer is not generally used except for internal implementation in the IDE.

FlushBuffer writes the current buffer to the stream, then resets an internal pointer to the correct position.

23.1.54.3.5 TWriter.SetRoot Method

Pascal

```
procedure SetRoot(Value: TComponent); override;
```

C++

```
virtual __fastcall SetRoot(TComponent * Value);
```

Description

This is SetRoot, a member of class TWriter.

23.1.54.3.6 TWriter.Write Method

Writes Count bytes from Buf to the writer object's associated stream.

Pascal

```
procedure Write(const Buf; Count: Longint);
```

C++

```
__fastcall Write(const  Buf, Longint Count);
```

Description

Do not call Write directly. It is used internally to write data to the stream. Many other writer methods call Write, usually after setting pertinent values or verifying data types.

See Also

ObjectBinaryToText

23.1.54.3.7 TWriter.WriteBinary Method

Pascal

```
procedure WriteBinary(WriteData: TStreamProc);
```

C++

```
__fastcall WriteBinary(TStreamProc WriteData);
```

Description

This is WriteBinary, a member of class TWriter.

23.1.54.3.8 TWriter.WriteBoolean Method

Writes the Boolean value passed in Value to the writer object's stream.

Pascal

```
procedure WriteBoolean(Value: Boolean);
```

C++

```
__fastcall WriteBoolean(Boolean Value);
```

Description

WriteBoolean is used internally by the component streaming system to write component properties to a stream. Use WriteBoolean for writing component boolean properties to streams.

WriteBoolean checks to ensure that Value is the correct type before calling Write (see page 3181) to write the boolean value and its value type to the stream.

See Also

Write (see page 3181)

23.1.54.3.9 TWriter.WriteChar Method

Writes the character passed in Value to the writer object's stream.

Pascal

```
procedure WriteChar(Value: Char);
```

C++

```
__fastcall WriteChar(Char Value);
```

Description

WriteChar is used internally by the component streaming system to write component properties to a stream. Use WriteChar for writing component character properties to streams.

WriteChar calls WriteString (see page 3190) which checks to ensure that Value is the correct type before calling Write (see

page 3181) to write the character and its value type to the stream.

Note: WriteChar calls StringChar to enable writing character properties that are upwardly compatible with string properties.

See Also

Write (see page 3181)

WriteString (see page 3190)

23.1.54.3.10 TWriter.WriteCollection Method

Writes the collection of objects passed in Value to the writer object's stream.

Pascal

```
procedure WriteCollection(Value: TCollection);
```

C++

```
__fastcall WriteCollection(TCollection Value);
```

Description

WriteCollection is used internally by the component streaming system to write component properties to a stream. Use WriteCollection for writing component properties that are collections to streams.

WriteCollection first writes the type identifier indicating a collection.

If the Value parameter is not nil (Delphi) or NULL (C++), WriteCollection next writes each element of the collection to the stream, bounding the elements with start-of-list and end-of-list markers. Otherwise, it skips the elements, assuming an empty collection.

See Also

Write (see page 3181)

WriteListBegin (see page 3187)

WriteListEnd (see page 3187)

23.1.54.3.11 TWriter.WriteComponent Method

Writes the component specified by Component to a stream.

Pascal

```
procedure WriteComponent(Component: TComponent);
```

C++

```
__fastcall WriteComponent(TComponent * Component);
```

Description

Never call WriteComponent directly. WriteComponent is recursively called for each owned component in Root (see page 2840).

WriteComponent sets the csWriting state in Component's ComponentState property before calling the WriteState method of Component and clears the csWriting flag when WriteState returns.

Note: The sequence of events is as follows: the writer's WriteComponent method calls the Component's WriteState method, which calls the writer's WriteData method. That method writes the properties for each child component, then calls WriteComponent.

Because the Component's WriteState is virtual, it is the Component's only opportunity to prepare itself to be streamed (i.e. to

consolidate its data.)

See Also

WriteDescendent (see page 3184)

UseQualifiedNames (see page 3193)

23.1.54.3.12 TWriter.WriteCurrency Method

Writes a currency value to the writer's stream.

Pascal

```
procedure WriteCurrency(const Value: Currency);
```

C++

```
__fastcall WriteCurrency(const Currency Value);
```

Description

WriteCurrency is used internally by the component streaming system to write component properties to a stream. Use WriteCurrency for writing component properties of type Currency to streams.

WriteCurrency first writes a type identifier before writing the currency value.

23.1.54.3.13 TWriter.WriteDate Method

Writes a datetime value to the writer's stream.

Pascal

```
procedure WriteDate(const Value: TDateTime);
```

C++

```
__fastcall WriteDate(const TDateTime Value);
```

Description

WriteDate is used internally by the component streaming system to write component properties to a stream. Use WriteDate for writing component properties of type TDateTime to streams.

WriteDate first writes a type identifier before writing the TDateTime value.

23.1.54.3.14 TWriter.WriteDescendent Method

Triggers the writing of descendant components in inherited forms.

Pascal

```
procedure WriteDescendent(Root: TComponent; AAncestor: TComponent);
```

C++

```
__fastcall WriteDescendent(TComponent * Root, TComponent * AAncestor);
```

Description

Never call WriteDescendent directly. It is part of a sequence of calls used for streaming descendant components in inherited forms.

WriteDescendent sets the writer object's Ancestor (see page 2839) and RootAncestor (see page 3192) properties to the value passed in AAncestor, sets the Root (see page 2840) property to the value passed in Root (see page 2840), then calls

WriteSignature (see page 3189) and WriteComponent (see page 3183) to write Root (see page 2840) and any components it owns to the writer object's stream.

WriteDescendent differs from WriteComponent (see page 3183) in that, by setting Ancestor (see page 2839), it uses Ancestor (see page 2839)'s property values as the defaults, rather than those defined by Root (see page 2840)'s type.

See Also

Ancestor (see page 2839)

Root (see page 2840)

WriteComponent (see page 3183)

23.1.54.3.15 TWriter.WriteDouble Method

Writes a value of type Double to the writer object’s stream.

Pascal

```
procedure WriteDouble(const Value: Double);
```

C++

```
__fastcall WriteDouble(const Double Value);
```

Description

WriteDouble is used internally by the component streaming system to write component properties to a stream. Use WriteDouble to write a value of type Double to the writer object’s stream.

WriteDouble checks to ensure that Value is the correct type before calling Write (see page 3181) to write the float value and its value type to the stream.

See Also

Write (see page 3181)

23.1.54.3.16 TWriter.WriteFloat Method

Writes the floating-point value passed in Value to the writer object's stream.

Pascal

```
procedure WriteFloat(const Value: Extended);
```

C++

```
__fastcall WriteFloat(const Extended Value);
```

Description

WriteFloat is used internally by the component streaming system to write component properties to a stream. Use WriteFloat for writing floating point data to streams.

WriteFloat checks to ensure that Value is the correct type before calling Write (see page 3181) to write the float value and its value type to the stream.

See Also

Write (see page 3181)

23.1.54.3.17 TWriter.WriteIdent Method

Writes the identifier passed in Ident to the writer object's stream.

Pascal

```
procedure WriteIdent(const Ident: string);
```

C++

```
__fastcall WriteIdent(const AnsiString Ident);
```

Description

WriteIdent is used internally by the component streaming system to write component properties to a stream. Use WriteIdent for writing component identifier properties to streams. Component names and enumerated type elements are examples of strings that must be restricted to identifier syntax.

WriteIdent checks for certain common identifiers (such as true, false, nil (Delphi), or NULL (C++)) and inserts a special token for these values. Otherwise, it writes the identifier as a string.

See Also

Write (see page 3181)

WriteStr (see page 3189)

23.1.54.3.18 WriteInteger Method

This is the overview for the WriteInteger method overload.

Overload List

	Name	Description
	TWriter.WriteInteger (Int64) (see page 3186)	Writes the integer value passed in Value to the writer object's stream.
	TWriter.WriteInteger (Longint) (see page 3186)	Writes the integer value passed in Value to the writer object's stream.

23.1.54.3.18.1 TWriter.WriteInteger Method (Int64)

Writes the integer value passed in Value to the writer object's stream.

Pascal

```
procedure WriteInteger(Value: Longint); overload;
procedure WriteInteger(Value: Int64); overload;
```

C++

```
__fastcall WriteInteger(Longint Value);
__fastcall WriteInteger(Int64 Value);
```

Description

WriteInteger is used internally by the component streaming system to write component properties to a stream. Use WriteInteger for writing component integer properties to streams.

WriteInteger checks to ensure that Value is the correct type before calling Write (see page 3181) to write the integer value and its value type to the stream. WriteInteger handles integers of different sizes.

See Also

Write (see page 3181)

23.1.54.3.19 TWriter.WriteListBegin Method

Writes a start-of-list marker to the writer object's associated stream.

Pascal

```
procedure WriteListBegin;
```

C++

```
__fastcall WriteListBegin();
```

Description

WriteListBegin is used by other methods that iterate through a group of items about to be written to the stream. WriteListBegin writes a start-of-list marker to the writer object's associated stream. Every call to WriteListBegin must have a corresponding call to WriteListEnd (see page 3187).

See Also

WriteListEnd (see page 3187)

23.1.54.3.20 TWriter.WriteListEnd Method

Writes an end-of-list marker to the writer object's associated stream.

Pascal

```
procedure WriteListEnd;
```

C++

```
__fastcall WriteListEnd();
```

Description

WriteListEnd is used by other methods that iterate through a group of items that are sequentially written to the stream during a single process.

A call to WriteListEnd is generally preceded by a writing loop. A call to WriteListEnd must correspond to a preceding call to WriteListBegin (see page 3187).

See Also

WriteListBegin (see page 3187)

23.1.54.3.21 TWriter.WritePrefix Method

Pascal

```
procedure WritePrefix(Flags: TFilerFlags; AChildPos: Integer);
```

C++

```
__fastcall WritePrefix(TFilerFlags Flags, int AChildPos);
```

Description

This is WritePrefix, a member of class TWriter.

23.1.54.3.22 TWriter.WriteProperties Method

Pascal

```
procedure WriteProperties(Instance: TPersistent);
```

C++

```
__fastcall WriteProperties(TPersistent * Instance);
```

Description

This is WriteProperties, a member of class TWriter.

23.1.54.3.23 TWriter.WriteProperty Method

Pascal

```
procedure WriteProperty(Instance: TPersistent; PropInfo: PPropInfo);
```

C++

```
__fastcall WriteProperty(TPersistent * Instance, PPropInfo PropInfo);
```

Description

This is WriteProperty, a member of class TWriter.

23.1.54.3.24 TWriter.WritePropName Method

Pascal

```
procedure WritePropName(const PropName: string);
```

C++

```
__fastcall WritePropName(const AnsiString PropName);
```

Description

This is WritePropName, a member of class TWriter.

23.1.54.3.25 TWriter.WriteRootComponent Method

Calls the WriteDescendent (see page 3184) method.

Pascal

```
procedure WriteRootComponent(Root: TComponent);
```

C++

```
__fastcall WriteRootComponent(TComponent * Root);
```

Description

WriteRootComponent is provided for backward compatibility only.

See Also

WriteDescendent (see page 3184)

23.1.54.3.26 TWriter.WriteSignature Method

Writes a filer signature to the writer object's associated stream.

Pascal

```
procedure WriteSignature;
```

C++

```
__fastcall WriteSignature();
```

Description

WriteSignature is used internally by several methods that write the filer signature before processing some action. For example, the WriteRootComponent (see page 3188) method calls WriteSignature before writing its component to the stream. By checking for the signature before loading objects, reader objects can guard against inadvertently reading invalid or corrupted data.

23.1.54.3.27 TWriter.WriteSingle Method

Writes a value of type Single (Delphi) or float (C++) to the writer's stream.

Pascal

```
procedure WriteSingle(const Value: Single);
```

C++

```
__fastcall WriteSingle(const Single Value);
```

Description

WriteSingle is used internally by the component streaming system to write component properties to a stream. Use WriteSingle for writing component properties of Delphi type Single (which corresponds to C++ type float) to streams.

WriteSingle first writes a type identifier before writing the value.

23.1.54.3.28 TWriter.WriteStr Method

Writes raw data to the writer object's stream.

Pascal

```
procedure WriteStr(const Value: string);
```

C++

```
__fastcall WriteStr(const AnsiString Value);
```

Description

Do not call WriteStr directly. WriteStr is for internal use by certain components. WriteStr writes the string passed in Value to the writer object's stream.

Warning: Always use WriteString (see page 3190) for writing component strings to streams. WriteStr can corrupt data if not used correctly.

See Also

WriteString (see page 3190)

23.1.54.3.29 TWriter.WriteString Method

Writes tagged data to the writer object's stream.

Pascal

```
procedure WriteString(const Value: string);
```

C++

```
__fastcall WriteString(const AnsiString Value);
```

Description

WriteString is used internally by the component streaming system to write component properties to a stream. WriteString is otherwise only used by component writers in the DefineProperties and WriteData procedures.

WriteString writes the string passed in Value to the writer object's stream. WriteString checks to ensure that Value is the correct type before calling Write (see page 3181) to write the string and its value type to the stream.

Warning: Always use WriteString for writing component strings to streams. The similarly-named WriteStr (see page 3189) method is for internal use by certain components and can corrupt data if not used correctly.

See Also

WriteChar (see page 3182)

WriteStr (see page 3189)

23.1.54.3.30 TWriter.WriteValue Method

Pascal

```
procedure WriteValue(Value: TValueType);
```

C++

```
__fastcall WriteValue(TValueType Value);
```

Description

This is WriteValue, a member of class TWriter.

23.1.54.3.31 TWriter.WriteVariant Method

Writes a Variant value to the writer's stream.

Pascal

```
procedure WriteVariant(const Value: Variant);
```

C++

```
__fastcall WriteVariant(const Variant Value);
```

Description

WriteVariant is used internally by the streaming system to write component properties to a stream. Use WriteVariant for writing component properties of type Variant to streams.

WriteVariant first writes a type identifier before writing the Variant value.

See Also

ReadVariant (see page 2955)

23.1.54.3.32 TWriter.WriteWideChar Method

Writes the wide character passed in Value to the writer object's stream.

Pascal

```
procedure WriteWideChar(Value: WideChar);
```

C++

```
__fastcall WriteWideChar(WideChar Value);
```

Description

WriteWideChar is used internally by the component streaming system to write component properties to a stream. Use WriteWideChar for writing component wide character properties to streams.

WriteWideChar calls WriteString (see page 3190) which checks to ensure that Value is the correct type before calling Write (see page 3181) to write the wide character and its value type to the stream.

Note: WriteWideChar calls StringChar to enable writing wide character properties that are upwardly compatible with string properties.

See Also

Write (see page 3181)

WriteString (see page 3190)

23.1.54.3.33 TWriter.WriteWideString Method

WriteWideString writes a wide string to the writer's stream.

Pascal

```
procedure WriteWideString(const Value: WideString);
```

C++

```
__fastcall WriteWideString(const BSTR Value);
```

Description

WriteWideString is used internally by the component streaming system to write component properties to a stream. Use WriteWideString for writing WideString component to streams.

WriteWideString first writes a type identifier and the length of the string before writing the value.

See Also

ObjectTextToBinary

WriteDescendent (see page 2994)

WriteComponentResFile

23.1.54.4 TWriter Properties

The properties of the TWriter class are listed here.

Public Properties

	Name	Description
	Position (see page 3192)	Represents the current writing position in the associated stream.
	RootAncestor (see page 3192)	Represents the ancestor of the component in the Root (see page 2840) property.
	UseQualifiedNames (see page 3193)	Indicates whether all class names should be qualified by the name of the unit in which they are defined.

23.1.54.4.1 TWriter.Position Property

Represents the current writing position in the associated stream.

Pascal

```
property Position: Longint;
```

C++

```
__property Longint Position;
```

Description

Position is used internally by writer objects to indicate the current writing position in the stream.

The value of Position will be inside the most recent buffer block read or the next block to be written. Thus, for writing, Position will generally be less than the stream's Position. When Position is set to a location outside the current buffer, the writer's buffer is flushed to the stream.

See Also

FlushBuffer (see page 3181)

23.1.54.4.2 TWriter.RootAncestor Property

Represents the ancestor of the component in the Root (see page 2840) property.

Pascal

```
property RootAncestor: TComponent;
```

C++

```
__property TComponent * RootAncestor;
```

Description

RootAncestor is used internally by writer objects for dealing with form inheritance. It is used to iterate through ancestor components when writing properties in inherited forms.

RootAncestor is always the ancestor form. For each component in Root (see page 2840), which is the inherited form, the Ancestor (see page 2839) property tracks a corresponding component in RootAncestor.

The writer object iterates through each of the Root (see page 2840) form's owned components, comparing each to the corresponding component in the RootAncestor form. It then writes only those properties in the current component that differ in some way from those in the Ancestor (see page 2839) component.

See Also

Ancestor (see page 2839)

Owner (see page 2959)

Root (see page 2840)

WriteDescendent (see page 3184)

23.1.54.4.3 TWriter.UseQualifiedNames Property

Indicates whether all class names should be qualified by the name of the unit in which they are defined.

Pascal

```
property UseQualifiedNames: Boolean;
```

C++

```
__property Boolean UseQualifiedNames;
```

Description

Set UseQualifiedNames to indicate whether class names need to be qualified by the name of the unit in which they are defined. In Windows versions of the IDE, for example, some components (such as TButton) appear both in the Windows-only and in the cross-platform component libraries. When writing such a component, setting UseQualifiedNames to true allows a reader to distinguish the Windows-only TButton control in StdCtrls (see page 20907) from the cross-platform TButton control in QStdCtrls.

See Also

WriteComponent (see page 3183)

23.1.54.5 TWriter Events

The events of the TWriter class are listed here.

Public Events

	Name	Description
	OnFindAncestor (see page 3193)	Occurs when a component is about to be written to a stream.
	OnFindMethodName (see page 3194)	This is OnFindMethodName, a member of class TWriter.

23.1.54.5.1 TWriter.OnFindAncestor Event

Occurs when a component is about to be written to a stream.

Pascal

```
property OnFindAncestor: TFindAncestorEvent;
```

C++

```
__property TFindAncestorEvent OnFindAncestor;
```

Description

OnFindAncestor allows the writer to explicitly specify the ancestor of a component when it is written to a stream. The WriteComponent (see page 3183) method generates this event to override the value of the Ancestor (see page 2839) property before writing a component to a stream.

See Also

Ancestor (see page 2839)

WriteComponent (see page 3183)

RootAncestor (see page 3192)

23.1.54.5.2 TWriter.OnFindMethodName Event

Pascal

```
property OnFindMethodName: TFindMethodNameEvent;
```

C++

```
__property TFindMethodNameEvent OnFindMethodName;
```

Description

This is OnFindMethodName, a member of class TWriter.

23.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDesignerNotify (see page 3195)	IDesignerNotify is the interface for responding to notifications about changes to components in the designer.
	IInterfaceComponentReference (see page 3197)	IInterfaceComponentReference is the interface for responding to requests for retrieving components.
	IInterfaceList (see page 3198)	IInterfaceList provides access to a list of interfaces.
	IStreamPersist (see page 3207)	IStreamPersist is the interface for responding to requests to load/save an object from/to a persistent stream.
	IStringsAdapter (see page 3208)	This is class Classes.IStringsAdapter.
	IVarStreamable (see page 3210)	IVarStreamable is the interface for loading and saving the values of Variants (see page 23567).
	IVCLComObject (see page 3211)	This is class Classes.IVCLComObject.

23.2.1 IDesignerNotify Interface

IDesignerNotify is the interface for responding to notifications about changes to components in the designer.

Class Hierarchy

Classes.IDesignerNotify

Pascal

```
IDesignerNotify = interface;
```

C++

```
__interface IDesignerNotify;
```

File

Classes

Description

IDesignerNotify introduces two methods, Modified (see page 3196) and Notification (see page 3196), that allow the designer to respond when components are added, deleted, or changed. These methods are called automatically by the form designer or by component and property editors.

See Also

IDesigner (see page 11149)

23.2.1.1 IDesignerNotify Members

The following tables list the members exposed by IDesignerNotify.

Public Methods

	Name	Description
	Modified (see page 3196)	Notifies property and component editors when a change is made to a component.
	Notification (see page 3196)	Allows the designer to respond when a notification is sent to the form.

23.2.1.2 IDesignerNotify Methods

The methods of the IDesignerNotify class are listed here.

Public Methods

	Name	Description
	Modified (see page 3196)	Notifies property and component editors when a change is made to a component.
	Notification (see page 3196)	Allows the designer to respond when a notification is sent to the form.

23.2.1.2.1 IDesignerNotify.Modified Method

Notifies property and component editors when a change is made to a component.

Pascal

```
procedure Modified;
```

C++

```
__fastcall Modified();
```

Description

When any change is made to a component the property and component editors call this method, allowing the designer to respond to the change.

See Also

Modified (see page 11038)

23.2.1.2.2 IDesignerNotify.Notification Method

Allows the designer to respond when a notification is sent to the form.

Pascal

```
procedure Notification(AnObject: TPersistent; Operation: TOperation);
```

C++

```
__fastcall Notification(TPersistent * AnObject, TOperation Operation);
```

Description

When a form receives a notification, it calls the Notification method of the designer, allowing the designer to respond to all the notifications the form receives.

See Also

Notification (see page 2783)

23.2.2 IInterfaceComponentReference Interface

IInterfaceComponentReference is the interface for responding to requests for retrieving components.

Class Hierarchy

Classes.IInterfaceComponentReference

Pascal

```
IInterfaceComponentReference = interface;
```

C++

```
__interface IInterfaceComponentReference;
```

File

Classes

Description

IInterfaceComponentReference introduces one method, GetComponent (see page 3197), that allows the designer to respond a request to retrieve a reference to the component associated with a class.

For example, the TComponent (see page 2762) class itself implements the IInterfaceComponentReference.

See Also

TComponent (see page 2762)

23.2.2.1 IInterfaceComponentReference Members

The following tables list the members exposed by IInterfaceComponentReference.

Public Methods

	Name	Description
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

23.2.2.2 IInterfaceComponentReference Methods

The methods of the IInterfaceComponentReference class are listed here.

Public Methods

	Name	Description
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

23.2.2.2.1 IInterfaceComponentReference.GetComponent Method

Returns a reference to the component associated by the implementing class.

Pascal

```
function GetComponent: TComponent;
```

C++

```
__fastcall TComponent * GetComponent();
```

Description

GetComponent returns a TComponent (see page 2762) value that is associated with the implementing class. For example, the TComponent (see page 2762) class itself implements the GetComponent to return a pointer to itself.

See Also

TComponent (see page 2762)

23.2.3 IInterfaceList Interface

IInterfaceList provides access to a list of interfaces.

Class Hierarchy

Classes.IInterfaceList

Pascal

```
IInterfaceList = interface;
```

C++

```
__interface IInterfaceList;
```

File

Classes

Description

Use IInterfaceList to manage a list of interfaces. Typically, IInterfaceList is implemented by the TInterfaceList (see page 2855) class.

Note: C++ method declarations that use IInterfaceList use the _di_IInterfaceList type instead. This type is a DelphiInterface wrapper around the IInterfaceList interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IInterfaceList >  _di_IInterfaceList;
```

See Also

TInterfaceList (see page 2855)

23.2.3.1 IInterfaceList Members

The following tables list the members exposed by IInterfaceList.

Public Methods

	Name	Description
	Add (see page 3199)	Adds an interface to the list.
	Clear (see page 3200)	Clears the interface list.
	Delete (see page 3200)	Deletes an interface from the list.
	Exchange (see page 3201)	Swaps the position of two interfaces in the list.
	First (see page 3201)	Returns the first interface in the list.

	Get (see page 3201)	Returns a specified interface from the list.
	GetCapacity (see page 3202)	Returns the value of the Capacity (see page 3205) property.
	GetCount (see page 3202)	Returns the value of the Count (see page 3206) property.
	IndexOf (see page 3202)	Returns the index of an interface.
	Insert (see page 3202)	Inserts an interface into the list at a specified position.
	Last (see page 3203)	Returns the last interface in the list.
	Lock (see page 3203)	Prevents other threads from accessing the list.
	Put (see page 3204)	Replaces an interface in the list with a specified interface.
	Remove (see page 3204)	Removes an interface from the list.
	SetCapacity (see page 3204)	Sets the value of the Capacity (see page 3205) property.
	SetCount (see page 3205)	Sets the value of the Count (see page 3206) property.
	Unlock (see page 3205)	Unlocks the list, allowing other threads to access it.

Public Properties

	Name	Description
	Capacity (see page 3205)	Specifies the list capacity.
	Count (see page 3206)	Specifies the number of interfaces in the list.
	Items (see page 3206)	Provides direct access to an interface in the list.

23.2.3.2 IInterfaceList Methods

The methods of the IInterfaceList class are listed here.

Public Methods

	Name	Description
	Add (see page 3199)	Adds an interface to the list.
	Clear (see page 3200)	Clears the interface list.
	Delete (see page 3200)	Deletes an interface from the list.
	Exchange (see page 3201)	Swaps the position of two interfaces in the list.
	First (see page 3201)	Returns the first interface in the list.
	Get (see page 3201)	Returns a specified interface from the list.
	GetCapacity (see page 3202)	Returns the value of the Capacity (see page 3205) property.
	GetCount (see page 3202)	Returns the value of the Count (see page 3206) property.
	IndexOf (see page 3202)	Returns the index of an interface.
	Insert (see page 3202)	Inserts an interface into the list at a specified position.
	Last (see page 3203)	Returns the last interface in the list.
	Lock (see page 3203)	Prevents other threads from accessing the list.
	Put (see page 3204)	Replaces an interface in the list with a specified interface.
	Remove (see page 3204)	Removes an interface from the list.
	SetCapacity (see page 3204)	Sets the value of the Capacity (see page 3205) property.
	SetCount (see page 3205)	Sets the value of the Count (see page 3206) property.
	Unlock (see page 3205)	Unlocks the list, allowing other threads to access it.

23.2.3.2.1 IInterfaceList.Add Method

Adds an interface to the list.

Pascal

```
function Add(const Item: IInterface): Integer;
```

C++

```
__fastcall int Add(const IInterface Item);
```

Description

Call Add to add an interface to the list.

See Also

Count (see page 3206)

Add

Items (see page 3206)

Delete (see page 3200)

Capacity (see page 3205)

23.2.3.2.2 IInterfaceList.Clear Method

Clears the interface list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to remove all interfaces from the list.

See Also

Items (see page 3206)

Delete (see page 3200)

23.2.3.2.3 IInterfaceList.Delete Method

Deletes an interface from the list.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Call Delete to delete an interface from the list.

See Also

Count (see page 3206)

Add (see page 3199)

Items (see page 3206)

Clear (see page 3200)

Remove (see page 3204)

23.2.3.2.4 IInterfaceList.Exchange Method

Swaps the position of two interfaces in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer);
```

C++

```
__fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to move the interface at position Index1 so that it appears at position Index2 and move the interface at position Index2 so that it appears at position Index1. Index1 and Index2 identify two positions (zero offset) in the Items (see page 3206) property array.

See Also

Items (see page 3206)

23.2.3.2.5 IInterfaceList.First Method

Returns the first interface in the list.

Pascal

```
function First: IInterface;
```

C++

```
__fastcall IInterface First();
```

Description

Call First to obtain the first interface in the list.

See Also

Items (see page 3206)

Last (see page 3203)

23.2.3.2.6 IInterfaceList.Get Method

Returns a specified interface from the list.

Pascal

```
function Get(Index: Integer): IInterface;
```

C++

```
__fastcall IInterface Get(int Index);
```

Description

Get is the read implementation of the Items (see page 3206) property.

Index identifies which interface to return, where 0 is the first interface, 1 is the second interface, and so on.

See Also

Items (see page 3206)

23.2.3.2.7 IInterfaceList.GetCapacity Method

Returns the value of the Capacity (see page 3205) property.

Pascal

```
function GetCapacity: Integer;
```

C++

```
__fastcall int GetCapacity();
```

Description

GetCapacity is the read implementation of the Capacity (see page 3205) property.

See Also

Capacity (see page 3205)

23.2.3.2.8 IInterfaceList.GetCount Method

Returns the value of the Count (see page 3206) property.

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

GetCount is the read implementation of the Count (see page 3206) property.

See Also

Count (see page 3206)

23.2.3.2.9 IInterfaceList.IndexOf Method

Returns the index of an interface.

Pascal

```
function IndexOf(const Item: IInterface): Integer;
```

C++

```
__fastcall int IndexOf(const IInterface Item);
```

Description

Call IndexOf to obtain the index of an interface.

See Also

Items (see page 3206)

23.2.3.2.10 IInterfaceList.Insert Method

Inserts an interface into the list at a specified position.

Pascal

```
procedure Insert(Index: Integer; const Item: IInterface);
```

C++

```
__fastcall Insert(int Index, const IInterface Item);
```

Description

Call Insert to insert an interface into the list. Item is the interface to insert, and Index indicates the position (zero-offset) where the interface should be added.

See Also

Count (see page 3206)

Add (see page 3199)

Items (see page 3206)

Delete (see page 3200)

Capacity (see page 3205)

23.2.3.2.11 IInterfaceList.Last Method

Returns the last interface in the list.

Pascal

```
function Last: IInterface;
```

C++

```
__fastcall IInterface Last();
```

Description

Call Last to obtain the last interface in the list.

See Also

First (see page 3201)

Items (see page 3206)

23.2.3.2.12 IInterfaceList.Lock Method

Prevents other threads from accessing the list.

Pascal

```
procedure Lock;
```

C++

```
__fastcall Lock();
```

Description

Call Lock to lock the list, preventing other threads from accessing the list.

See Also

Unlock (see page 3205)

23.2.3.2.13 IInterfaceList.Put Method

Replaces an interface in the list with a specified interface.

Pascal

```
procedure Put(Index: Integer; const Item: IInterface);
```

C++

```
__fastcall Put(int Index, const IInterface Item);
```

Description

Put is the write implementation of the Items (see page 3206) property.

Index is the index of the interface to replace.

Item is the interface that replaces the interface identified by Index.

See Also

Items (see page 3206)

23.2.3.2.14 IInterfaceList.Remove Method

Removes an interface from the list.

Pascal

```
function Remove(const Item: IInterface): Integer;
```

C++

```
__fastcall int Remove(const IInterface Item);
```

Description

Call Remove to remove an interface from the list.

Remove returns the index of the removed interface, or –1 if the interface was not found.

See Also

Add (see page 3199)

Insert (see page 3202)

Delete (see page 3200)

Clear (see page 3200)

23.2.3.2.15 IInterfaceList.SetCapacity Method

Sets the value of the Capacity (see page 3205) property.

Pascal

```
procedure SetCapacity(NewCapacity: Integer);
```

C++

```
__fastcall SetCapacity(int NewCapacity);
```

Description

SetCapacity is the write implementation of the Capacity (see page 3205) property.

NewCapacity is the new capacity for the interface list.

See Also

Capacity (see page 3205)

23.2.3.2.16 IInterfaceList.SetCount Method

Sets the value of the Count (see page 3206) property.

Pascal

```
procedure SetCount(NewCount: Integer);
```

C++

```
__fastcall SetCount(int NewCount);
```

Description

SetCount is the write implementation of the Count (see page 3206) property.

NewCount is the new number of interfaces in the list.

See Also

Count (see page 3206)

23.2.3.2.17 IInterfaceList.Unlock Method

Unlocks the list, allowing other threads to access it.

Pascal

```
procedure Unlock;
```

C++

```
__fastcall Unlock();
```

Description

Call Unlock to unlock the list so that other threads can have access to the interfaces it contains.

See Also

Lock (see page 3203)

23.2.3.3 IInterfaceList Properties

The properties of the IInterfaceList class are listed here.

Public Properties

	Name	Description
	Capacity (see page 3205)	Specifies the list capacity.
	Count (see page 3206)	Specifies the number of interfaces in the list.
	Items (see page 3206)	Provides direct access to an interface in the list.

23.2.3.3.1 IInterfaceList.Capacity Property

Specifies the list capacity.

Pascal

```
property Capacity: Integer;
```

C++

```
__property int Capacity;
```

Description

Use Capacity to determine the list capacity. Before adding many interfaces to the list, you can improve performance by setting Capacity to the final number of interfaces. This prevents the interface list from having to reallocate the list every time an interface is added.

See Also

Count (see page 3206)

Add (see page 3199)

Items (see page 3206)

23.2.3.3.2 IInterfaceList.Count Property

Specifies the number of interfaces in the list.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of interfaces in the list.

See Also

Capacity (see page 3205)

Add (see page 3199)

Items (see page 3206)

Delete (see page 3200)

23.2.3.3.3 IInterfaceList.Items Property

Provides direct access to an interface in the list.

Pascal

```
property Items [Index: Integer]: IInterface;
```

C++

```
__property IInterface Items[int Index];
```

Description

Use Items to directly access an interface in the list. Index identifies each interface by its position in the list, where 0 is the first item, 1 is the second item, and so on.

Note: In Delphi, Items is the default property of IInterfaceList (see page 3198). This means that the name of the property can be omitted in code, and the subscript applied directly to the interface.

See Also

Count (see page 3206)

Add (see page 3199)

Delete (see page 3200)

23.2.4 IStreamPersist Interface

IStreamPersist is the interface for responding to requests to load/save an object from/to a persistent stream.

Class Hierarchy

Classes.IStreamPersist

Pascal

```
IStreamPersist = interface;
```

C++

```
__interface IStreamPersist;
```

File

Classes

Description

IStreamPersist introduces two methods, SaveToStream (see page 3208), and LoadFromStreamthat allows the designer to respond a request to store or retrieve the implementing object to a persistent stream.

You use SaveToStream (see page 3208) to serialise an object, and save this data in a stream independent of the running application. This serialised version of the object literally persists and is available for loading back using LoadFromStream (see page 3208). It is then de-serialised, and reconstituted as an object.

For example, the TGraphic class itself implements the IStreamPersist.

See Also

TGraphic (see page 14516)

23.2.4.1 IStreamPersist Members

The following tables list the members exposed by IStreamPersist.

Public Methods

	Name	Description
	LoadFromStream (see page 3208)	Loads an object from a persistent stream.
	SaveToStream (see page 3208)	Saves the implementing class instance to a persistent stream.

23.2.4.2 IStreamPersist Methods

The methods of the IStreamPersist class are listed here.

Public Methods

	Name	Description
	LoadFromStream (see page 3208)	Loads an object from a persistent stream.
	SaveToStream (see page 3208)	Saves the implementing class instance to a persistent stream.

23.2.4.2.1 IStreamPersist.LoadFromStream Method

Loads an object from a persistent stream.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to reconstitute a serialised version of an object saved to a persistent stream by SaveToStream (see page 3208).

See Also

TGraphic (see page 14516)

23.2.4.2.2 IStreamPersist.SaveToStream Method

Saves the implementing class instance to a persistent stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to serialise an object, and save this data in a stream independent of the running application. This serialised version of the object literally persists and is available for loading back using LoadFromStream (see page 3208) at any time. It is then de-serialised, and reconstituted as an object.

See Also

TGraphic (see page 14516)

23.2.5 IStringsAdapter Interface

Class Hierarchy

Classes.IStringsAdapter

Pascal

```
IStringsAdapter = interface;
```

C++

```
__interface IStringsAdapter;
```

File

Classes

Description

This is class Classes.IStringsAdapter.

23.2.5.1 IStringsAdapter Members

The following tables list the members exposed by IStringsAdapter.

Public Methods

	Name	Description
	ReferenceStrings (see page 3209)	This is ReferenceStrings, a member of class IStringsAdapter.
	ReleaseStrings (see page 3209)	This is ReleaseStrings, a member of class IStringsAdapter.

23.2.5.2 IStringsAdapter Methods

The methods of the IStringsAdapter class are listed here.

Public Methods

	Name	Description
	ReferenceStrings (see page 3209)	This is ReferenceStrings, a member of class IStringsAdapter.
	ReleaseStrings (see page 3209)	This is ReleaseStrings, a member of class IStringsAdapter.

23.2.5.2.1 IStringsAdapter.ReferenceStrings Method

Pascal

```
procedure ReferenceStrings(S: TStrings);
```

C++

```
__fastcall ReferenceStrings(TStrings S);
```

Description

This is ReferenceStrings, a member of class IStringsAdapter.

23.2.5.2.2 IStringsAdapter.ReleaseStrings Method

Pascal

```
procedure ReleaseStrings;
```

C++

```
__fastcall ReleaseStrings();
```

Description

This is ReleaseStrings, a member of class IStringsAdapter.

23.2.6 IVarStreamable Interface

IVarStreamable is the interface for loading and saving the values of Variants (see page 23567).

Class Hierarchy

Classes.IVarStreamable

Pascal

```
IVarStreamable = interface;
```

C++

```
__interface IVarStreamable;
```

File

Classes

Description

Implement IVarStreamable on a custom Variant type class to allow Variants (see page 23567) of that type to load or save their values. When a TCustomVaraintType descendant implements the IVarStreamable interface, then when Variants (see page 23567) of that custom type are used as the values of published properties, their values are loaded from and saved to form files using the IVarStreamable methods. Without the IVarStreamable interface, the value of the Variant is loaded from and saved to form files as a string.

IVarStreamable defines two methods, StreamIn (see page 3211), and StreamOut (see page 3211), for reading and writing the Variant's value.

See Also

TCustomVariantType (see page 23581)

Loading and Saving Custom Variant Values

23.2.6.1 IVarStreamable Members

The following tables list the members exposed by IVarStreamable.

Public Methods

	Name	Description
	StreamIn (see page 3211)	Reads in the value of the Variant from a stream.
	StreamOut (see page 3211)	Writes the value of the Variant to a stream.

23.2.6.2 IVarStreamable Methods

The methods of the IVarStreamable class are listed here.

Public Methods

	Name	Description
	StreamIn (see page 3211)	Reads in the value of the Variant from a stream.
	StreamOut (see page 3211)	Writes the value of the Variant to a stream.

23.2.6.2.1 IVarStreamable.StreamIn Method

Reads in the value of the Variant from a stream.

Pascal

```
procedure StreamIn(var Dest: TVarData; const Stream: TStream);
```

C++

```
__fastcall StreamIn(TVarData Dest, const TStream Stream);
```

Description

StreamIn reads the Variant's value from a stream and fills in a TVarData data structure to reflect the value.

Dest is the TVarDatathat is filled in by StreamIn.

Stream is a stream that is positioned so that the next value that can be read from the stream is the value of the Variant.

See Also

StreamOut (see page 3211)

23.2.6.2.2 IVarStreamable.StreamOut Method

Writes the value of the Variant to a stream.

Pascal

```
procedure StreamOut(const Source: TVarData; const Stream: TStream);
```

C++

```
__fastcall StreamOut(const TVarData Source, const TStream Stream);
```

Description

StreamIn (see page 3211) writes the value from a TVarData value to a specified stream.

Source is the TVarData that stores the data for the Variant that needs to write its value.

Stream is a stream to which StreamOut writes the value stored in Source.

See Also

StreamIn (see page 3211)

23.2.7 IVCLComObject Interface

Class Hierarchy

Classes.IVCLComObject

Pascal

```
IVCLComObject = interface;
```

C++

```
__interface IVCLComObject;
```

File

Classes

Description

This is class Classes.IVCLComObject.

23.2.7.1 IVCLComObject Members

The following tables list the members exposed by IVCLComObject.

Public Methods

	Name	Description
	FreeOnRelease (see page 3212)	This is FreeOnRelease, a member of class IVCLComObject.
	GetIDsOfNames (see page 3212)	This is GetIDsOfNames, a member of class IVCLComObject.
	GetTypeInfo (see page 3213)	This is GetTypeInfo, a member of class IVCLComObject.
	GetTypeInfoCount (see page 3213)	This is GetTypeInfoCount, a member of class IVCLComObject.
	Invoke (see page 3213)	This is Invoke, a member of class IVCLComObject.
	SafeCallException (see page 3213)	This is SafeCallException, a member of class IVCLComObject.

23.2.7.2 IVCLComObject Methods

The methods of the IVCLComObject class are listed here.

Public Methods

	Name	Description
	FreeOnRelease (see page 3212)	This is FreeOnRelease, a member of class IVCLComObject.
	GetIDsOfNames (see page 3212)	This is GetIDsOfNames, a member of class IVCLComObject.
	GetTypeInfo (see page 3213)	This is GetTypeInfo, a member of class IVCLComObject.
	GetTypeInfoCount (see page 3213)	This is GetTypeInfoCount, a member of class IVCLComObject.
	Invoke (see page 3213)	This is Invoke, a member of class IVCLComObject.
	SafeCallException (see page 3213)	This is SafeCallException, a member of class IVCLComObject.

23.2.7.2.1 IVCLComObject.FreeOnRelease Method

Pascal

```
procedure FreeOnRelease;
```

C++

```
__fastcall FreeOnRelease();
```

Description

This is FreeOnRelease, a member of class IVCLComObject.

23.2.7.2.2 IVCLComObject.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class IVCLComObject.

23.2.7.2.3 IVCLComObject.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class IVCLComObject.

23.2.7.2.4 IVCLComObject.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class IVCLComObject.

23.2.7.2.5 IVCLComObject.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class IVCLComObject.

23.2.7.2.6 IVCLComObject.SafeCallException Method

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult;
```

C++

```
__fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

This is SafeCallException, a member of class IVCLComObject.

23.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	ActivateClassGroup (see page 3215)	Activates a group of classes that derive from TPersistent (see page 2928).
	ActiveClassGroup (see page 3216)	Activates a group of classes that derive from TPersistent (see page 2928).
	AllocateHWnd (see page 3217)	DeallocateHWnd (see page 3221) is used to destroy a hidden window created using AllocateHWnd.
	AncestorIsValid (see page 3217)	AncestorIsValid determines if one component is an ancestor of another.
	BeginGlobalLoading (see page 3218)	This is function Classes.BeginGlobalLoading.
	BinToHex (see page 3218)	Converts a binary value into its hexadecimal representation.
	Bounds (see page 3218)	Creates a TRect structure from the top-left coordinate, and width and height values of a rectangle.
	CheckSynchronize (see page 3219)	Allows background threads to synchronize their execution with the main thread.
	ClassGroupOf (see page 3220)	Returns the group of persistent classes a specified class or instance belongs to.
	ClassGroupOf (see page 3220)	Returns the group of persistent classes a specified class or instance belongs to.
	CollectionsEqual (see page 3220)	Compares the contents of two collections.
	CountGenerations (see page 3221)	Returns the number of intermediate classes between a derived class and its ancestor.
	DeallocateHWnd (see page 3221)	Frees a window that was created using AllocateHWnd (see page 3217).
	EndGlobalLoading (see page 3222)	This is function Classes.EndGlobalLoading.
	ExtractStrings (see page 3222)	Fills a string list with substrings parsed from a delimited list.
	FindClass (see page 3223)	Finds and returns a class that is derived from TPersistent (see page 2928).
	FindGlobalComponent (see page 3223)	Returns a top-level container component.
	FindIdentToInt (see page 3224)	Returns the TIdentToInt (see page 3295) conversion routine for a given data type.
	FindIntToIdent (see page 3224)	Returns the TIntToIdent (see page 3296) conversion routine for a given data type.
	FindNestedComponent (see page 3225)	FindNestedComponent returns a component contained within another.
	FindRootDesigner (see page 3225)	This is function Classes.FindRootDesigner.
	FreeObjectInstance (see page 3226)	This is function Classes.FreeObjectInstance.
	GetClass (see page 3226)	Returns a registered persistent class given its name.
	GetFixupInstanceNames (see page 3228)	This is function Classes.GetFixupInstanceNames.
	GetFixupReferenceNames (see page 3228)	This is function Classes.GetFixupReferenceNames.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GetUltimateOwner (see page 3228)	Returns the top-level owner of a specified persistent object.
	GlobalFixupReferences (see page 3229)	This is function Classes.GlobalFixupReferences.
	GroupDescendentsWith (see page 3229)	Adds a specified class to the group in which another class appears.
	HexToBin (see page 3230)	Converts a string of hexadecimal digits to the corresponding binary value.
	IdentToInt (see page 3230)	Uses a mapping array to convert string identifiers into their corresponding integer values.
	InitComponentRes (see page 3231)	This is function Classes.InitComponentRes.
	InitInheritedComponent (see page 3231)	Initializes streaming of a form file for an inherited root class.
	IntToIdent (see page 3232)	Uses a mapping array to convert integers into their corresponding string identifiers.
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	InvalidPoint (see page 3233)	Indicates whether a specified point is equal to (-1,-1).
	IsDefaultPropertyValue (see page 3233)	This is function Classes.IsDefaultPropertyValue.

	IsUniqueGlobalComponentName (see page 3234)	Indicates whether a proposed component name is unambiguous.
	LineStart (see page 3234)	Finds the end of the last whole line in a buffer.
	MakeObjectInstance (see page 3235)	This is function Classes.MakeObjectInstance.
	NotifyGlobalLoading (see page 3235)	This is function Classes.NotifyGlobalLoading.
	ObjectBinaryToText (see page 3235)	Converts the binary representation of an object into more readily understandable text.
	ObjectBinaryToText (see page 3235)	Converts the binary representation of an object into more readily understandable text.
	ObjectResourceToText (see page 3239)	Converts the binary representation of an object resource into more readily understandable text.
	ObjectResourceToText (see page 3239)	Converts the binary representation of an object resource into more readily understandable text.
	ObjectTextToBinary (see page 3240)	Converts a symbolic text representation of an object into the binary version that is used to save the object to files or memory streams.
	ObjectTextToBinary (see page 3240)	Converts a symbolic text representation of an object into the binary version that is used to save the object to files or memory streams.
	ObjectTextToResource (see page 3244)	Converts a symbolic text representation of an object into an internal binary representation.
	ObjectTextToResource (see page 3244)	Converts a symbolic text representation of an object into an internal binary representation.
	Point (see page 3244)	Creates a TPoint structure from a pair of coordinates.
	PointsEqual (see page 3245)	Indicates whether two points have the same coordinates.
	PointsEqual (see page 3245)	Indicates whether two points have the same coordinates.
	ReadComponentRes (see page 3245)	Reads components and their properties from a specified resource.
	ReadComponentResEx (see page 3246)	Reads a component from a resource.
	ReadComponentResFile (see page 3247)	Reads components and their properties from a specified Windows resource file.
	Rect (see page 3249)	Creates a TRect structure from a set of coordinates.
	Rect (see page 3249)	Creates a TRect structure from a set of coordinates.
	RedirectFixupReferences (see page 3250)	This is function Classes.RedirectFixupReferences.
	RegisterClass (see page 3250)	Registers a class of persistent object so that it's class type can be retrieved.
	RegisterClassAlias (see page 3254)	Registers a class that is identical to another class except for the name.
	RegisterClasses (see page 3255)	Registers a set of classes.
	RegisterComponents (see page 3256)	Registers a set of components so that they all appear on the same page of the component palette.
	RegisterFindGlobalComponentProc (see page 3259)	This is function Classes.RegisterFindGlobalComponentProc.
	RegisterIntegerConsts (see page 3259)	Registers conversion functions for string identifiers that represent type values.
	RegisterNoIcon (see page 3260)	Registers a set of components but does not add them to the component palette.
	RegisterNonActiveX (see page 3260)	Prevents a set of components from being made available to the ActiveX wizard.
	RemoveFixupReferences (see page 3261)	This is function Classes.RemoveFixupReferences.
	RemoveFixups (see page 3261)	This is function Classes.RemoveFixups.
	SmallPoint (see page 3262)	Creates a TSmallPoint structure from a pair of coordinates.
	StartClassGroup (see page 3262)	Starts a class group derived from TPersistent (see page 2928).
	TestStreamFormat (see page 3263)	Identifies the format of a form file when reading it from a stream.
	UnRegisterClass (see page 3263)	Unregisters an object class.
	UnRegisterClasses (see page 3264)	Unregisters a set of classes.
	UnregisterFindGlobalComponentProc (see page 3264)	This is function Classes.UnregisterFindGlobalComponentProc.
	UnregisterIntegerConsts (see page 3264)	Unregisters conversion functions for string identifiers that represent type values.
	UnRegisterModuleClasses (see page 3265)	Unregisters all classes defined in a specified module.
	WriteComponentResFile (see page 3266)	Writes components and their properties to a file using a resource file format.

23.3.1 Classes.ActivateClassGroup Function

Activates a group of classes that derive from TPersistent (see page 2928).

Pascal

```
function ActivateClassGroup(AClass: TPersistentClass): TPersistentClass;
```

C++

```
TPersistentClass ActivateClassGroup(TPersistentClass AClass);
```

File

Classes

Description

The streaming system allows the classes that can be loaded and saved to be registered in separate groups. This allows the IDE to distinguish between cross-platform and Windows-only classes. Call ActivateClassGroup to activate the group of classes that contains the class specified by AClass. If AClass is in more than one group, all groups that contain the class are activated.

ActivateClassGroup returns the class that was last used to activate a class group.

If the requested class group cannot be activated ActivateClassGroup raises an exception.

See Also

StartClassGroup (see page 3262)

GroupDescendantsWith

RegisterClasses (see page 3255)

23.3.2 Classes.ActiveClassGroup Function

Activates a group of classes that derive from TPersistent (see page 2928).

Pascal

```
function ActiveClassGroup: TPersistentClass;
```

C++

```
TPersistentClass ActiveClassGroup();
```

File

Classes

Description

The streaming system allows the classes that can be loaded and saved to be registered in separate groups. This allows the IDE to distinguish between cross-platform and Windows-only classes. Call ActivateClassGroup (see page 3215) to activate the group of classes that contains the class specified by AClass. If AClass is in more than one group, all groups that contain the class are activated.

ActiveClassGroup returns the class that was last used to activate a class group.

If the requested class group cannot be activated ActiveClassGroup raises an exception.

See Also

StartClassGroup (see page 3262)

GroupDescendantsWith

RegisterClasses (see page 3255)

23.3.3 Classes.AllocateHWnd Function

DeallocateHWnd (see page 3221) is used to destroy a hidden window created using AllocateHWnd.

Pascal

```
function AllocateHWnd(Method: TWndMethod): HWND;
```

C++

```
HWND AllocateHWnd(TWndMethod Method);
```

File

Classes

Description

HWnd means a 'Handle on a window'. For Windowless applications, you can call AllocateHWnd to allocate such a handle. This handle is used to allow a Windowless application to proces Windows messages.

You call DeallocateHWnd (see page 3221) to clean up resources after calling AllocateHWnd. You pass the **HWnd** that was allocated to AllocateHWnd.

See Also

AllocateHWnd

TWndMethod (see page 3307)

23.3.4 Classes.AncestorIsValid Function

AncestorIsValid determines if one component is an ancestor of another.

Pascal

```
function AncestorIsValid(Ancestor: TPersistent; Root: TComponent; RootAncestor: TComponent):
Boolean;
```

C++

```
Boolean AncestorIsValid(TPersistent * Ancestor, TComponent * Root, TComponent * RootAncestor);
```

File

Classes

Description

Call AncestorIsValid to determine if component **Root** has the specified **RootAncestor** ancestor. The TObject InheritsFrom method is used to determine this. true is returned if the ancestor is valid, otheriwise false.

See Also

TComponent

TObject

TPersistent

23.3.5 Classes.BeginGlobalLoading Function

Pascal

```
procedure BeginGlobalLoading;
```

C++

```
BeginGlobalLoading();
```

File

Classes

Description

This is function Classes.BeginGlobalLoading.

23.3.6 Classes.BinToHex Function

Converts a binary value into its hexadecimal representation.

Pascal

```
procedure BinToHex(Buffer: PChar; Text: PChar; BufSize: Integer);
```

C++

```
BinToHex(const char * Buffer, const char * Text, int BufSize);
```

File

Classes

Description

Call BinToHex to convert the binary value in a buffer into a string that is its hexadecimal representation.

Buffer is a buffer of bytes that contains the binary value.

Text returns a null-terminated string that represents the value of Buffer as a hexadecimal number.

BufSize is the size of Buffer. Text needs to point to a sequence of characters that has at least 2*BufSize bytes because each hexadecimal character represents two bytes.

See Also

HexToBin (see page 3230)

IntToHex

23.3.7 Classes.Bounds Function

Creates a TRect structure from the top-left coordinate, and width and height values of a rectangle.

Pascal

```
function Bounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer): TRect;
```

C++

```
TRect Bounds(int ALeft, int ATop, int AWidth, int AHeight);
```

File

Classes

Description

Call Bounds to create a TRect that represents the rectangle with the specified values. Use Rect (see page 3249) to construct parameters for functions that require TBounds, rather than setting up local variables for each parameter.

Note: Bounds is a useful alternative to Rect (see page 3249) if the rectangle coordinates would have to be calculated.

See Also

Rect (see page 3249)

Point (see page 3244)

23.3.8 Classes.CheckSynchronize Function

Allows background threads to synchronize their execution with the main thread.

Pascal

```
function CheckSynchronize(Timeout: Integer = 0): Boolean;
```

C++

```
Boolean CheckSynchronize(int Timeout = 0);
```

File

Classes

Description

It is not necessary to call CheckSynchronize in a GUI application. The call to CheckSynchronize is made automatically by the application object. In a non-GUI application, you must call CheckSynchronize if you use the Synchronize method of TThread (see page 3108). To do this, set the WakeMainThread (see page 3314) variable to a procedure that calls CheckSynchronize.

CheckSynchronize allows background threads to synchronize their execution with the main thread, so that it is safe to make method calls in the background thread.

CheckSynchronize returns **True** if a method was synchronized, **False** if it does nothing.

Warning: You should not modify WakeMainThread (see page 3314) for GUI applications because a working handler has been assigned. Console applications may assign a handler to WakeMainThread (see page 3314) if the application needs to be notified of a thread synchronization call. If your console application assigns a handler, this is an optimization that only accelerates deliver of notification that a synchronization request is available. You must use CheckSynchronize to perforrm the synchronization itself.

See Also

TThread (see page 3108)

WakeMainThread (see page 3314)

23.3.9 Classes.ClassGroupOf Function

Returns the group of persistent classes a specified class or instance belongs to.

Pascal

```
function ClassGroupOf(AClass: TPersistentClass): TPersistentClass; overload;
function ClassGroupOf(Instance: TPersistent): TPersistentClass; overload;
```

C++

```
TPersistentClass ClassGroupOf(TPersistentClass AClass);
TPersistentClass ClassGroupOf(TPersistent * Instance);
```

File

Classes

Description

The streaming system allows the classes that can be loaded and saved to be registered in separate groups. This allows the IDE to distinguish between cross-platform and Windows-only classes.

StartClassGroup (see page 3262) starts a new group. GroupDescendantsWith adds a class to an existing group.

ClassGroupOf returns the group that either a **AClass** class has been registered to, or the class of the specified **Instance** has been registered to.

See Also

GroupDescendantsWith

RegisterClass (see page 3250)

RegisterClasses (see page 3255)

StartClassGroup (see page 3262)

23.3.10 Classes.CollectionsEqual Function

Compares the contents of two collections.

Pascal

```
function CollectionsEqual(C1: TCollection; C2: TCollection; Owner1: TComponent; Owner2:
TComponent): Boolean;
```

C++

```
Boolean CollectionsEqual(TCollection C1, TCollection C2, TComponent * Owner1, TComponent *
Owner2);
```

File

Classes

Description

Call CollectionsEqual to determine whether two collections contain identical information. CollectionsEqual returns true if all the items in each collection have the same settings, and the items appear in the same order. CollectionsEqual returns false if the collections differ in number or order of items, or if any of the items in the collections differ.

C1 and C2 are the collections to compare.

Owner1 and Owner2 are the Owners of the collections. Owner1 and Owner2 must be "root" components, such as forms or data modules. They are used for resolving name references in the properties of the collections.

See Also

CompareMem

TStrings (see page 3029)

23.3.11 Classes.CountGenerations Function

Returns the number of intermediate classes between a derived class and its ancestor.

Pascal

```
function CountGenerations(Ancestor: TClass; Descendent: TClass): Integer;
```

C++

```
int CountGenerations(TClass Ancestor, TClass Descendent);
```

File

Classes

Description

Use CountGenerations to determine how close a derived class is to one of its ancestors. For example, if Ancestor and Descendant are the same class, CountGenerations returns 0. If Descendant is derived directly from Ancestor, CountGenerations returns 1.

Ancestor is the ancestor class.

Descendant is the descendant class. If it is not the same as Ancestor or does not derive from Ancestor, CountGenerations returns –1.

Tip: To check that Descendant derives from Ancestor using Delphi, use the is operator to check that Descendant is Ancestor before calling CountGenerations. In C++, use the static InheritsFrom method of Descendant.

23.3.12 Classes.DeallocateHWnd Function

Frees a window that was created using AllocateHWnd (see page 3217).

Pascal

```
procedure DeallocateHWnd(Wnd: HWND);
```

C++

```
DeallocateHWnd(HWND Wnd);
```

File

Classes

Description

Call DeallocateHWnd to free a window that was created using the AllocateHWnd (see page 3217) function. Windows must be freed to release the system resources that they consume.

The Wnd parameter is the window handle of the window to be freed. This value is the same as the handle returned by the call to AllocateHWnd (see page 3217).

Warning: Do not use DeallocateHWnd on the handle of a windowed control. Windowed controls free their handles using the protected DestroyHandle method, which ensures that the control is left in a consistent state.

See Also

AllocateHWnd (see page 3217)

TWinControl

23.3.13 Classes.EndGlobalLoading Function

Pascal

```
procedure EndGlobalLoading;
```

C++

```
EndGlobalLoading();
```

File

Classes

Description

This is function Classes.EndGlobalLoading.

23.3.14 Classes.ExtractStrings Function

Fills a string list with substrings parsed from a delimited list.

Pascal

```
function ExtractStrings(Separators: TSysCharSet; WhiteSpace: TSysCharSet; Content: PChar;
Strings: TStrings): Integer;
```

C++

```
int ExtractStrings(TSysCharSet Separators, TSysCharSet WhiteSpace, const char * Content,
TStrings Strings);
```

File

Classes

Description

Use ExtractStrings to fill a string list with the substrings of the null-terminated string specified by Content.

Separators is a set of characters that are used as delimiters, separating the substrings. Carriage returns, newline characters, and quote characters (single or double) are always treated as separators. Separators are ignored when inside a quoted string until the final end quote. (Note that quoted characters can appear in a quoted string if the quote character is doubled.)

WhiteSpace is a set of characters to be ignored when parsing Content if they occur at the beginning of a string.

Content is the null-terminated string to parse into substrings.

Strings is a string list to which all substrings parsed from Content are added. The string list is not cleared by ExtractStrings, so any strings already in the string list are preserved.

ExtractStrings returns the number of strings added to the Strings parameter.

Note: ExtractStrings does not add empty strings to the list.

See Also

ExtractHTTPFields

23.3.15 Classes.FindClass Function

Finds and returns a class that is derived from TPersistent (see page 2928).

Pascal

```
function FindClass(const ClassName: string): TPersistentClass;
```

C++

```
TPersistentClass FindClass(const AnsiString ClassName);
```

File

Classes

Description

Call FindClass to locate a class type by name. FindClass searches the classes that the streaming system knows about. Classes (see page 2685) can be registered with a call to RegisterClasses (see page 3255) so that the streaming system will recognize that class in a stream and know how to construct it.

If the requested class name cannot be found, FindClass raises an exception.

See Also

RegisterClasses (see page 3255)

GetClass (see page 3226)

23.3.16 Classes.FindGlobalComponent Function

Returns a top-level container component.

Pascal

```
function FindGlobalComponent(const Name: string): TComponent;
```

C++

```
TComponent * FindGlobalComponent(const AnsiString Name);
```

File

Classes

Description

FindGlobalComponent is used by the component streaming system to implement form linking. When a component property refers to a component on another form, data module, or other top-level container component, the streaming system calls

FindGlobalComponent to locate the root object in the form linking reference (e.g. Form1 in Form1.Edit1 (Delphi) or Form1->Edit1 (C++)). If the object cannot be found, FindGlobalComponent returns nil (Delphi) or NULL (C++).

See Also

EnumModules

EnumResourceModules

LibModuleList

IsUniqueGlobalComponentName (see page 3234)

23.3.17 Classes.FindIdentToInt Function

Returns the TIdentToInt (see page 3295) conversion routine for a given data type.

Pascal

```
function FindIdentToInt(AIntegerType: Pointer): TIdentToInt;
```

C++

```
TIdentToInt FindIdentToInt(void * AIntegerType);
```

File

Classes

Description

RegisterIntegerConsts (see page 3259) is used internally within Delphi to define conversions between name-string and integer value pairs. For example, the Graphics (see page 14387) unit uses this routine to register named colours, such as 'clMaroon', which is registered as integer value $000080. The conversion function is defined by type, TColor in this example.

FindIdentToInt is called to return the TIdentToInt (see page 3295) routine to be called to perform an Ident string to integer value conversion. You pass a data type in **AIntegerType** that identifies the conversion. For example, you would pass TypeInfo(TColor) if you wanted to be returned the Graphics (see page 14387) unit registered TColor value converion function.

See Also

IdentToInt (see page 3230)

RegisterIntegerConsts (see page 3259)

TIdentToInt (see page 3295)

23.3.18 Classes.FindIntToIdent Function

Returns the TIntToIdent (see page 3296) conversion routine for a given data type.

Pascal

```
function FindIntToIdent(AIntegerType: Pointer): TIntToIdent;
```

C++

```
TIntToIdent FindIntToIdent(void * AIntegerType);
```

File

Classes

Description

RegisterIntegerConsts (see page 3259) is used internally within Delphi to define conversions between name-string and integer value pairs. For example, the Graphics (see page 14387) unit uses this routine to register named colours, such as 'clMaroon', which is registered as integer value $000080. The conversion function is defined by type, TColor in this example.

FindIntToIdent is called to return the TIntToIdent (see page 3296) routine to be called to perform an integer value to Ident string conversion. You pass a data type in **AIntegerType** that identifies the conversion. For example, you would pass TypeInfo(TColor) if you wanted to be returned the Graphics (see page 14387) unit registered TColor value conversion function.

See Also

IntToIdent (see page 3232)

RegisterIntegerConsts (see page 3259)

TIntToIdent (see page 3296)

23.3.19 Classes.FindNestedComponent Function

FindNestedComponent returns a component contained within another.

Pascal

```
function FindNestedComponent(Root: TComponent; const NamePath: string): TComponent;
```

C++

```
TComponent * FindNestedComponent(TComponent * Root, const AnsiString NamePath);
```

File

Classes

Description

Call FindNestedComponent to find a component by name contained within a specified containing component.

Root specifies the containing component object.

NamePath gives the name of the component nested in **Root**.

If found, a reference to the nested component is returned.

See Also

TComponent

23.3.20 Classes.FindRootDesigner Function

Pascal

```
function FindRootDesigner(Obj: TPersistent): IDesignerNotify;
```

C++

```
IDesignerNotify FindRootDesigner(TPersistent * Obj);
```

File

Classes

Description

This is function Classes.FindRootDesigner.

23.3.21 Classes.FreeObjectInstance Function

Pascal

```
procedure FreeObjectInstance(ObjectInstance: Pointer);
```

C++

```
FreeObjectInstance(void * ObjectInstance);
```

File

Classes

Description

This is function Classes.FreeObjectInstance.

23.3.22 Classes.GetClass Function

Returns a registered persistent class given its name.

Pascal

```
function GetClass(const AClassName: string): TPersistentClass;
```

C++

```
TPersistentClass GetClass(const AnsiString AClassName);
```

File

Classes

Description

Call GetClass to obtain a class from a class name. This class can be used as a parameter to routines that require a class.

The Class must be registered before GetClass can find it. Form classes and component classes that are referenced in a form declaration (instance variables) are automatically registered when the form is loaded. Other classes can be registered by calling RegisterClass (see page 3250) or RegisterClasses (see page 3255).

Note: To obtain an unregistered class from a class name in C++, use the __classid routine.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
```

```
  event handler (or a similar place) you must register the
  graphics classes so that GetClass can find them.
  */
  TMetaClass *MetaClass;

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
    TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
  //  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
    Edit1->Text = GraphicExtension(mygraphclass);
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    MetaClass = __classid(TIcon); // ico
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(Graphics::TBitmap); // bmp
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TMetafile); // emf
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TShape);  // nographic extension
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TImage); // nographic extension
    RegisterClasses(&MetaClass, 0);
  }
```

Delphi Examples:

```
  {
  The following example allows users to type the name of a
  graphics class into an edit control and when a button is
  pressed, the name of the default extension for that class is
  displayed in another edit control.  In the form's OnCreate
  event handler (or a similar place) you must register the
  graphics classes so that GetClass can find them.
  }

  uses ExtCtrls;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    myClassFinder: TClassFinder;
    mygraphclass: TGraphicClass;
  begin
    { make sure the classes are registered so that GetClass will work -- }
    { Usually, this goes in the initialization section where it is only executed once }
    RegisterClasses([TIcon, TBitmap, TButton, TShape, TImage, TMetafile]);
    try
      myClassFinder := TClassFinder.Create(TIcon, False);
      mygraphclass := TGraphicClass(myClassFinder.GetClass(Edit2.Text));
  //    mygraphclass := TGraphicClass(GetClass(Edit2.Text));  // works as well
      Edit1.Text := GraphicExtension(mygraphclass);
    except
      on EAccessViolation do
        MessageDlg('Invalid class name.', mtError, [mbOK], 0)
    end;
  end;
```

See Also

RegisterClass (see page 3250)

FindClass (see page 3223),

23.3.23 Classes.GetFixupInstanceNames Function

Pascal

```
procedure GetFixupInstanceNames(Root: TComponent; const ReferenceRootName: string; Names:
TStrings);
```

C++

```
GetFixupInstanceNames(TComponent * Root, const AnsiString ReferenceRootName, TStrings Names);
```

File

Classes

Description

This is function Classes.GetFixupInstanceNames.

23.3.24 Classes.GetFixupReferenceNames Function

Pascal

```
procedure GetFixupReferenceNames(Root: TComponent; Names: TStrings);
```

C++

```
GetFixupReferenceNames(TComponent * Root, TStrings Names);
```

File

Classes

Description

This is function Classes.GetFixupReferenceNames.

23.3.25 Classes.GetUltimateOwner Function

Returns the top-level owner of a specified persistent object.

Pascal

```
function GetUltimateOwner(ACollectionItem: TCollectionItem): TPersistent; overload;
function GetUltimateOwner(ACollection: TCollection): TPersistent; overload;
function GetUltimateOwner(APersistent: TPersistent): TPersistent; overload;
```

C++

```
TPersistent * GetUltimateOwner(TCollectionItem ACollectionItem);
TPersistent * GetUltimateOwner(TCollection ACollection);
TPersistent * GetUltimateOwner(TPersistent * APersistent);
```

File

Classes

Description

Left undocumented because it doesn't really do the right thing.

Call GetUltimateOwner to obtain the ultimate owner of a persistent object. GetUltimateOwner traverses the ownership hierarchy, finding first the Owner, and then that Owner's Owner, and so on, until there are no more owners.

The ultimate owner is typically the form or data module that contains the object instance. However, if one of the Owners (other than a form or data module) does not have an Owner, GetUltimateOwner returns nil (Delphi) or NULL (C++).

See Also

GetParentForm

23.3.26 Classes.GlobalFixupReferences Function

Pascal

```
procedure GlobalFixupReferences;
```

C++

```
GlobalFixupReferences();
```

File

Classes

Description

This is function Classes.GlobalFixupReferences.

23.3.27 Classes.GroupDescendentsWith Function

Adds a specified class to the group in which another class appears.

Pascal

```
procedure GroupDescendentsWith(AClass: TPersistentClass; AClassGroup: TPersistentClass);
```

C++

```
GroupDescendentsWith(TPersistentClass AClass, TPersistentClass AClassGroup);
```

File

Classes

Description

Call GroupDescendentsWith to add the class specified by AClass to the same group as the one that contains AClassGroup. If AClassGroup is a member of more than one group, GroupDescendentsWith adds AClass to the group that contains the nearest ancestor of AClassGroup. (The nearest ancestor is the ancestor for which CountGenerations (see page 3221) returns the lowest value).

If AClassGroup is not a member of any group, GroupDescendentsWith raises an exception.

See Also

ActivateClassGroup (see page 3215)

StartClassGroup (see page 3262)

CountGenerations (see page 3221)

23.3.28 Classes.HexToBin Function

Converts a string of hexadecimal digits to the corresponding binary value.

Pascal

```
function HexToBin(Text: PChar; Buffer: PChar; BufSize: Integer): Integer;
```

C++

```
int HexToBin(const char * Text, const char * Buffer, int BufSize);
```

File

Classes

Description

Call HexToBin to convert the hexadecimal string Text to the binary value it represents.

Text is a string representation of a hexadecimal value.

Buffer returns the resulting value in binary.

BufSize is the size of Buffer. Text needs to point to at least 2*BufSize hexadecimal characters, because each two hexadecimal characters represent one byte.

HexToBin returns the number of characters in Buffer that have not been used because Text did not contain valid hexadecimal characters ('0'..'f').

Note: The hexadecimal number must use lower-case characters; HexToBind does not recognize upper-case characters.

See Also

BinToHex (see page 3218)

23.3.29 Classes.IdentToInt Function

Uses a mapping array to convert string identifiers into their corresponding integer values.

Pascal

```
function IdentToInt(const Ident: string; var Int: Longint; const Map: array of
TIdentMapEntry): Boolean;
```

C++

```
Boolean IdentToInt(const AnsiString Ident, Longint Int, const array of TIdentMapEntry Map);
```

File

Classes

Description

IdentToInt provides the underlying translation from string identifiers to integers that occurs, for example, when you register a mapping using the RegisterIntegerConsts (see page 3259) procedure in Delphi.

Ident is the string identifier to translate.

Int returns the corresponding integer value.

Mapis an array of records (Delphi) or structs (C++) that describe the mapping. Each member of the array contains a Value field, which is the integer value to return and a Name field, which is the string identifier to translate.

Note: In C++, Map_Size is the index of the last entry in Map (one less than the number of elements).

IdentToInt looks for the string specified by Ident as the Name field on an entry in Map. If it finds a match, it sets Int to the corresponding Value field and returns true. If it does not find a match, it returns False.

See Also

RegisterIntegerConsts (see page 3259)

IntToIdent (see page 3232)

23.3.30 Classes.InitComponentRes Function

Pascal

```
function InitComponentRes(const ResName: string; Instance: TComponent): Boolean;
```

C++

```
Boolean InitComponentRes(const AnsiString ResName, TComponent * Instance);
```

File

Classes

Description

This is function Classes.InitComponentRes.

23.3.31 Classes.InitInheritedComponent Function

Initializes streaming of a form file for an inherited root class.

Pascal

```
function InitInheritedComponent(Instance: TComponent; RootAncestor: TClass): Boolean;
```

C++

```
Boolean InitInheritedComponent(TComponent * Instance, TClass RootAncestor);
```

File

Classes

Description

Call InitInheritedComponent from the constructor of a root class to start streaming in of information in the associated form file.

Instance is the object being instantiated.

RootAncestor is the base root class of which Instance may represent a descendant. This class must be a root class, meaning a class such as TCustomForm, TFrame, or TDataModule (see page 2824), which is the starting point of the streaming process (the component associated with the form file).

InitInheritedComponent returns true if the form file was successfully streamed in, false otherwise.

The call to InitInheritedComponent is only required for descendant classes of the root class, and must follow the construction of the object instance except for streaming in of persistent properties in the form file. The following Delphi and C++ code samples show typical root class contstructors:

constructor TMyRootClass.Create(AOwner: TComponent (see page 2762));

```
begin
  inherited Create(AOwner); { first construct an object instance }
  if (ClassType <> TMyRootClass) and not (csDesigning in ComponentState) then
  begin
    if not InitInheritedComponent(Self, TMyRootClass) then
      raise EResNotFound.CreateFmt(SResNotFound, [ClassName]);
  end;
end;
```

void TMyRootClass.TMyRootClass(TComponent (see page 2762) AOwner);

```
{
  if ( (ClassType != TMyRootClass) &&
    !(ComponentState.Contains(csDesigning))
  {
    if !(InitInheritedComponent(this, TMyRootClass))
      throw EResNotFound(SResNotFound, TVarRec theClassName[] =
        {ClassName}, 1);
  }
}
```

TCustomForm

TDataModule (see page 2824)

TDataModule (see page 2824)

23.3.32 Classes.IntToIdent Function

Uses a mapping array to convert integers into their corresponding string identifiers.

Pascal

```
function IntToIdent(Int: Longint; var Ident: string; const Map: array of TIdentMapEntry):
Boolean;
```

C++

```
Boolean IntToIdent(Longint Int, AnsiString Ident, const array of TIdentMapEntry Map);
```

File

Classes

Description

IntToIdent provides the underlying translation from string identifiers to integers that occurs, for example, when you register a mapping using the RegisterIntegerConsts (see page 3259) procedure in Delphi.

Int is the integer to translate.

Ident returns the corresponding string identifier.

Map is an array of records (Delphi) or structs (C++) that describe the mapping. Each member of the array contains a Value field, which is the integer value to translate and a Name field, which is the corresponding string identifier.

Note: In C++, Map_Size is the index of the last entry in Map (one less than the number of elements).

IntToIdent looks for the integer specified by Int as the Value field on an entry in Map. If it finds a match, it sets Ident to the corresponding Name field and returns true. If it does not find a match, it returns false.

See Also

RegisterIntegerConsts (see page 3259)

IdentToInt (see page 3230)

23.3.33 Classes.InvalidPoint Function

Indicates whether a specified point is equal to (-1,-1).

Pascal

```
function InvalidPoint(X: Integer; Y: Integer): Boolean; overload;
function InvalidPoint(const At: TPoint): Boolean; overload;
function InvalidPoint(const At: TSmallPoint): Boolean; overload;
```

C++

```
Boolean InvalidPoint(int X, int Y);
Boolean InvalidPoint(const TPoint At);
Boolean InvalidPoint(const TSmallPoint At);
```

File

Classes

Description

The point (-1,-1) is often used, by convention, to represent an invalid set of coordinates. This convention is often employed by Windows API functionsand by several Linux utilities. When working with other code that uses this convention, use InvalidPoint to identify coordinate values that are invalid.

At is the point to examine.

X and Y identify the point by giving the X and Y coordinates respectively.

InvalidPoint returns true if the specified point is (-1,-1), false otherwise.

23.3.34 Classes.IsDefaultPropertyValue Function

Pascal

```
function IsDefaultPropertyValue(Instance: TObject; PropInfo: PPropInfo; OnGetLookupInfo:
TGetLookupInfoEvent; Writer: TWriter = nil; OnFindMethodName: TFindMethodNameEvent = nil):
Boolean;
```

C++

```
Boolean IsDefaultPropertyValue(TObject * Instance, PPropInfo PropInfo, TGetLookupInfoEvent
OnGetLookupInfo, TWriter Writer = nil, TFindMethodNameEvent OnFindMethodName = nil);
```

File

Classes

Description

This is function Classes.IsDefaultPropertyValue.

23.3.35 Classes.IsUniqueGlobalComponentName Function

Indicates whether a proposed component name is unambiguous.

Pascal

```
function IsUniqueGlobalComponentName(const Name: string): Boolean;
```

C++

```
Boolean IsUniqueGlobalComponentName(const AnsiString Name);
```

File

Classes

Description

IsUniqueGlobalComponentName returns true if the name specified by Name is not currently used by any component on any form, data module, or other top-level container component. IsUniqueGlobalComponentName returns false if another component is already using Name (in which case, references to the component should be qualified by the root object's name.

See Also

FindGlobalComponent (see page 3223)

UniqueString

23.3.36 Classes.LineStart Function

Finds the end of the last whole line in a buffer.

Pascal

```
function LineStart(Buffer: PChar; BufPos: PChar): PChar;
```

C++

```
const char * LineStart(const char * Buffer, const char * BufPos);
```

File

Classes

Description

Use LineStart to find the start of the last partial line in the buffer. LineStart starts at BufPos and scans backwards for a line-feed character (\n). It returns a pointer to that character. If no line-feed char is found, it returns the Buffer pointer. Buffer should point to the beginning of a block of memory and BufPos to the end of the block you want to scan.

Note: The undocumented TParser (see page 2915) class uses LineStart to locate line-endings in chunks of text read into a fixed-size buffer. When the last full line of text is parsed, the parser moves the last partial line of text from the end of the buffer to

the front and fills the rest of the buffer with new data from disk.

23.3.37 Classes.MakeObjectInstance Function

Pascal

```
function MakeObjectInstance(Method: TWndMethod): Pointer;
```

C++

```
void * MakeObjectInstance(TWndMethod Method);
```

File

Classes

Description

This is function Classes.MakeObjectInstance.

23.3.38 Classes.NotifyGlobalLoading Function

Pascal

```
procedure NotifyGlobalLoading;
```

C++

```
NotifyGlobalLoading();
```

File

Classes

Description

This is function Classes.NotifyGlobalLoading.

23.3.39 Classes.ObjectBinaryToText Function

Converts the binary representation of an object into more readily understandable text.

Pascal

```
procedure ObjectBinaryToText(Input: TStream; Output: TStream); overload;
procedure ObjectBinaryToText(Input: TStream; Output: TStream; var OriginalFormat:
TStreamOriginalFormat); overload;
```

C++

```
ObjectBinaryToText(TStream Input, TStream Output);
ObjectBinaryToText(TStream Input, TStream Output, TStreamOriginalFormat OriginalFormat);
```

File

Classes

Description

Call ObjectBinaryToText to convert the representation of an object as it is saved in files and memory streams into a text version that human readers can understand. ObjectBinaryToText creates a TReader (see page 2933) object for the Input stream, and uses this to read the saved representation of the object. A symbolic text representation is then written to the Output stream. OriginalFormat indicates the format in which the object was saved.

Use the WriteComponent method of the Input stream to write a binary representation before calling ObjectBinaryToText.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
 delete pss;
 return as;
}
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)

{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)
    Memo1: TMemo;
    Button1: TButton;
    Button2: TButton;
    procedure Button1Click(Sender: TObject);
```

```
    procedure Button2Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);

TReader (see page 2933)

TStream (see page 2973)

23.3.40 Classes.ObjectResourceToText Function

Converts the binary representation of an object resource into more readily understandable text.

Pascal

```
procedure ObjectResourceToText(Input: TStream; Output: TStream); overload;
procedure ObjectResourceToText(Input: TStream; Output: TStream; var OriginalFormat:
TStreamOriginalFormat); overload;
```

C++

```
ObjectResourceToText(TStream Input, TStream Output);
ObjectResourceToText(TStream Input, TStream Output, TStreamOriginalFormat OriginalFormat);
```

File

Classes

Description

Call ObjectResourceToText to convert the representation of an object as it is saved in module resource files into a text version that that human readers can understand. ObjectResourceToText is the same as ObjectBinaryToText (see page 3235), except that it reads from a stream that includes a resource header.

ObjectResourceToText converts the binary version of a form, as stored in a form file, into the text version that can be seen by right clicking the form and choosing View As Text.

Use the WriteComponentRes method of the Input stream to write the binary representation before calling ObjectResourceToText.

See Also

TResourceStream (see page 2968)

TStream (see page 2973)

23.3.41 Classes.ObjectTextToBinary Function

Converts a symbolic text representation of an object into the binary version that is used to save the object to files or memory streams.

Pascal

```
procedure ObjectTextToBinary(Input: TStream; Output: TStream); overload;
procedure ObjectTextToBinary(Input: TStream; Output: TStream; var OriginalFormat:
TStreamOriginalFormat); overload;
```

C++

```
ObjectTextToBinary(TStream Input, TStream Output);
ObjectTextToBinary(TStream Input, TStream Output, TStreamOriginalFormat OriginalFormat);
```

File

Classes

Description

Call ObjectTextToBinary to create the internal representation of a component from a symbolic text representation. ObjectTextToBinary creates a TWriter (see page 3175) object for the Output stream, and uses this to write the form file representation of the object from the symbolic representation that is read from the Input stream. OriginalFormat indicates whether the output stream stores the object in binary or text format.

Use the ReadComponent method of the output stream to obtain the actual object.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.
```

```
  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

TStream (see page 2973)

TWriter (see page 3175)

23.3.42 Classes.ObjectTextToResource Function

Converts a symbolic text representation of an object into an internal binary representation.

Pascal

```
procedure ObjectTextToResource(Input: TStream; Output: TStream); overload;
procedure ObjectTextToResource(Input: TStream; Output: TStream; var OriginalFormat:
TStreamOriginalFormat); overload;
```

C++

```
ObjectTextToResource(TStream Input, TStream Output);
ObjectTextToResource(TStream Input, TStream Output, TStreamOriginalFormat OriginalFormat);
```

File

Classes

Description

Call ObjectTextToResource to create a component from the representation of an object as it is saved in module resource files. ObjectTextToResource is the same as ObjectTextToBinary (see page 3240), except that it skips over any object headers and includes a resource header instead. Use the ReadComponentRes (see page 3245) method of the output stream to obtain the actual object.

ObjectTextToResource converts the text version of a form that can be seen by right clicking the form and choosing View As Text into the binary version which is stored in a form file.

ReadComponentRes (see page 3245)

ReadComponentResFile (see page 3247)

TResourceStream (see page 2968)

TStream (see page 2973)

23.3.43 Classes.Point Function

Creates a TPoint structure from a pair of coordinates.

Pascal

```
function Point(AX: Integer; AY: Integer): TPoint;
```

C++

```
TPoint Point(int AX, int AY);
```

File

Classes

Description

Call Point to create a TPoint that represents the specified coordinates.

C++ Examples:

```
/*
This example draws a polygon in the specified shape, and
fills it with the color teal.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPoint points[4];
  points[0] = Point(10,10);
  points[1] = Point(30,10);
  points[2] = Point(130,30);
  points[3] = Point(240,120);
  ((TPaintBox *)Sender)->Canvas->Brush->Color = clTeal;
  ((TPaintBox *)Sender)->Canvas->Polygon(points, 3);
}
```

Delphi Examples:

```
{
This example draws a polygon in the specified shape, and
fills it with the color teal.
}
procedure TForm1.FormPaint(Sender: TObject);
begin
  Canvas.Brush.Color := clTeal;
  Canvas.Polygon([Point(10, 10), Point(30, 10),
    Point(130, 30), Point(240, 120)]);
end;
```

See Also

SmallPoint (see page 3262)

23.3.44 Classes.PointsEqual Function

Indicates whether two points have the same coordinates.

Pascal

```
function PointsEqual(const P1: TPoint; const P2: TPoint): Boolean; overload;
function PointsEqual(const P1: TSmallPoint; const P2: TSmallPoint): Boolean; overload;
```

C++

```
Boolean PointsEqual(const TPoint P1, const TPoint P2);
Boolean PointsEqual(const TSmallPoint P1, const TSmallPoint P2);
```

File

Classes

Description

Call PointsEqual to compare two points. PointsEqual returns true if P1 has the same coordinates as P2, false if the two points differ.

23.3.45 Classes.ReadComponentRes Function

Reads components and their properties from a specified resource.

Pascal

```
function ReadComponentRes(const ResName: string; Instance: TComponent): TComponent;
```

C++

```
TComponent * ReadComponentRes(const AnsiString ResName, TComponent * Instance);
```

File

Classes

Description

Call ReadComponentRes to create a component from its representation in a resource header. The ResName parameter is the name assigned to the resource for the component. The Instance parameter is an instance of the component that should be filled in with the attributes of the saved resource. Instance must be an object of the same class as the saved resource, or one of its descendants. Create an instance of the appropriate type of object, and then call ReadComponentRes to read in its property settings. If Instance is nil (Delphi) or NULL (C++), the object class is read from the resource.

ReadComponentRes returns an instance of the component that was read from the resource.

See Also

ReadComponentResFile (see page 3247)

TResourceStream (see page 2968)

WriteComponentResFile (see page 3266)

ReadComponentResEx (see page 3246)

23.3.46 Classes.ReadComponentResEx Function

Reads a component from a resource.

Pascal

```
function ReadComponentResEx(HInstance: THandle; const ResName: string): TComponent;
```

C++

```
TComponent * ReadComponentResEx(THandle HInstance, const AnsiString ResName);
```

File

Classes

Description

Use ReadComponentResEx to load a component from a resource stored in a particular module (as opposed to ReadComponentRes (see page 3245), which assumes the current module).

The HInstance parameter is the instance handle for the module that stores the component as a resource. The ResName parameter is the name assigned to the resource for the component.

ReadComponentResEx returns an instance of the component that was read from the resource.

See Also

ObjectTextToResource (see page 3244)

ReadComponentResFile (see page 3247)

TResourceStream (see page 2968)

WriteComponentResFile (see page 3266)

ReadComponentRes (see page 3245)

23.3.47 Classes.ReadComponentResFile Function

Reads components and their properties from a specified Windows resource file.

Pascal

```
function ReadComponentResFile(const FileName: string; Instance: TComponent): TComponent;
```

C++

```
TComponent * ReadComponentResFile(const AnsiString FileName, TComponent * Instance);
```

File

Classes

Description

Call ReadComponentResFile to create a component and its children from their representation in a Windowsresource file.

The FileName parameter is the name of the compiled resource file that contains the component resource.

The Instance parameter is an instance of the type of component that should be read. Create an instance of the appropriate type of object, and then call ReadComponentResFile to read in its property settings. If Instance is nil (Delphi) or NULL (C++), the object class is read from the resource. Before passing an Instance parameter of nil (Delphi) or NULL (C++), all classes being read must have been registered using the RegisterClass (see page 3250) or RegisterClasses (see page 3255) routine.

ReadComponentResFile returns an instance of the component that was read from the resource file.

Delphi Examples:

```
{
ReadComponentResFile, WriteComponentResFile example
The following code defines a component class (TStreamable
class) and a persistent class (TContainedClass) that is the
type of a property on the component class. When a button is
clicked, an instance of the component class is created, saved
to a file, deleted, and then loaded from the file. By setting
a breakpoint on the property setter of the TContainedClass
SomeData property, you can watch how the streaming system
sets property values when it reads them from a file.
The following unit defines the classes to stream:
}

{$R-,T-,H+,X+}

type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TContainedClass = class(TPersistent)
  private
    FSomeData: Integer;
    procedure SetSomeData(Value: Integer);
```

```
    public
      constructor Create;
      // Only published properties
      // are automatically streamed.
    published
      property SomeData: Integer read FSomeData write SetSomeData;
    end;

    TStreamableClass = class(TComponent)
    private
      FContainedClass: TContainedClass;
    public
      constructor Create(AOwner: TComponent); override;
      destructor Destroy; override;
      // Only published properties
      // are automatically streamed.
    published
      property ContainedClass: TContainedClass read FContainedClass write FContainedClass;
    end;

  var
    Form1: TForm1;

  implementation

  {$R *.dfm}

  procedure TContainedClass.SetSomeData(Value: Integer);
  begin
  { Place a breakpoint here and notice how the data is streamed back. }
    FSomeData := Value;
  end;

  constructor TContainedClass.Create;
  begin
    FSomeData := 42;
  end;

  constructor TStreamableClass.Create(AOwner: TComponent);
  begin
    inherited Create(AOwner);
    FContainedClass := TContainedClass.Create;
  end;

  destructor TStreamableClass.Destroy;
  begin
    FContainedClass.Free;
  end;

  {
  The following OnClick event handler should be added to a
  button on the application's main form. It causes the above
  classes to be streamed out and in. Note that you must add
  StrmExmpl to the uses clause of unit1.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    AClassInstance: TStreamableClass;
  begin
    AClassInstance := TStreamableClass.Create(nil);
    WriteComponentResFile('Test', AClassInstance);
    FreeAndNil(AClassInstance);

    AClassInstance := Classes.ReadComponentResFile('Test', nil) as TStreamableClass;
    FreeAndNil(AClassInstance);
  end;
```

```
initialization
  RegisterClasses([TContainedClass, TStreamableClass]);
```

23.3.48 Classes.Rect Function

Creates a TRect structure from a set of coordinates.

Pascal

```
function Rect(ALeft: Integer; ATop: Integer; ARight: Integer; ABottom: Integer): TRect;
overload;
function Rect(const ATopLeft: TPoint; const ABottomRight: TPoint): TRect; overload;
```

C++

```
TRect Rect(int ALeft, int ATop, int ARight, int ABottom);
TRect Rect(const TPoint ATopLeft, const TPoint ABottomRight);
```

File

Classes

Description

Call Rect to create a TRect that represents the rectangle with the specified coordinates. Use Rect to construct parameters for functions that require TRect, rather than setting up local variables for each parameter.

C++ Examples:

```
/*
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TRect TheRect = Rect(10,10,100,100);
  Canvas->TextRect(TheRect, 10, 10, "Hello World");
  Canvas->Brush->Color = clBlack;
  Canvas->FrameRect(TheRect);
}
```

Delphi Examples:

```
{
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
var TheRect: TRect;
begin
  TheRect := Rect(10,10,100,100);
  Form1.Canvas.TextRect(TheRect,10,10,'Hello, world!');
  Form1.Canvas.Brush.Color := clBlack;
  Form1.Canvas.FrameRect(TheRect);
end;
```

Pascal

```
procedure RedirectFixupReferences(Root: TComponent; const OldRootName: string; const
NewRootName: string);
```

C++

```
RedirectFixupReferences(TComponent * Root, const AnsiString OldRootName, const AnsiString
NewRootName);
```

File

Classes

Description

This is function Classes.RedirectFixupReferences.

23.3.50 Classes.RegisterClass Function

Registers a class of persistent object so that it's class type can be retrieved.

Pascal

```
procedure RegisterClass(AClass: TPersistentClass);
```

C++

```
RegisterClass(TPersistentClass AClass);
```

File

Classes

Description

Call RegisterClass to register a class with the streaming system. Form classes and component classes that are referenced in a form declaration (instance variables) are automatically registered. Any other classes used by an application must be explicitly registered by calling RegisterClass if instances are to be saved.

Once classes are registered, they can be loaded or saved by the component streaming system. IdentToInt (see page 3230) returns nil (Delphi) or NULL (C++) when passed the class name of an unregistered class, and FindClass (see page 3223) raises an exception for unregistered classes.

The AClass parameter is the class that is descended from TPersistent (see page 2928). Put the call to RegisterClass in a Register procedure. In Delphi, you can also put the call in the initialization section of the unit in which the class is defined. In C++, the call can also go in the namespace of the compilation unit that defines the class.

If the class is already registered, RegisterClass does nothing. If a different class with the same name is already registered, RegisterClass raises an EFilerError (see page 2696) exception.

Note: Registering a component using the RegisterNoIcon (see page 3260) or RegisterComponents (see page 3256) method does not automatically register the class. It is still necessary to call RegisterClass for components.

C++ Examples:

```
/*
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
*/
class MyScrollBar : public TScrollBar
{
__published:    // IDE-managed Components
private:    // User declarations
public:     // User declarations
    __fastcall MyScrollBar(TComponent* Owner);
};

__fastcall MyScrollBar::MyScrollBar(TComponent* Owner)
    : TScrollBar(Owner)
{
}

void RegisterClassesWithStreamingSystem(void)
{
  // Make sure that as part of the startup
  // code our streaming classes are registered
  // with the streaming system.

  #pragma startup RegisterClassesWithStreamingSystem

  Classes::RegisterClass(__classid(MyScrollBar));
}

MyScrollBar *ScrollBar1;

AnsiString __fastcall ComponentToString(TComponent *c)
{
 AnsiString as;
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);

 try
 {
    pms->WriteComponent(c);
    pms->Seek(0, soFromBeginning);
    ObjectBinaryToText(pms, pss);
    pss->Seek(0, soFromBeginning);
    as = pss->DataString;
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 delete pms;
```

```
 delete pss;
 return as;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Text = ComponentToString(ScrollBar1);
}

TComponent *__fastcall StringToComponent(AnsiString as)

{
 TMemoryStream* pms = new TMemoryStream();
 TStringStream* pss = new TStringStream(as);
 TComponent *pc;

 try
 {
    ObjectTextToBinary(pss, pms);
    pms->Seek(0, soFromBeginning);
 }
 catch(...)
 {
    ShowMessage("Streaming error.");
 }

 pc = pms->ReadComponent(NULL);
 delete pms;
 delete pss;
 return pc;
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  TComponent *temp = StringToComponent(Memo1->Text);
  ScrollBar1->Free();

  ScrollBar1 = dynamic_cast<MyScrollBar *>(temp);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ScrollBar1 = new MyScrollBar(Form1);
  ScrollBar1->Parent = Form1;
  ScrollBar1->Visible = TRUE;
  ScrollBar1->Top = 48;
  ScrollBar1->Left = 250;
  ScrollBar1->Name = "Ricksbar";
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete ScrollBar1;
}
```

Delphi Examples:

```
{
This example shows how to use the built-in component
streaming support to convert any component into a string and
convert that string back into a component.
}
type
  TForm1 = class(TForm)
    Memo1: TMemo;
```

```
    Button1: TButton;
    Button2: TButton;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);

23.3.51 Classes.RegisterClassAlias Function

Registers a class that is identical to another class except for the name.

Pascal

```
procedure RegisterClassAlias(AClass: TPersistentClass; const Alias: string);
```

C++

```
RegisterClassAlias(TPersistentClass AClass, const AnsiString Alias);
```

File

Classes

Description

Component writers call RegisterClassAlias to register custom classes that are identical to another persistent class except for the name. Registering a class allows it to be loaded and saved by the component streaming system.

The AClass parameter identifies the previously registered persistent class to which the new class is identical. The Alias parameter specifies the class name of the new class.

See Also

RegisterClass (see page 3250)

23.3.52 Classes.RegisterClasses Function

Registers a set of classes.

Pascal

```
procedure RegisterClasses(AClasses: array of TPersistentClass);
```

C++

```
RegisterClasses(array of TPersistentClass AClasses);
```

File

Classes

Description

Call RegisterClasses to register a set of custom classes in a single line. Each class is registered by calling RegisterClass (see page 3250). Unregistered classes can't be loaded or saved by the component streaming system.

Note: In C++, the AClasses parameter identifies the classes to be registered These must be descendants of TPersistent (see page 2928). The AClasses_Size parameter indicates the index of the last class in AClasses (one less than the total number of classes).

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
TMetaClass *MetaClass;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
```

```
    MetaClass = __classid(Graphics::TBitmap); // bmp
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TMetafile); // emf
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TShape);  // nographic extension
    RegisterClasses(&MetaClass, 0);
    MetaClass = __classid(TImage); // nographic extension
    RegisterClasses(&MetaClass, 0);
  }
```

Delphi Examples:

```
{
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
}

uses ExtCtrls;

procedure TForm1.Button1Click(Sender: TObject);
var
  myClassFinder: TClassFinder;
  mygraphclass: TGraphicClass;
begin
  { make sure the classes are registered so that GetClass will work -- }
  { Usually, this goes in the initialization section where it is only executed once }
  RegisterClasses([TIcon, TBitmap, TButton, TShape, TImage, TMetafile]);
  try
    myClassFinder := TClassFinder.Create(TIcon, False);
    mygraphclass := TGraphicClass(myClassFinder.GetClass(Edit2.Text));
//    mygraphclass := TGraphicClass(GetClass(Edit2.Text));  // works as well
    Edit1.Text := GraphicExtension(mygraphclass);
  except
    on EAccessViolation do
      MessageDlg('Invalid class name.', mtError, [mbOK], 0)
  end;
end;
```

See Also

IdentToInt (see page 3230)

UnRegisterModuleClasses (see page 3265)

23.3.53 Classes.RegisterComponents Function

Registers a set of components so that they all appear on the same page of the component palette.

Pascal

```
procedure RegisterComponents(const Page: string; ComponentClasses: array of TComponentClass);
```

C++

```
RegisterComponents(const AnsiString Page, array of TComponentClass ComponentClasses);
```

File

Classes

Description

Call RegisterComponents to install a set of components in the IDE. Once a component is registered, it appears on the component palette, where it can be selected and placed on forms or data modules. Registered components can communicate with the Object Inspector to allow the user to get and set properties and events.

Set the Page parameter to the name of the page on the component palette where the components should appear. If the named page already exists, the components are added to that page. If the named page does not exist, a new palette page with that name is created.

Pass the components to be registered in the ComponentClasses parameter.

Note: In C++, the ComponentClasses_Size parameter indicates the index of the last class in the ComponentClasses array (one less than the number of classes).

Call RegisterComponents from the implementation of the Register procedure in one of the units that defines the custom components. The units that define the components must then be compiled into a package and the package must be installed before the custom components appear in the component palette.

Note: After components are registered, users can move them to different palette pages. Once this happens, the component always appears on the new page. Calling RegisterComponents a second time does not influence the page on which the component appears.

Delphi Examples:

```
{
The following code registers several components, some on the
MySystem palette page that already exists, and some on a new
palette page that is created when when the components are
installed.
}
type
  TForm1 = class(TForm)
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TDemoLabel = class(TGraphicControl)
  private
    FFocusControl: TWinControl;
    procedure SetFocusControl(Value: TWinControl);
    procedure CMDialogChar(var Message: TCMDialogChar); message CM_DIALOGCHAR;
    procedure CMTextChanged(var Message: TMessage); message CM_TEXTCHANGED;

C++

```
RegisterFindGlobalComponentProc(TFindGlobalComponent AFindGlobalComponent);
```

File

Classes

Description

This is function Classes.RegisterFindGlobalComponentProc.

23.3.55 Classes.RegisterIntegerConsts Function

Registers conversion functions for string identifiers that represent type values.

Pascal

```
procedure RegisterIntegerConsts(AIntegerType: Pointer; AIdentToInt: TIdentToInt; AIntToIdent:
TIntToIdent);
```

C++

```
RegisterIntegerConsts(void * AIntegerType, TIdentToInt AIdentToInt, TIntToIdent AIntToIdent);
```

File

Classes

Description

RegisterIntegerConsts (which can only be called in Delphi) registers conversion functions for type identifiers. Call RegisterIntegerConsts from the initialization section of the unit that defines an integer-based type and a set of strings that represent the values of that type.

AIntegerType is a pointer to the type information for the integer-based type whose values are represented as strings. Its value can be obtained from the base type using the TypeInfo function.

AIdentToInt is the conversion function that converts strings that are symbolic representations of values to the corresponding integers.

AIntToIdent is the conversion function that converts values that are instances of the base type to the corresponding string representation.

Once the conversion functions are registered, string identifiers can represent type values and the conversion functions are used

to convert the string identifiers into the underlying integer values. For example, the TColor type uses this system to convert between the type constants in the Graphics (see page 14387) unit and numeric TColor values.

TColor

TypeInfo

IdentToInt (see page 3230)

IntToIdent (see page 3232)

UnregisterIntegerConsts (see page 3264)

23.3.56 Classes.RegisterNoIcon Function

Registers a set of components but does not add them to the component palette.

Pascal

```
procedure RegisterNoIcon(const ComponentClasses: array of TComponentClass);
```

C++

```
RegisterNoIcon(const array of TComponentClass ComponentClasses);
```

File

Classes

Description

Call RegisterNoIcon to register a set of custom components so that objects from that class can use the Object Inspector. Because the components are not added to the component palette, instances of components registered using RegisterNoIcon must be explicitly created by calling the constructor, usually from another component.

The ComponentClasses parameter is an array of custom classes that are descended from TComponent (see page 2762).

Note: In C++, the ComponentClasses_Size parameter is index of the last class in the array (one less than the number of classes).

Put the call to RegisterNoIcon in the Register procedure.

To add the components to the component palette, use RegisterComponents (see page 3256) instead.

See Also

RegisterNonActiveX (see page 3260)

23.3.57 Classes.RegisterNonActiveX Function

Prevents a set of components from being made available to the ActiveX wizard.

Pascal

```
procedure RegisterNonActiveX(const ComponentClasses: array of TComponentClass; AxRegType:
TActiveXRegType);
```

C++

```
RegisterNonActiveX(const array of TComponentClass ComponentClasses, TActiveXRegType AxRegType);
```

File

Classes

Description

Call RegisterNonActiveX to prevent a registered set of custom components from being converted into ActiveX controls using the ActiveX wizard. The components must still be registered using RegisterComponents (see page 3256) or RegisterNoIcon (see page 3260) if they are to work with the Object Inspector.

The ComponentClasses parameter is an array of custom classes that are descended from TComponent (see page 2762).

Note: In C++, the ComponentClasses_Size is the index of the last class in ComponentClasses (one less than the number of classes).

The AxRegType parameter indicates whether only the components in the ComponentClasses array should be blocked from the ActiveX wizard (when AxRegType is axrComponentOnly), or whether their descendants should be prohibited from becoming ActiveX controls as well (when AxRegType is axrIncludeDescendants).

Put the call to RegisterNonActiveX in the Register procedure.

23.3.58 Classes.RemoveFixupReferences Function

Pascal

```
procedure RemoveFixupReferences(Root: TComponent; const RootName: string);
```

C++

```
RemoveFixupReferences(TComponent * Root, const AnsiString RootName);
```

File

Classes

Description

This is function Classes.RemoveFixupReferences.

23.3.59 Classes.RemoveFixups Function

Pascal

```
procedure RemoveFixups(Instance: TPersistent);
```

C++

```
RemoveFixups(TPersistent * Instance);
```

File

Classes

Description

This is function Classes.RemoveFixups.

23.3.60 Classes.SmallPoint Function

Creates a TSmallPoint structure from a pair of coordinates.

Pascal

```
function SmallPoint(AX: SmallInt; AY: SmallInt): TSmallPoint;
```

C++

```
TSmallPoint SmallPoint(SmallInt AX, SmallInt AY);
```

File

Classes

Description

Call SmallPoint to create a TSmallPoint that represents the specified coordinates.

See Also

Point (see page 3244)

23.3.61 Classes.StartClassGroup Function

Starts a class group derived from TPersistent (see page 2928).

Pascal

```
procedure StartClassGroup(AClass: TPersistentClass);
```

C++

```
StartClassGroup(TPersistentClass AClass);
```

File

Classes

Description

The streaming system allows the classes that can be loaded and saved to be registered in separate groups. This allows the IDE to distinguish between cross-platform and Windows-only classes. StartClassGroup creates a new group of classes, and adds the class specified by AClass to that group.

See Also

ActivateClassGroup (see page 3215)

GroupDescendantsWith

23.3.62 Classes.TestStreamFormat Function

Identifies the format of a form file when reading it from a stream.

Pascal

```
function TestStreamFormat(Stream: TStream): TStreamOriginalFormat;
```

C++

```
TStreamOriginalFormat TestStreamFormat(TStream Stream);
```

File

Classes

Description

Call TestStreamFormat to check the signature of a stream that reads a form file to determine whether it was stored in binary or text format.

Stream is the stream to check.

TestStreamFormat checks the signature of the stream and returns sofBinary if the form file was saved in binary format, sofText if it was saved in text format, and sofUnknown if it could not tell. A return value of sofUnknown usually indicates that the stream is not reading a form file or that the stream is not positioned at the start of the file.

See Also

IdentToInt (see page 3230)

23.3.63 Classes.UnRegisterClass Function

Unregisters an object class.

Pascal

```
procedure UnRegisterClass(AClass: TPersistentClass);
```

C++

```
UnRegisterClass(TPersistentClass AClass);
```

File

Classes

Description

Call UnRegisterClass to unregister an object class. When a class is unregistered, it can't be loaded or saved by the component streaming system.

After unregistering a class, its name can be reused to register another object class.

See Also

IdentToInt (see page 3230)

UnRegisterModuleClasses (see page 3265)

23.3.64 Classes.UnRegisterClasses Function

Unregisters a set of classes.

Pascal

```
procedure UnRegisterClasses(AClasses: array of TPersistentClass);
```

C++

```
UnRegisterClasses(array of TPersistentClass AClasses);
```

File

Classes

Description

Call UnRegisterClasses to unregister several persistent object classes in a single line. When a class is unregistered, it can't be loaded or saved by the component streaming system.

The AClasses parameter specifies the classes (descendants of TPersistent (see page 2928)) to unregister.

Note: In C++, the AClasses_Size parameter indicates the index of the last class in the AClasses array (one less than the number of classes).

After unregistering a class, its name can be reused to register another object class.

23.3.65 Classes.UnregisterFindGlobalComponentProc Function

Pascal

```
procedure UnregisterFindGlobalComponentProc(AFindGlobalComponent: TFindGlobalComponent);
```

C++

```
UnregisterFindGlobalComponentProc(TFindGlobalComponent AFindGlobalComponent);
```

File

Classes

Description

This is function Classes.UnregisterFindGlobalComponentProc.

23.3.66 Classes.UnregisterIntegerConsts Function

Unregisters conversion functions for string identifiers that represent type values.

Pascal

```
procedure UnregisterIntegerConsts(AIntegerType: Pointer; AIdentToInt: TIdentToInt;
AIntToIdent: TIntToIdent);
```

C++

```
UnregisterIntegerConsts(void * AIntegerType, TIdentToInt AIdentToInt, TIntToIdent AIntToIdent);
```

File

Classes

Description

UnregisterIntegerConsts, which can only be called in Delphi, unregisters conversion functions that were previously registered by a call to RegisterIntegerConsts (see page 3259). Call UnregisterIntegerConsts from the finalization section of the unit that defines the constants and registers the conversion functions in its initialization section. Once the conversion functions are unregistered, string identifiers can't be used to represent type values.

AIntegerType is a pointer to the type information for the integer-based type whose values are represented as strings. Its value can be obtained from the base type using the TypeInfo function.

AIdentToInt is the conversion function that converts strings that are symbolic representations of values to the corresponding integers.

AIntToIdent is the conversion function that converts values that are instances of the base type to the corresponding string representation.

See Also

RegisterIntegerConsts (see page 3259)

23.3.67 Classes.UnRegisterModuleClasses Function

Unregisters all classes defined in a specified module.

Pascal

```
procedure UnRegisterModuleClasses(Module: HMODULE);
```

C++

```
UnRegisterModuleClasses(HMODULE Module);
```

File

Classes

Description

Call UnRegisterModuleClasses to unregister all object classes that were registered by the module with the handle specified by the Module parameter. When a class is unregistered, it can't be loaded or saved by the component streaming system.

After unregistering a class, its name can be reused to register another object class.

See Also

IdentToInt (see page 3230)

23.3.68 Classes.WriteComponentResFile Function

Writes components and their properties to a file using a resource file format.

Pascal

```
procedure WriteComponentResFile(const FileName: string; Instance: TComponent);
```

C++

```
WriteComponentResFile(const AnsiString FileName, TComponent * Instance);
```

File

Classes

Description

Use WriteComponentResFile to save the component specified by the Instance parameter to the specified file, storing it in a resource-file format.

To read a component written with WriteComponentResFile, call ReadComponentResFile (see page 3247).

Delphi Examples:

```
{
ReadComponentResFile, WriteComponentResFile example
The following code defines a component class (TStreamable
class) and a persistent class (TContainedClass) that is the
type of a property on the component class. When a button is
clicked, an instance of the component class is created, saved
to a file, deleted, and then loaded from the file. By setting
a breakpoint on the property setter of the TContainedClass
SomeData property, you can watch how the streaming system
sets property values when it reads them from a file.
The following unit defines the classes to stream:
}

{$R-,T-,H+,X+}

type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TContainedClass = class(TPersistent)
  private
    FSomeData: Integer;
    procedure SetSomeData(Value: Integer);
  public
    constructor Create;
    // Only published properties
    // are automatically streamed.
  published
    property SomeData: Integer read FSomeData write SetSomeData;
  end;

  TStreamableClass = class(TComponent)
  private
```

```
    FContainedClass: TContainedClass;
  public
    constructor Create(AOwner: TComponent); override;
    destructor Destroy; override;
    // Only published properties
    // are automatically streamed.
  published
    property ContainedClass: TContainedClass read FContainedClass write FContainedClass;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

procedure TContainedClass.SetSomeData(Value: Integer);
begin
{ Place a breakpoint here and notice how the data is streamed back. }
  FSomeData := Value;
end;

constructor TContainedClass.Create;
begin
  FSomeData := 42;
end;

constructor TStreamableClass.Create(AOwner: TComponent);
begin
  inherited Create(AOwner);
  FContainedClass := TContainedClass.Create;
end;

destructor TStreamableClass.Destroy;
begin
  FContainedClass.Free;
end;

{
The following OnClick event handler should be added to a
button on the application's main form. It causes the above
classes to be streamed out and in. Note that you must add
StrmExmpl to the uses clause of unit1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  AClassInstance: TStreamableClass;
begin
  AClassInstance := TStreamableClass.Create(nil);
  WriteComponentResFile('Test', AClassInstance);
  FreeAndNil(AClassInstance);

  AClassInstance := Classes.ReadComponentResFile('Test', nil) as TStreamableClass;
  FreeAndNil(AClassInstance);
end;

initialization
  RegisterClasses([TContainedClass, TStreamableClass]);
```

ReadComponentResFile (see page 3247)

23.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TActiveXRegType (see page 3268)	TActiveXRegType is used when excluding a component class from the ActiveX Wizard.
	TAlignment (see page 3269)	TAlignment specifies how text is aligned within a control.
	TBiDiMode (see page 3269)	TBiDiMode specifies the reading order (bidirectional mode) of a control.
	TCollectionNotification (see page 3270)	TCollectionNotification indicates the type of change that is made to the items in a collection.
	TDuplicates (see page 3271)	TDuplicates indicates the response when an application attempts to add a duplicate entry to a list.
	TFilerFlag (see page 3271)	TFilerFlag indicates information about how a filer should read or write a component and TFilerFlags (see page 3289) is a set of TFilerFlag values.
	THelpType (see page 3272)	THelpType indicates whether components invoke the help system using a context ID or a keyword.
	TListAssignOp (see page 3273)	TListAssignOp indicates how two lists should be merged.
	TListNotification (see page 3274)	TListNotification defines list processing action types.
	TOperation (see page 3275)	TOperation represents the types of operations whose occurrence is broadcast by the Notification method.
	TSeekOrigin (see page 3276)	TSeekOrigin indicates where to start a seek operation.
	TStreamOriginalFormat (see page 3276)	TStreamOriginalFormat indicates the format in which a form file is saved.
	TStreamOwnership (see page 3277)	TStreamOwnership indicates whether a stream object should be freed by the object that uses it.
	TThreadPriority (see page 3278)	TThreadPriority indicates the scheduling priority of a thread object on Windows.
	TValueType (see page 3279)	TValueType defines the kinds of values written to and read from filer objects.
	TVerticalAlignment (see page 3280)	TVerticalAlignment specifies how text is vertically aligned within a control.

Records

	Name	Description
	TIdentMapEntry (see page 3273)	TIdentMapEntry is used to perform ident string to integer value mapping.
	TStringItem (see page 3277)	TStringItem defines a TStringList (see page 3006) entry.
	TSynchronizeRecord (see page 3278)	This is record Classes.TSynchronizeRecord.

23.4.1 Classes.TActiveXRegType Enumeration

TActiveXRegType is used when excluding a component class from the ActiveX Wizard.

Pascal

```
TActiveXRegType = (
  axrComponentOnly,
  axrIncludeDescendants
);
```

C++

```
enum TActiveXRegType {
  axrComponentOnly,
  axrIncludeDescendants
};
```

File

Classes

Description

The TActiveXRegType type indicates whether a component's descendants should be excluded from the ActiveX Wizard when the component is excluded. The following table lists the possible values:

Value	Meaning
axrComponentOnly	Only the component class is blocked from appearing in the ActiveX Wizard.
axrIncludeDescendants	The component class and any of its descendants are blocked from the Wizard.

23.4.2 Classes.TAlignment Enumeration

TAlignment specifies how text is aligned within a control.

Pascal

```
TAlignment = (
  taLeftJustify,
  taRightJustify,
  taCenter
);
```

C++

```
enum TAlignment {
  taLeftJustify,
  taRightJustify,
  taCenter
};
```

File

Classes

Description

The following are possible values of TAlignment:

Value	Meaning
taLeftJustify	Text is left-justified: Lines all begin at the left edge of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is right-justified: Lines all end at the right edge of the control.

See Also

Alignment

23.4.3 Classes.TBiDiMode Enumeration

TBiDiMode specifies the reading order (bidirectional mode) of a control.

Pascal

```
TBiDiMode = (
  bdLeftToRight,
  bdRightToLeft,
  bdRightToLeftNoAlign,
  bdRightToLeftReadingOnly
);
```

C++

```
enum TBiDiMode {
  bdLeftToRight,
  bdRightToLeft,
  bdRightToLeftNoAlign,
  bdRightToLeftReadingOnly
};
```

File

Classes

Description

TBiDiMode determines the reading order of the text, placement of the vertical scrollbar, and any alignment modifications. It is used to tailor the user interface for locales where text is bi-directional.

The following table describes the possible values:

Value	Meaning
bdLeftToRight	Reading order is left to right. Alignment is not changed. The vertical scroll bar appears on the right edge of the control.
bdRightToLeft	Reading order is right to left. Alignment is changed. The vertical scroll bar appears on the left edge of the control.
bdRightToLeftNoAlign	Reading order is right to left. Alignment is not changed. The vertical scroll bar appears on the left edge of the control.
bdRightToLeftReadingOnly	Reading order is right to left. Alignment and scroll bar are not changed.

23.4.4 Classes.TCollectionNotification Enumeration

TCollectionNotification indicates the type of change that is made to the items in a collection.

Pascal

```
TCollectionNotification = (
  cnAdded,
  cnExtracting,
  cnDeleting
);
```

C++

```
enum TCollectionNotification {
  cnAdded,
  cnExtracting,
  cnDeleting
};
```

File

Classes

Description

The following table lists the values for TCollectionNotification:

Value	Meaning
cnAdded	An item was just added to the collection.
cnExtracting	An item is about to be removed from the collection (but not freed).
cnDeleting	An item is about to be removed from the collection and then freed.

See Also

TCollection

23.4.5 Classes.TDuplicates Enumeration

TDuplicates indicates the response when an application attempts to add a duplicate entry to a list.

Pascal

```
TDuplicates = (
  dupIgnore,
  dupAccept,
  dupError
);
```

C++

```
enum TDuplicates {
  dupIgnore,
  dupAccept,
  dupError
};
```

File

Classes

Description

TDuplicates can have one of the following values:

Value	Meaning
dupIgnore	Ignore attempts to add duplicate entries (do not add the duplicate).
dupAccept	Allow the list to contain duplicate entries (add the duplicate).
dupError	Raise an exception when the application tries to add a duplicate.

See Also

TStrings

23.4.6 Classes.TFilerFlag Enumeration

TFilerFlag indicates information about how a filer should read or write a component and TFilerFlags (see page 3289) is a set of TFilerFlag values.

Pascal

```
TFilerFlag = (
  ffInherited,
  ffChildPos,
  ffInline
);
```

C++

```
enum TFilerFlag {
  ffInherited,
  ffChildPos,
  ffInline
};
```

File

Classes

Description

TFilerFlag values are written to form files as a prefix to saved components. They indicate any special status of the component that the streaming system must take into account. TFilerFlags (see page 3289) is a set containing all the flags (if any) that pertain to a single component.

The following table lists the possible TFilerFlag values:

Value	Meaning
ffInherited	The component is an inherited form.
ffChildPos	The order in which this component is created is important.
ffInline	The component is a top-level component such as a form or data module.

23.4.7 Classes.THelpType Enumeration

THelpType indicates whether components invoke the help system using a context ID or a keyword.

Pascal

```
THelpType = (
  htKeyword,
  htContext
);
```

C++

```
enum THelpType {
  htKeyword,
  htContext
};
```

File

Classes

Description

These are the possible values of the THelpType type:

Value	Meaning
htKeyword	Help topics are identified by a string. The HelpKeyword property is used to identify help topics. This mechanism is available for all help systems.
htContext	Help topics are identified by a context ID. The HelpContext property is used to identify help topics. This mechanism is not available for all help systems, but is typically faster for those systems that support it.

23.4.8 Classes.TIdentMapEntry Record

TIdentMapEntry is used to perform ident string to integer value mapping.

Pascal

```
TIdentMapEntry = record
  Value: Integer;
  Name: String;
end;
```

C++

```
struct TIdentMapEntry {
  int Value;
  AnsiString Name;
};
```

File

Classes

Description

The TIdentMapEntry type declares a record of two fields. **Name** gives the ident name as a string. **Value** gives the integer value of this ident.

RegisterIntegerConsts (see page 3259) function registers pairs of ident strings and their corresponding values. It uses IdentToInt (see page 3230) and IntToIdent (see page 3232) to perform the mappings between the ident names and their values.

These routines in turn use TIdentMapEntry arrays to hold these mappings.

For example, the Graphics (see page 14387) unit uses TIdentMapEntry internally to hold the mapping of color names to integer values, such as 'clMaroon' to $000080.

See Also

IdentToInt (see page 3230)

IntToIdent (see page 3232)

RegisterIntegerConsts (see page 3259)

23.4.9 Classes.TListAssignOp Enumeration

TListAssignOp indicates how two lists should be merged.

Pascal

```
TListAssignOp = (
  laCopy,
  laAnd,
  laOr,
  laXor,
  laSrcUnique,
  laDestUnique
);
```

C++

```
enum TListAssignOp {
  laCopy,
  laAnd,
  laOr,
  laXor,
  laSrcUnique,
  laDestUnique
};
```

File

Classes

Description

TListAssignOps describes how the Assign method combines a source and destination list:

Value	Meaning
laAnd	Removes all elements from the destination list that do not appear in the source list. The destination list ends up containing the intersection of the two lists.
laCopy	Overwrites the destination list with the source list.
laDestUnique	Removes all elements from the destination list that appear in the source list. The destination list ends up containing the elements unique to the original destination list. (same as laOr followed by laXor)
laOr	Adds any elements from the source list that do not already appear in the destination list. The destination list ends up containing the union of the two lists.
laSrcUnique	Replaces the destination list with those elements of the source list that do not appear in the destination list. (same as laAnd followed by laXor)
laXor	Removes all elements from the destination list that appear in the source list and adds any elements from the source list that do not appear in the original destination list. The destination list ends up with the elements unique to both the source and destination lists.

23.4.10 Classes.TListNotification Enumeration

TListNotification defines list processing action types.

Pascal

```
TListNotification = (
  lnAdded,
  lnExtracted,
  lnDeleted
);
```

C++

```
enum TListNotification {
```

```
    lnAdded,
    lnExtracted,
    lnDeleted
  };
```

File

Classes

Description

The TListNotification type enumerates the different event types for a list object.

lnAdded means an entry was added to the list.

lnExtracted means an entry was deleted from the list. The entry was specified by reference.

lnDeleted means an entry was deleted from the list. The entry was specified by list position.

TListNotification is principally used internally by TList (see page 2868).

See Also

TList (see page 2868)

23.4.11 Classes.TOperation Enumeration

TOperation represents the types of operations whose occurrence is broadcast by the Notification method.

Pascal

```
  TOperation = (
    opInsert,
    opRemove
  );
```

C++

```
  enum TOperation {
    opInsert,
    opRemove
  };
```

File

Classes

Description

The TOperation type is used in the Notification method to indicate whether the notification indicates the creation or deletion of an object. The following table gives the possible values:

Value	Meaning
opInsert	The specified object has just been created.
opRemove	The specified object has been destroyed, and its memory is about to be freed.

See Also

TComponent

23.4.12 Classes.TSeekOrigin Enumeration

TSeekOrigin indicates where to start a seek operation.

Pascal

```
TSeekOrigin = (
  soBeginning,
  soCurrent,
  soEnd
);
```

C++

```
enum TSeekOrigin {
  soBeginning,
  soCurrent,
  soEnd
};
```

File

Classes

Description

The TSeekOrigin type indicates where to start a seek origin and the direction in which to seek. The following table lists the possible values:

Value	Meaning
soBeginning	Seek from the beginning of the resource. The seek operation moves to a specified position (offset), which must be greater than or equal to zero.
soCurrent	Seek from the current position in the resource. The seek operation moves to an offset from the current position (position + offset). The offset is positive to move forward, negative to move backward.
soEnd	Seek from the end of the resource. The seek operation moves to an offset from the end of the resource, where the offset is expressed as a negative value because it is moving toward the beginning of the resource.

Warning: Using these constants may generate unwanted/wrong code, because an overloaded seek method will be used, which uses `offest : longint`, thus limiting seekrange to 2GB.

23.4.13 Classes.TStreamOriginalFormat Enumeration

TStreamOriginalFormat indicates the format in which a form file is saved.

Pascal

```
TStreamOriginalFormat = (
  sofUnknown,
  sofBinary,
  sofText
);
```

C++

```
enum TStreamOriginalFormat {
  sofUnknown,
  sofBinary,
```

```
  sofText
};
```

File

Classes

Description

Form files can be saved in binary format or as a text file, depending on the options set in the Environment Options dialog. TStreamOriginalFormat specifies the format used for saving a form file. It is one of the following values:

Value	Meaning
sofUnknown	The format of the file from which a form is being read or to which it is being written is unknown. If the format can't be deduced from the stream, an exception is raised.
sofBinary	The form is being read from or written to a form file that uses binary format.
sofText	The form is being read from or written to a text file.

23.4.14 Classes.TStreamOwnership Enumeration

TStreamOwnership indicates whether a stream object should be freed by the object that uses it.

Pascal

```
TStreamOwnership = (
  soReference,
  soOwned
);
```

C++

```
enum TStreamOwnership {
  soReference,
  soOwned
};
```

File

Classes

Description

The following are possible values of TStreamOwnership:

Value	Meaning
soReference	The stream is an independent object with a different Owner. The object that uses the stream does not free it when it is destroyed.
soOwned	The stream is owned by the object that uses it (and exists solely for that object). The object that uses the stream frees the associated stream when it no longer needs to use the stream.

23.4.15 Classes.TStringItem Record

TStringItem defines a TStringList (see page 3006) entry.

Pascal

```
TStringItem = record
  FString: string;
  FObject: TObject;
end;
```

C++

```
struct TStringItem {
  AnsiString FString;
  TObject * FObject;
};
```

File

Classes

Description

The TStringItem type defines a data structure used internally in Delphi.

It is used by TStringList (see page 3006) to hold a list entry.

FString defines string for a list entry.

FObject points to an optional TObject associated with the string.

See Also

TStringList (see page 3006)

23.4.16 Classes.TSynchronizeRecord Record

Pascal

```
TSynchronizeRecord = record
  FThread: TObject;
  FMethod: TThreadMethod;
  FSynchronizeException: TObject;
end;
```

C++

```
struct TSynchronizeRecord {
  TObject * FThread;
  TThreadMethod FMethod;
  TObject * FSynchronizeException;
};
```

File

Classes

Description

This is record Classes.TSynchronizeRecord.

23.4.17 Classes.TThreadPriority Enumeration

TThreadPriority indicates the scheduling priority of a thread object on Windows.

Pascal

```
TThreadPriority = (
  tpIdle,
  tpLowest,
  tpLower,
  tpNormal,
  tpHigher,
  tpHighest,
  tpTimeCritical
);
```

C++

```
enum TThreadPriority {
  tpIdle,
  tpLowest,
  tpLower,
  tpNormal,
  tpHigher,
  tpHighest,
  tpTimeCritical
};
```

File

Classes

Description

The following are possible values of TThreadPriority:

Values	Meaning
tpIdle	The thread executes only when the system is idle. The system will not interrupt other threads to execute a thread with tpIdle priority.
tpLowest	The thread's priority is two points below normal.
tpLower	The thread's priority is one point below normal.
tpNormal	The thread has normal priority.
tpHigher	The thread's priority is one point above normal.
tpHighest	The thread's priority is two points above normal.
tpTimeCritical	The thread gets highest priority.

See Also

TThread

23.4.18 Classes.TValueType Enumeration

TValueType defines the kinds of values written to and read from filer objects.

Pascal

```
TValueType = (
  vaNull,
  vaList,
  vaInt8,
  vaInt16,
  vaInt32,
```

```
    vaExtended,
    vaString,
    vaIdent,
    vaFalse,
    vaTrue,
    vaBinary,
    vaSet,
    vaLString,
    vaNil,
    vaCollection,
    vaSingle,
    vaCurrency,
    vaDate,
    vaWString,
    vaInt64,
    vaUTF8String,
    vaDouble
  );
```

C++

```
  enum TValueType {
    vaNull,
    vaList,
    vaInt8,
    vaInt16,
    vaInt32,
    vaExtended,
    vaString,
    vaIdent,
    vaFalse,
    vaTrue,
    vaBinary,
    vaSet,
    vaLString,
    vaNil,
    vaCollection,
    vaSingle,
    vaCurrency,
    vaDate,
    vaWString,
    vaInt64,
    vaUTF8String,
    vaDouble
  };
```

File

Classes

Description

TValueType is the type used by the TReader (see page 2933) and TWriter (see page 3175) filer objects to type check property values that are read from and written to streams when streaming components and their properties.

See Also

TReader

TWriter

23.4.19 Classes.TVerticalAlignment Enumeration

TVerticalAlignment specifies how text is vertically aligned within a control.

Pascal

```
TVerticalAlignment = (
  taAlignTop,
  taAlignBottom,
  taVerticalCenter
);
```

C++

```
enum TVerticalAlignment {
  taAlignTop,
  taAlignBottom,
  taVerticalCenter
};
```

File

Classes

Description

The following are possible values of TVerticalAlignment:

Value	Meaning
taAlignTop	Text is aligned to the top edge of the control.
taAlignCenter	Text is vertically centered in the control.
taVerticalJustify	Text is vertically-justified: Lines are spaced out to fill the height of the control.

23.5 Types

The following table lists types in this documentation.

Types

Name	Description
PPointerList (see page 3283)	PPointerList is a pointer to a TPointerList (see page 3299) type.
PStringItem (see page 3284)	PStringItem is a TStringItem (see page 3277) pointer.
PStringItemList (see page 3284)	PStringItemList is a TStringItemList (see page 3304) pointer.
PSynchronizeRecord (see page 3285)	This is type Classes.PSynchronizeRecord.
TAncestorNotFoundEvent (see page 3285)	TAncestorNotFoundEvent is a procedure called by the TReader (see page 2933) class OnAncestorNotFound event.
TBasicActionClass (see page 3285)	TBasicActionClass defines the metaclass for TBasicAction (see page 2707).
TBasicActionLinkClass (see page 3286)	TBasicActionLinkClass defines the metaclass for TBasicActionLink (see page 2720).
TCollectionItemClass (see page 3286)	TCollectionItemClass defines the metaclass for TCollectionItem (see page 2755).
TComponentClass (see page 3287)	TComponentClass defines the metaclass for TComponent (see page 2762).
TComponentName (see page 3287)	TComponentName is the type for the Name property of all components.
TComponentState (see page 3287)	TComponentState is a set of flags that describe the current state of a component.
TComponentStyle (see page 3288)	TComponentStyle is a set of flags that describe the current Style of a component.
TCreateComponentEvent (see page 3289)	TCreateComponentEvent is a type of procedure called by the TReader (see page 2933) class OnCreateComponentEvent event.
TFilerFlags (see page 3289)	TFilerFlags is the set of TFilerFlag (see page 3271) values.
TFindAncestorEvent (see page 3290)	TFindAncestorEvent is a procedure called by the TWriter (see page 3175) class OnFindAncestor event.
TFindComponentClassEvent (see page 3290)	This is type Classes.TFindComponentClassEvent.
TFindComponentInstanceEvent (see page 3291)	This is type Classes.TFindComponentInstanceEvent.
TFindGlobalComponent (see page 3291)	This is type Classes.TFindGlobalComponent.
TFindMethodEvent (see page 3291)	TFindMethodEvent is a procedure called by the TReader (see page 2933) class OnFindMethod event.
TFindMethodInstanceEvent (see page 3292)	TFindMethodInstanceEvent is a procedure called by the TReader (see page 2933) class OnFindMethodInstance event.
TFindMethodNameEvent (see page 3292)	TFindMethodNameEvent is a procedure called by the TWriter (see page 3175) class OnFindMethodName event.
TGetChildProc (see page 3292)	TGetChildProc is a type of procedure called used internally by the TComponent (see page 2762) class.
TGetClass (see page 3293)	TGetClass is a callback procedure used by the TClassFinder (see page 2728) class.
TGetLookupInfoEvent (see page 3293)	This is type Classes.TGetLookupInfoEvent.
TGetModuleProc (see page 3294)	This is type Classes.TGetModuleProc.
TGetStrProc (see page 3294)	TGetStrProc is a general purpose type of callback procedure invoked for each of a set of strings.
THelpContext (see page 3295)	THelpContext is the range of values that a HelpContext value may have.
TIdentToInt (see page 3295)	TIdentToInt is a type of callback function used by the IdentToInt (see page 3230) routine.
TIntToIdent (see page 3296)	TIntToIdent is a type of callback function used by the IntToIdent (see page 3232) routine.
TIsUniqueGlobalComponentName (see page 3296)	TIsUniqueGlobalComponentName is a type of function used by IsUniqueGlobalComponentName (see page 3234).
TLeftRight (see page 3297)	TLeftRight is a subset of TAlignment (see page 3269) that allows left or right justification.
TListSortCompare (see page 3297)	TListSortCompare is a type of callback function called used internally by the TList (see page 2868) class.
TNotifyEvent (see page 3298)	TNotifyEvent is used for events that do not require parameters.

TParserErrorEvent (see page 3298)	TParserErrorEvent is a callback procedure used by the TClassFinder (see page 2728) class.
TPersistentClass (see page 3299)	TPersistentClass defines the metaclass for TPersistent (see page 2928).
TPointerList (see page 3299)	TPointerList is an array of pointers.
TReadComponentsProc (see page 3300)	TReadComponentsProc is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.
TReaderError (see page 3300)	TReaderError is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.
TReaderProc (see page 3301)	TReaderProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.
TReferenceNameEvent (see page 3301)	TReferenceNameEvent is a procedure called by the TReader (see page 2933) class OnReferenceNameEvent event.
TSetNameEvent (see page 3302)	TSetNameEvent is a procedure called by the TReader (see page 2933) class OnSetNameEvent event.
TShiftState (see page 3302)	TShiftState indicates the state of the Alt, Ctrl, and Shift keys and the mouse buttons.
TShortCut (see page 3303)	TStringsDefined (see page 3306) defines an enumeration of string delimiter names.
TStreamProc (see page 3304)	TStreamProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineBinaryProperty methods.
TStringItemList (see page 3304)	TStringItemList defines an array of TStringItems.
TStringListSortCompare (see page 3305)	TStringListSortCompare is a type of callback function called used internally by the TStringList (see page 3006) class.
TStringsDefined (see page 3306)	This is type Classes.TStringsDefined.
TThreadMethod (see page 3306)	This is type Classes.TThreadMethod.
TTopBottom (see page 3306)	TTopBottom is a subset of TVerticalAlignment (see page 3280) that allows top or bottom alignment.
TWndMethod (see page 3307)	TWndMethod is the type for Windows message procedures.
TWriterProc (see page 3307)	TWriterProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.

23.5.1 Classes.PPointerList Type

PPointerList is a pointer to a TPointerList (see page 3299) type.

Pascal

```
PPointerList = ^TPointerList;
```

C++

```
^TPointerList PPointerList;
```

File

Classes

Description

PPointerList is principally used by the TList (see page 2868) property of the TList (see page 2868) class to provide a pointer to the list of pointers that TList (see page 2868) holds.

See Also

TList (see page 2868)

TPointerList (see page 3299)

23.5.2 Classes.PStringItem Type

PStringItem is a TStringItem (see page 3277) pointer.

Pascal

```
PStringItem = ^TStringItem;
```

C++

```
^TStringItem PStringItem;
```

File

Classes

Description

PStringItem is used internally by TStringList (see page 3006) to point to a TStringItem (see page 3277) value.

TStringItem (see page 3277) comprises :

FString defines string for a list entry.

FObject points to an optional TObject associated with the string.

See Also

TStringItem (see page 3277)

TStringList (see page 3006)

23.5.3 Classes.PStringItemList Type

PStringItemList is a TStringItemList (see page 3304) pointer.

Pascal

```
PStringItemList = ^TStringItemList;
```

C++

```
^TStringItemList PStringItemList;
```

File

Classes

Description

PStringItemList is used internally by TStringList (see page 3006) to refer to its internal array of TStringItem (see page 3277) values. This array holds the list of strings.

TStringItem (see page 3277) comprises :

FString defines string for a list entry.

FObject points to an optional TObject associated with the string.

See Also

TStringItem (see page 3277)

TStringList (see page 3006)

23.5.4 Classes.PSynchronizeRecord Type

Pascal

```
PSynchronizeRecord = ^TSynchronizeRecord;
```

C++

```
^TSynchronizeRecord PSynchronizeRecord;
```

File

Classes

Description

This is type Classes.PSynchronizeRecord.

23.5.5 Classes.TAncestorNotFoundEvent Type

TAncestorNotFoundEvent is a procedure called by the TReader (see page 2933) class OnAncestorNotFound event.

Pascal

```
TAncestorNotFoundEvent = procedure (Reader: TReader; const ComponentName: string;
ComponentClass: TPersistentClass; var Component: TComponent) of object;
```

C++

```
(Reader: TReader; const ComponentName: string; ComponentClass: TPersistentClass; var
Component: TComponent) ( TAncestorNotFoundEvent)();
```

File

Classes

Description

TAncestorNotFoundEvent is for internal use only.

See Also

OnAncestorNotFound (see page 2961)

TReader (see page 2933)

23.5.6 Classes.TBasicActionClass Type

TBasicActionClass defines the metaclass for TBasicAction (see page 2707).

Pascal

```
TBasicActionClass = class of TBasicAction;
```

C++

```
TBasicAction TBasicActionClass;
```

File

Classes

Description

TBasicActionClass is the metaclass for TBasicAction (see page 2707). Its value is the class reference for TBasicAction (see page 2707) or for one of its descendants.

See Also

TBasicAction (see page 2707)

23.5.7 Classes.TBasicActionLinkClass Type

TBasicActionLinkClass defines the metaclass for TBasicActionLink (see page 2720).

Pascal

```
TBasicActionLinkClass = class of TBasicActionLink;
```

C++

```
TBasicActionLink TBasicActionLinkClass;
```

File

Classes

Description

TBasicActionLinkClass is the metaclass for TBasicActionLink (see page 2720). Its value is the class reference for TBasicActionLink (see page 2720) or for one of its descendants.

See Also

TBasicActionLink (see page 2720)

23.5.8 Classes.TCollectionItemClass Type

TCollectionItemClass defines the metaclass for TCollectionItem (see page 2755).

Pascal

```
TCollectionItemClass = class of TCollectionItem;
```

C++

```
TCollectionItem TCollectionItemClass;
```

File

Classes

Description

TCollectionItemClass is the metaclass for TCollectionItem (see page 2755). Its value is the class reference for TCollectionItem (see page 2755) or for one of its descendants.

23.5.9 Classes.TComponentClass Type

TComponentClass defines the metaclass for TComponent (see page 2762).

Pascal

```
TComponentClass = class of TComponent;
```

C++

```
TComponent * TComponentClass;
```

File

Classes

Description

TComponentClass is the metaclass for TComponent (see page 2762). Its value is the class reference for TComponent (see page 2762) or for one of its descendants.

23.5.10 Classes.TComponentName Type

TComponentName is the type for the Name property of all components.

Pascal

```
TComponentName = type string;
```

C++

```
type string TComponentName;
```

File

Classes

Description

TComponentName is a string that represents the name of a component.

23.5.11 Classes.TComponentState Type

TComponentState is a set of flags that describe the current state of a component.

Pascal

```
TComponentState = set of (csLoading, csReading, csWriting, csDestroying, csDesigning,
csAncestor, csUpdating, csFixups, csFreeNotification, csInline, csDesignInstance);
```

C++

```
(csLoading, csReading, csWriting, csDestroying, csDesigning, csAncestor, csUpdating, csFixups,
csFreeNotification, csInline, csDesignInstance) TComponentState;
```

File

Classes

Description

TComponentState defines the set of possible state flags for the ComponentState property of a TComponent (see page 2762) instance. The following table lists the possible values for the TComponentState type and the meaning corresponding to each flag:

Flag	Component state
csAncestor	The component was introduced in an ancestor form. Only set if csDesigning is also set.
csDesigning	The component is in a form being manipulated by the form designer.
csDestroying	The component is about to be destroyed.
csFixups	The component is linked to a component in another form that has not yet been loaded. This flag is cleared when all pending fix-ups are resolved.
csFreeNotification	One or more other components have requested that this component notify them when it is destroyed. This flag is set when another component calls this component's FreeNotification method.
csInline	The component is a top-level component that can be modified at design time and also embedded in a form. This flag is used to identify nested frames while loading and saving.
csLoading	A filer object is currently loading the component. This flag is set when the component is first created and not cleared until the component and all its children are fully loaded (when the Loaded method is called).
csReading	The component is reading its property values from a stream. Note that the csLoading flag is always set as well when csReading is set. That is, csReading is set for the subinterval of the time when a component is loading that covers reading in property values.
csUpdating	The component is being updated to reflect changes in an ancestor form. Only set if csAncestor is also set.
csWriting	The component is writing its property values to a stream.
csDesignInstance	The component is the root object in a designer. For example, it is set for a frame when you are designing it, but not on a frame that acts like a component. This flag always appears with csDesigning.

23.5.12 Classes.TComponentStyle Type

TComponentStyle is a set of flags that describe the current Style of a component.

Pascal

```
TComponentStyle = set of (csInheritable, csCheckPropAvail, csSubComponent, csTransient);
```

C++

```
(csInheritable, csCheckPropAvail, csSubComponent, csTransient) TComponentStyle;
```

File

Classes

Description

The following table indicates the meaning of the various TComponentStyle flags:

Value	Meaning
csInheritable	Descendant form types can inherit from the component. If any of the components in a form do not have the csInheritable style, the form cannot be used as the ancestor of an inherited form.
csCheckPropAvail	The component needs to check its properties for readability. This is only used for COM controls (on Windows), where the Object Inspector cannot tell directly that a property is readable, and therefore displayable.

csSubComponent	The component is a subcomponent of the component that is the value of its Owner property. Unlike top-level components, subcomponents are not saved with the form or data module in which they reside. Instead, a subcomponent appears as the value of a published property of its Owner, and its published properties and events are saved in the form file with the owning component.
csTransient	The component is a temporary object that should not be saved in a form file.

23.5.13 Classes.TCreateComponentEvent Type

TCreateComponentEvent is a type of procedure called by the TReader (see page 2933) class OnCreateComponentEvent event.

Pascal

```
TCreateComponentEvent = procedure (Reader: TReader; ComponentClass: TComponentClass; var
Component: TComponent) of object;
```

C++

```
(Reader: TReader; ComponentClass: TComponentClass; var Component: TComponent) (
TCreateComponentEvent)();
```

File

Classes

Description

TCreateComponentEvent is for internal use only.

See Also

TReader (see page 2933)

23.5.14 Classes.TFilerFlags Type

TFilerFlags is the set of TFilerFlag (see page 3271) values.

Pascal

```
TFilerFlags = set of TFilerFlag;
```

C++

```
TFilerFlag TFilerFlags;
```

File

Classes

Description

TFilerFlags values are written to form files as a prefix to saved components. They indicate any special status of the component that the streaming system must take into account. TFilerFlags is a set containing all the flags that might pertain to a single component.

The following table lists the set of TFilerFlags values:

Value	Meaning
ffInherited	The component is an inherited form.
ffChildPos	The order in which this component is created is important.
ffInline	The component is a top-level component such as a form or data module.

See Also

TFilerFlag (see page 3271)

23.5.15 Classes.TFindAncestorEvent Type

TFindAncestorEvent is a procedure called by the TWriter (see page 3175) class OnFindAncestor event.

Pascal

```
TFindAncestorEvent = procedure (Writer: TWriter; Component: TComponent; const Name: string;
var Ancestor, RootAncestor: TComponent) of object;
```

C++

```
(Writer: TWriter; Component: TComponent; const Name: string; var Ancestor, RootAncestor:
TComponent) ( TFindAncestorEvent)();
```

File

Classes

Description

TFindAncestorEvent is for internal use only.

See Also

TWriter (see page 3175)

23.5.16 Classes.TFindComponentClassEvent Type

Pascal

```
TFindComponentClassEvent = procedure (Reader: TReader; const ClassName: string; var
ComponentClass: TComponentClass) of object;
```

C++

```
(Reader: TReader; const ClassName: string; var ComponentClass: TComponentClass) (
TFindComponentClassEvent)();
```

File

Classes

Description

This is type Classes.TFindComponentClassEvent.

23.5.17 Classes.TFindComponentInstanceEvent Type

Pascal

```
TFindComponentInstanceEvent = procedure (Reader: TReader; const Name: string; var Instance:
Pointer) of object;
```

C++

```
(Reader: TReader; const Name: string; var Instance: Pointer) ( TFindComponentInstanceEvent)();
```

File

Classes

Description

This is type Classes.TFindComponentInstanceEvent.

23.5.18 Classes.TFindGlobalComponent Type

Pascal

```
TFindGlobalComponent = function (const Name: string): TComponent;
```

C++

```
(const Name: string): TComponent ( TFindGlobalComponent)();
```

File

Classes

Description

This is type Classes.TFindGlobalComponent.

23.5.19 Classes.TFindMethodEvent Type

TFindMethodEvent is a procedure called by the TReader (see page 2933) class OnFindMethod event.

Pascal

```
TFindMethodEvent = procedure (Reader: TReader; const MethodName: string; var Address: Pointer;
var Error: Boolean) of object;
```

C++

```
(Reader: TReader; const MethodName: string; var Address: Pointer; var Error: Boolean) (
TFindMethodEvent)();
```

File

Classes

Description

TFindMethodEvent is for internal use only.

See Also

TReader (see page 2933)

23.5.20 Classes.TFindMethodInstanceEvent Type

TFindMethodInstanceEvent is a procedure called by the TReader (see page 2933) class OnFindMethodInstance event.

Pascal

```
TFindMethodInstanceEvent = procedure (Reader: TReader; const MethodName: string; var Method:
TMethod; var Error: Boolean) of object;
```

C++

```
(Reader: TReader; const MethodName: string; var Method: TMethod; var Error: Boolean) (
TFindMethodInstanceEvent)();
```

File

Classes

Description

TFindMethodInstanceEvent is for internal use only.

See Also

TReader (see page 2933)

23.5.21 Classes.TFindMethodNameEvent Type

TFindMethodNameEvent is a procedure called by the TWriter (see page 3175) class OnFindMethodName event.

Pascal

```
TFindMethodNameEvent = procedure (Writer: TWriter; Method: TMethod; var MethodName: string) of
object;
```

C++

```
(Writer: TWriter; Method: TMethod; var MethodName: string) ( TFindMethodNameEvent)();
```

File

Classes

Description

TFindMethodNameEvent is for internal use only.

See Also

TWriter (see page 3175)

23.5.22 Classes.TGetChildProc Type

TGetChildProc is a type of procedure called used internally by the TComponent (see page 2762) class.

Pascal

```
TGetChildProc = procedure (Child: TComponent) of object;
```

C++

```
(Child: TComponent) ( TGetChildProc)();
```

File

Classes

Description

TGetChildProc is for internal use only.

See Also

TComponent (see page 2762)

23.5.23 Classes.TGetClass Type

TGetClass is a callback procedure used by the TClassFinder (see page 2728) class.

Pascal

```
TGetClass = procedure (AClass: TPersistentClass) of object;
```

C++

```
(AClass: TPersistentClass) ( TGetClass)();
```

File

Classes

Description

TGetClass is a type of call back procedure that is called for each class reference found by the TClassFinder (see page 2728) class GetClasses method.

The class is passed to this procedure in **AClass**.

See Also

TClassFinder (see page 2728)

GetClasses (see page 2731)

23.5.24 Classes.TGetLookupInfoEvent Type

Pascal

```
TGetLookupInfoEvent = procedure (var Ancestor: TPersistent; var Root, LookupRoot,
RootAncestor: TComponent) of object;
```

C++

```
(var Ancestor: TPersistent; var Root, LookupRoot, RootAncestor: TComponent) (
TGetLookupInfoEvent)();
```

File

Classes

Description

This is type Classes.TGetLookupInfoEvent.

23.5.25 Classes.TGetModuleProc Type

Pascal

```
TGetModuleProc = procedure (const FileName, UnitName, FormName, DesignClass: string;
CoClasses: TStrings) of object;
```

C++

```
(const FileName, UnitName, FormName, DesignClass: string; CoClasses: TStrings) (
TGetModuleProc)();
```

File

Classes

Description

This is type Classes.TGetModuleProc.

23.5.26 Classes.TGetStrProc Type

TGetStrProc is a general purpose type of callback procedure invoked for each of a set of strings.

Pascal

```
TGetStrProc = procedure (const S: string) of object;
```

C++

```
(const S: string) ( TGetStrProc)();
```

File

Classes

Description

TGetChildProc (see page 3292) is used by a number of routines, such as -- to define the callback procedure to be called for each of a set of strings.

The string value is passed to the procedure in the **S** parameter.

See Also

GetCursorValues (see page 6251)

GetColorValues (see page 14619)

GetCharsetValues (see page 14615)

23.5.27 Classes.THelpContext Type

THelpContext is the range of values that a HelpContext value may have.

Pascal

```
THelpContext = -MaxLongint..MaxLongint;
```

C++

```
-MaxLongint..MaxLongint THelpContext;
```

File

Classes

Description

Help context specifies the help context for the action when it is set. THelpContext is the return type from the HelpContext property of a visual controls.

See Also

HelpContext (see page 311)

23.5.28 Classes.TIdentToInt Type

TIdentToInt is a type of callback function used by the IdentToInt (see page 3230) routine.

Pascal

```
TIdentToInt = function (const Ident: string; var Int: Longint): Boolean;
```

C++

```
(const Ident: string; var Int: Longint): Boolean ( TIdentToInt)();
```

File

Classes

Description

IdentToInt (see page 3230) provides the underlying translation from string identifiers to integers that occurs, for example, when you register a mapping using the RegisterIntegerConsts (see page 3259) procedure in Delphi.

Ident is the string identifier to translate.

Int returns the corresponding integer value.

See Also

RegisterIntegerConsts (see page 3259)

IntToIdent (see page 3232)

TIntToIdent (see page 3296)

23.5.29 Classes.TIntToIdent Type

TIntToIdent is a type of callback function used by the IntToIdent (see page 3232) routine.

Pascal

```
TIntToIdent = function (Int: Longint; var Ident: string): Boolean;
```

C++

```
(Int: Longint; var Ident: string): Boolean ( TIntToIdent)();
```

File

Classes

Description

TIntToIdent provides the underlying translation from integers to string identifiers that occurs, for example, when you register a mapping using the RegisterIntegerConsts (see page 3259) procedure in Delphi.

Int is the integer value to translate.

Ident is the corresponding string value.

See Also

RegisterIntegerConsts (see page 3259)

IntToIdent (see page 3232)

TIdentToInt (see page 3295)

23.5.30 Classes.TIsUniqueGlobalComponentName Type

TIsUniqueGlobalComponentName is a type of function used by IsUniqueGlobalComponentName (see page 3234).

Pascal

```
TIsUniqueGlobalComponentName = function (const Name: string): Boolean;
```

C++

```
(const Name: string): Boolean ( TIsUniqueGlobalComponentName)();
```

File

Classes

Description

TIsUniqueGlobalComponentName is a type cast of the IsUniqueGlobalComponentName (see page 3234) function.

IsUniqueGlobalComponentName (see page 3234) is used to determine whether a proposed component name is already used on any component on any form, data module, or other top-level container component.

See Also

IsUniqueGlobalComponentName (see page 3234)

23.5.31 Classes.TLeftRight Type

TLeftRight is a subset of TAlignment (see page 3269) that allows left or right justification.

Pascal

```
TLeftRight = taLeftJustify..taRightJustify;
```

C++

```
taLeftJustify..taRightJustify TLeftRight;
```

File

Classes

Description

TLeftRight is a subset of the TAlignment (see page 3269) type that allows left or right justification, but no center justification. The following table lists the possible values.

Value	Meaning
taLeftJustify	Left-justified: The left edges line up.
taRightJustify	Right-justified: The right edges line up.

See Also

TAlignment

23.5.32 Classes.TListSortCompare Type

TListSortCompare is a type of callback function called used internally by the TList (see page 2868) class.

Pascal

```
TListSortCompare = function (Item1, Item2: Pointer): Integer;
```

C++

```
(Item1, Item2: Pointer): Integer ( TListSortCompare)();
```

File

Classes

Description

You define a TListSortCompare function when you need to use the TList (see page 2868) Sort method. It is invoked by the internal implementation of the Sort method to sort the TList (see page 2868) elements into sequence. This user supplied aspect of the sort process is required since TList (see page 2868) is a list of pointers with no inherent sort sequence.

Item1 and **Item2** are 2 elements from the list. When these are passed to the TListSortCompare function, the Sort method is asking which order they should be in. The comparison returns a value determined by the relative values of **Item1** and **Item2**, as shown in this table:

Value	Description
>0 (positive)	**Item1** is less than **Item2**

0	**Item1** is equal to **Item2**
<0 (negative)	**Item1** is greater than **Item2**

See Also

Sort (see page 2892)

TList (see page 2868)

23.5.33 Classes.TNotifyEvent Type

TNotifyEvent is used for events that do not require parameters.

Pascal

```
TNotifyEvent = procedure (Sender: TObject) of object;
```

C++

```
(Sender: TObject) ( TNotifyEvent)();
```

File

Classes

Description

The TNotifyEvent type is the type for events that have no event-specific parameters. These events simply notify the component that a specific event occurred. For example, OnClick, which is of type TNotifyEvent, notifies the control that a click event occurred on the control.

The **Sender** parameter is the object whose event handler is called. For example, with the OnClick event of a button, the **Sender** parameter is the button component that is clicked.

23.5.34 Classes.TParserErrorEvent Type

TParserErrorEvent is a callback procedure used by the TClassFinder (see page 2728) class.

Pascal

```
TParserErrorEvent = procedure (Sender: TObject; const Message: string; var Handled: Boolean)
of object;
```

C++

```
(Sender: TObject; const Message: string; var Handled: Boolean) ( TParserErrorEvent)();
```

File

Classes

Description

TParserErrorEvent is a type of call back procedure that is called by the TParser (see page 2915) class OnError event.

Sender is a reference to the TParser (see page 2915) instance that has encountered an error and invoked the callback procedure.

Message is the error message.

Handled is a set to false if you want the error to raise an exception. If you want processing to continue, set this value to true.

See Also

TParser (see page 2915)

OnError (see page 2927)

23.5.35 Classes.TPersistentClass Type

TPersistentClass defines the metaclass for TPersistent (see page 2928).

Pascal

```
TPersistentClass = class of TPersistent;
```

C++

```
TPersistent * TPersistentClass;
```

File

Classes

Description

TPersistentClass is the metaclass for TPersistent (see page 2928). Its value is the class reference for TPersistent (see page 2928) or for one of its descendants.

See Also

TPersistent (see page 2928)

23.5.36 Classes.TPointerList Type

TPointerList is an array of pointers.

Pascal

```
TPointerList = array[0..MaxListSize - 1] of Pointer;
```

C++

```
array[0..MaxListSize - 1] of Pointer TPointerList;
```

File

Classes

Description

The TList (see page 2868) property of the TList (see page 2868) class returns a PPointerList (see page 3283) pointer to the list of pointers that TList (see page 2868) holds. TPointerList describes this array of pointers.

See Also

TList (see page 2868)

PPointerList (see page 3283)

23.5.37 Classes.TReadComponentsProc Type

TReadComponentsProc is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.

Pascal

```
TReadComponentsProc = procedure (Component: TComponent) of object;
```

C++

```
(Component: TComponent) ( TReadComponentsProc)();
```

File

Classes

Description

TReadComponentsProc is for internal use only.

See Also

ReadComponents (see page 2946)

TReader (see page 2933)

23.5.38 Classes.TReaderError Type

TReaderError is a type of callback procedure called used internally by the TReader (see page 2933) class ReadComponents method.

Pascal

```
TReaderError = procedure (Reader: TReader; const Message: string; var Handled: Boolean) of
object;
```

C++

```
(Reader: TReader; const Message: string; var Handled: Boolean) ( TReaderError)();
```

File

Classes

Description

TReaderError is a type of call back procedure that is called by the TReader (see page 2933) class OnError event.

Reader is a reference to the TReader (see page 2933) instance that has encountered an error and invoked the callback procedure.

Message is the error message.

Handled is a set to false if you want the error to raise an exception. If you want processing to continue, set this value to true.

See Also

OnError (see page 2961)

TReader (see page 2933)

23.5.39 Classes.TReaderProc Type

TReaderProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.

Pascal

```
TReaderProc = procedure (Reader: TReader) of object;
```

C++

```
(Reader: TReader) ( TReaderProc)();
```

File

Classes

Description

DefineProperty introduces an abstract method that allows descendants to read or write data like a property.

Each descendant filer object declares a DefineProperty method that defines the data that the descendant object will read or write as if the data were a property.

TReaderProc is the callback procedure parameter in that DefineProperty. When called, it supplies the TFiler (see page 2834) or descendant object, allowing read access.

See Also

DefineProperty (see page 2838)

DefineProperty (see page 2940)

DefineProperty (see page 3180)

TFiler (see page 2834)

TReader (see page 2933)

TWriter (see page 3175)

23.5.40 Classes.TReferenceNameEvent Type

TReferenceNameEvent is a procedure called by the TReader (see page 2933) class OnReferenceNameEvent event.

Pascal

```
TReferenceNameEvent = procedure (Reader: TReader; var Name: string) of object;
```

C++

```
(Reader: TReader; var Name: string) ( TReferenceNameEvent)();
```

File

Classes

Description

TReferenceNameEvent is for internal use only.

See Also

OnReferenceNameEvent

TReader (see page 2933)

23.5.41 Classes.TSetNameEvent Type

TSetNameEvent is a procedure called by the TReader (see page 2933) class OnSetNameEvent event.

Pascal

```
TSetNameEvent = procedure (Reader: TReader; Component: TComponent; var Name: string) of object;
```

C++

```
(Reader: TReader; Component: TComponent; var Name: string) ( TSetNameEvent)();
```

File

Classes

Description

TSetNameEvent is for internal use only.

See Also

OnSetNameEvent

TReader (see page 2933)

23.5.42 Classes.TShiftState Type

TShiftState indicates the state of the Alt, Ctrl, and Shift keys and the mouse buttons.

Pascal

```
TShiftState = set of (ssShift, ssAlt, ssCtrl, ssLeft, ssRight, ssMiddle, ssDouble);
```

C++

```
(ssShift, ssAlt, ssCtrl, ssLeft, ssRight, ssMiddle, ssDouble) TShiftState;
```

File

Classes

Description

The TShiftState type is used by key-event and mouse-event handlers to determine the state of the Alt, Ctrl, and Shift keys and the state of the mouse buttons when the event occurs. It is a set of flags that indicate the following:

Value	Meaning
ssShift	The Shift key is held down.
ssAlt	The Alt key is held down.
ssCtrl	The Ctrl key is held down.
ssLeft	The left mouse button is held down.

ssRight	The right mouse button is held down.
ssMiddle	The middle mouse button is held down.
ssDouble	The mouse was double-clicked.

TControl

TControl

OnKeyDown

OnKeyUp

23.5.43 Classes.TShortCut Type

TStringsDefined (see page 3306) defines an enumeration of string delimiter names.

Pascal

```
TShortCut = Low(Word)..High(Word);
```

C++

```
Low(Word)..High(Word) TShortCut;
```

File

Classes

Description

The TStringsDefined (see page 3306) type is used internally by Delphi as the set of possible string delimiters. The values are :

Value	Meaning
sdDelimiter	Separator between strings in a list. Such as read/set by Delimiter and used in DelimitedText.
sdQuoteChar	Quote character around strings in a list. Such as read/set by QuoteChar and used in DelimitedText.
sdNameValueSeparator	Defines the character that separates name and value pair strings (normally '='). Such as read/set by the NameValueSeparator property. Used by Names, Values and ValueFromIndex
sdLineBreak	Defines the line break character(s). Such as read/set by the LineBreak property.
sdStrictDelimiter	Defines whether only the specified sdDelimiter can be used to separate strings in a DelimitedText, or whether blanks or a non printable character can be used as well.

Note: References to TStrings (see page 3029) equally apply to TStringList (see page 3006).

See Also

DelimitedText (see page 3074)

Delimiter (see page 3074)

LineBreak (see page 3075)

NameValueSeparator (see page 3077)

Names (see page 3075)

QuoteChar (see page 3080)

StrictDelimiter (see page 3080)

TStrings (see page 3029)

TStringList (see page 3006)

ValueFromIndex (see page 3085)

Values (see page 3086)

23.5.44 Classes.TStreamProc Type

TStreamProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineBinaryProperty methods.

Pascal

```
TStreamProc = procedure (Stream: TStream) of object;
```

C++

```
(Stream: TStream) ( TStreamProc)();
```

File

Classes

Description

DefineBinaryProperty introduces an abstract method that allows descendants to read or write binary data like a property.

Each descendant Filer object declares a DefineProperty method that defines the data that the descendant object will read or write as if the data were a property.

TStreamProc is the callback procedure parameter in that DefineBinaryProperty. When called, it supplies the TFiler (see page 2834) or descendant object, allowing binary data read and write access.

See Also

DefineBinaryProperty (see page 2837)

DefineBinaryProperty (see page 2939)

DefineBinaryProperty (see page 3179)

TFiler (see page 2834)

TReader (see page 2933)

TWriter (see page 3175)

23.5.45 Classes.TStringItemList Type

TStringItemList defines an array of TStringItems.

Pascal

```
TStringItemList = array[0..MaxListSize] of TStringItem;
```

C++

```
array[0..MaxListSize] of TStringItem TStringItemList;
```

File

Classes

Description

TStringItemList is used internally by TStringList (see page 3006) to refer to its internal array of TStringItem (see page 3277) values. This array holds the list of strings.

TStringItem (see page 3277) comprises :

FString defines string for a list entry.

FObject points to an optional TObject associated with the string.

See Also

TStringItem (see page 3277)

TStringList (see page 3006)

23.5.46 Classes.TStringListSortCompare Type

TStringListSortCompare is a type of callback function called used internally by the TStringList (see page 3006) class.

Pascal

```
TStringListSortCompare = function (List: TStringList; Index1, Index2: Integer): Integer;
```

C++

```
(List: TStringList; Index1, Index2: Integer): Integer ( TStringListSortCompare)();
```

File

Classes

Description

You define a TStringListSortCompare function when you need to use the TStringList (see page 3006) CustomSort method. The procedure defined by TStringListSortCompare is invoked by CustomSort to sort the TStringList (see page 3006) elements into sequence.

CustomSort is used instead of Sort when the sort sequence required differs from the default alphanumeric sequence.

List is the list of strings.

Index1 and **Index2** are indexes into the list. When these are passed to the TListSortCompare (see page 3297) function, the CustomSort method is asking which order they should be in.

You return 0 if the entry referred to by **Index1** equals the entry referred to by **Index2**

You return less than 0 if the entry referred to by **Index1** is less than the entry referred to by **Index2**

You return a number above 0 if the entry referred to by **Index1** is greater than the entry referred to by **Index2**

Note: One of the principle advantages of the CustomSort method is that a TStringList (see page 3006) may be sorted according to the objects optionally attachable to each string.

See Also

CustomSort (see page 3014)

TStringList (see page 3006)

23.5.47 Classes.TStringsDefined Type

Pascal

```
TStringsDefined = set of (sdDelimiter, sdQuoteChar, sdNameValueSeparator, sdLineBreak,
sdStrictDelimiter);
```

C++

```
(sdDelimiter, sdQuoteChar, sdNameValueSeparator, sdLineBreak, sdStrictDelimiter)
TStringsDefined;
```

File

Classes

Description

This is type Classes.TStringsDefined.

23.5.48 Classes.TThreadMethod Type

Pascal

```
TThreadMethod = procedure of object;
```

C++

```
( TThreadMethod)();
```

File

Classes

Description

This is type Classes.TThreadMethod.

23.5.49 Classes.TTopBottom Type

TTopBottom is a subset of TVerticalAlignment (see page 3280) that allows top or bottom alignment.

Pascal

```
TTopBottom = taAlignTop..taAlignBottom;
```

C++

```
taAlignTop..taAlignBottom TTopBottom;
```

File

Classes

Description

TTopBottom is a subset of the TVerticalAlignment (see page 3280) type that allows top or bottom alignment, but no vertical center alignment. The following table lists the possible values.

Value	Meaning
taAlignTop	Text is aligned to the top edge of the control.
taAlignBottom	Text is aligned to the bottom edge of the control.

See Also

TVerticalAlignment (see page 3280)

23.5.50 Classes.TWndMethod Type

TWndMethod is the type for Windows message procedures.

Pascal

```
TWndMethod = procedure (var Message: TMessage) of object;
```

C++

```
(var Message: TMessage) ( TWndMethod)();
```

File

Classes

Description

Each Window has a message procedure that responds to calls from Windows. These calls can originate from Windows (such as paint messages), from user actions (such as mouse messages), or from your messages that you send in your own code.

TWndMethod is the type for VCL-based message procedures. Message procedures of this type can be assigned to controls using the WindowProc method. In addition, a window that implements this procedure but which is not associated with a control can be created using the AllocateHWnd (see page 3217) function.

The Message parameter encapsulates the message to which the procedure responds. It contains fields for the incoming message parameters and a result field that holds the return value.

See Also

TControl (see page 5724)

AllocateHWnd (see page 3217)

23.5.51 Classes.TWriterProc Type

TWriterProc is a type of callback procedure called used by TFiler (see page 2834) and descendant DefineProperty methods.

Pascal

```
TWriterProc = procedure (Writer: TWriter) of object;
```

C++

```
(Writer: TWriter) ( TWriterProc)();
```

File

Classes

Description

DefineProperty introduces an abstract method that allows descendants to read or write data like a property.

Each descendant filer object declares a DefineProperty method that defines the data that the descendant object will read or write as if the data were a property.

TWriterProc is the callback procedure parameter in that DefineProperty. When called, it supplies the TFiler (see page 2834) or descendant object, allowing write access.

See Also

DefineProperty (see page 2838)

DefineProperty (see page 2940)

DefineProperty (see page 3180)

TFiler (see page 2834)

TReader (see page 2933)

TWriter (see page 3175)

23.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AddDataModule (see page 3309)	Defines a procedure to be called when a TDataModule (see page 2824) class is created.
ApplicationHandleException (see page 3310)	This is variable Classes.ApplicationHandleException.
ApplicationShowException (see page 3310)	This is variable Classes.ApplicationShowException.
CreateVCLComObjectProc (see page 3310)	This is variable Classes.CreateVCLComObjectProc.
CurrentGroup (see page 3311)	Keeps track of which objects are associated with which packages.
GlobalNameSpace (see page 3311)	This is variable Classes.GlobalNameSpace.
IsUniqueGlobalComponentNameProc (see page 3311)	IsUniqueGlobalComponentNameProc is called by IsUniqueGlobalComponentName (see page 3234).
RegisterComponentsProc (see page 3312)	RegisterComponentsProc is called by RegisterComponents (see page 3256).
RegisterNoIconProc (see page 3313)	RegisterNoIconProc is called by RegisterNoIcon (see page 3260).
RegisterNonActiveXProc (see page 3313)	RegisterNonActiveXProc is called by RegisterNonActiveX (see page 3260).
RemoveDataModule (see page 3314)	Defines a procedure to be called when a TDataModule (see page 2824) class is destroyed.
WakeMainThread (see page 3314)	Represents a method (event handler) that is forced into the main thread's queue.

23.6.1 Classes.AddDataModule Variable

Defines a procedure to be called when a TDataModule (see page 2824) class is created.

Pascal

```
AddDataModule: procedure (DataModule: TDataModule) of object = nil;
```

C++

```
procedure (DataModule: TDataModule) of object AddDataModule = nil;
```

File

Classes

Description

If the AddDataModule variable is set, both Create and CreateNew will invoke the procedure it defines, passing itself in the **Sender** parameter.

See Also

Create (see page 2827)

CreateNew (see page 2828)

23.6.2 Classes.ApplicationHandleException Variable

Pascal

```
ApplicationHandleException: procedure (Sender: TObject) of object = nil;
```

C++

```
procedure (Sender: TObject) of object ApplicationHandleException = nil;
```

File

Classes

Description

This is variable Classes.ApplicationHandleException.

23.6.3 Classes.ApplicationShowException Variable

Pascal

```
ApplicationShowException: procedure (E: Exception) of object = nil;
```

C++

```
procedure (E: Exception) of object ApplicationShowException = nil;
```

File

Classes

Description

This is variable Classes.ApplicationShowException.

23.6.4 Classes.CreateVCLComObjectProc Variable

Pascal

```
CreateVCLComObjectProc: procedure(Component: TComponent) = nil;
```

C++

```
procedure(Component: TComponent) CreateVCLComObjectProc = nil;
```

File

Classes

Description

This is variable Classes.CreateVCLComObjectProc.

23.6.5 Classes.CurrentGroup Variable

Keeps track of which objects are associated with which packages.

Pascal

```
CurrentGroup: Integer = -1;
```

C++

```
int CurrentGroup = -1;
```

File

Classes

Description

When a design-time package registers a property editor class, the registration list has to keep track of what package that property editor class is associated with. Tracking this association ensures that if the package needs to be unloaded at design time (to recompile the package), the registration list knows which property classes to delete from its list. CurrentGroup is used to obtain an indicator that represents this association. It gets incremented every time a package is loaded at design time.

CurrentGroup is used to write design-time tools that keep track of things stored in other packages.

See Also

RegisterPropertyEditor

23.6.6 Classes.GlobalNameSpace Variable

Pascal

```
GlobalNameSpace: IReadWriteSync;
```

C++

```
IReadWriteSync GlobalNameSpace;
```

File

Classes

Description

This is variable Classes.GlobalNameSpace.

23.6.7 Classes.IsUniqueGlobalComponentNameProc Variable

IsUniqueGlobalComponentNameProc is called by IsUniqueGlobalComponentName (see page 3234).

Pascal

```
IsUniqueGlobalComponentNameProc: TIsUniqueGlobalComponentName;
```

C++

```
TIsUniqueGlobalComponentName IsUniqueGlobalComponentNameProc;
```

File

Classes

Description

IsUniqueGlobalComponentName (see page 3234) is used to determine whether a proposed component name is already used on any component on any form, data module, or other top-level container component.

If IsUniqueGlobalComponentNameProc is defined, it is invoked by IsUniqueGlobalComponentName (see page 3234) in place of this checking process.

See Also

IsUniqueGlobalComponentName (see page 3234)

TIsUniqueGlobalComponentName (see page 3296)

23.6.8 Classes.RegisterComponentsProc Variable

RegisterComponentsProc is called by RegisterComponents (see page 3256).

Pascal

```
RegisterComponentsProc: procedure(const Page: string; const ComponentClasses: array of
TComponentClass) = nil;
```

C++

```
procedure(const Page: string; const ComponentClasses: array of TComponentClass)
RegisterComponentsProc = nil;
```

File

Classes

Description

RegisterComponents (see page 3256) is used to install a set of components in the IDE. When it is invoked, it expects RegisterComponentsProc to be defined, and will throw an exception if not. If defined, it is invoked to carry out the component registration.

The **Page** parameter defines the name of the page on the component palette where the components will appear.

ComponentClasses parameter defines an array of Components to be added to the component palette.

See Also

RegisterComponents (see page 3256)

RegisterNoIconProc (see page 3313)

RegisterNonActiveXProc (see page 3313)

23.6.9 Classes.RegisterNoIconProc Variable

RegisterNoIconProc is called by RegisterNoIcon (see page 3260).

Pascal

```
RegisterNoIconProc: procedure(const ComponentClasses: array of TComponentClass) = nil;
```

C++

```
procedure(const ComponentClasses: array of TComponentClass) RegisterNoIconProc = nil;
```

File

Classes

Description

RegisterNoIcon (see page 3260) is used to register a set of custom components so that objects from that class can use the Object Inspector. When it is invoked, it expects RegisterNoIconProc to be defined, and will throw an exception if not. If defined, it is invoked to carry out the registration.

ComponentClasses parameter defines an array of Components to be registered.

See Also

RegisterComponents (see page 3256)

RegisterComponentsProc (see page 3312)

RegisterNonActiveXProc (see page 3313)

23.6.10 Classes.RegisterNonActiveXProc Variable

RegisterNonActiveXProc is called by RegisterNonActiveX (see page 3260).

Pascal

```
RegisterNonActiveXProc: procedure(const ComponentClasses: array of TComponentClass; AxRegType:
TActiveXRegType) = nil;
```

C++

```
procedure(const ComponentClasses: array of TComponentClass; AxRegType: TActiveXRegType)
RegisterNonActiveXProc = nil;
```

File

Classes

Description

RegisterNonActiveX (see page 3260) is used to prevent a registered set of custom components from being converted into ActiveX controls using the ActiveX wizard. It expects RegisterNonActiveXProc to be defined, and will throw an exception if not. If defined, it is invoked to carry out the protective process.

ComponentClasses parameter an array of custom classes that are descended from TComponent (see page 2762).

The **AxRegType** parameter indicates whether only the components in the **ComponentClasses** array should be blocked from the ActiveX wizard (when AxRegType is axrComponentOnly), or whether their descendants should be prohibited from becoming

ActiveX controls as well (when AxRegType is axrIncludeDescendants).

See Also

RegisterComponents (see page 3256)

RegisterComponentsProc (see page 3312)

RegisterNoIconProc (see page 3313)

23.6.11 Classes.RemoveDataModule Variable

Defines a procedure to be called when a TDataModule (see page 2824) class is destroyed.

Pascal

```
RemoveDataModule: procedure (DataModule: TDataModule) of object = nil;
```

C++

```
procedure (DataModule: TDataModule) of object RemoveDataModule = nil;
```

File

Classes

Description

If the RemoveDataModule variable is set, Destroy will invoke the procedure it defines, passing itself in the **Sender** parameter.

See Also

Destroy (see page 2829)

23.6.12 Classes.WakeMainThread Variable

Represents a method (event handler) that is forced into the main thread's queue.

Pascal

```
WakeMainThread: TNotifyEvent = nil;
```

C++

```
TNotifyEvent WakeMainThread = nil;
```

File

Classes

Description

Assign a method to WakeMainThread before calling a thread's Synchronize method. When you call a thread's Synchronize method, it calls the method assigned to WakeMainThread once it has obtained a lock on the main GUI thread. This allows other threads to quickly synchronize with the GUI thread even if no events are being processed due to an idle state.

Warning: Warning:Only set WakeMainThread from the application's main thread. This variable should never be set by a secondary thread while another thread's Synchronize method is executing.

See Also

CheckSynchronize (see page 3219)

TThread (see page 3108)

TApplication

23.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
fmCreate (see page 3316)	Specifies a file to be created with a specific name.
MaxListSize (see page 3317)	Defines the maximum capacity of certain list classes and types.
scAlt (see page 3317)	Specifies that the Alt key was pressed in a short cut menu.
scCtrl (see page 3318)	Specifies that the Ctrl key was pressed in a short cut menu.
scNone (see page 3318)	Specifies that none of the Shift, Ctrl or Alt keys were pressed in a short cut menu.
scShift (see page 3319)	Specifies that the Shift was pressed in a short cut menu.
soFromBeginning (see page 3319)	Specifies that a stream seek operation should move relative to the stream beginning.
soFromCurrent (see page 3320)	Specifies that a stream seek operation should move relative to the current position.
soFromEnd (see page 3320)	Specifies that a stream seek operation should move relative to the stream end.
toEOF (see page 3321)	Specifies a TParser (see page 2915) End of file token.
toFloat (see page 3322)	Specifies a TParser (see page 2915) floating point number token.
toInteger (see page 3322)	Specifies a TParser (see page 2915) integer token.
toString (see page 3323)	Specifies a TParser (see page 2915) string token.
toSymbol (see page 3324)	Specifies a TParser (see page 2915) symbol token.
toWString (see page 3324)	Specifies a TParser (see page 2915) wide string token.

23.7.1 Classes.fmCreate Constant

Specifies a file to be created with a specific name.

Pascal

```
fmCreate = $FFFF;
```

C++

```
fmCreate = 0xFFFF;
```

File

Classes

Description

fmCreate is one of the values you pass to the Create method when specifying a file to be ready for read/write. The TFileStream (see page 2841) is used to read and write files. It specifies that a new file is to be created.

See Also

fmOpenRead (see page 23046)

fmOpenReadWrite (see page 23047)

fmOpenWrite (see page 23047)

faShareCompat

faShareDenyNone

faShareDenyRead

faShareDenyWrite

faShareExclusive

FileMode (see page 22644)

Create (see page 2843)

23.7.2 Classes.MaxListSize Constant

Defines the maximum capacity of certain list classes and types.

Pascal

```
MaxListSize = Maxint div 16;
```

C++

```
MaxListSize = Maxint div 16;
```

File

Classes

Description

MaxListSize degines the maximum capacity - the maximum number of elements - of list types such as TList (see page 2868). This integer value is a 1/16th of MaxInt - the maximum size of an Integer data type.

See Also

TList (see page 2868)

TPointerList (see page 3299)

TStringItemList (see page 3304)

23.7.3 Classes.scAlt Constant

Specifies that the Alt key was pressed in a short cut menu.

Pascal

```
scAlt = $8000;
```

C++

```
scAlt = 0x8000;
```

File

Classes

Description

scAlt is principally used in the TShortCut (see page 3303) value used by routines such as ShortCut. ShortCut is used to generate short cut menus at run time.

See Also

scCtrl (see page 3318)

scNone (see page 3318)

scShift (see page 3319)

ShortCut

TShortCut (see page 3303)

23.7.4 Classes.scCtrl Constant

Specifies that the Ctrl key was pressed in a short cut menu.

Pascal

```
scCtrl = $4000;
```

C++

```
scCtrl = 0x4000;
```

File

Classes

Description

scCtrl is principally used in the TShortCut (see page 3303) value used by routines such as ShortCut. ShortCut is used to generate short cut menus at run time.

See Also

scAlt (see page 3317)

scNone (see page 3318)

scShift (see page 3319)

ShortCut

TShortCut (see page 3303)

23.7.5 Classes.scNone Constant

Specifies that none of the Shift, Ctrl or Alt keys were pressed in a short cut menu.

Pascal

```
scNone = 0;
```

C++

```
scNone = 0;
```

File

Classes

Description

scNone is principally used in the TShortCut (see page 3303) value used by routines such as ShortCut. ShortCut is used to generate short cut menus at run time.

See Also

scAlt (see page 3317)

scCtrl (see page 3318)

scShift (see page 3319)

ShortCut

TShortCut (see page 3303)

23.7.6 Classes.scShift Constant

Specifies that the Shift was pressed in a short cut menu.

Pascal

```
scShift = $2000;
```

C++

```
scShift = 0x2000;
```

File

Classes

Description

scShift is principally used in the TShortCut (see page 3303) value used by routines such as ShortCut. ShortCut is used to generate short cut menus at run time.

See Also

scAlt (see page 3317)

scCtrl (see page 3318)

scNone (see page 3318)

ShortCut

TShortCut (see page 3303)

23.7.7 Classes.soFromBeginning Constant

Specifies that a stream seek operation should move relative to the stream beginning.

Pascal

```
soFromBeginning = 0;
```

C++

```
soFromBeginning = 0;
```

File

Classes

Description

soFromBeginning is one of the TSeekOrigin (see page 3276) values you use to pass to the TSream Seek method. It specifies that the seek proceed to an offset from the beginning of the stream.

See Also

Seek (see page 2988)

TStream (see page 2973)

soFromCurrent (see page 3320)

soFromEnd (see page 3320)

TSeekOrigin (see page 3276)

23.7.8 Classes.soFromCurrent Constant

Specifies that a stream seek operation should move relative to the current position.

Pascal

```
soFromCurrent = 1;
```

C++

```
soFromCurrent = 1;
```

File

Classes

Description

soFromCurrent is one of the TSeekOrigin (see page 3276) values you use to pass to the TSream Seek method. It specifies that the seek proceed to an offset from the current position in the stream.

See Also

Seek (see page 2988)

TStream (see page 2973)

soFromBeginning (see page 3319)

soFromEnd (see page 3320)

TSeekOrigin (see page 3276)

23.7.9 Classes.soFromEnd Constant

Specifies that a stream seek operation should move relative to the stream end.

Pascal

```
soFromEnd = 2;
```

C++

```
soFromEnd = 2;
```

File

Classes

Description

soFromEnd is one of the TSeekOrigin (see page 3276) values you use to pass to the TSream Seek method. It specifies that the seek proceed to an offset from the end of the stream.

See Also

Seek (see page 2988)

TStream (see page 2973)

soFromCurrent (see page 3320)

soFromBeginning (see page 3319)

TSeekOrigin (see page 3276)

23.7.10 Classes.toEOF Constant

Specifies a TParser (see page 2915) End of file token.

Pascal

```
toEOF = Char(0);
```

C++

```
toEOF = Char(0);
```

File

Classes

Description

toEOF is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toEOF specifies that the end of the file (EOF) has occured.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

See Also

toFloat (see page 3322)

toInteger (see page 3322)

toString (see page 3323)

toSymbol (see page 3324)

toWString (see page 3324)

TParser (see page 2915)

23.7.11 Classes.toFloat Constant

Specifies a TParser (see page 2915) floating point number token.

Pascal

```
toFloat = Char(4);
```

C++

```
toFloat = Char(4);
```

File

Classes

Description

toFloat is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toFloat specifies that a floating point number value has been encountered. The value is available in the TokenFloat property. It is also available in its original string form in the TokenString property.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

See Also

toEOF (see page 3321)

toInteger (see page 3322)

TokenFloat (see page 2923)

TokenString (see page 2924)

toString (see page 3323)

toSymbol (see page 3324)

toWString (see page 3324)

TParser (see page 2915)

23.7.12 Classes.toInteger Constant

Specifies a TParser (see page 2915) integer token.

Pascal

```
toInteger = Char(3);
```

C++

```
toInteger = Char(3);
```

File

Classes

Description

toInteger is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toInteger specifies that an integer value has been encountered. The value is available in the TokenInteger property. It is also available in its original string form in the TokenString property.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

See Also

toEOF (see page 3321)

toFloat (see page 3322)

TokenInteger

toSymbol (see page 3324)

toWString (see page 3324)

TParser (see page 2915)

23.7.13 Classes.toString Constant

Specifies a TParser (see page 2915) string token.

Pascal

```
toString = Char(2);
```

C++

```
toString = Char(2);
```

File

Classes

Description

toString is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toString specifies that a string value has been encountered. The value is available in the TokenString property.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

TokenString (see page 2924)

toInteger (see page 3322)

toSymbol (see page 3324)

toWString (see page 3324)

TParser (see page 2915)

23.7.14 Classes.toSymbol Constant

Specifies a TParser (see page 2915) symbol token.

Pascal

```
toSymbol = Char(1);
```

C++

```
toSymbol = Char(1);
```

File

Classes

Description

toSymbol is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toSymbol specifies that a symbol value has been encountered. 'object', 'Left' and 'end' are typical DFM symbols. They are like Delphi keywords, as opposed to integer, string, widestring and float values that occur following a symbol and '=' sign combination.

The value is available in the TokenString property.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

toString (see page 3323)

toWString (see page 3324)

TParser (see page 2915)

23.7.15 Classes.toWString Constant

Specifies a TParser (see page 2915) wide string token.

Pascal

```
toWString = Char(5);
```

C++

```
toWString = Char(5);
```

File

Classes

Description

toWString is one of a number of Char values that are used by the TParser (see page 2915). These are tokens, representing the type of information that TParser (see page 2915) has found whilst parsing.

toWString specifies that a wide string value has been encountered. The value is available in the TokenWideString property.

Note: TParser (see page 2915) is principally used internally by Delphi to parse DFM (form) source files. It can be used as a more general parser, but only for files similar in format to DFM files.

24 Clipbrd Namespace

This is namespace Clipbrd.

Topics

Name	Description
Classes (see page 3328)	The following table lists classes in this documentation.
Functions (see page 3351)	The following table lists functions in this documentation.
Variables (see page 3354)	The following table lists variables in this documentation.

Classes

	Name	Description
	TClipboard (see page 3328)	TClipboard represents the system clipboard.

Functions

	Name	Description
	Clipboard (see page 3351)	Returns an instance of TClipboard (see page 3328).
	SetClipboard (see page 3353)	Replaces the single global clipboard instance with another clipboard object.

Variables

Name	Description
CF_COMPONENT (see page 3354)	This is variable Clipbrd.CF_COMPONENT.
CF_PICTURE (see page 3354)	This is variable Clipbrd.CF_PICTURE.

24.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TClipboard (see page 3328)	TClipboard represents the system clipboard.

24.1.1 TClipboard Class

TClipboard represents the system clipboard.

Class Hierarchy

Pascal

```
TClipboard = class(TPersistent);
```

C++

```
class TClipboard : public TPersistent;
```

File

Clipbrd

Description

TClipboard is a wrapper for the system clipboard, which contains information that has been cut or copied from an application.

Do not instantiate separate TClipboard objects by calling the constructor. Instead, use the global instance of TClipboard returned by the Clipboard (see page 3351) function. This allows applications to share a single instance of TClipboard and safeguards against accidental deletion of the clipboard.

Before calling Clipboard (see page 3351), your application must include the Clipbrd (see page 3327) unit. That is, in Delphi, the uses clause must include Clipbrd (see page 3327) and in C++ you must have an include statement for Clipbrd.hpp.

TClipboard's properties provide information about the formats that the clipboard is registered to handle.

TClipboard's methods

store and retrieve data in appropriate formats.

open and close the clipboard, maintaining a reference count.

manage formats for objects in the clipboard.

24.1.1.1 TClipboard Members

The following tables list the members exposed by TClipboard.

Protected Methods

	Name	Description
V	AssignTo (see page 3333)	Copies the properties of an object to a destination object.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	MainWndProc (see page 3342)	This is MainWndProc, a member of class TClipboard.
	SetBuffer (see page 3345)	This is SetBuffer, a member of class TClipboard.
V	WndProc (see page 3346)	This is WndProc, a member of class TClipboard.

Protected Properties

	Name	Description
R	Handle (see page 3349)	This is Handle, a member of class TClipboard.
R	OpenRefCount (see page 3349)	This is OpenRefCount, a member of class TClipboard.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 3331)	Copies an object to the clipboard.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 3333)	Deletes the contents of the clipboard.
V	Close (see page 3336)	Closes the clipboard if it is open.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 3330)	Destroys the TPersistent instance and frees its memory.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetAsHandle (see page 3336)	Returns a Windows handle to data from the clipboard in the specified format.
	GetComponent (see page 3339)	Retrieves a component from the clipboard.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetTextBuf (see page 3340)	Retrieves text from the clipboard and copies it to a buffer.
	HasFormat (see page 3340)	Indicates whether the clipboard contains data in a specified format.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Open (see page 3342)	Opens the clipboard, preventing other applications from changing its contents until the clipboard is closed.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetAsHandle (see page 3343)	Places data represented by a specified handle on the clipboard.
	SetComponent (see page 3345)	Copies a component to the clipboard.
	SetTextBuf (see page 3346)	Writes a text buffer to the Clipboard (see page 3351).

Public Properties

	Name	Description
	AsText (see page 3347)	Represents the contents of the clipboard as a string.
R	FormatCount (see page 3348)	Specifies the number of formats in the Formats (see page 3348) array property.
R	Formats (see page 3348)	Provides indexed access to all the formats the clipboard contains.

24.1.1.2 TClipboard.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TClipboard();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Destroy (see page 22287)

24.1.1.3 TClipboard Methods

The methods of the TClipboard class are listed here.

Protected Methods

	Name	Description
V	AssignTo (see page 3333)	Copies the properties of an object to a destination object.
	MainWndProc (see page 3342)	This is MainWndProc, a member of class TClipboard.
	SetBuffer (see page 3345)	This is SetBuffer, a member of class TClipboard.
V	WndProc (see page 3346)	This is WndProc, a member of class TClipboard.

Public Methods

	Name	Description
V	Assign (see page 3331)	Copies an object to the clipboard.
V	Clear (see page 3333)	Deletes the contents of the clipboard.
V	Close (see page 3336)	Closes the clipboard if it is open.
	GetAsHandle (see page 3336)	Returns a Windows handle to data from the clipboard in the specified format.

	GetComponent (see page 3339)	Retrieves a component from the clipboard.
	GetTextBuf (see page 3340)	Retrieves text from the clipboard and copies it to a buffer.
	HasFormat (see page 3340)	Indicates whether the clipboard contains data in a specified format.
V	Open (see page 3342)	Opens the clipboard, preventing other applications from changing its contents until the clipboard is closed.
	SetAsHandle (see page 3343)	Places data represented by a specified handle on the clipboard.
	SetComponent (see page 3345)	Copies a component to the clipboard.
	SetTextBuf (see page 3346)	Writes a text buffer to the Clipboard (see page 3351).

24.1.1.3.1 TClipboard.Assign Method

Copies an object to the clipboard.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to copy pictures to and from the clipboard. For example, the following code copies the bitmap from a TBitmap instance (Bitmap1) to the clipboard.

```
Clipboard.Assign(Bitmap1); {Delphi}
Clipboard()->Assign(Bitmap1); // C++
```

If a bitmap is on the clipboard, the following code copies it to Bitmap1.

```
Bitmap1.Assign(Clipboard); {Delphi}
Bitmap1->Assign(Clipboard()); // C++
```

The Formats (see page 3348) property lists the formats used by the clipboard. Different kinds of graphic object (such as bitmaps and metafiles) have their own formats. Use the HasFormat (see page 3340) method to determine whether the information on the clipboard is stored in a format compatible with the object you want to assign it to.

C++ Examples:

```
/*
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
*/

#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *FormImage = GetFormImage();
  try
  {
    Clipboard()->Assign(FormImage);
    Image1->Picture->Assign(Clipboard());
  }
  __finally
  {
    delete FormImage;
  }
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Shape1->Shape = stEllipse;
  Shape1->Brush->Color = clLime;
  Image1->Stretch = true;
}
```

Delphi Examples:

```
{
The following line copies the bitmap of a speed button named
SpeedButton1 to the clipboard and then copies the clipboard
to the image picture.  Note that you must add Clipbrd to the
uses clause.
}
uses Clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Clipboard.Assign(SpeedButton1.Glyph);
  Image1.Stretch := True;
  Image1.Picture.Assign(Clipboard);
end;
{
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FormImage: TBitmap;
begin
  FormImage := GetFormImage;
  try
    Clipboard.Assign(FormImage);
    Image1.Picture.Assign(Clipboard);
  finally
    FormImage.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Shape1.Shape := stEllipse;
  Shape1.Brush.Color := clLime;
  Image1.Stretch := True;
end;
```

See Also

Formats (see page 3348)

HasFormat (see page 3340)

Assign (see page 14402)

Assign (see page 2930)

24.1.1.3.2 TClipboard.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

24.1.1.3.3 TClipboard.Clear Method

Deletes the contents of the clipboard.

Pascal

```
procedure Clear; virtual;
```

C++

```
virtual __fastcall Clear();
```

Description

Call Clear to empty the clipboard.

Clear is called automatically by TClipboard (see page 3328) operations that add data to the clipboard.

C++ Examples:

```
/*
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
```

```
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
*/
#include <Clipbrd.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (Clipboard()->HasFormat(CF_TEXT))
  {
    Edit1->Text = Clipboard()->AsText;
    Clipboard()->Clear();
  }
  else
    MessageDlg(
      "There is no text on the Clipboard",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
```

```
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
if Clipboard.HasFormat(CF_TEXT) then
  begin
  Edit1.Text := Clipboard.AsText;
  Clipboard.Clear;
  end
else
  MessageDlg(
    'There is no text on the Clipboard',
    mtInformation, [mbOK],0);
end;
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
   Clipboard.Clear;
 end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
```

```
    try
      Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
  Shared\Images\Splash\256color\factory.bmp');
      Bitmap.SaveToClipBoardFormat(
        MyFormat,
        AData,
        APalette);
      ClipBoard.SetAsHandle(MyFormat,AData);
    finally
      Bitmap.Free;
    end;
  end;
```

24.1.1.3.4 TClipboard.Close Method

Closes the clipboard if it is open.

Pascal

```
procedure Close; virtual;
```

C++

```
virtual __fastcall Close();
```

Description

Call Close when you are finished adding items to the clipboard.

The clipboard can be opened with multiple calls to the Open (see page 3342) method before being closed. Open (see page 3342) and Close maintain a count of the number of times the clipboard has been opened and will not close it until Close has been called the same number of times.

Delphi Examples:

```
{
Open, Close, GetAsHandle example
The following code locks the memory for text on the Clipboard, then reads the text.
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
  MyHandle: THandle;
  TextPtr: PChar;
begin
  ClipBoard.Open;
try
  MyHandle := Clipboard.GetAsHandle(CF_TEXT);
  TextPtr := GlobalLock(MyHandle);
  ListBox1.Items.Add(StrPas(TextPtr));
  GlobalUnlock(MyHandle);
finally
  Clipboard.Close;
end;
end;
```

See Also

Open (see page 3342)

24.1.1.3.5 TClipboard.GetAsHandle Method

Returns a Windows handle to data from the clipboard in the specified format.

Pascal

```
function GetAsHandle(Format: Word): THandle;
```

C++

```
__fastcall THandle GetAsHandle(Word Format);
```

Description

GetAsHandle retrieves data from the clipboard using Windows handles.

The handle returned by GetAsHandle is not owned by the application and is valid only as long as the clipboard is open. If you need it for longer, copy the data to another handle.

The Format parameter can specify any of the formats listed under the HasFormat (see page 3340) method. Applications can also define and register their own formats. See the Windows API Help for more information.

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
```

```
        DataHandle,
        APalette);
      // save the data to the clipboard using that format and
      // the generated data
      Clipboard()->SetAsHandle(MyFormat,DataHandle);
    }
    catch (...)
    {
       ShowMessage("Failed to copy image to clipboard!");
    }
    delete Bitmap;
  }
```

Delphi Examples:

```
{
Open, Close, GetAsHandle example
The following code locks the memory for text on the Clipboard, then reads the text.
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
  MyHandle: THandle;
  TextPtr: PChar;
begin
  ClipBoard.Open;
try
  MyHandle := Clipboard.GetAsHandle(CF_TEXT);
  TextPtr := GlobalLock(MyHandle);
  ListBox1.Items.Add(StrPas(TextPtr));
  GlobalUnlock(MyHandle);
finally
  Clipboard.Close;
end;
end;
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
   Clipboard.Clear;
 end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
```

```
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
    Bitmap.SaveToClipBoardFormat(
      MyFormat,
      AData,
      APalette);
    ClipBoard.SetAsHandle(MyFormat,AData);
  finally
    Bitmap.Free;
  end;
end;
```

SetAsHandle (see page 3343)

HasFormat (see page 3340)

24.1.1.3.6 TClipboard.GetComponent Method

Retrieves a component from the clipboard.

Pascal

```
function GetComponent(Owner: TComponent; Parent: TComponent): TComponent;
```

C++

```
__fastcall TComponent * GetComponent(TComponent * Owner, TComponent * Parent);
```

Description

Use GetComponent to retrieve a component that is stored on the clipboard.

Owner becomes the owner of the retrieved component and Parent becomes its parent. Owner is usually a form, but both parameters can be nil (Delphi) or NULL (C++).

Before a class is read from the clipboard, it must be registered by a call to RegisterClasses. If you try to read an unregistered class, you'll get an EClassNotFound exception.

Delphi Examples:

```
{
This example uses a button and a group box on a form. When
the user clicks the button, the button is copied to the
Clipboard and then retrieved from the Clipboard and placed
in the new parent of the button, the group box. The name of
the original button is changed to avoid having two components
with the same name at the same time.
}
implementation

uses Clipbrd;

{$R *.dfm}

procedure TForm1.Button1Click(Sender: TObject);
var
  groupButton : TButton;
begin
  { copy the button to the clipboard }
  Clipboard.SetComponent(Button1);
  { rename the button which is still on the form }
```

```
    Button1.Name := 'OriginalButton';
    { Now retrieve the button from the clipboard }
    { and add it to GroupBox1 }
    { Note that the clipboard button is named Button1, while }
    { the source button has been renamed to 'OriginalButton' }
    groupButton := TButton(Clipboard.GetComponent(Self, GroupBox1));
    groupButton.top := Button1.top + 30;
  end;

  initialization
    RegisterClasses([TButton]);{ registers the TButton class }
```

See Also

EClassNotFound (see page 2694)

RegisterClasses

SetComponent (see page 3345)

24.1.1.3.7 TClipboard.GetTextBuf Method

Retrieves text from the clipboard and copies it to a buffer.

Pascal

```
function GetTextBuf(Buffer: PChar; BufSize: Integer): Integer;
```

C++

```
__fastcall int GetTextBuf(const char * Buffer, int BufSize);
```

Description

Use GetTextBuf to retrieve text from the clipboard and copy it into the buffer pointed to by Buffer. GetTextBuf copies up to the number of characters given by BufSize and returns the number of characters copied. The resulting text in Buffer is a null-terminated string.

See Also

SetTextBuf (see page 3346)

GetAsHandle (see page 3336)

24.1.1.3.8 TClipboard.HasFormat Method

Indicates whether the clipboard contains data in a specified format.

Pascal

```
function HasFormat(Format: Word): Boolean;
```

C++

```
__fastcall Boolean HasFormat(Word Format);
```

Description

Use HasFormat to find out whether the clipboard contains data encoded in a specific format. HasFormat returns true if the format is present and false otherwise. TClipboard (see page 3328) keeps a list of available formats in the Formats (see page 3348) array property.

Some of the possible values of the Format parameter follow. HasFormat supports additional formats provided by Windows or by other applications as well as custom formats registered with TPicture::.RegisterClipboardFormat.

Value	Meaning
CF_TEXT	Text with a CR-LF combination at the end of each line. A null character identifies the end of the text.
CF_BITMAP	A Windows bitmap graphic.
CF_METAFILEPICT	A Windows metafile graphic.
CF_PICTURE (see page 3354)	An object of type TPicture.
CF_COMPONENT (see page 3354)	Any persistent object.

C++ Examples:

```
/*
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
*/
#include <Clipbrd.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (Clipboard()->HasFormat(CF_TEXT))
  {
    Edit1->Text = Clipboard()->AsText;
    Clipboard()->Clear();
  }
  else
    MessageDlg(
      "There is no text on the Clipboard",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
if Clipboard.HasFormat(CF_TEXT) then
  begin
  Edit1.Text := Clipboard.AsText;
  Clipboard.Clear;
  end
else
  MessageDlg(
    'There is no text on the Clipboard',
    mtInformation, [mbOK],0);
end;
```

Pasting Graphics from the Clipboard

24.1.1.3.9 TClipboard.MainWndProc Method

Pascal

```
procedure MainWndProc(var Message: TMessage);
```

C++

```
__fastcall MainWndProc(TMessage Message);
```

Description

This is MainWndProc, a member of class TClipboard.

24.1.1.3.10 TClipboard.Open Method

Opens the clipboard, preventing other applications from changing its contents until the clipboard is closed.

Pascal

```
procedure Open; virtual;
```

C++

```
virtual __fastcall Open();
```

Description

Call Open before adding a series of items to the clipboard. This prevents other applications from overwriting the clipboard until it is closed. (When adding a single item to the clipboard, there is no need to call Open.)

When an application has finished adding items to the clipboard, it should call the Close (see page 3336) method. The clipboard can be opened with multiple calls to the Open method before being closed. Open and Close (see page 3336) maintain a count of the number of times the clipboard has been opened and will not close it until Close (see page 3336) has been called the same number of times.

Delphi Examples:

```
{
Open, Close, GetAsHandle example
The following code locks the memory for text on the Clipboard, then reads the text.
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
  MyHandle: THandle;
  TextPtr: PChar;
begin
  ClipBoard.Open;
try
  MyHandle := Clipboard.GetAsHandle(CF_TEXT);
  TextPtr := GlobalLock(MyHandle);
  ListBox1.Items.Add(StrPas(TextPtr));
  GlobalUnlock(MyHandle);
finally
  Clipboard.Close;
end;
end;
```

See Also

Close (see page 3336)

24.1.1.3.11 TClipboard.SetAsHandle Method

Places data represented by a specified handle on the clipboard.

Pascal

```
procedure SetAsHandle(Format: Word; Value: THandle);
```

C++

```
__fastcall SetAsHandle(Word Format, THandle Value);
```

Description

SetAsHandle writes data represented by the specified handle (Value) to the clipboard using the specified format.

Do not delete a handle after passing it to SetAsHandle. The handle belongs to the clipboard, which will free it.

The Format parameter can specify any of the formats listed under the HasFormat (see page 3340) method. Applications can also define and register their own formats. See the Windows API Help for more information.

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
```

```
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
   Clipboard.Clear;
 end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
    Bitmap.SaveToClipBoardFormat(
      MyFormat,
      AData,
      APalette);
    ClipBoard.SetAsHandle(MyFormat,AData);
  finally
    Bitmap.Free;
  end;
```

```
end;
```

See Also

GetAsHandle (see page 3336)

HasFormat (see page 3340)

24.1.1.3.12 TClipboard.SetBuffer Method

Pascal

```
procedure SetBuffer(Format: Word; var Buffer; Size: Integer);
```

C++

```
__fastcall SetBuffer(Word Format,  Buffer, int Size);
```

Description

This is SetBuffer, a member of class TClipboard.

24.1.1.3.13 TClipboard.SetComponent Method

Copies a component to the clipboard.

Pascal

```
procedure SetComponent(Component: TComponent);
```

C++

```
__fastcall SetComponent(TComponent * Component);
```

Description

Use SetComponent to copy a component to the clipboard.

Delphi Examples:

```
{
This example uses a button and a group box on a form. When
the user clicks the button, the button is copied to the
Clipboard and then retrieved from the Clipboard and placed
in the new parent of the button, the group box. The name of
the original button is changed to avoid having two components
with the same name at the same time.
}
implementation

uses Clipbrd;

{$R *.dfm}

procedure TForm1.Button1Click(Sender: TObject);
var
  groupButton : TButton;
begin
  { copy the button to the clipboard }
  Clipboard.SetComponent(Button1);
  { rename the button which is still on the form }
  Button1.Name := 'OriginalButton';
  { Now retrieve the button from the clipboard }
  { and add it to GroupBox1 }
  { Note that the clipboard button is named Button1, while }
  { the source button has been renamed to 'OriginalButton' }
  groupButton := TButton(Clipboard.GetComponent(Self, GroupBox1));
```

```
  groupButton.top := Button1.top + 30;
end;

initialization
  RegisterClasses([TButton]);{ registers the TButton class }
```

See Also

GetComponent (see page 3339)

24.1.1.3.14 TClipboard.SetTextBuf Method

Writes a text buffer to the Clipboard (see page 3351).

Pascal

```
procedure SetTextBuf(Buffer: PChar);
```

C++

```
__fastcall SetTextBuf(const char * Buffer);
```

Description

Use SetTextBuf to copy text to the clipboard from a buffer. Buffer must point to a null-terminated string.

See Also

GetTextBuf (see page 3340)

24.1.1.3.15 TClipboard.WndProc Method

Pascal

```
procedure WndProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

This is WndProc, a member of class TClipboard.

24.1.1.4 TClipboard Properties

The properties of the TClipboard class are listed here.

Protected Properties

	Name	Description
R	Handle (see page 3349)	This is Handle, a member of class TClipboard.
R	OpenRefCount (see page 3349)	This is OpenRefCount, a member of class TClipboard.

Public Properties

	Name	Description
	AsText (see page 3347)	Represents the contents of the clipboard as a string.
R	FormatCount (see page 3348)	Specifies the number of formats in the Formats (see page 3348) array property.
R	Formats (see page 3348)	Provides indexed access to all the formats the clipboard contains.

24.1.1.4.1 TClipboard.AsText Property

Represents the contents of the clipboard as a string.

Pascal

```
property AsText: string;
```

C++

```
__property AnsiString AsText;
```

Description

Use the AsText property to place text in and retrieve text from the clipboard. The clipboard must contain a string or an exception occurs. To determine if the clipboard contains a string, pass CF_TEXT to the HasFormat (see page 3340) method.

C++ Examples:

```
/*
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
*/
#include <Clipbrd.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (Clipboard()->HasFormat(CF_TEXT))
  {
    Edit1->Text = Clipboard()->AsText;
    Clipboard()->Clear();
  }
  else
    MessageDlg(
      "There is no text on the Clipboard",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This example uses a button and an TEdit on a form. When the
user clicks the button, any text on the clipboard is pasted
into the TEdit.  If there is no text on the clipboard, a
message box appears.
Note:  To use this example, you must add Clipbrd to the uses
clause.  Load the Clipboard by performing a copy in any
application.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
if Clipboard.HasFormat(CF_TEXT) then
  begin
  Edit1.Text := Clipboard.AsText;
  Clipboard.Clear;
  end
else
  MessageDlg(
    'There is no text on the Clipboard',
    mtInformation, [mbOK],0);
end;
```

See Also

GetTextBuf (see page 3340)

HasFormat (see page 3340)

SetTextBuf (see page 3346)

24.1.1.4.2 TClipboard.FormatCount Property

Specifies the number of formats in the Formats (see page 3348) array property.

Pascal

```
property FormatCount: Integer;
```

C++

```
__property int FormatCount;
```

Description

Use FormatCount to find the number of different format types used to encode the information currently stored in the clipboard. FormatCount is read-only.

To find out if a particular format is available on the clipboard, use the HasFormat (see page 3340) method.

Delphi Examples:

```
{
FormatCount, Formats example
The following code adds each format on the Clipboard to ListBox1 when Button1 is clicked.
Note: You will need to add Clipbrd to the uses clause (Delphi) or include <Clipbrd.hpp> (C++).
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Clipboard.FormatCount - 1 do
    ListBox1.Items.Add(IntToStr(Clipboard.Formats[I]));
end;
```

See Also

Formats (see page 3348)

HasFormat (see page 3340)

RegisterClipboardFormat (see page 14592)

24.1.1.4.3 TClipboard.Formats Property

Provides indexed access to all the formats the clipboard contains.

Pascal

```
property Formats [Index: Integer]: Word;
```

C++

```
__property Word Formats[int Index];
```

Description

Read Formats to determine what formats encode the information currently on the clipboard. Each format can be accessed by its position in the array.

Usually, when an application copies or cuts something to the clipboard, it places it there in multiple formats. An application can place items of a particular format on the clipboard and retrieve items with a particular format from the clipboard if the format is in the Formats array. To find out if a particular format is available on the clipboard, use the HasFormat (see page 3340) method.

When reading information from the clipboard, use the Formats array to choose the best possible encoding for information that can be encoded in several ways.

Before you can write information to the clipboard in a particular format, the format must be registered. To register a new format, use the RegisterClipboardFormat method of TPicture.

Delphi Examples:

```
{
FormatCount, Formats example
The following code adds each format on the Clipboard to ListBox1 when Button1 is clicked.
Note: You will need to add Clipbrd to the uses clause (Delphi) or include <Clipbrd.hpp> (C++).
}

uses clipbrd;

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Clipboard.FormatCount - 1 do
    ListBox1.Items.Add(IntToStr(Clipboard.Formats[I]));
end;
```

See Also

HasFormat (see page 3340)

FormatCount (see page 3348)

RegisterClipboardFormat (see page 14592)

24.1.1.4.4 TClipboard.Handle Property

Pascal

```
property Handle: HWND;
```

C++

```
__property HWND Handle;
```

Description

This is Handle, a member of class TClipboard.

24.1.1.4.5 TClipboard.OpenRefCount Property

Pascal

```
property OpenRefCount: Integer;
```

C++

```
__property int OpenRefCount;
```

Description

This is OpenRefCount, a member of class TClipboard.

24.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Clipboard (see page 3351)	Returns an instance of TClipboard (see page 3328).
	SetClipboard (see page 3353)	Replaces the single global clipboard instance with another clipboard object.

24.2.1 Clipbrd.Clipboard Function

Returns an instance of TClipboard (see page 3328).

Pascal

```
function Clipboard: TClipboard;
```

C++

```
TClipboard Clipboard();
```

File

Clipbrd

Description

Applications use a single instance of TClipboard (see page 3328) for interacting with the system clipboard. If the application has never used the clipboard, calling Clipboard creates a new instance of TClipboard (see page 3328). If the clipboard has already been used, Clipboard returns the previously created TClipboard (see page 3328) object.

To use Clipboard and the TClipboard (see page 3328) object, add the appropriate unit to the uses clause (Delphi) or include it in the source module (C++).

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
```

```
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
   Clipboard.Clear;
 end;
end;

procedure TForm1.Button2Click(Sender: TObject);
```

```
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
    Bitmap.SaveToClipBoardFormat(
      MyFormat,
      AData,
      APalette);
    ClipBoard.SetAsHandle(MyFormat,AData);
  finally
    Bitmap.Free;
  end;
end;
```

See Also

TClipboard (see page 3328)

24.2.2 Clipbrd.SetClipboard Function

Replaces the single global clipboard instance with another clipboard object.

Pascal

```
function SetClipboard(NewClipboard: TClipboard): TClipboard;
```

C++

```
TClipboard SetClipboard(TClipboard NewClipboard);
```

File

Clipbrd

Description

Use SetClipboard to replace the global clipboard instance with a customized descendant of TClipboard (see page 3328). SetClipboard returns the currently instantiated clipboard, if any. After replacing the global clipboard instance using SetClipboard, an application must free the old clipboard that is returned.

See Also

Clipboard (see page 3351)

24.3 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CF_COMPONENT (see page 3354)	This is variable Clipbrd.CF_COMPONENT.
CF_PICTURE (see page 3354)	This is variable Clipbrd.CF_PICTURE.

24.3.1 Clipbrd.CF_COMPONENT Variable

Pascal

```
CF_COMPONENT: Word;
```

C++

```
Word CF_COMPONENT;
```

File

Clipbrd

Description

This is variable Clipbrd.CF_COMPONENT.

24.3.2 Clipbrd.CF_PICTURE Variable

Pascal

```
CF_PICTURE: Word;
```

C++

```
Word CF_PICTURE;
```

File

Clipbrd

Description

This is variable Clipbrd.CF_PICTURE.

25 CmAdmCtl Namespace

This is namespace CmAdmCtl.

Topics

Name	Description
Classes (see page 3356)	The following table lists classes in this documentation.

Classes

	Name	Description
	CoCOMAdminCatalog (see page 3356)	This is class CmAdmCtl.CoCOMAdminCatalog.
	CoCOMAdminCatalogCollection (see page 3357)	This is class CmAdmCtl.CoCOMAdminCatalogCollection.
	CoCOMAdminCatalogObject (see page 3358)	This is class CmAdmCtl.CoCOMAdminCatalogObject.
	TCOMAdminCatalog (see page 3359)	TCOMAdminCatalog allows an application to act as an Automation controller for the COM+ administration tool.
	TCOMAdminCatalogCollection (see page 3380)	TCOMAdminCatalogCollection represents a collection from the COM+ catalog.
	TCOMAdminCatalogObject (see page 3396)	TCOMAdminCatalogObject represents an item in a collection from the COM+ catalog.

25.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	CoCOMAdminCatalog (see page 3356)	This is class CmAdmCtl.CoCOMAdminCatalog.
	CoCOMAdminCatalogCollection (see page 3357)	This is class CmAdmCtl.CoCOMAdminCatalogCollection.
	CoCOMAdminCatalogObject (see page 3358)	This is class CmAdmCtl.CoCOMAdminCatalogObject.
	TCOMAdminCatalog (see page 3359)	TCOMAdminCatalog allows an application to act as an Automation controller for the COM+ administration tool.
	TCOMAdminCatalogCollection (see page 3380)	TCOMAdminCatalogCollection represents a collection from the COM+ catalog.
	TCOMAdminCatalogObject (see page 3396)	TCOMAdminCatalogObject represents an item in a collection from the COM+ catalog.

25.1.1 CoCOMAdminCatalog Class

Class Hierarchy

CmAdmCtl.CoCOMAdminCatalog

Pascal

```
CoCOMAdminCatalog = class;
```

C++

```
class CoCOMAdminCatalog;
```

File

CmAdmCtl

Description

This is class CmAdmCtl.CoCOMAdminCatalog.

25.1.1.1 CoCOMAdminCatalog Members

The following tables list the members exposed by CoCOMAdminCatalog.

Public Methods

	Name	Description
	Create (see page 3357)	This is Create, a member of class CoCOMAdminCatalog.

25.1.1.2 CoCOMAdminCatalog Methods

The methods of the CoCOMAdminCatalog class are listed here.

Public Methods

	Name	Description
	Create (see page 3357)	This is Create, a member of class CoCOMAdminCatalog.

25.1.1.2.1 CoCOMAdminCatalog.Create Method

Pascal

```
class function Create: ICOMAdminCatalog;
```

C++

```
__fastcall ICOMAdminCatalog Create();
```

Description

This is Create, a member of class CoCOMAdminCatalog.

25.1.2 CoCOMAdminCatalogCollection Class

Class Hierarchy

CmAdmCtl.CoCOMAdminCatalogCollection

Pascal

```
CoCOMAdminCatalogCollection = class;
```

C++

```
class CoCOMAdminCatalogCollection;
```

File

CmAdmCtl

Description

This is class CmAdmCtl.CoCOMAdminCatalogCollection.

25.1.2.1 CoCOMAdminCatalogCollection Members

The following tables list the members exposed by CoCOMAdminCatalogCollection.

Public Methods

	Name	Description
	Create (see page 3358)	This is Create, a member of class CoCOMAdminCatalogCollection.

25.1.2.2 CoCOMAdminCatalogCollection Methods

The methods of the CoCOMAdminCatalogCollection class are listed here.

Public Methods

	Name	Description
	Create (see page 3358)	This is Create, a member of class CoCOMAdminCatalogCollection.

25.1.2.2.1 CoCOMAdminCatalogCollection.Create Method

Pascal

```
class function Create: ICatalogCollection;
```

C++

```
__fastcall ICatalogCollection Create();
```

Description

This is Create, a member of class CoCOMAdminCatalogCollection.

25.1.3 CoCOMAdminCatalogObject Class

Class Hierarchy

CmAdmCtl.CoCOMAdminCatalogObject

Pascal

```
CoCOMAdminCatalogObject = class;
```

C++

```
class CoCOMAdminCatalogObject;
```

File

CmAdmCtl

Description

This is class CmAdmCtl.CoCOMAdminCatalogObject.

25.1.3.1 CoCOMAdminCatalogObject Members

The following tables list the members exposed by CoCOMAdminCatalogObject.

Public Methods

	Name	Description
	Create (see page 3359)	This is Create, a member of class CoCOMAdminCatalogObject.

25.1.3.2 CoCOMAdminCatalogObject Methods

The methods of the CoCOMAdminCatalogObject class are listed here.

Public Methods

	Name	Description
	Create (see page 3359)	This is Create, a member of class CoCOMAdminCatalogObject.

25.1.3.2.1 CoCOMAdminCatalogObject.Create Method

Pascal

```
class function Create: ICatalogObject;
```

C++

```
__fastcall ICatalogObject Create();
```

Description

This is Create, a member of class CoCOMAdminCatalogObject.

25.1.4 TCOMAdminCatalog Class

TCOMAdminCatalog allows an application to act as an Automation controller for the COM+ administration tool.

Class Hierarchy

Pascal

```
TCOMAdminCatalog = class(TOleServer);
```

C++

```
class TCOMAdminCatalog : public TOleServer;
```

File

CmAdmCtl

Description

Use TCOMAdminCatalog to automate the administration of COM+ applications and services. TCOMAdminCatalog lets you read and write information that is stored on the COM+ catalog, which holds all COM+ configuration data. TCOMAdminCatalog implements the ICOMAdminCatalog interface, to let you

Access collections on the catalog.

Install COM+ applications and components.

Start and stop services.

Connect (see page 3365) to and administer remote servers.

Use the Connect (see page 3365) method to access the COMAdminCatalog server. You can then use the methods of TCOMAdminCatalog to send commands that administer COM+ applications on this or another machine.

See Also

TComAdminCatalogObject

TCOMAdminCatalogCollection (see page 3380)

25.1.4.1 TCOMAdminCatalog Members

The following tables list the members exposed by TCOMAdminCatalog.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_AddRef (see page 18104)	Increments the reference count for the number of interface references dependent on the OLE server.
	_Release (see page 2769)	Called when an application releases a component interface.
	_Release (see page 18104)	Decrements the reference count for the calling interface on a object.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ConnectEvents (see page 18105)	Establishes a connection using the EventDispatch (see page 18111) property as an event sink.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DisconnectEvents (see page 18106)	Terminates a connection that was established using the ConnectEvents (see page 18105) method.
	GetAutoConnect (see page 18106)	Returns the value of the AutoConnect (see page 18110) property.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetConnectKind (see page 18106)	Returns the value of the ConnectKind (see page 18110) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetServer (see page 18107)	Returns an interface for the COM server.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	InitServerData (see page 3372)	Initializes the ServerData property to reflect the type library information of the COM server.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	InvokeEvent (see page 18107)	Dispatches an event from the COM server to the appropriate event handler.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 18108)	Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 18110) is True true.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 18108)	Returns a reference to a specified interface if the OLE server supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoConnect (see page 18109)	Sets the value of the AutoConnect (see page 18110) property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.

	SetConnectKind (see page 18109)	Sets the value of the ConnectKind (see page 18110) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	EventDispatch (see page 18111)	This is EventDispatch, a member of class TOleServer.
	ServerData (see page 18111)	Encodes information about the COM server to which ServerData connects.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
	BackupREGDB (see page 3365)	Backs up the COM+ class registration database to a specified file.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Connect (see page 3365)	Establishes a connection to the COM server that implements the COM+ administration catalog.
	ConnectTo (see page 3366)	Connects the TCOMAdminCatalog (see page 3359) component to an existing ICOMAdminCatalog interface.
V	Create (see page 3363)	Creates a new instance of TCOMAdminCatalog (see page 3359).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 3364)	Frees an instance of TCOMAdminCatalog (see page 3359)
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Disconnect (see page 3366)	Terminates the connection to the COM server.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	ExportApplication (see page 3367)	Exports a COM+ application or application proxy to a file for installation on other machines.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	Get_MajorVersion (see page 3367)	Returns the value of the Get_MajorVersion property.
	Get_MinorVersion (see page 3368)	Returns the value of the Get_MinorVersion property.
	GetCollection (see page 3368)	Returns a TCOMAdminCatalogCollection (see page 3380) object for a specified collection.
	GetCollectionByQuery (see page 3368)	Retrieves a collection from the COM+ catalog given all of its parent items.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetEventClassesForIID (see page 3369)	Retrieves a list of event classes that implement a specified interface.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetMultipleComponentsInfo (see page 3370)	Returns information about COM+ components found in specified .dll files.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	ICOMAdminCatalog_Connect (see page 3371)	ICOMAdminCatalog_Connects to a remote computer so that you can administer the collections on that machine.
	ImportComponent (see page 3371)	Imports a registered in-process component to a COM+ application.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstallApplication (see page 3372)	Installs a COM+ application or application proxy from a file.
	InstallComponent (see page 3373)	Installs a component into a COM+ application, and provides default configuration in the COM+ class registration database (RegDB).
	InstallEventClass (see page 3373)	Installs a COM+ event class into an application.
	InstallMultipleComponents (see page 3374)	Installs components from multiple files into a COM+ application.
	InstallMultipleEventClasses (see page 3375)	Installs event classes from multiple files into a COM+ application.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryApplicationFile (see page 3375)	Retrieves information about a COM+ application from a COM+ application file.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshComponents (see page 3376)	Refreshes component registration information from the Registry (see page 18633).
	RefreshRouter (see page 3376)	Refreshes the data being used by the component load balancing service on a CLB server.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	RestoreREGDB (see page 3376)	Restores the COM+ class registration database (RegDB) from a specified file.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.

V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ServiceCheck (see page 3377)	Checks the status of a COM+ service.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	ShutdownApplication (see page 3377)	Initiates shutdown of a COM+ application server process.
	StartApplication (see page 3378)	Launches a COM+ server application in a dedicated process.
	StartRouter (see page 3378)	Starts the component load balancing service on a CLB server.
	StopRouter (see page 3378)	Stops the component load balancing service on a CLB server.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	DefaultInterface (see page 3379)	Provides access to the default interface for the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	MajorVersion (see page 3379)	Indicates the major version number of the COMAdmin Library
R	MinorVersion (see page 3380)	Indicates the minor version number of the COMAdmin Library
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	AutoConnect (see page 18110)	Specifies whether the component automatically connects to the server.
	ConnectKind (see page 18110)	Indicates the type of process to which the ConnectKind component establishes a connection.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	RemoteMachineName (see page 18111)	Specifies the machine running the COM server when ConnectKind (see page 18110) is ckRemote.
	Tag (see page 2808)	Stores an integer value as part of a component.

25.1.4.2 TCOMAdminCatalog.Create Constructor

Creates a new instance of TCOMAdminCatalog (see page 3359).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCOMAdminCatalog(TComponent * AOwner);
```

Description

Call Create to instantiate TCOMAdminCatalog (see page 3359) at runtime. TCOMAdminCatalog (see page 3359) objects added at design time are instantiated automatically.

Owner specifies the component (typically a form or data module) that is responsible for freeing the TCOMAdminCatalog (see page 3359) instance.

See Also

Owner (see page 2807)

25.1.4.3 TCOMAdminCatalog.Destroy Destructor

Frees an instance of TCOMAdminCatalog (see page 3359)

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCOMAdminCatalog();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TCOMAdminCatalog (see page 3359) component reference is not nil before calling Destroy. Destroy disconnects from the server, if necessary, before freeing the component.

See Also

Free (see page 22300)

25.1.4.4 TCOMAdminCatalog Methods

The methods of the TCOMAdminCatalog class are listed here.

Protected Methods

	Name	Description
	InitServerData (see page 3372)	Initializes the ServerData property to reflect the type library information of the COM server.

Public Methods

	Name	Description
	BackupREGDB (see page 3365)	Backs up the COM+ class registration database to a specified file.
	Connect (see page 3365)	Establishes a connection to the COM server that implements the COM+ administration catalog.
	ConnectTo (see page 3366)	Connects the TCOMAdminCatalog (see page 3359) component to an existing ICOMAdminCatalog interface.
	Disconnect (see page 3366)	Terminates the connection to the COM server.
	ExportApplication (see page 3367)	Exports a COM+ application or application proxy to a file for installation on other machines.
	Get_MajorVersion (see page 3367)	Returns the value of the Get_MajorVersion property.
	Get_MinorVersion (see page 3368)	Returns the value of the Get_MinorVersion property.
	GetCollection (see page 3368)	Returns a TCOMAdminCatalogCollection (see page 3380) object for a specified collection.
	GetCollectionByQuery (see page 3368)	Retrieves a collection from the COM+ catalog given all of its parent items.
	GetEventClassesForIID (see page 3369)	Retrieves a list of event classes that implement a specified interface.
	GetMultipleComponentsInfo (see page 3370)	Returns information about COM+ components found in specified .dll files.
	ICOMAdminCatalog_Connect (see page 3371)	ICOMAdminCatalog_Connects to a remote computer so that you can administer the collections on that machine.
	ImportComponent (see page 3371)	Imports a registered in-process component to a COM+ application.
	InstallApplication (see page 3372)	Installs a COM+ application or application proxy from a file.
	InstallComponent (see page 3373)	Installs a component into a COM+ application, and provides default configuration in the COM+ class registration database (RegDB).
	InstallEventClass (see page 3373)	Installs a COM+ event class into an application.
	InstallMultipleComponents (see page 3374)	Installs components from multiple files into a COM+ application.
	InstallMultipleEventClasses (see page 3375)	Installs event classes from multiple files into a COM+ application.
	QueryApplicationFile (see page 3375)	Retrieves information about a COM+ application from a COM+ application file.

	RefreshComponents (see page 3376)	Refreshes component registration information from the Registry (see page 18633).
	RefreshRouter (see page 3376)	Refreshes the data being used by the component load balancing service on a CLB server.
	RestoreREGDB (see page 3376)	Restores the COM+ class registration database (RegDB) from a specified file.
	ServiceCheck (see page 3377)	Checks the status of a COM+ service.
	ShutdownApplication (see page 3377)	Initiates shutdown of a COM+ application server process.
	StartApplication (see page 3378)	Launches a COM+ server application in a dedicated process.
	StartRouter (see page 3378)	Starts the component load balancing service on a CLB server.
	StopRouter (see page 3378)	Stops the component load balancing service on a CLB server.

25.1.4.4.1 TCOMAdminCatalog.BackupREGDB Method

Backs up the COM+ class registration database to a specified file.

Pascal

```
procedure BackupREGDB(const bstrBackupFilePath: WideString);
```

C++

```
__fastcall BackupREGDB(const BSTR bstrBackupFilePath);
```

Description

Call BackupREGDB to back up the COM+ class registration database (RegDB). The database can be restored at a later date using the RestoreREGDB (see page 3376) method.

bstrBackupFilePath specifies the fully-qualified name of the file to which RegDB will be backed up.

See Also

RestoreREGDB (see page 3376)

InstallComponent (see page 3373)

25.1.4.4.2 TCOMAdminCatalog.Connect Method

Establishes a connection to the COM server that implements the COM+ administration catalog.

Pascal

```
procedure Connect; override;
```

C++

```
virtual __fastcall Connect();
```

Description

Call Connect to connect the TCOMAdminCatalog (see page 3359) component to the COM server it uses to administer the COM+ catalog data store. If the AutoConnect property is true, the TCOMAdminCatalog (see page 3359) component automatically calls Connect when the application is first run.

Do not use Connect if the value of ConnectKind is ckAttachToInterface. When attaching to an interface, use the ConnectTo (see page 3366) method instead.

If the value of ConnectKind is ckRemote, the RemoteMachineName property must be set before calling Connect.

Note: Do not confuse Connect with the ICOMAdminCatalog_Connect (see page 3371) method. Connect establishes a connection to the server that TCOMAdminCatalog (see page 3359) represents, while ICOMAdminCatalog_Connect (see page 3371) connects to a remote machine on which you want to administer COM+ applications and services.

See Also

AutoConnect (see page 18110)

Disconnect (see page 3366)

ConnectKind (see page 18110)

RemoteMachineName (see page 18111)

ICOMAdminCatalog_Connect (see page 3371)

ConnectTo (see page 3366)

25.1.4.4.3 TCOMAdminCatalog.ConnectTo Method

Connects the TCOMAdminCatalog (see page 3359) component to an existing ICOMAdminCatalog interface.

Pascal

```
procedure ConnectTo(svrIntf: ICOMAdminCatalog);
```

C++

```
__fastcall ConnectTo(ICOMAdminCatalog svrIntf);
```

Description

Use ConnectTo when the ConnectKind property is ckAttachToInterface. ConnectTo allows the TCOMAdminCatalog (see page 3359) to use an existing ICOMAdminCatalog interface rather than establishing a new connection to the server and obtaining a new interface.

If the ConnectKind property is not ckAttachToInterface, use the Connect (see page 3365) method instead.

See Also

Connect (see page 3365)

Disconnect (see page 3366)

ConnectKind (see page 18110)

25.1.4.4.4 TCOMAdminCatalog.Disconnect Method

Terminates the connection to the COM server.

Pascal

```
procedure Disconnect; override;
```

C++

```
virtual __fastcall Disconnect();
```

Description

Call Disconnect to release a connection formed using the Connect (see page 3365) or ConnectTo (see page 3366) method.

See Also

AutoConnect (see page 18110)

Connect (see page 3365)

ConnectTo (see page 3366)

25.1.4.4.5 TCOMAdminCatalog.ExportApplication Method

Exports a COM+ application or application proxy to a file for installation on other machines.

Pascal

```
procedure ExportApplication(const bstrApplIdOrName: WideString; const bstrApplicationFile:
WideString; lOptions: Integer);
```

C++

```
__fastcall ExportApplication(const BSTR bstrApplIdOrName, const BSTR bstrApplicationFile, int
lOptions);
```

Description

Use ExportApplication to create a file that the InstallApplication (see page 3372) method can use to install a COM+ application or application proxy on other machines.

bstrApplIdOrName is the name or GUID that identifies the application to be exported.

bstrApplicationFile is the name of the file to which ExportApplication exports bstrApplIDOrName. This file name should include the file path. If you do not provide a file name, ExportApplication creates a file with the same name as the application in the default directory.

lOptions indicate how the application should be exported. The value of lOptions is a sum that represents a set of the following flags.

Flag	Meaning
0	Do not export users with roles.
1	Export users with roles.
2	Export application as an application proxy.
4	Overwrite files.

If no option flags are provided, ExportApplication exports the specified COM+ application to an MSI file, without the users assigned to application roles.

InstallApplication (see page 3372)

QueryApplicationFile (see page 3375)

25.1.4.4.6 TCOMAdminCatalog.Get_MajorVersion Method

Returns the value of the Get_MajorVersion property.

Pascal

```
function Get_MajorVersion: Integer;
```

C++

```
__fastcall int Get_MajorVersion();
```

Description

Get_Get_MajorVersion is the read implementation of the Get_MajorVersion property.

See Also

Get_MajorVersion

25.1.4.4.7 TCOMAdminCatalog.Get_MinorVersion Method

Returns the value of the Get_MinorVersion property.

Pascal

```
function Get_MinorVersion: Integer;
```

C++

```
__fastcall int Get_MinorVersion();
```

Description

Get_Get_MinorVersion is the read implementation of the Get_MinorVersion property.

See Also

Get_MinorVersion

25.1.4.4.8 TCOMAdminCatalog.GetCollection Method

Returns a TCOMAdminCatalogCollection (see page 3380) object for a specified collection.

Pascal

```
function GetCollection(const bstrCollName: WideString): TCOMAdminCatalogCollection;
```

C++

```
__fastcall TCOMAdminCatalogCollection GetCollection(const BSTR bstrCollName);
```

Description

GetCollection retrieves a top-level collection from the COM+ catalog, such as Applications. Subcollections (collections that are not top-level collections, such as Components) must be fetched using the GetCollection method of their parent collection or using the GetCollectionByQuery (see page 3368) method.

bstrCollName is the name of the desired collection. The available collections depend on your version of the COMAdmin Library. See the Microsoft documentation for a list of the available collections in your version of the COMAdmin Library.

Note: The TCOMAdminCatalogCollection (see page 3380) object that GetCollection returns does not contain data from the catalog for items contained in the collection. Use the Populate method to read in data for items in the collection.

See Also

GetCollectionByQuery (see page 3368)

Populate (see page 3391)

GetCollection (see page 3389)

ICOMAdminCatalog_Connect (see page 3371)

25.1.4.4.9 TCOMAdminCatalog.GetCollectionByQuery Method

Retrieves a collection from the COM+ catalog given all of its parent items.

Pascal

```
function GetCollectionByQuery(const bstrCollName: WideString; var aQuery: PSafeArray):
TCOMAdminCatalogCollection;
```

C++

```
__fastcall TCOMAdminCatalogCollection GetCollectionByQuery(const BSTR bstrCollName, PSafeArray
aQuery);
```

Description

Call GetCollectionByQuery to obtain a collection on the catalog given the Key property of each of its parent items. The Key property for each parent item is a GUID that uniquely identifies it on the COM+ catalog.

bstrCollName is the name of the desired collection. The available collections depend on your version of the COMAdmin Library. See the Microsoft documentation for a list of the available collections in your version of the COMAdmin Library.

aQuery is a safe array of containing the Key property for each parent item of the desired collection.

Note: If bstrCollName is 'ErrorInfo', 'RelatedCollectionInfo', or 'PropertyInfo', GetCollectionByQuery ignores the aQuery parameter and returns the named collection immediately relative to the Root collection. To obtain these collections relative to an arbitrary collection in the catalog, use the GetCollection (see page 3368) method of the parent collection.

Note: The TCOMAdminCatalogCollection (see page 3380) object that GetCollectionByQuery returns does not contain data from the catalog for items contained in the collection. Use the Populate method to read in data for items in the collection.

See Also

Populate (see page 3391)

GetCollection (see page 3368)

Key (see page 3405)

GetCollection (see page 3389)

25.1.4.4.10 TCOMAdminCatalog.GetEventClassesForIID Method

Retrieves a list of event classes that implement a specified interface.

Pascal

```
procedure GetEventClassesForIID(const bstrIID: WideString; out varCLSIDS: PSafeArray; out
varProgIDs: PSafeArray; out varDescriptions: PSafeArray);
```

C++

```
__fastcall GetEventClassesForIID(const BSTR bstrIID, PSafeArray varCLSIDS, PSafeArray
varProgIDs, PSafeArray varDescriptions);
```

Description

Call GetEventClassesForIID to determine the available COM+ event objects that implement a specified interface.

bstrIID is the GUID for the interface that you want the event classes to implement. If bstrIID is nil (Delphi) or NULL (C++), GetEventClassesForIID returns all event classes registered on the machine.

varCLSIDS returns an array of CLSIDs for the event classes that implement bstrIID.

varProgIDS returns an array of ProgIDs for the event classes that implement bstrIID.

varDescriptions returns an array of description strings for the event classes that implement bstrIID.

See Also

InstallEventClass (see page 3373)

InstallMultipleEventClasses (see page 3375)

25.1.4.4.11 TCOMAdminCatalog.GetMultipleComponentsInfo Method

Returns information about COM+ components found in specified .dll files.

Pascal

```
procedure GetMultipleComponentsInfo(const bstrApplIdOrName: WideString; var varFileNames:
PSafeArray; out varCLSIDS: PSafeArray; out varClassNames: PSafeArray; out varFileFlags:
PSafeArray; out varComponentFlags: PSafeArray);
```

C++

```
__fastcall GetMultipleComponentsInfo(const BSTR bstrApplIdOrName, PSafeArray varFileNames,
PSafeArray varCLSIDS, PSafeArray varClassNames, PSafeArray varFileFlags, PSafeArray
varComponentFlags);
```

Description

Call GetMultipleComponentsInfo to obtain information on the objects that a specified set of .dll files make available.

bstrApplIdOrName specifes the name or GUID of the application to which the .dll files belong.

varFileNames is an array of WideString values, each of which is the name of a .dll.

varCLSIDS returns an array of CLSIDs for the COM+ components in the specified .dll files.

varClassNames returns an array of class names for the component classes in the specified .dll files.

varFileFlags returns an array of file flags that return information about the specified files. Each entry in the array is built from the following flags:

FlagValue

ComAdminFileFlagLoadable1

ComAdminFileFlagCOM2

COMAdminFileFlagContainsRS4

COMAdminFileFlagContainsComp8

COMAdminFileFlagContainsTLB16

COMAdminFileFlagSelfReg32

COMAdminFileFlagSelfUnReg64

COMAdminFileFlagUnloadableDLL128

COMAdminFileFlagDoesNotExist256

COMAdminFileFlagAlreadyInstalled512

COMAdminFileFlagBadTLB1024

COMAdminFileFlagGetClassObjFailed2048

COMAdminFileFlagClassNotAvailable4096

COMAdminFileFlagRegistrar8192

COMAdminFileFlagNoRegistrar16384

COMAdminFileFlagDLLRegsvrFailed32768

COMAdminFileFlagRegTLBFailed65536

COMAdminFileFlagRegistrarFailed131072

COMAdminFileFlagError262144

varComponentFlags returns an array of file flags that return information about the components in the specified files. Each entry in the array is built from the following flags:

FlagValue

COMAdminComponentFlagTypeInfoFound1

COMAdminComponentCOMPlusPropertiesFound2

COMAdminComponentProxyFound4

COMAdminComponentInterfacesFound8

COMAdminComponentAlreadyInstalled16

COMAdminComponentNotInApplication32

See Also

InstallMultipleComponents (see page 3374)

RefreshComponents (see page 3376)

25.1.4.4.12 TCOMAdminCatalog.ICOMAdminCatalog_Connect Method

ICOMAdminCatalog_Connects to a remote computer so that you can administer the collections on that machine.

Pascal

```
function ICOMAdminCatalog_Connect(const bstrConnectString: WideString):
TCOMAdminCatalogCollection;
```

C++

```
__fastcall TCOMAdminCatalogCollection ICOMAdminCatalog_Connect(const BSTR bstrConnectString);
```

Description

Call ICOMAdminCatalog_ICOMAdminCatalog_Connect to administer the COM+ components and services on a remote machine.

bstrICOMAdminCatalog_ConnectString is the name of the remote computer whose COM+ components and services you want to administer.

ICOMAdminCatalog_ICOMAdminCatalog_Connect returns the root collection on the remote computer. The root collection contains the top-level collections on the catalog of the remote machine. It does not contain any TCOMAdminCatalogObject (see page 3396) objects or support any properties. You can't use the Add or Remove methods of this TCOMAdminCatalogCollection (see page 3380) object.

See Also

GetCollection (see page 3368)

25.1.4.4.13 TCOMAdminCatalog.ImportComponent Method

Imports a registered in-process component to a COM+ application.

Pascal

```
procedure ImportComponent(const bstrApplIdOrName: WideString; const bstrCLSIDOrProgId:
WideString);
```

C++

```
__fastcall ImportComponent(const BSTR bstrApplIdOrName, const BSTR bstrCLSIDOrProgId);
```

Description

Do not use ImportComponent. Use the InstallComponent (see page 3373) method instead. InstallComponent (see page 3373) fully registers the component in the COM+ class registration database (RegDB), whereas ImportComponent does not bring any interface, method, or type library information for the component into the COM+ class registration database. This restricts how the component can be configured. When you export a COM+ application that has an imported component to an application proxy, the proxy will contain no interface or type library information for the component, and marshalling for that component will fail.

bstrAppIdOrName is the name or GUID that represents the application into which to import the component.

bstrCLSIDOrProgID is the CLSID or ProgID that identifies the component to import.

See Also

InstallComponent (see page 3373)

25.1.4.4.14 TCOMAdminCatalog.InitServerData Method

Initializes the ServerData property to reflect the type library information of the COM server.

Pascal

```
procedure InitServerData; override;
```

C++

```
virtual __fastcall InitServerData();
```

Description

The InitServerData constructor calls InitServerData to initialize ServerData with information from the COM server's type library.

InitServerData is an abstract a pure virtual method in InitServerData. Each InitServerData descendant implements this method so that the ServerData property reflects its particular COM server.

See Also

ServerData (see page 18111)

Create (see page 18101)

25.1.4.4.15 TCOMAdminCatalog.InstallApplication Method

Installs a COM+ application or application proxy from a file.

Pascal

```
procedure InstallApplication(const bstrApplicationFile: WideString; const
bstrDestinationDirectory: WideString; lOptions: Integer; const bstrUserId: WideString; const
bstrPassword: WideString; const bstrRSN: WideString);
```

C++

```
__fastcall InstallApplication(const BSTR bstrApplicationFile, const BSTR
bstrDestinationDirectory, int lOptions, const BSTR bstrUserId, const BSTR bstrPassword, const
BSTR bstrRSN);
```

Description

Use InstallApplication to install an application or application proxy that was previously saved by a call to the ExportApplication (see page 3367) method.

bstrApplicationFile is the name of the file created by ExportApplication (see page 3367).

bstrDestinationDirectory is the directory where the components in the application should be installed. If this parameter is nil (Delphi) or NULL (C++), InstallApplication uses the default directory.

lOptions is a set of flags that modify how the application is installed. It is a sum of 0 or more of the following flags:

Flag	Meaning
0	Don't install any users saved in the application file.
1	Install all users that are saved in the application file.
2	Overwrite any files that already exist in the target directory.

bstrUserId specifies the user ID under which to run the application. This value can be nil (Delphi) or NULL (C++).

bstrPassword specifies the password under which to run the application. This value can be nil (Delphi) or NULL (C++).

bstrRSN specifies the remote server name when bstrApplicationFile is an application proxy.

See Also

ExportApplication (see page 3367)

QueryApplicationFile (see page 3375)

25.1.4.4.16 TCOMAdminCatalog.InstallComponent Method

Installs a component into a COM+ application, and provides default configuration in the COM+ class registration database (RegDB).

Pascal

```
procedure InstallComponent(const bstrApplIdOrName: WideString; const bstrDLL: WideString;
const bstrTLB: WideString; const bstrPSDLL: WideString);
```

C++

```
__fastcall InstallComponent(const BSTR bstrApplIdOrName, const BSTR bstrDLL, const BSTR
bstrTLB, const BSTR bstrPSDLL);
```

Description

InstallComponent installs all components (COM classes) in a .dll file into a COM+ application, and registers the components in the COM+ class registration database (RegDB) as configured components, providing a default configuration.

bstrApplIdOrName is the name or GUID that represents the application into which to install the components.

bstrDLL is the name of the .dll file that implements the component or components.

bstrTLB is the name of the external type library file for the .dll. If the type library is embedded in the .dll, the parameter should be an empty string.

bstrPSDLL is the name of the proxy-stub .dll file. If there is no proxy-stub .dll associated with the component, set this parameter to an empty string.

See Also

InstallMultipleComponents (see page 3374)

RefreshComponents (see page 3376)

25.1.4.4.17 TCOMAdminCatalog.InstallEventClass Method

Installs a COM+ event class into an application.

Pascal

```
procedure InstallEventClass(const bstrApplIdOrName: WideString; const bstrDLL: WideString;
const bstrTLB: WideString; const bstrPSDLL: WideString);
```

C++

```
__fastcall InstallEventClass(const BSTR bstrApplIdOrName, const BSTR bstrDLL, const BSTR
bstrTLB, const BSTR bstrPSDLL);
```

Description

Use InstallEventClass to install event classes from a .dll that holds dummy implementations of the event classes. The .dll must be self-registering, there must be a type library to describe the interfaces that the event classes implement, and each event class must have a CLSID and a ProgID.

The dummy implementation of the event class is never actually run. It exists only to register the event class. When the publisher creates the event class, the Events system provides an implementation to send the event to subscribers.

bstrApplIdOrName is the name or GUID that represents the application into which to install the event classes.

bstrDLL is the name of the self-registering .dll file that contains the event classes.

bstrTLB is the name of the external type library file for the .dll. If the type library is embedded in the .dll, set this parameter to an empty string.

bstrPSDLL is the name of the proxy-stub .dll file. If there is no proxy-stub .dll associated with the event class, set this parameter to an empty string.

See Also

InstallMultipleEventClasses (see page 3375)

25.1.4.4.18 TCOMAdminCatalog.InstallMultipleComponents Method

Installs components from multiple files into a COM+ application.

Pascal

```
procedure InstallMultipleComponents(const bstrApplIdOrName: WideString; var varFileNames:
PSafeArray; var varCLSIDS: PSafeArray);
```

C++

```
__fastcall InstallMultipleComponents(const BSTR bstrApplIdOrName, PSafeArray varFileNames,
PSafeArray varCLSIDS);
```

Description

InstallMultipleComponents installs the components in the specified files into the specified COM+ application.

bstrApplIdOrName is the name or GUID that represents the application into which to install the components.

varFileNames is an array of strings, where each string is the name of a .dll file that implements the components to install.

varCLSIDS is an array of Variants (see page 23567) holding CLSIDs for the components to install.

See Also

InstallComponent (see page 3373)

ImportComponent (see page 3371)

25.1.4.4.19 TCOMAdminCatalog.InstallMultipleEventClasses Method

Installs event classes from multiple files into a COM+ application.

Pascal

```
procedure InstallMultipleEventClasses(const bstrApplIdOrName: WideString; var varFileNames:
PSafeArray; var varCLSIDS: PSafeArray);
```

C++

```
__fastcall InstallMultipleEventClasses(const BSTR bstrApplIdOrName, PSafeArray varFileNames,
PSafeArray varCLSIDS);
```

Description

Use InstallMultipleEventClasses to install event classes from multiple self-registering .dll files, each of which holds the dummy implementation of one or more COM+ event classes. There must be a type library to describe the interfaces that the event classes implement, and each event class must have a CLSID and a ProgID.

The dummy implementation of the event class is never actually run. It exists only to register the event class. When the publisher creates the event class, the Events system provides an implementation to send the event to subscribers.

bstrApplIdOrName is the name or GUID that represents the application into which to install the event classes.

varFileNames is an array of strings, where each string is the name of a self-registering .dll file that contains the event classes to install.

varCLSIDS is an array of Variants (see page 23567) holding CLSIDs for the event classes to install.

See Also

InstallEventClass (see page 3373)

25.1.4.4.20 TCOMAdminCatalog.QueryApplicationFile Method

Retrieves information about a COM+ application from a COM+ application file.

Pascal

```
procedure QueryApplicationFile(const bstrApplicationFile: WideString; out bstrApplicationName:
WideString; out bstrApplicationDescription: WideString; out bHasUsers: WordBool; out bIsProxy:
WordBool; out varFileNames: PSafeArray);
```

C++

```
__fastcall QueryApplicationFile(const BSTR bstrApplicationFile, BSTR bstrApplicationName, BSTR
bstrApplicationDescription, WordBool bHasUsers, WordBool bIsProxy, PSafeArray varFileNames);
```

Description

Call QueryApplicationFile to obtain information about a COM+ application from its application file. An application file is created by the ExportApplication (see page 3367) method.

bstrApplicationFile is the name of the ApplicationFile from which to retrieve information.

bstrApplicationName returns the name of the application.

bstrApplicationDescription returns a brief description of the application.

bHasUsers returns true if the application file includes user information associated with its roles, false otherwise.

bIsProxy returns true if the application file contains an application proxy, false otherwise.

varFileNames returns an array of all .dll files containing components that are installed in the application.

See Also

ExportApplication (see page 3367)

25.1.4.4.21 TCOMAdminCatalog.RefreshComponents Method

Refreshes component registration information from the Registry (see page 18633).

Pascal

```
procedure RefreshComponents;
```

C++

```
__fastcall RefreshComponents();
```

Description

RefreshComponents compares CLSIDs and ProgIDs between the COM+ class registration database (RegDB) and the Registry (see page 18633) for mismatches. When it detects a mismatch in CLSIDs and ProgIDs, RefreshComponents updates the COM+ class registration database (RegDB).

RefreshComponents only updates CLSID information. It does not update interface or method information. Components that are refreshed using RefreshComponents can not be configured or secured at the interface or method levels in COM+ applications.

Note: You generally should not use RefreshComponents. The recommended way to update components in COM+ applications is to remove and reinstall the components using InstallComponent (see page 3373), so that complete registration information is updated in RegDB.

See Also

InstallComponent (see page 3373)

25.1.4.4.22 TCOMAdminCatalog.RefreshRouter Method

Refreshes the data being used by the component load balancing service on a CLB server.

Pascal

```
procedure RefreshRouter;
```

C++

```
__fastcall RefreshRouter();
```

Description

Do not use the RefreshRouter method. It is deprecated.

See Also

RestoreREGDB (see page 3376)

ServiceCheck (see page 3377)

25.1.4.4.23 TCOMAdminCatalog.RestoreREGDB Method

Restores the COM+ class registration database (RegDB) from a specified file.

Pascal

```
procedure RestoreREGDB(const bstrBackupFilePath: WideString);
```

C++

```
__fastcall RestoreREGDB(const BSTR bstrBackupFilePath);
```

Description

Call RestoreREGDB to restore the COM+ class registration database (RegDB) from a file that was previously created by the BackupREGDB (see page 3365) method This requires a system reboot in order to take effect.

bstrBackupFilePath is the file previously created by the BackupREGDB (see page 3365) method.

See Also

BackupREGDB (see page 3365)

RefreshComponents (see page 3376)

25.1.4.4.24 TCOMAdminCatalog.ServiceCheck Method

Checks the status of a COM+ service.

Pascal

```
function ServiceCheck(lService: Integer): Integer;
```

C++

```
__fastcall int ServiceCheck(int lService);
```

Description

Call ServiceCheck to check the status of the service specified by lService. A value of 1 specifies the Component Load Balancing service. At present, TCOMAdminCatalog (see page 3359) does not support any other services.

SericeCheck returns one of the following values:

Value	Meaning
0	Service is currently stopped.
1	Service is due to start up.
2	Service is due to stop.
3	Service is running normally.
4	Service is due to continue.
5	Service is due to pause.
6	Service is currently paused.
7	Service status is unknown.

25.1.4.4.25 TCOMAdminCatalog.ShutdownApplication Method

Initiates shutdown of a COM+ application server process.

Pascal

```
procedure ShutdownApplication(const bstrApplIdOrName: WideString);
```

C++

```
__fastcall ShutdownApplication(const BSTR bstrApplIdOrName);
```

Description

Call ShutdownApplication to shut down a COM+ application process.

bstrApplIdOrName is the GUID or name that identifies the application to shut down.

See Also

StartApplication (see page 3378)

25.1.4.4.26 TCOMAdminCatalog.StartApplication Method

Launches a COM+ server application in a dedicated process.

Pascal

```
procedure StartApplication(const bstrApplIdOrName: WideString);
```

C++

```
__fastcall StartApplication(const BSTR bstrApplIdOrName);
```

Description

Call StartApplication to start up a COM+ server application. The components in the application are launched in a new dedicated process.

bstrApplIdOrName is the GUID or name that identifies the application to start.

See Also

ShutdownApplication (see page 3377)

25.1.4.4.27 TCOMAdminCatalog.StartRouter Method

Starts the component load balancing service on a CLB server.

Pascal

```
procedure StartRouter;
```

C++

```
__fastcall StartRouter();
```

Description

StartRouter starts the component load balancing service if it is installed. Subsequent component activation requests are then routed across the application cluster that the router defines.

StartRouter does nothing if called on a machine that does not act as the component load balancing (CLB) server.

See Also

StopRouter (see page 3378)

ServiceCheck (see page 3377)

25.1.4.4.28 TCOMAdminCatalog.StopRouter Method

Stops the component load balancing service on a CLB server.

Pascal

```
procedure StopRouter;
```

C++

```
__fastcall StopRouter();
```

Description

When called on a machine acting as the component load balancing (CLB) server, StopRouter stops the server from routing component activation requests to other servers in the application cluster.

See Also

StartRouter (see page 3378)

ServiceCheck (see page 3377)

25.1.4.5 TCOMAdminCatalog Properties

The properties of the TCOMAdminCatalog class are listed here.

Public Properties

	Name	Description
R	DefaultInterface (see page 3379)	Provides access to the default interface for the component.
R	MajorVersion (see page 3379)	Indicates the major version number of the COMAdmin Library
R	MinorVersion (see page 3380)	Indicates the minor version number of the COMAdmin Library

25.1.4.5.1 TCOMAdminCatalog.DefaultInterface Property

Provides access to the default interface for the component.

Pascal

```
property DefaultInterface: ICOMAdminCatalog;
```

C++

```
__property ICOMAdminCatalog DefaultInterface;
```

Description

Use DefaultInterface to access the default interface for TCOMAdminCatalog (see page 3359). This is the ICOMAdminCatalog interface, whose properties and methods are surfaced as properties and methods of TCOMAdminCatalog (see page 3359).

25.1.4.5.2 TCOMAdminCatalog.MajorVersion Property

Indicates the major version number of the COMAdmin Library

Pascal

```
property MajorVersion: Integer;
```

C++

```
__property int MajorVersion;
```

Description

Use MajorVersion to determine the major version number of the COMAdmin Library, which TCOMAdminCatalog (see page 3359) uses to administer COM+ applications.

See Also

MinorVersion (see page 3380)

25.1.4.5.3 TCOMAdminCatalog.MinorVersion Property

Indicates the minor version number of the COMAdmin Library

Pascal

```
property MinorVersion: Integer;
```

C++

```
__property int MinorVersion;
```

Description

Use MinorVersion to determine the minor version number of the COMAdmin Library, which TCOMAdminCatalog (see page 3359) uses to administer COM+ applications.

See Also

MajorVersion (see page 3379)

25.1.5 TCOMAdminCatalogCollection Class

TCOMAdminCatalogCollection represents a collection from the COM+ catalog.

Class Hierarchy

Pascal

```
TCOMAdminCatalogCollection = class(TOleServer);
```

C++

```
class TCOMAdminCatalogCollection : public TOleServer;
```

File

CmAdmCtl

Description

Use TCOMAdminCatalogCollection to work with one of the collections in the COM+ catalog. Use the GetCollection (see page 3389) method of TCOMAdminCatlog to obtain a TCOMAdminCatalogCollection object for a specific collection. Each collection corresponds to a folder that appears in the Component Services administration tool.

TCOMAdminCatalogCollection implements the ICatalogCollection interface, to let you enumerate, add, remove, and retrieve items in a collection, and to access related collections. Each item is represented by a TCOMAdminCatalogObject (see page 3396) instance.

Note: Typically, when you first obtain a TCOMAdminCatalogCollection object, it does not contain data from the catalog for items in the collection. Use the Populate (see page 3391) method to read in data for items in the collection before using the other properties and methods.

See Also

TCOMAdminCatalog (see page 3359)

TCOMAdminCatalogObject (see page 3396)

TCOMAdminCatalog (see page 3359)

25.1.5.1 TCOMAdminCatalogCollection Members

The following tables list the members exposed by TCOMAdminCatalogCollection.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_AddRef (see page 18104)	Increments the reference count for the number of interface references dependent on the OLE server.
	_Release (see page 2769)	Called when an application releases a component interface.
	_Release (see page 18104)	Decrements the reference count for the calling interface on a object.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ConnectEvents (see page 18105)	Establishes a connection using the EventDispatch (see page 18111) property as an event sink.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DisconnectEvents (see page 18106)	Terminates a connection that was established using the ConnectEvents (see page 18105) method.
	GetAutoConnect (see page 18106)	Returns the value of the AutoConnect (see page 18110) property.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetConnectKind (see page 18106)	Returns the value of the ConnectKind (see page 18110) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetServer (see page 18107)	Returns an interface for the COM server.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	InitServerData (see page 3390)	Initializes the ServerData property to reflect the type library information of the COM server.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	InvokeEvent (see page 18107)	Dispatches an event from the COM server to the appropriate event handler.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 18108)	Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 18110) is True true.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 18108)	Returns a reference to a specified interface if the OLE server supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.

	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoConnect (see page 18109)	Sets the value of the AutoConnect (see page 18110) property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetConnectKind (see page 18109)	Sets the value of the ConnectKind (see page 18110) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	EventDispatch (see page 18111)	This is EventDispatch, a member of class TOleServer.
	ServerData (see page 18111)	Encodes information about the COM server to which ServerData connects.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	Add (see page 3386)	Adds a new item to the end of the collection.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Connect (see page 3386)	Not used in TCOMAdminCatalogCollection (see page 3380).
	ConnectTo (see page 3386)	Connects the TCOMAdminCatalogCollection (see page 3380) component to an existing ICatalogCollection interface.
	Create (see page 3384)	Creates a new instance of TCOMAdminCatalogCollection (see page 3380).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 3385)	Frees an instance of TCOMAdminCatalogCollection (see page 3380)
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Disconnect (see page 3387)	Terminates the connection to the COM server.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	Get_AddEnabled (see page 3387)	Returns the value of the Get_AddEnabled property.
	Get_Count (see page 3388)	Returns the number of items in the collection.
	Get_DataStoreMajorVersion (see page 3388)	Returns the value of the Get_DataStoreMajorVersion property.
	Get_DataStoreMinorVersion (see page 3388)	Returns the value of the Get_DataStoreMinorVersion property.
	Get_Item (see page 3389)	Returns a specified item from the collection.
	Get_Name (see page 3389)	Returns the value of the Get_Name property
	Get_RemoveEnabled (see page 3389)	Returns the value of the Get_RemoveEnabled property.
	GetCollection (see page 3389)	Returns a TCOMAdminCatalogCollectionCollection object for a specified collection.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetUtilInterface (see page 3390)	Returns the utility interface associated with this collection.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Populate (see page 3391)	Fills the collection object with items from the catalog.
	PopulateByKey (see page 3391)	Populates the collection with information for the specified objects.
	PopulateByQuery (see page 3392)	Reserved for future use.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Remove (see page 3392)	Removes an item from the collection
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveChanges (see page 3392)	Commits any changes to the collection by writing them to the COM+ catalog.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	AddEnabled (see page 3393)	Indicates whether the Add (see page 3386) method can add items to the collection.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Count (see page 3393)	Indicates the number of items in the collection.
R	DataStoreMajorVersion (see page 3394)	Indicates the major version number of the COMAdmin Library
R	DataStoreMinorVersion (see page 3394)	Indicates the minor version number of the COMAdmin Library
R	DefaultInterface (see page 3395)	Provides access to the default interface for the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Name (see page 3395)	Indicates the Name of the collection.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	RemoveEnabled (see page 3395)	Indicates whether the Remove (see page 3392) method can remove items from the collection.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	AutoConnect (see page 18110)	Specifies whether the component automatically connects to the server.
	ConnectKind (see page 18110)	Indicates the type of process to which the ConnectKind component establishes a connection.
	RemoteMachineName (see page 18111)	Specifies the machine running the COM server when ConnectKind (see page 18110) is ckRemote.
	Tag (see page 2808)	Stores an integer value as part of a component.

25.1.5.2 TCOMAdminCatalogCollection.Create Constructor

Creates a new instance of TCOMAdminCatalogCollection (see page 3380).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCOMAdminCatalogCollection(TComponent * AOwner);
```

Description

Call Create to instantiate TCOMAdminCatalogCollection (see page 3380) at runtime. Once you have created a TCOMAdminCatalogCollection (see page 3380) object, you must bind it to an ICatalogCollection interface before you can use it. Use the ConnectTo (see page 3386) method to bind a TCOMAdminCatalogCollection (see page 3380) object to an ICatalogCollection interface.

Note: When you obtain a TCOMAdminCatalogCollection (see page 3380) instance from a method on the TCOMAdminCatalog (see page 3359) object or from another collection, it is already bound to an ICatalogCollection interface.

Owner specifies the component (typically a form or data module) that is responsible for freeing the TCOMAdminCatalogCollection (see page 3380) instance.

See Also

Owner (see page 2807)

ConnectTo (see page 3386)

25.1.5.3 TCOMAdminCatalogCollection.Destroy Destructor

Frees an instance of TCOMAdminCatalogCollection (see page 3380)

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCOMAdminCatalogCollection();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TCOMAdminCatalogCollection (see page 3380) component reference is not nil before calling Destroy.

Note that freeing the TCOMAdminCatalogCollection (see page 3380) object does not remove the collection from the COM+ catalog, it merely deletes the object that lets you work with that collection.

See Also

Free (see page 22300)

25.1.5.4 TCOMAdminCatalogCollection Methods

The methods of the TCOMAdminCatalogCollection class are listed here.

Protected Methods

	Name	Description
	InitServerData (see page 3390)	Initializes the ServerData property to reflect the type library information of the COM server.

Public Methods

	Name	Description
	Add (see page 3386)	Adds a new item to the end of the collection.
	Connect (see page 3386)	Not used in TCOMAdminCatalogCollection (see page 3380).
	ConnectTo (see page 3386)	Connects the TCOMAdminCatalogCollection (see page 3380) component to an existing ICatalogCollection interface.
	Disconnect (see page 3387)	Terminates the connection to the COM server.
	Get_AddEnabled (see page 3387)	Returns the value of the Get_AddEnabled property.
	Get_Count (see page 3388)	Returns the number of items in the collection.
	Get_DataStoreMajorVersion (see page 3388)	Returns the value of the Get_DataStoreMajorVersion property.
	Get_DataStoreMinorVersion (see page 3388)	Returns the value of the Get_DataStoreMinorVersion property.
	Get_Item (see page 3389)	Returns a specified item from the collection.
	Get_Name (see page 3389)	Returns the value of the Get_Name property
	Get_RemoveEnabled (see page 3389)	Returns the value of the Get_RemoveEnabled property.
	GetCollection (see page 3389)	Returns a TCOMAdminCatalogCollectionCollection object for a specified collection.
	GetUtilInterface (see page 3390)	Returns the utility interface associated with this collection.
	Populate (see page 3391)	Fills the collection object with items from the catalog.
	PopulateByKey (see page 3391)	Populates the collection with information for the specified objects.

	PopulateByQuery (see page 3392)	Reserved for future use.
	Remove (see page 3392)	Removes an item from the collection
	SaveChanges (see page 3392)	Commits any changes to the collection by writing them to the COM+ catalog.

25.1.5.4.1 TCOMAdminCatalogCollection.Add Method

Adds a new item to the end of the collection.

Pascal

```
function Add: TCOMAdminCatalogObject;
```

C++

```
__fastcall TCOMAdminCatalogObject Add();
```

Description

Call the Add method to create a new object in a collection. Add returns the TCOMAdminCatalogObject (see page 3396) that represents the new item.

Not all collections allow you to add items. Check the AddEnabled (see page 3393) property before trying to call Add. To install or create objects in collections where AddEnabled (see page 3393) is false, use the catalog utility interfaces.

Note: Add does not commit the change to the catalog data store. To cause the new item to be written to the data store, call the SaveChanges (see page 3392) method.

See Also

SaveChanges (see page 3392)

AddEnabled (see page 3393)

25.1.5.4.2 TCOMAdminCatalogCollection.Connect Method

Not used in TCOMAdminCatalogCollection (see page 3380).

Pascal

```
procedure Connect; override;
```

C++

```
virtual __fastcall Connect();
```

Description

Do not use the Connect method. TCOMAdminCatalogCollection (see page 3380) objects never directly launch the COM server. Rather, obtain a TCOMAdminCatalogCollection (see page 3380) object that is already bound to an ICatalogCollection interface from a method such as the parent collection's GetCollection (see page 3389) method.

See Also

ConnectTo (see page 3386)

GetCollection (see page 3368)

GetCollection (see page 3389)

25.1.5.4.3 TCOMAdminCatalogCollection.ConnectTo Method

Connects the TCOMAdminCatalogCollection (see page 3380) component to an existing ICatalogCollection interface.

Pascal

```
procedure ConnectTo(svrIntf: ICatalogCollection);
```

C++

```
__fastcall ConnectTo(ICatalogCollection svrIntf);
```

Description

Use ConnectTo when the ConnectKind property is ckAttachToInterface. ConnectTo allows the TCOMAdminCatalogCollection (see page 3380) to use an existing ICatalogCollection interface.

Typically, applications do not need to use the ConnectTo method. Rather, they obtain a TCOMAdminCatalogCollection (see page 3380) object that is already bound to an ICatalogCollection object by calling a method such as GetCollection (see page 3389).

See Also

Connect (see page 3386)

GetCollection (see page 3368)

GetCollection (see page 3389)

ConnectKind (see page 18110)

25.1.5.4.4 TCOMAdminCatalogCollection.Disconnect Method

Terminates the connection to the COM server.

Pascal

```
procedure Disconnect; override;
```

C++

```
virtual __fastcall Disconnect();
```

Description

Disconnect releases the ICatalogCollection interface that TCOMAdminCatalogCollection (see page 3380) uses to implement its properties and methods. Once you have called Disconnect, you can no longer use the TCOMAdminCatalogCollection (see page 3380) instance, unless you rebind it to another interface using the ConnectTo (see page 3386) method.

See Also

ConnectTo (see page 3386)

25.1.5.4.5 TCOMAdminCatalogCollection.Get_AddEnabled Method

Returns the value of the Get_AddEnabled property.

Pascal

```
function Get_AddEnabled: WordBool;
```

C++

```
__fastcall WordBool Get_AddEnabled();
```

Description

Get_Get_AddEnabled is the read implementation of the Get_AddEnabled property.

See Also

Get_AddEnabled

25.1.5.4.6 TCOMAdminCatalogCollection.Get_Count Method

Returns the number of items in the collection.

Pascal

```
function Get_Count: Integer;
```

C++

```
__fastcall int Get_Count();
```

Description

Get_Get_Count is the read implementation of the Get_Count property.

See Also

Get_Count

25.1.5.4.7 TCOMAdminCatalogCollection.Get_DataStoreMajorVersion Method

Returns the value of the Get_DataStoreMajorVersion property.

Pascal

```
function Get_DataStoreMajorVersion: Integer;
```

C++

```
__fastcall int Get_DataStoreMajorVersion();
```

Description

Get_Get_DataStoreMajorVersion is the read implementation of the Get_DataStoreMajorVersion property.

See Also

Get_DataStoreMajorVersion

25.1.5.4.8 TCOMAdminCatalogCollection.Get_DataStoreMinorVersion Method

Returns the value of the Get_DataStoreMinorVersion property.

Pascal

```
function Get_DataStoreMinorVersion: Integer;
```

C++

```
__fastcall int Get_DataStoreMinorVersion();
```

Description

Get_Get_DataStoreMinorVersion is the read implementation of the Get_DataStoreMinorVersion property.

See Also

Get_DataStoreMinorVersion

25.1.5.4.9 TCOMAdminCatalogCollection.Get_Item Method

Returns a specified item from the collection.

Pascal

```
function Get_Item(lIndex: Integer): TCOMAdminCatalogObject;
```

C++

```
__fastcall TCOMAdminCatalogObject Get_Item(int lIndex);
```

Description

Call Get_Get_Item to access an item in the collection

lIndex is the index of the item. It can have any value from 0 to one less than the value of the Count (see page 3393) property.

See Also

Count (see page 3393)

25.1.5.4.10 TCOMAdminCatalogCollection.Get_Name Method

Returns the value of the Get_Name property

Pascal

```
function Get_Name: OleVariant;
```

C++

```
__fastcall OleVariant Get_Name();
```

Description

GetGet_Name is the read implementation of the Get_Name property.

See Also

Get_Name

25.1.5.4.11 TCOMAdminCatalogCollection.Get_RemoveEnabled Method

Returns the value of the Get_RemoveEnabled property.

Pascal

```
function Get_RemoveEnabled: WordBool;
```

C++

```
__fastcall WordBool Get_RemoveEnabled();
```

Description

Get_Get_RemoveEnabled is the read implementation of the Get_RemoveEnabled property.

See Also

Get_RemoveEnabled

25.1.5.4.12 TCOMAdminCatalogCollection.GetCollection Method

Returns a TCOMAdminCatalogCollectionCollection object for a specified collection.

Pascal

```
function GetCollection(const bstrCollName: WideString; varObjectKey: OleVariant):
TCOMAdminCatalogCollection;
```

C++

```
__fastcall TCOMAdminCatalogCollection GetCollection(const BSTR bstrCollName, OleVariant
varObjectKey);
```

Description

GetCollection retrieves a sub-collection that is contained in this collection.

bstrCollName is the name of the desired collection. The available collections depend on your version of the COMAdmin Library. See the Microsoft documentation for a list of the available collections in your version of the COMAdmin Library.

Key is the Key property of the item to which the collection belongs.

Note: The TCOMAdminCatalogCollectionCollection object that GetCollection returns does not contain data from the catalog for items contained in the collection. Use its Populate (see page 3391) method to read in data for items in the collection.

See Also

Key (see page 3405)

Populate (see page 3391)

25.1.5.4.13 TCOMAdminCatalogCollection.GetUtilInterface Method

Returns the utility interface associated with this collection.

Pascal

```
function GetUtilInterface: IDispatch;
```

C++

```
__fastcall IDispatch GetUtilInterface();
```

Description

Call the GetUtilInterface method to obtain an interface to the utility object associated with the collection. Not every collection has an associated utility object. The following table lists the collections for which GetUtilInterface returns an interface, along with the name of the associated utility object:

Collection name	Utility object
Packages	PackageUtil
ComponentsInPackage	ComponentUtil
RemoteComponents	RemoteComponentUtil
RolesForPackageComponent	RoleAssociationUtil
RolesForPackageComponentInterface	RoleAssociationUtil

25.1.5.4.14 TCOMAdminCatalogCollection.InitServerData Method

Initializes the ServerData property to reflect the type library information of the COM server.

Pascal

```
procedure InitServerData; override;
```

C++

```
virtual __fastcall InitServerData();
```

Description

The InitServerData constructor calls InitServerData to initialize ServerData with information from the COM server's type library.

InitServerData is an abstract a pure virtual method in InitServerData. Each InitServerData descendant implements this method so that the ServerData property reflects its particular COM server.

See Also

ServerData (see page 18111)

Create (see page 18101)

25.1.5.4.15 TCOMAdminCatalogCollection.Populate Method

Fills the collection object with items from the catalog.

Pascal

```
procedure Populate;
```

C++

```
__fastcall Populate();
```

Description

Call Populate to set the items of the collection to those currently saved for this collection in the COM+ catalog. When you first obtain an instance of TCOMAdminCatalogCollection (see page 3380), it does not yet contain any items, and you must call Populate to fill it with the associated items.

After making changes to the collection (such as adding or removing objects or changing object properties) are not saved to the COM+ catalog until you call the SaveChanges (see page 3392) method. Thus, if you call Populate after making changes but before calling SaveChanges (see page 3392), all your changes are rolled back and the collection is restored to the state that is saved in the COM+ catalog.

See Also

PopulateByQuery (see page 3392)

PopulateByKey (see page 3391)

TCOMAdminCatalog (see page 3359)

SaveChanges (see page 3392)

25.1.5.4.16 TCOMAdminCatalogCollection.PopulateByKey Method

Populates the collection with information for the specified objects.

Pascal

```
procedure PopulateByKey(aKeys: PSafeArray);
```

C++

```
__fastcall PopulateByKey(PSafeArray aKeys);
```

Description

Use PopulateByKey to refresh the items in the collection that have a specified key. PopulateByKey reloads all items from the

COM+ catalog that have the specified keys.

aKeys is an array of Key values that represent the Key property for each item to be loaded from the COM+ catalog.

See Also

Populate (see page 3391)

PopulateByQuery (see page 3392)

Key (see page 3405)

25.1.5.4.17 TCOMAdminCatalogCollection.PopulateByQuery Method

Reserved for future use.

Pascal

```
procedure PopulateByQuery(const bstrQueryString: WideString; lQueryType: Integer);
```

C++

```
__fastcall PopulateByQuery(const BSTR bstrQueryString, int lQueryType);
```

Description

PopulateByQuery is not currently implemented.

See Also

Populate (see page 3391)

PopulateByKey (see page 3391)

25.1.5.4.18 TCOMAdminCatalogCollection.Remove Method

Removes an item from the collection

Pascal

```
procedure Remove(lIndex: Integer);
```

C++

```
__fastcall Remove(int lIndex);
```

Description

Remove deletes an item from the collection given its index, and re-indexes the items with higher indices. These changes are not reflected on the COM+ catalog data store until you call SaveChanges (see page 3392).

See Also

RemoveEnabled (see page 3395)

SaveChanges (see page 3392)

25.1.5.4.19 TCOMAdminCatalogCollection.SaveChanges Method

Commits any changes to the collection by writing them to the COM+ catalog.

Pascal

```
function SaveChanges: Integer;
```

C++

```
__fastcall int SaveChanges();
```

Description

Call SaveChanges to save all pending changes made to the collection and the items it contains to the COM+ catalog data store. SaveChanges returns the number of changes written to the COM+ catalog.

See Also

Populate (see page 3391)

25.1.5.5 TCOMAdminCatalogCollection Properties

The properties of the TCOMAdminCatalogCollection class are listed here.

Public Properties

	Name	Description
R	AddEnabled (see page 3393)	Indicates whether the Add (see page 3386) method can add items to the collection.
R	Count (see page 3393)	Indicates the number of items in the collection.
R	DataStoreMajorVersion (see page 3394)	Indicates the major version number of the COMAdmin Library
R	DataStoreMinorVersion (see page 3394)	Indicates the minor version number of the COMAdmin Library
R	DefaultInterface (see page 3395)	Provides access to the default interface for the component.
R	Name (see page 3395)	Indicates the Name of the collection.
R	RemoveEnabled (see page 3395)	Indicates whether the Remove (see page 3392) method can remove items from the collection.

25.1.5.5.1 TCOMAdminCatalogCollection.AddEnabled Property

Indicates whether the Add (see page 3386) method can add items to the collection.

Pascal

```
property AddEnabled: WordBool;
```

C++

```
__property WordBool AddEnabled;
```

Description

Read AddEnabled to determine whether your application can add items to this collection. When AddEnabled is false, the Add (see page 3386) method fails.

See Also

Add (see page 3386)

25.1.5.5.2 TCOMAdminCatalogCollection.Count Property

Indicates the number of items in the collection.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of items in the collection. Count acts as an upper bound for the index to the Get_Item (see page 3389) method.

When you first obtain a TCOMAdminCatalogCollection (see page 3380) object, the value of Count is 0. Call the Populate (see page 3391) method to fill the collection with its items to determine the actual number of items in this collection of the COM+ catalog.

To change the value of Count, add items using the Add (see page 3386) method or delete them using the Remove (see page 3392) method.

See Also

Add (see page 3386)

Remove (see page 3392)

Get_Item (see page 3389)

Populate (see page 3391)

25.1.5.5.3 TCOMAdminCatalogCollection.DataStoreMajorVersion Property

Indicates the major version number of the COMAdmin Library

Pascal

```
property DataStoreMajorVersion: Integer;
```

C++

```
__property int DataStoreMajorVersion;
```

Description

Use DataStoreMajorVersion to determine the major version number of the COMAdmin Library. This is the same as the MajorVersion property of the TCOMAdminCatalog (see page 3359) object that contains this collection.

See Also

DataStoreMinorVersion (see page 3394)

MajorVersion (see page 3379)

25.1.5.5.4 TCOMAdminCatalogCollection.DataStoreMinorVersion Property

Indicates the minor version number of the COMAdmin Library

Pascal

```
property DataStoreMinorVersion: Integer;
```

C++

```
__property int DataStoreMinorVersion;
```

Description

Use DataStoreMinorVersion to determine the minor version number of the COMAdmin Library. This is the same as the MinorVersion property of the TCOMAdminCatalog (see page 3359) object that contains this collection.

See Also

DataStoreMajorVersion (see page 3394)

MinorVersion (see page 3380)

25.1.5.5.5 TCOMAdminCatalogCollection.DefaultInterface Property

Provides access to the default interface for the component.

Pascal

```
property DefaultInterface: ICatalogCollection;
```

C++

```
__property ICatalogCollection DefaultInterface;
```

Description

Use DefaultInterface to access the default interface for TCOMAdminCatalogCollection (see page 3380). This is the ICatalogCollection interface, whose properties and methods are surfaced as properties and methods of TCOMAdminCatalogCollection (see page 3380).

25.1.5.5.6 TCOMAdminCatalogCollection.Name Property

Indicates the Name of the collection.

Pascal

```
property Name: OleVariant;
```

C++

```
__property OleVariant Name;
```

Description

Use Name to determine the name of the collection. This is the name by which you can identify the collection, for example, when calling the GetCollection (see page 3389) method to obtain a TCOMAdminCatalogCollection (see page 3380) instance.

See Also

GetCollection (see page 3368)

GetCollection (see page 3389)

25.1.5.5.7 TCOMAdminCatalogCollection.RemoveEnabled Property

Indicates whether the Remove (see page 3392) method can remove items from the collection.

Pascal

```
property RemoveEnabled: WordBool;
```

C++

```
__property WordBool RemoveEnabled;
```

Description

Read RemoveEnabled to determine whether your application can remove items from this collection. When RemoveEnabled is false, the Remove (see page 3392) method fails.

See Also

Remove (see page 3392)

25.1.6 TCOMAdminCatalogObject Class

TCOMAdminCatalogObject represents an item in a collection from the COM+ catalog.

Class Hierarchy

Pascal

```
TCOMAdminCatalogObject = class(TOleServer);
```

C++

```
class TCOMAdminCatalogObject : public TOleServer;
```

File

CmAdmCtl

Description

Use TCOMAdminCatalogObject to work with one of the items in a COM+ catalog collection. Use the Get_Item method of TCOMAdminCatlogCollection to obtain a TCOMAdminCatalogObject instance for a specific item. Each item corresponds to one of the items in a folder that appears in the Component Services administration tool.

TCOMAdminCatalogObject implements the ICatalogObject interface, to let you get and set properties on the items in a catalog collection. Any changes you make to the item are not reflected on the catalog data store until you call SaveChanges for the collection that contains the item.

See Also

TCOMAdminCatalog (see page 3359)

TCOMAdminCatalogCollection (see page 3380)

TCOMAdminCatalogCollection (see page 3380)

TCOMAdminCatalogCollection (see page 3380)

25.1.6.1 TCOMAdminCatalogObject Members

The following tables list the members exposed by TCOMAdminCatalogObject.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_AddRef (see page 18104)	Increments the reference count for the number of interface references dependent on the OLE server.
	_Release (see page 2769)	Called when an application releases a component interface.

	_Release (see page 18104)	Decrements the reference count for the calling interface on a object.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ConnectEvents (see page 18105)	Establishes a connection using the EventDispatch (see page 18111) property as an event sink.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DisconnectEvents (see page 18106)	Terminates a connection that was established using the ConnectEvents (see page 18105) method.
	GetAutoConnect (see page 18106)	Returns the value of the AutoConnect (see page 18110) property.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetConnectKind (see page 18106)	Returns the value of the ConnectKind (see page 18110) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetServer (see page 18107)	Returns an interface for the COM server.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	InitServerData (see page 3403)	Initializes the ServerData property to reflect the type library information of the COM server.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	InvokeEvent (see page 18107)	Dispatches an event from the COM server to the appropriate event handler.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 18108)	Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 18110) is True true.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 18108)	Returns a reference to a specified interface if the OLE server supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoConnect (see page 18109)	Sets the value of the AutoConnect (see page 18110) property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetConnectKind (see page 18109)	Sets the value of the ConnectKind (see page 18110) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.

	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	EventDispatch (see page 18111)	This is EventDispatch, a member of class TOleServer.
	ServerData (see page 18111)	Encodes information about the COM server to which ServerData connects.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Connect (see page 3401)	Not used in TCOMAdminCatalogObject (see page 3396).
	ConnectTo (see page 3401)	Connects the TCOMAdminCatalogObject (see page 3396) component to an existing ICatalogObject interface.
	Create (see page 3400)	Creates a new instance of TCOMAdminCatalogObject (see page 3396).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 3400)	Frees an instance of TCOMAdminCatalogObject (see page 3396)
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Disconnect (see page 3402)	Terminates the connection to the COM server.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	Get_Key (see page 3402)	Returns the value of the Get_Key property.
	Get_Name (see page 3402)	Returns the value of the Get_Name property.
	Get_Valid (see page 3403)	Returns the value of the Get_Valid property.
	Get_Value (see page 3403)	Returns the value of the Get_Value property.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.

	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsPropertyReadOnly (see page 3404)	Indicates whether a specified property is read-only.
	IsPropertyWriteOnly (see page 3404)	Indicates whether a specified property is write-only.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Set_Value (see page 3404)	Sets the value of the Set_Value property.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	DefaultInterface (see page 3405)	Provides access to the default interface for the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Key (see page 3405)	Uniquely identifies the catalog item.
R	Name (see page 3406)	Indicates the Name of the object.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	Valid (see page 3406)	Indicates whether all properties of the object have been successfully read from the catalog data store.
	Value (see page 3407)	Represents a the value of a named property of the catalog object.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	AutoConnect (see page 18110)	Specifies whether the component automatically connects to the server.
	ConnectKind (see page 18110)	Indicates the type of process to which the ConnectKind component establishes a connection.
	RemoteMachineName (see page 18111)	Specifies the machine running the COM server when ConnectKind (see page 18110) is ckRemote.
	Tag (see page 2808)	Stores an integer value as part of a component.

25.1.6.2 TCOMAdminCatalogObject.Create Constructor

Creates a new instance of TCOMAdminCatalogObject (see page 3396).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCOMAdminCatalogObject(TComponent * AOwner);
```

Description

Call Create to instantiate TCOMAdminCatalogObject (see page 3396) at runtime. Once you create a TCOMAdminCatalogObject (see page 3396), you must bind it to an ICatalogObject interface before you can use it. Use the ConnectTo (see page 3401) method to bind a TCOMAdminCatalogObject (see page 3396) instance to an ICatalogObject interface.

Note: The TCOMAdminCatalogObject (see page 3396) instance that the catalog object returns from its Get_Item method is already bound to an ICatalogObject interface.

Owner specifies the component (typically a form or data module) that is responsible for freeing the TCOMAdminCatalogObject (see page 3396) instance.

See Also

Owner (see page 2807)

ConnectTo (see page 3401)

Get_Item (see page 3389)

25.1.6.3 TCOMAdminCatalogObject.Destroy Destructor

Frees an instance of TCOMAdminCatalogObject (see page 3396)

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCOMAdminCatalogObject();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TCOMAdminCatalogObject (see page 3396) component reference is not nil before calling Destroy.

Note that freeing a TCOMAdminCatalogObject (see page 3396) instance does not delete the item from its collection. It merely frees the object that lets you work with the item.

See Also

Free (see page 22300)

25.1.6.4 TCOMAdminCatalogObject Methods

The methods of the TCOMAdminCatalogObject class are listed here.

Protected Methods

	Name	Description
	InitServerData (see page 3403)	Initializes the ServerData property to reflect the type library information of the COM server.

Public Methods

	Name	Description
	Connect (see page 3401)	Not used in TCOMAdminCatalogObject (see page 3396).
	ConnectTo (see page 3401)	Connects the TCOMAdminCatalogObject (see page 3396) component to an existing ICatalogObject interface.
	Disconnect (see page 3402)	Terminates the connection to the COM server.
	Get_Key (see page 3402)	Returns the value of the Get_Key property.
	Get_Name (see page 3402)	Returns the value of the Get_Name property.
	Get_Valid (see page 3403)	Returns the value of the Get_Valid property.
	Get_Value (see page 3403)	Returns the value of the Get_Value property.
	IsPropertyReadOnly (see page 3404)	Indicates whether a specified property is read-only.
	IsPropertyWriteOnly (see page 3404)	Indicates whether a specified property is write-only.
	Set_Value (see page 3404)	Sets the value of the Set_Value property.

25.1.6.4.1 TCOMAdminCatalogObject.Connect Method

Not used in TCOMAdminCatalogObject (see page 3396).

Pascal

```
procedure Connect; override;
```

C++

```
virtual __fastcall Connect();
```

Description

Do not use the Connect method. TCOMAdminCatalogObject (see page 3396) objects never directly launch the COM server. Rather, obtain a TCOMAdminCatalogObject (see page 3396) object that is already bound to an ICatalogCollection interface from the parent collection's Get_Item method.

See Also

ConnectTo (see page 3401)

Get_Item (see page 3389)

25.1.6.4.2 TCOMAdminCatalogObject.ConnectTo Method

Connects the TCOMAdminCatalogObject (see page 3396) component to an existing ICatalogObject interface.

Pascal

```
procedure ConnectTo(svrIntf: ICatalogObject);
```

C++

```
__fastcall ConnectTo(ICatalogObject svrIntf);
```

Description

Use ConnectTo when the ConnectKind property is ckAttachToInterface. ConnectTo allows the TCOMAdminCatalogObject (see page 3396) to use an existing ICatalogCollection interface.

Typically, applications do not need to use the ConnectTo method. Rather, they obtain a TCOMAdminCatalogObject (see page 3396) object that is already bound to an ICatalogCollection object by calling the collection object's Get_Item method.

See Also

Create (see page 3400)

Get_Item (see page 3389)

ConnectKind (see page 18110)

25.1.6.4.3 TCOMAdminCatalogObject.Disconnect Method

Terminates the connection to the COM server.

Pascal

```
procedure Disconnect; override;
```

C++

```
virtual __fastcall Disconnect();
```

Description

Disconnect releases the ICatalogObject interface that TCOMAdminCatalogObject (see page 3396) uses to implement its properties and methods. Once you have called Disconnect, you can no longer use the TCOMAdminCatalogObject (see page 3396) instance, unless you rebind it to another interface using the ConnectTo (see page 3401) method.

See Also

Destroy (see page 3400)

ConnectTo (see page 3401)

25.1.6.4.4 TCOMAdminCatalogObject.Get_Key Method

Returns the value of the Get_Key property.

Pascal

```
function Get_Key: OleVariant;
```

C++

```
__fastcall OleVariant Get_Key();
```

Description

Get_Get_Key is the read implementation of the Get_Key property.

See Also

Get_Key

25.1.6.4.5 TCOMAdminCatalogObject.Get_Name Method

Returns the value of the Get_Name property.

Pascal

```
function Get_Name: OleVariant;
```

C++

```
__fastcall OleVariant Get_Name();
```

Description

Get_Get_Name is the read implementation of the Get_Name property.

See Also

Get_Name

25.1.6.4.6 TCOMAdminCatalogObject.Get_Valid Method

Returns the value of the Get_Valid property.

Pascal

```
function Get_Valid: WordBool;
```

C++

```
__fastcall WordBool Get_Valid();
```

Description

Get_Get_Valid is the read implementation of the Get_Valid property.

See Also

Get_Valid

25.1.6.4.7 TCOMAdminCatalogObject.Get_Value Method

Returns the value of the Get_Value property.

Pascal

```
function Get_Value(const bstrPropName: WideString): OleVariant;
```

C++

```
__fastcall OleVariant Get_Value(const BSTR bstrPropName);
```

Description

Get_Get_Value is the read implementation of the Get_Value property.

bstrPropName is the name of the property whose value you want to read.

See Also

Get_Value

25.1.6.4.8 TCOMAdminCatalogObject.InitServerData Method

Initializes the ServerData property to reflect the type library information of the COM server.

Pascal

```
procedure InitServerData; override;
```

C++

```
virtual __fastcall InitServerData();
```

Description

The InitServerData constructor calls InitServerData to initialize ServerData with information from the COM server's type library.

InitServerData is an abstract a pure virtual method in InitServerData. Each InitServerData descendant implements this method

so that the ServerData property reflects its particular COM server.

See Also

ServerData (see page 18111)

Create (see page 18101)

25.1.6.4.9 TCOMAdminCatalogObject.IsPropertyReadOnly Method

Indicates whether a specified property is read-only.

Pascal

```
function IsPropertyReadOnly(const bstrPropName: WideString): WordBool;
```

C++

```
__fastcall WordBool IsPropertyReadOnly(const BSTR bstrPropName);
```

Description

Call IsPropertyReadOnly to determine whether you can use the Value (see page 3407) property to set a specific property. If IsPropertyReadOnly returns true, you can use Value (see page 3407) to read the property's value but not set it. If IsPropertyReadOnly returns false, you can use Value (see page 3407) to set the property's value as well.

bstrPropName is the name of the property.

See Also

Value (see page 3407)

IsPropertyWriteOnly (see page 3404)

25.1.6.4.10 TCOMAdminCatalogObject.IsPropertyWriteOnly Method

Indicates whether a specified property is write-only.

Pascal

```
function IsPropertyWriteOnly(const bstrPropName: WideString): WordBool;
```

C++

```
__fastcall WordBool IsPropertyWriteOnly(const BSTR bstrPropName);
```

Description

Call IsPropertyWriteOnly to determine whether you can read the value of a specific property using the Value (see page 3407) property. If IsPropertyWriteOnly returns true, you can use Value (see page 3407) to set the property's value but not read it. If IsPropertyWriteOnly returns false, you can use Value (see page 3407) to read the property's value as well.

bstrPropName is the name of the property.

See Also

IsPropertyReadOnly (see page 3404)

Value (see page 3407)

25.1.6.4.11 TCOMAdminCatalogObject.Set_Value Method

Sets the value of the Set_Value property.

Pascal

```
procedure Set_Value(const bstrPropName: WideString; retval: OleVariant);
```

C++

```
__fastcall Set_Value(const BSTR bstrPropName, OleVariant retval);
```

Description

Set_Set_Value is the write implementation of the Set_Value property.

bstrPropName is the name of the property to set.

retVal is the new value for that property.

See Also

Set_Value

IsPropertyReadOnly (see page 3404)

25.1.6.5 TCOMAdminCatalogObject Properties

The properties of the TCOMAdminCatalogObject class are listed here.

Public Properties

	Name	Description
R	DefaultInterface (see page 3405)	Provides access to the default interface for the component.
R	Key (see page 3405)	Uniquely identifies the catalog item.
R	Name (see page 3406)	Indicates the Name of the object.
R	Valid (see page 3406)	Indicates whether all properties of the object have been successfully read from the catalog data store.
	Value (see page 3407)	Represents a the value of a named property of the catalog object.

25.1.6.5.1 TCOMAdminCatalogObject.DefaultInterface Property

Provides access to the default interface for the component.

Pascal

```
property DefaultInterface: ICatalogObject;
```

C++

```
__property ICatalogObject DefaultInterface;
```

Description

Use DefaultInterface to access the default interface for TCOMAdminCatalogObject (see page 3396). This is the ICatalogObject interface, whose properties and methods are surfaced as properties and methods of TCOMAdminCatalogObject (see page 3396).

25.1.6.5.2 TCOMAdminCatalogObject.Key Property

Uniquely identifies the catalog item.

Pascal

```
property Key: OleVariant;
```

C++

```
__property OleVariant Key;
```

Description

The Key property serves as the primary identifier for an object. In some cases, Key is a GUID, such as CLSID for a component; in some cases it is the item name, as with roles. To determine the meaning of the Key property, check the Microsoft documentation for the specific collection to which this item belongs.

Note: If you add a new object to a collection and save it with the Key property of an existing object, you overwrite the existing object.

See Also

Name (see page 3406)

25.1.6.5.3 TCOMAdminCatalogObject.Name Property

Indicates the Name of the object.

Pascal

```
property Name: OleVariant;
```

C++

```
__property OleVariant Name;
```

Description

Use Name to determine the name of the item.

Note: Although every item has a name, the primary identifier for collection items is the Key (see page 3405) property.

See Also

Key (see page 3405)

25.1.6.5.4 TCOMAdminCatalogObject.Valid Property

Indicates whether all properties of the object have been successfully read from the catalog data store.

Pascal

```
property Valid: WordBool;
```

C++

```
__property WordBool Valid;
```

Description

Read Valid to determine whether the object has been initialized to reflect the properties stored in the COM+ catalog for this item. Valid is true if the properties were successfully read from the catalog, false if they could not be read from the catalog. For example, Valid is false for a new item that has never been written to the COM+ catalog.

See Also

Value (see page 3407)

TCOMAdminCatalog (see page 3359)

Populate (see page 3391)

SaveChanges (see page 3392)

25.1.6.5.5 TCOMAdminCatalogObject.Value Property

Represents a the value of a named property of the catalog object.

Pascal

```
property Value [const bstrPropName: WideString]: OleVariant;
```

C++

```
__property OleVariant Value[BSTR const bstrPropName];
```

Description

Use Value to get or set a named property of this item.

bstrPropName is the name of the property to get or set. Valid (see page 3406) property names depend on the type of the item (the collection to which the item belongs). To determine the available properties for this object, check the Microsoft documentation for the specific collection to which this item belongs.

Tip: Use the IsPropertyReadOnly (see page 3404) and IsPropertyWriteOnly (see page 3404) methods to determine whether you can get or set a specific property.

See Also

IsPropertyReadOnly (see page 3404)

IsPropertyWriteOnly (see page 3404)

26 ComApp Namespace

This is namespace ComApp.

ComClassManager

CreateComObject

CreateOleObject

TComObject (see page 5553)

26.1.1.1 TWebAppAutoObjectFactory Members

The following tables list the members exposed by TWebAppAutoObjectFactory.

Public Methods

	Name	Description
	Create (see page 3410)	Instantiates a class factory object.

26.1.1.2 TWebAppAutoObjectFactory.Create Constructor

Instantiates a class factory object.

Pascal

```
constructor Create(AClassID: TGuid; const AClassName: string; const ADescription: string);
```

C++

```
__fastcall TWebAppAutoObjectFactory(TGuid AClassID, const AnsiString AClassName, const
AnsiString ADescription);
```

Description

Create TComObjectFactory instantiates a class factory, usually when the server is loaded. Class factories should be instantiated in the initialization section of the unit that includes their associated server, so that they are automatically available when the server is loaded.

Create TComObjectFactory allocates memory for a class factory object, and adds the object to the class factory list managed by the ComClassManager. Then Create TComObjectFactory initializes the following properties with values passed to it:

Sets ClassID to the ClassID parameter.

Sets ClassName to the ClassName parameter.

Sets Description to the Description parameter.

27 ComCtrls Namespace

This is namespace ComCtrls.

Topics

Name	Description
Classes (see page 3419)	The following table lists classes in this documentation.
Functions (see page 5435)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5438)	The following table lists structs, records, enums in this documentation.
Types (see page 5477)	The following table lists types in this documentation.
Constants (see page 5521)	The following table lists constants in this documentation.

Classes

	Name	Description
	ECommonCalendarError (see page 3420)	ECommonCalendarError is the exception class for invalid entries in a TCommonCalendar (see page 3558) component.
	EDateTimeError (see page 3421)	EDateTimeError is the exception class for invalid date and time entries.
	EMonthCalError (see page 3421)	EMonthCalError is the exception class for invalid entries in a TMonthCalendar (see page 4397) component.
	ETreeViewError (see page 3422)	ETreeViewError is the exception class for tree view errors.
	TAnimate (see page 3422)	TAnimate is an animation control.
	TComboBoxEx (see page 3463)	TComboBoxEx represents a combo box that supports extended combo box features such as images on the list entries.
	TComboBoxExActionLink (see page 3531)	This is class ComCtrls.TComboBoxExActionLink.
	TComboBoxExStrings (see page 3535)	This is class ComCtrls.TComboBoxExStrings.
	TComboExItem (see page 3546)	TComboExItem represents an item in an extended combo box.
	TComboExItems (see page 3552)	TComboExItems manages a collection of TComboExItem (see page 3546) objects.
	TCommonCalendar (see page 3558)	TCommonCalendar is the base class for the controls TDateTimePicker (see page 4049) and TMonthCalendar (see page 4397).
	TConversion (see page 3582)	TConversion converts rich text data from one encoding format to another.
	TCoolBand (see page 3584)	TCoolBand represents a band within a TCoolBar (see page 3603).
	TCoolBands (see page 3596)	TCoolBands is a container for TCoolBand (see page 3584) objects.
	TCoolBar (see page 3603)	TCoolBar displays a collection of windowed controls within movable, resizable bands.
	TCustomComboBoxEx (see page 3678)	TCustomComboBoxEx is the base class for combo box components that support extended combo box features such as images on the list entries.
	TCustomHeaderControl (see page 3702)	TCustomHeaderControl represents a spreadsheet-style header.

	TCustomHotKey (see page 3739)	TCustomHotKey is the base class for objects that wrap the Windows accelerator key Common Control.
	TCustomListView (see page 3757)	TCustomListView is the base type for all list view components, including TListView (see page 4285).
	TCustomRichEdit (see page 3854)	TCustomRichEdit is the base type for rich edit controls such as TRichEdit (see page 4685).
	TCustomStatusBar (see page 3892)	TCustomStatusBar is the base class for objects that represent status bars.
	TCustomTabControl (see page 3921)	TCustomTabControl is the base type for tab control components such as TTabControl (see page 4841) and TPageControl (see page 4459).
	TCustomTreeView (see page 3957)	TCustomTreeView is the base type for tree-view components such as TTreeView (see page 5293).
	TCustomUpDown (see page 4027)	TCustomUpDown is the base type for up-down size controls such as TUpDown (see page 5380).
	TDateTimePicker (see page 4049)	TDateTimePicker displays a list box for entering dates or times.
	THeaderControl (see page 4118)	THeaderControl is a container for THeaderSection (see page 4173) objects. It provides a set of resizable column headers.
	THeaderSection (see page 4173)	THeaderSection represents a section of a header control.
	THeaderSections (see page 4185)	THeaderSections is a container for THeaderSection (see page 4173) objects.
	THotKey (see page 4190)	THotKey is a wrapper for a Windows Common Control hot key.
	TIconOptions (see page 4233)	TIconOptions describes how the icons in a list view should be arranged.
	TListColumn (see page 4236)	TListColumn represents a column in a report-style list view.
	TListColumns (see page 4245)	TListColumns is a collection of TListColumn (see page 4236) objects.
	TListItem (see page 4250)	TListItem is an individual item of a TListView (see page 4285) control.
	TListItems (see page 4270)	TListItems maintains the collection of items that appear in a list view control.
	TListItemsEnumerator (see page 4283)	This is class ComCtrls.TListItemsEnumerator.
	TListView (see page 4285)	TListView displays a list of items in various ways.
	TListViewActionLink (see page 4388)	This is class ComCtrls.TListViewActionLink.
	TMonthCalColors (see page 4392)	TMonthCalColors defines a color scheme for TDateTimePicker (see page 4049) or TMonthCalendar (see page 4397)'s drop-down calendar.
	TMonthCalendar (see page 4397)	TMonthCalendar is stand-alone calendar in which a user can select a date or range of dates.
	TPageControl (see page 4459)	TPageControl is a set of pages used to make a multiple page dialog box.
	TPageScroller (see page 4548)	TPageScroller defines a display area for a narrow window, such as a toolbar.
	TParaAttributes (see page 4606)	TParaAttributes represents paragraph formatting properties for a rich edit control.
	TProgressBar (see page 4615)	TProgressBar displays a simple progress bar.
	TRichEdit (see page 4685)	TRichEdit is a wrapper for a Windows rich text edit control.
	TStatusBar (see page 4769)	TStatusBar represents a status bar.
	TStatusPanel (see page 4825)	TStatusPanel represents a single panel of a status bar.
	TStatusPanels (see page 4834)	TStatusPanels is a container for TStatusPanel (see page 4825) objects.
	TTabControl (see page 4841)	TTabControl is a tab set that has the appearance of notebook dividers.
	TTabSheet (see page 4919)	TTabSheet is an individual page in a TPageControl (see page 4459) object.
	TTextAttributes (see page 4982)	TTextAttributes represents the font characteristics of a section of text in a rich edit control.
	TToolBar (see page 4994)	TToolBar manages tool buttons and other controls, arranging them in rows and automatically adjusting their sizes and positions.
	TToolBarDockObject (see page 5102)	This is class ComCtrls.TToolBarDockObject.
	TToolBarEnumerator (see page 5105)	This is class ComCtrls.TToolBarEnumerator.
	TToolButton (see page 5107)	TToolButton is a button control in a TToolBar (see page 4994) object.
	TToolButtonActionLink (see page 5166)	TToolButtonActionLink is an action link designed for tool button control clients.
	TTrackBar (see page 5172)	TTrackBar is a wrapper for a track bar control.
	TTreeNode (see page 5230)	TTreeNode describes an individual node in a tree view control.
	TTreeNodes (see page 5266)	TTreeNodes maintains a list of tree nodes in a tree view control.
	TTreeNodesEnumerator (see page 5291)	This is class ComCtrls.TTreeNodesEnumerator.
	TTreeView (see page 5293)	TTreeView represents a window that displays a hierarchical list of items, such as the headings in a document, the entries in an index, or the files and directories on a disk.
	TUpDown (see page 5380)	TUpDown is a wrapper for a Windows up-down control.
	TWorkArea (see page 5425)	TWorkArea represents a rectangular subregion of a list view's client area.

	TWorkAreas (see page 5429)	TWorkAreas is a collection of TWorkArea (see page 5425) objects.

Constants

Name	Description
CN_BANDCHANGE (see page 5521)	This is constant ComCtrls.CN_BANDCHANGE.
CN_DROPDOWNCLOSED (see page 5521)	This is constant ComCtrls.CN_DROPDOWNCLOSED.
ColumnHeaderWidth (see page 5522)	This is constant ComCtrls.ColumnHeaderWidth.
ColumnTextWidth (see page 5522)	This is constant ComCtrls.ColumnTextWidth.
ComCtlVersionIE3 (see page 5522)	This is constant ComCtrls.ComCtlVersionIE3.
ComCtlVersionIE4 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE4.
ComCtlVersionIE401 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE401.
ComCtlVersionIE5 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE5.
ComCtlVersionIE501 (see page 5524)	This is constant ComCtrls.ComCtlVersionIE501.
ComCtlVersionIE6 (see page 5524)	This is constant ComCtrls.ComCtlVersionIE6.

Functions

	Name	Description
	CheckCommonControl (see page 5435)	This is function ComCtrls.CheckCommonControl.
	CheckToolMenuDropdown (see page 5435)	Displays a tool button's dropdown menu.
	GetComCtlVersion (see page 5436)	Indicates which version of ComCtl32.dll is installed.
	InitCommonControl (see page 5437)	This is function ComCtrls.InitCommonControl.

Structs, Records, Enums

	Name	Description
	TAddMode (see page 5439)	This is record ComCtrls.TAddMode.
	TAttributeType (see page 5440)	This is record ComCtrls.TAttributeType.
	TAutoCompleteOption (see page 5440)	TAutoCompleteOption and TAutoCompleteOptions (see page 5480) specify a set of autocomplete options.
	TCalDayOfWeek (see page 5441)	TCalDayOfWeek represents a day of the week.
	TComboBoxExStyle (see page 5442)	TComboBoxExStyle is the type for the Style property of extended combo box controls.
	TComboBoxExStyleEx (see page 5442)	TComboBoxExStyleEx and TComboBoxExStyles (see page 5481) configure the behavior of extended combo box controls.
	TCommonAVI (see page 5443)	This is record ComCtrls.TCommonAVI.
	TConsistentAttribute (see page 5444)	This is record ComCtrls.TConsistentAttribute.
	TConversionFormat (see page 5444)	This is record ComCtrls.TConversionFormat.
	TCoolBandMaximize (see page 5445)	TCoolBandMaximize specifies the conditions under which a TCoolBand (see page 3584) is maximized.
	TCustomDrawStage (see page 5445)	TCustomDrawStage specifies a stage in the custom drawing process.
	TCustomDrawTarget (see page 5446)	TCustomDrawTarget specifies the target of a custom drawing event.
	TDateTimeKind (see page 5447)	This is record ComCtrls.TDateTimeKind.
	TDisplayCode (see page 5447)	This is record ComCtrls.TDisplayCode.
	TDTCalAlignment (see page 5447)	This is record ComCtrls.TDTCalAlignment.
	TDTDateFormat (see page 5448)	This is record ComCtrls.TDTDateFormat.
	TDTDateMode (see page 5448)	This is record ComCtrls.TDTDateMode.
	THeaderSectionStyle (see page 5449)	This is record ComCtrls.THeaderSectionStyle.
	THeaderStyle (see page 5449)	THeaderStyle specifies the style of a header control.
	THitTest (see page 5450)	THitTest and THitTests (see page 5488) are used in the GetHitTestInfoAt method.
	THKInvalidKey (see page 5451)	This is record ComCtrls.THKInvalidKey.
	THKModifier (see page 5451)	This is record ComCtrls.THKModifier.
	TIconArrangement (see page 5452)	TIconArrangement indicates how the icons for items are arranged.
	TItemChange (see page 5452)	TItemChange describes the type of change a list item undergoes.
	TItemFind (see page 5453)	TItemFind identifies the type of search in an OnDataFind event handler.
	TItemRequests (see page 5454)	This is record ComCtrls.TItemRequests.

	TItemState (see page 5454)	TItemState and TItemStates (see page 5489) specify the state of an item in a list view control.
	TListArrangement (see page 5455)	This is record ComCtrls.TListArrangement.
	TListHotTrackStyle (see page 5456)	TListHotTrackStyle and TListHotTrackStyles (see page 5489) specify hot tracking styles for a list view control.
	TMultiSelectStyles (see page 5456)	This is record ComCtrls.TMultiSelectStyles.
	TNodeAttachMode (see page 5457)	TNodeAttachMode identifies a new or changed tree node relationship.
	TNodeCache (see page 5457)	TNodeCache is the type for a cached tree-view node.
	TNodeDataInfo (see page 5458)	This is record ComCtrls.TNodeDataInfo.
	TNodeInfo (see page 5458)	This is record ComCtrls.TNodeInfo.
	TNodeState (see page 5459)	This is record ComCtrls.TNodeState.
	TNumberingStyle (see page 5459)	This is record ComCtrls.TNumberingStyle.
	TPageScrollerButton (see page 5460)	TPageScrollerButton identifies a button on a page scroller.
	TPageScrollerButtonState (see page 5460)	TPageScrollerButtonState indicates the state of a page scroller button.
	TPageScrollerOrientation (see page 5461)	TPageScrollerOrientation indicates the orientation of a page scroller control.
	TPositionToolTip (see page 5462)	Specifies the position of the tool tip.
	TProgressBarOrientation (see page 5462)	TProgressBarOrientation specifies the orientation of a progress bar.
	TRichEditStreamInfo (see page 5463)	This is record ComCtrls.TRichEditStreamInfo.
	TSearchDirection (see page 5463)	Indicates the direction in which to search for the nearest item to a specified item or point.
	TSearchType (see page 5464)	Specifies search options.
	TSectionTrackState (see page 5464)	This is record ComCtrls.TSectionTrackState.
	TSortType (see page 5465)	TSortType indicates the criteria to use when sorting items.
	TStatusPanelBevel (see page 5466)	TStatusPanelBevel indicates the type of bevel around a panel in a status bar.
	TStatusPanelStyle (see page 5466)	TStatusPanelStyle indicates the kind of contents in a status bar panel.
	TTabPosition (see page 5467)	This is record ComCtrls.TTabPosition.
	TTabStyle (see page 5467)	TTabStyle indicates whether a TTabSet control is owner-drawn.
	TTBDrawingStyle (see page 5468)	Specifies the drawing style for the tool bar.
	TTickMark (see page 5468)	TTickMark indicates the location of the tick marks on a track bar.
	TTickStyle (see page 5469)	TTickStyle indicates how a track bar determines the increments at which tick marks appear.
	TToolButtonState (see page 5470)	This is record ComCtrls.TToolButtonState.
	TToolButtonStyle (see page 5470)	TToolButtonStyle indicates the type of control a TToolButton (see page 5107) object represents.
	TTrackBarOrientation (see page 5471)	TTrackBarOrientation indicates whether a trackbar is horizontal or vertical.
	TUDAlignButton (see page 5471)	This is record ComCtrls.TUDAlignButton.
	TUDBtnType (see page 5472)	This is record ComCtrls.TUDBtnType.
	TUDOrientation (see page 5472)	This is record ComCtrls.TUDOrientation.
	TUpDownDirection (see page 5473)	TUpDownDirection indicates the direction in which the position of an updown control changes.
	TViewStyle (see page 5473)	TViewStyle indicates how a list view control displays its items.

Types

Name	Description
PConversionFormat (see page 5479)	This is type ComCtrls.PConversionFormat.
PNodeCache (see page 5479)	PNodeCache is a pointer to a TNodeCache (see page 5457) object.
PNodeInfo (see page 5480)	This is type ComCtrls.PNodeInfo.
PRichEditStreamInfo (see page 5480)	This is type ComCtrls.PRichEditStreamInfo.
TAutoCompleteOptions (see page 5480)	TAutoCompleteOptions specify options that control autocompletion.
TComboBoxExStyles (see page 5481)	TComboBoxExStyles is the type for the Style property of extended combo box controls.
TComboExItemClass (see page 5481)	This is type ComCtrls.TComboExItemClass.
TComboExItemsClass (see page 5482)	This is type ComCtrls.TComboExItemsClass.
TConsistentAttributes (see page 5482)	This is type ComCtrls.TConsistentAttributes.
TConversionClass (see page 5482)	This is type ComCtrls.TConversionClass.
TCustomDrawPanelEvent (see page 5483)	TCustomDrawPanelEvent is the type of the OnDrawPanel event handler.
TCustomDrawSectionEvent (see page 5483)	This is type ComCtrls.TCustomDrawSectionEvent.

TCustomDrawState (see page 5483)	TCustomDrawState specifies a custom drawing state.
TCustomHCCreateSectionClassEvent (see page 5484)	This is type ComCtrls.TCustomHCCreateSectionClassEvent.
TCustomSectionNotifyEvent (see page 5484)	This is type ComCtrls.TCustomSectionNotifyEvent.
TCustomSectionTrackEvent (see page 5485)	This is type ComCtrls.TCustomSectionTrackEvent.
TDateTimeColors (see page 5485)	TDateTimeColors specifies colors used in a calendar control.
TDrawPanelEvent (see page 5485)	This is type ComCtrls.TDrawPanelEvent.
TDrawSectionEvent (see page 5486)	This is type ComCtrls.TDrawSectionEvent.
TDrawTabEvent (see page 5486)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet control.
TDTParseInputEvent (see page 5487)	This is type ComCtrls.TDTParseInputEvent.
THCCreateSectionClassEvent (see page 5487)	This is type ComCtrls.THCCreateSectionClassEvent.
THeaderSectionClass (see page 5487)	This is type ComCtrls.THeaderSectionClass.
THitTests (see page 5488)	This is type ComCtrls.THitTests.
THKInvalidKeys (see page 5488)	This is type ComCtrls.THKInvalidKeys.
THKModifiers (see page 5488)	This is type ComCtrls.THKModifiers.
TItemRequest (see page 5489)	This is type ComCtrls.TItemRequest.
TItemStates (see page 5489)	TItemState (see page 5454) and TItemStates specify the state of an item in a list view control.
TListHotTrackStyles (see page 5489)	TListHotTrackStyle (see page 5456) and TListHotTrackStyles specify hot tracking styles for a list view control.
TListItemClass (see page 5490)	This is type ComCtrls.TListItemClass.
TLVAdvancedCustomDrawEvent (see page 5490)	This is type ComCtrls.TLVAdvancedCustomDrawEvent.
TLVAdvancedCustomDrawItemEvent (see page 5491)	This is type ComCtrls.TLVAdvancedCustomDrawItemEvent.
TLVAdvancedCustomDrawSubItemEvent (see page 5491)	This is type ComCtrls.TLVAdvancedCustomDrawSubItemEvent.
TLVChangeEvent (see page 5491)	This is type ComCtrls.TLVChangeEvent.
TLVChangingEvent (see page 5492)	This is type ComCtrls.TLVChangingEvent.
TLVColumnClickEvent (see page 5492)	This is type ComCtrls.TLVColumnClickEvent.
TLVColumnRClickEvent (see page 5492)	This is type ComCtrls.TLVColumnRClickEvent.
TLVCompareEvent (see page 5493)	This is type ComCtrls.TLVCompareEvent.
TLVCreateItemClassEvent (see page 5493)	This is type ComCtrls.TLVCreateItemClassEvent.
TLVCustomDrawEvent (see page 5493)	This is type ComCtrls.TLVCustomDrawEvent.
TLVCustomDrawItemEvent (see page 5494)	This is type ComCtrls.TLVCustomDrawItemEvent.
TLVCustomDrawSubItemEvent (see page 5494)	This is type ComCtrls.TLVCustomDrawSubItemEvent.
TLVDeletedEvent (see page 5494)	TLVDeletedEvent is the type of a list view's OnDeletion event handler.
TLVDrawItemEvent (see page 5495)	TLVDrawItemEvent is the type of the list view OnCustomDrawItem and OnDrawItem event handlers.
TLVEditedEvent (see page 5495)	This is type ComCtrls.TLVEditedEvent.
TLVEditingEvent (see page 5496)	This is type ComCtrls.TLVEditingEvent.
TLVInfoTipEvent (see page 5496)	This is type ComCtrls.TLVInfoTipEvent.
TLVNotifyEvent (see page 5496)	This is type ComCtrls.TLVNotifyEvent.
TLVOwnerDataEvent (see page 5497)	TLVOwnerDataEvent is the type of a list view's OnData event handler.
TLVOwnerDataFindEvent (see page 5497)	TLVOwnerDataFindEvent is the type of a list view's OnDataFind event handler.
TLVOwnerDataHintEvent (see page 5498)	TLVOwnerDataHintEvent is the type of a list view's OnDataHint event handler.
TLVOwnerDataStateChangeEvent (see page 5498)	TLVOwnerDataStateChangeEvent is the type of a list view's OnDataStateChange event handler.
TLVSelectItemEvent (see page 5499)	This is type ComCtrls.TLVSelectItemEvent.
TLVSubItemImageEvent (see page 5499)	This is type ComCtrls.TLVSubItemImageEvent.
TMultiSelectStyle (see page 5499)	This is type ComCtrls.TMultiSelectStyle.
TOnGetMonthInfoEvent (see page 5500)	TOnGetMonthInfoEvent is the type of the TCommonCalendar.OnGetMonthInfo event handler.
TOwnerDrawState (see page 5500)	Indicates state information that can influence how an item is drawn.
TPageScrollEvent (see page 5501)	TPageScrollEvent is the type of a page scroller's OnScroll event handler.
TProgressRange (see page 5502)	This is type ComCtrls.TProgressRange.
TRichEditProtectChange (see page 5502)	This is type ComCtrls.TRichEditProtectChange.
TRichEditResizeEvent (see page 5502)	This is type ComCtrls.TRichEditResizeEvent.
TRichEditSaveClipboard (see page 5503)	This is type ComCtrls.TRichEditSaveClipboard.

TSBCreatePanelClassEvent (see page 5503)	TSBCreatePanelClassEvent is the type of the OnCreatePanelClass event handler.
TSearchTypes (see page 5503)	Set of TSearchType (see page 5464).
TSectionDragEvent (see page 5505)	TSectionDragEvent is the type for event handlers that respond when the user drags a section in a header control.
TSectionNotifyEvent (see page 5506)	This is type ComCtrls.TSectionNotifyEvent.
TSectionTrackEvent (see page 5506)	This is type ComCtrls.TSectionTrackEvent.
TStatusPanelClass (see page 5507)	TStatusPanelClass defines the metaclass for TStatusPanel (see page 4825).
TTabChangingEvent (see page 5507)	This is type ComCtrls.TTabChangingEvent.
TTabGetImageEvent (see page 5507)	This is type ComCtrls.TTabGetImageEvent.
TTBAdvancedCustomDrawBtnEvent (see page 5508)	This is type ComCtrls.TTBAdvancedCustomDrawBtnEvent.
TTBAdvancedCustomDrawEvent (see page 5508)	This is type ComCtrls.TTBAdvancedCustomDrawEvent.
TTBButtonEvent (see page 5508)	TTBButtonEvent is the type of event handlers that respond when the user adds or deletes a tool button in the toolbar customize dialog.
TTBCustomDrawBtnEvent (see page 5509)	This is type ComCtrls.TTBCustomDrawBtnEvent.
TTBCustomDrawEvent (see page 5509)	This is type ComCtrls.TTBCustomDrawEvent.
TTBCustomDrawFlags (see page 5509)	TTBCustomDrawFlags is the type of the OnAdvancedCustomDrawButton event handler.
TTBCustomizeQueryEvent (see page 5510)	TTBCustomizeQueryEvent is the type of event handlers that allow a toolbar to decide whether to allow a user customization.
TTBGradientDrawingOptions (see page 5511)	Specifies the style of the gradient.
TTBNewButtonEvent (see page 5511)	This is type ComCtrls.TTBNewButtonEvent.
TToolButtonActionLinkClass (see page 5511)	This is type ComCtrls.TToolButtonActionLinkClass.
TTreeNodeClass (see page 5512)	This is type ComCtrls.TTreeNodeClass.
TTVAdvancedCustomDrawEvent (see page 5512)	Used in the TCustomTreeView.OnAdvancedCustomDraw event.
TTVAdvancedCustomDrawItemEvent (see page 5513)	Used in the TCustomTreeView.OnAdvancedCustomDrawItem event.
TTVChangedEvent (see page 5513)	Used in the TCustomTreeView.OnChange event.
TTVChangingEvent (see page 5514)	Used in the TCustomTreeView.OnChanging event.
TTVCollapsingEvent (see page 5514)	Used in the TCustomTreeView.OnCollapsing event.
TTVCompareEvent (see page 5515)	Used in the TCustomTreeView.OnCompare event.
TTVCreateNodeClassEvent (see page 5516)	This is type ComCtrls.TTVCreateNodeClassEvent.
TTVCustomDrawEvent (see page 5516)	Used in the TCustomTreeView.OnCustomDraw event.
TTVCustomDrawItemEvent (see page 5516)	Used in the TCustomTreeView.OnCustomDrawItem event.
TTVEditedEvent (see page 5517)	Used in the TCustomTreeView.OnEdited event.
TTVEditingEvent (see page 5518)	Used in the TCustomTreeView.OnEditing event.
TTVExpandedEvent (see page 5518)	Represents the event handler for events that notify a tree view of changes to one of its nodes.
TTVExpandingEvent (see page 5519)	Used in the TCustomTreeView.OnExpanding event.
TUDChangingEvent (see page 5519)	This is type ComCtrls.TUDChangingEvent.
TUDChangingEventEx (see page 5520)	This is type ComCtrls.TUDChangingEventEx.
TUDClickEvent (see page 5520)	This is type ComCtrls.TUDClickEvent.
TWidth (see page 5520)	This is type ComCtrls.TWidth.

27.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ECommonCalendarError (see page 3420)	ECommonCalendarError is the exception class for invalid entries in a TCommonCalendar (see page 3558) component.
	EDateTimeError (see page 3421)	EDateTimeError is the exception class for invalid date and time entries.
	EMonthCalError (see page 3421)	EMonthCalError is the exception class for invalid entries in a TMonthCalendar (see page 4397) component.
	ETreeViewError (see page 3422)	ETreeViewError is the exception class for tree view errors.
	TAnimate (see page 3422)	TAnimate is an animation control.
	TComboBoxEx (see page 3463)	TComboBoxEx represents a combo box that supports extended combo box features such as images on the list entries.
	TComboBoxExActionLink (see page 3531)	This is class ComCtrls.TComboBoxExActionLink.
	TComboBoxExStrings (see page 3535)	This is class ComCtrls.TComboBoxExStrings.
	TComboExItem (see page 3546)	TComboExItem represents an item in an extended combo box.
	TComboExItems (see page 3552)	TComboExItems manages a collection of TComboExItem (see page 3546) objects.
	TCommonCalendar (see page 3558)	TCommonCalendar is the base class for the controls TDateTimePicker (see page 4049) and TMonthCalendar (see page 4397).
	TConversion (see page 3582)	TConversion converts rich text data from one encoding format to another.
	TCoolBand (see page 3584)	TCoolBand represents a band within a TCoolBar (see page 3603).
	TCoolBands (see page 3596)	TCoolBands is a container for TCoolBand (see page 3584) objects.
	TCoolBar (see page 3603)	TCoolBar displays a collection of windowed controls within movable, resizable bands.
	TCustomComboBoxEx (see page 3678)	TCustomComboBoxEx is the base class for combo box components that support extended combo box features such as images on the list entries.
	TCustomHeaderControl (see page 3702)	TCustomHeaderControl represents a spreadsheet-style header.
	TCustomHotKey (see page 3739)	TCustomHotKey is the base class for objects that wrap the Windows accelerator key Common Control.
	TCustomListView (see page 3757)	TCustomListView is the base type for all list view components, including TListView (see page 4285).
	TCustomRichEdit (see page 3854)	TCustomRichEdit is the base type for rich edit controls such as TRichEdit (see page 4685).
	TCustomStatusBar (see page 3892)	TCustomStatusBar is the base class for objects that represent status bars.
	TCustomTabControl (see page 3921)	TCustomTabControl is the base type for tab control components such as TTabControl (see page 4841) and TPageControl (see page 4459).
	TCustomTreeView (see page 3957)	TCustomTreeView is the base type for tree-view components such as TTreeView (see page 5293).
	TCustomUpDown (see page 4027)	TCustomUpDown is the base type for up-down size controls such as TUpDown (see page 5380).
	TDateTimePicker (see page 4049)	TDateTimePicker displays a list box for entering dates or times.
	THeaderControl (see page 4118)	THeaderControl is a container for THeaderSection (see page 4173) objects. It provides a set of resizable column headers.
	THeaderSection (see page 4173)	THeaderSection represents a section of a header control.
	THeaderSections (see page 4185)	THeaderSections is a container for THeaderSection (see page 4173) objects.
	THotKey (see page 4190)	THotKey is a wrapper for a Windows Common Control hot key.
	TIconOptions (see page 4233)	TIconOptions describes how the icons in a list view should be arranged.
	TListColumn (see page 4236)	TListColumn represents a column in a report-style list view.
	TListColumns (see page 4245)	TListColumns is a collection of TListColumn (see page 4236) objects.
	TListItem (see page 4250)	TListItem is an individual item of a TListView (see page 4285) control.
	TListItems (see page 4270)	TListItems maintains the collection of items that appear in a list view control.
	TListItemsEnumerator (see page 4283)	This is class ComCtrls.TListItemsEnumerator.

	TListView (see page 4285)	TListView displays a list of items in various ways.
	TListViewActionLink (see page 4388)	This is class ComCtrls.TListViewActionLink.
	TMonthCalColors (see page 4392)	TMonthCalColors defines a color scheme for TDateTimePicker (see page 4049) or TMonthCalendar (see page 4397)'s drop-down calendar.
	TMonthCalendar (see page 4397)	TMonthCalendar is stand-alone calendar in which a user can select a date or range of dates.
	TPageControl (see page 4459)	TPageControl is a set of pages used to make a multiple page dialog box.
	TPageScroller (see page 4548)	TPageScroller defines a display area for a narrow window, such as a toolbar.
	TParaAttributes (see page 4606)	TParaAttributes represents paragraph formatting properties for a rich edit control.
	TProgressBar (see page 4615)	TProgressBar displays a simple progress bar.
	TRichEdit (see page 4685)	TRichEdit is a wrapper for a Windows rich text edit control.
	TStatusBar (see page 4769)	TStatusBar represents a status bar.
	TStatusPanel (see page 4825)	TStatusPanel represents a single panel of a status bar.
	TStatusPanels (see page 4834)	TStatusPanels is a container for TStatusPanel (see page 4825) objects.
	TTabControl (see page 4841)	TTabControl is a tab set that has the appearance of notebook dividers.
	TTabSheet (see page 4919)	TTabSheet is an individual page in a TPageControl (see page 4459) object.
	TTextAttributes (see page 4982)	TTextAttributes represents the font characteristics of a section of text in a rich edit control.
	TToolBar (see page 4994)	TToolBar manages tool buttons and other controls, arranging them in rows and automatically adjusting their sizes and positions.
	TToolBarDockObject (see page 5102)	This is class ComCtrls.TToolBarDockObject.
	TToolBarEnumerator (see page 5105)	This is class ComCtrls.TToolBarEnumerator.
	TToolButton (see page 5107)	TToolButton is a button control in a TToolBar (see page 4994) object.
	TToolButtonActionLink (see page 5166)	TToolButtonActionLink is an action link designed for tool button control clients.
	TTrackBar (see page 5172)	TTrackBar is a wrapper for a track bar control.
	TTreeNode (see page 5230)	TTreeNode describes an individual node in a tree view control.
	TTreeNodes (see page 5266)	TTreeNodes maintains a list of tree nodes in a tree view control.
	TTreeNodesEnumerator (see page 5291)	This is class ComCtrls.TTreeNodesEnumerator.
	TTreeView (see page 5293)	TTreeView represents a window that displays a hierarchical list of items, such as the headings in a document, the entries in an index, or the files and directories on a disk.
	TUpDown (see page 5380)	TUpDown is a wrapper for a Windows up-down control.
	TWorkArea (see page 5425)	TWorkArea represents a rectangular subregion of a list view's client area.
	TWorkAreas (see page 5429)	TWorkAreas is a collection of TWorkArea (see page 5425) objects.

27.1.1 ECommonCalendarError Class

ECommonCalendarError is the exception class for invalid entries in a TCommonCalendar (see page 3558) component.

Class Hierarchy

Pascal

```
ECommonCalendarError = class(Exception);
```

C++

```
class ECommonCalendarError : public Exception;
```

File

ComCtrls

Description

Exceptions derived from ECommonCalendarError are raised by TCommonCalendar (see page 3558) descendants when an invalid date or time is entered.

See Also

TCommonCalendar (see page 3558)

EMonthCalError (see page 3421)

EDateTimeError (see page 3421)

27.1.2 EDateTimeError Class

EDateTimeError is the exception class for invalid date and time entries.

Class Hierarchy

Pascal

```
EDateTimeError = class(ECommonCalendarError);
```

C++

```
class EDateTimeError : public ECommonCalendarError;
```

File

ComCtrls

Description

EDateTimeError is raised by TDateTimePicker (see page 4049) when an invalid date or time is entered.

See Also

TDateTimePicker (see page 4049)

27.1.3 EMonthCalError Class

EMonthCalError is the exception class for invalid entries in a TMonthCalendar (see page 4397) component.

Class Hierarchy

Pascal

```
EMonthCalError = class(ECommonCalendarError);
```

C++

```
class EMonthCalError : public ECommonCalendarError;
```

File

ComCtrls

Description

EMonthCalError is raised by TMonthCalendar (see page 4397) when an invalid date is entered.

See Also

TMonthCalendar (see page 4397)

27.1.4 ETreeViewError Class

ETreeViewError is the exception class for tree view errors.

Class Hierarchy

Pascal

```
ETreeViewError = class(Exception);
```

C++

```
class ETreeViewError : public Exception;
```

File

ComCtrls

Description

ETreeViewError is raised when an error is made in a TCustomTreeView (see page 3957) or TTreeNode (see page 5230) object.

See Also

TCollection (see page 2731)

TComponent (see page 2762)

TCustomTreeView (see page 3957)

TTreeNode (see page 5230)

27.1.5 TAnimate Class

TAnimate is an animation control.

Class Hierarchy

Pascal

```
TAnimate = class(TWinControl);
```

C++

```
class TAnimate : public TWinControl;
```

File

ComCtrls

Description

A TAnimate control displays an animation clip, consisting of a series of image frames. The control can load an animation from a file, a resource, or a set of standard animations. To specify an animation, set the FileName (see page 3450), CommonAVI (see page 3448), ResName (see page 3455), or ResID properties. At design time, you can browse through the frames of the animation using the context menu.

27.1.5.1 TAnimate Members

The following tables list the members exposed by TAnimate.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 3435)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.

	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 3436)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 3436)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 3437)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 3437)	This is DoClose, a member of class TAnimate.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoOpen (see page 3437)	This is DoOpen, a member of class TAnimate.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStart (see page 3437)	This is DoStart, a member of class TAnimate.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoStop (see page 3438)	This is DoStop, a member of class TAnimate.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.

	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 3438)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.

	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.

	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.

	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 3433)	Creates and initializes an animation control.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.

	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.

	Play (see page 3438)	Displays a sequence of frames from the AVI clip.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	Reset (see page 3439)	Clears the values of StartFrame (see page 3457) and StopFrame (see page 3458), and displays the first frame in the animation.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	Seek (see page 3439)	Displays a specified frame in the sequence.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Stop (see page 3440)	Interrupts the animation control when it is playing.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.

R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	FrameCount (see page 3451)	Indicates the total number of frames in the AVI clip.
R	FrameHeight (see page 3451)	Indicates the height, in pixels, of each image in the animation.
R	FrameWidth (see page 3451)	Indicates the width, in pixels, of each image in the animation.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	Open (see page 3452)	Indicates whether the animation is loaded into memory.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ResHandle (see page 3454)	Specifies the Windows handle for the module that contains the AVI clip as a resource.
	ResId (see page 3455)	Specifies the resource ID of the animation.
	ResName (see page 3455)	Specifies the resource name of the animation.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClose (see page 3461)	Occurs immediately after the animation control is closed.
	OnOpen (see page 3461)	Occurs immediately after the animation control is opened.
	OnStart (see page 3462)	Occurs immediately after the animation control starts playing.
	OnStop (see page 3462)	Occurs when the animation control finishes playing.

Published Properties

	Name	Description
	Active (see page 3441)	Indicates whether the animation control is playing the Animation.
	Align (see page 3442)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 3446)	Specifies how the control is anchored to its parent.
	AutoSize (see page 3446)	Specifies whether the control sizes itself automatically to fit animation.
	BorderWidth (see page 3447)	Specifies the width of the control's border.
	Center (see page 3447)	Determines whether the frames of the AVI clip are centered in the animation control.
	Color (see page 3447)	Specifies the background color of the control.
	CommonAVI (see page 3448)	Indicates whether the animation control displays a one of the common Windows AVI clips provided in Shell32.dll.
	Constraints (see page 3450)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	FileName (see page 3450)	Specifies file containing animation.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 3453)	Determines where a control looks for its color information.
	ParentShowHint (see page 3453)	Determines where a control looks to find out if its Help Hint should be shown.
	Repetitions (see page 3454)	Specifies the number of times to repeat the sequence of frames.
	ShowHint (see page 3456)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	StartFrame (see page 3457)	Specifies the first frame displayed when the animation control is activated.
	StopFrame (see page 3458)	Specifies the last frame displayed when the animation control is activated.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Timers (see page 3458)	Specifies whether the frames are displayed using a timer.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Transparent (see page 3459)	Specifies whether the background color of the frame matches the Color (see page 3447) property.
	Visible (see page 3459)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

27.1.5.2 TAnimate.Create Constructor

Creates and initializes an animation control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAnimate(TComponent * AOwner);
```

Description

Call Create to instantiate an animation control at runtime. Animation controls placed on forms at design time are created automatically.

AOwner is the component that is responsible for freeing the TAnimate (see page 3422) instance. It becomes the value of the Owner property.

C++ Examples:

```
/*
To run this example, create a new project, place a button on
the form, and insert the example code to the button click
event. Place the button on the bottom of the form to leave
room for the TAnimate component that will be created on the
fly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TForm *TempForm = new TForm(this);
  TAnimate *pAnimate = new TAnimate(TempForm);
  pAnimate->Parent = TempForm;
  pAnimate->CommonAVI = aviFindFile;
  pAnimate->Active = true;
  TempForm->Show();
  // Simulate a lengthy process.  Alter this value
  // to accommodate your machine speed.
  for (int i = 0; i < 90000000; i++)
    Application->ProcessMessages();
  delete TempForm;
}
```

Delphi Examples:

```
{
To run this example, create a new project, place a button on
the form, and insert the example code to the button click
event. Place the button on the bottom of the form to leave
room for the TAnimate component that will be created on the
fly.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TempForm: TForm;
  I: Integer;
begin
  TempForm := TForm.Create(Self);
  with TAnimate.Create(TempForm) do
  try
    Parent := TempForm;
    CommonAVI := aviFindFile;
    Active := True;
    TempForm.Show;
    // Simulate a lengthy process.  Alter this value
    // to accommodate your machine speed.
    for I := 0 to 90000000 do Application.ProcessMessages;
  finally
    TempForm.Release;
  end;
```

```
end;
```

CreateParented (see page 6123)

Owner (see page 2807)

27.1.5.3 TAnimate Methods

The methods of the TAnimate class are listed here.

Protected Methods

	Name	Description
	CanAutoSize (see page 3435)	Indicates how the control can be resized.
	CreateParams (see page 3436)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 3436)	Creates the underlying window.
	DestroyWnd (see page 3437)	Destroys the control's window.
	DoClose (see page 3437)	This is DoClose, a member of class TAnimate.
	DoOpen (see page 3437)	This is DoOpen, a member of class TAnimate.
	DoStart (see page 3437)	This is DoStart, a member of class TAnimate.
	DoStop (see page 3438)	This is DoStop, a member of class TAnimate.
	Loaded (see page 3438)	Initializes the control after it is loaded from a stream.

Public Methods

	Name	Description
	Play (see page 3438)	Displays a sequence of frames from the AVI clip.
	Reset (see page 3439)	Clears the values of StartFrame (see page 3457) and StopFrame (see page 3458), and displays the first frame in the animation.
	Seek (see page 3439)	Displays a specified frame in the sequence.
	Stop (see page 3440)	Interrupts the animation control when it is playing.

27.1.5.3.1 TAnimate.CanAutoSize Method

Indicates how the control can be resized.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize (see page 3446) property is true and an attempt is made to resize the control. It allows the animation control to adjust to the size of animation frames.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. If the Open (see page 3452) property is true, CanAutoSize adjusts these values so that they reflect the dimensions of the AVI video images and returns true. If the animation control is not Open (see page 3452), CanAutoSize returns false.

See Also

AutoSize (see page 5803)

FrameWidth (see page 3451)

FrameHeight (see page 3451)

27.1.5.3.2 TAnimate.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

27.1.5.3.3 TAnimate.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

27.1.5.3.4 TAnimate.DestroyWnd Method

Destroys the control's window.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

DestroyWnd is called when the control needs to replace its window. For example, changing properties that are implemented by window parameter settings require the control to be destroyed and then recreated using the CreateWnd method.

Before the window is destroyed, DestroyWnd saves a copy of the control's text in memory, frees any device contexts, and finally calls DestroyWindowHandle. When the window is recreated, the stored copy of the control's text is assigned to the new window.

See Also

DestroyWindowHandle (see page 6140)

RecreateWnd (see page 6171)

27.1.5.3.5 TAnimate.DoClose Method

Pascal

```
procedure DoClose; virtual;
```

C++

```
virtual __fastcall DoClose();
```

Description

This is DoClose, a member of class TAnimate.

27.1.5.3.6 TAnimate.DoOpen Method

Pascal

```
procedure DoOpen; virtual;
```

C++

```
virtual __fastcall DoOpen();
```

Description

This is DoOpen, a member of class TAnimate.

27.1.5.3.7 TAnimate.DoStart Method

Pascal

```
procedure DoStart; virtual;
```

C++

```
virtual __fastcall DoStart();
```

Description

This is DoStart, a member of class TAnimate.

27.1.5.3.8 TAnimate.DoStop Method

Pascal

```
procedure DoStop; virtual;
```

C++

```
virtual __fastcall DoStop();
```

Description

This is DoStop, a member of class TAnimate.

27.1.5.3.9 TAnimate.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded (see page 2782)

Action (see page 5797)

ActionChange (see page 5737)

27.1.5.3.10 TAnimate.Play Method

Displays a sequence of frames from the AVI clip.

Pascal

```
procedure Play(FromFrame: Word; ToFrame: Word; Count: Integer);
```

C++

```
__fastcall Play(Word FromFrame, Word ToFrame, int Count);
```

Description

Call Play to display the specified sequence of frames, repeating the sequence Count times. FromFrame is the first frame in the sequence, where 1 specifies the first frame in the clip, 2 specifies the second frame, and so on. ToFrame is the last frame in the sequence. The value of ToFrame should be greater than or equal to FromFrame and less than or equal to the value of the FrameCount (see page 3451) property. Count specifies the number of times the sequence should be repeated. If Count is 0,

the sequence is repeated until the Stop (see page 3440) method is called.

If the animation control is not Open (see page 3452) when Play is called, Play sets Open (see page 3452) to true.

Note: Calling Play is the same as setting StartFrame (see page 3457) to FromFrame, StopFrame (see page 3458) to ToFrame, Repetitions (see page 3454) to Count, and then setting Active (see page 3441) to true.

See Also

Active (see page 3441)

Open (see page 3452)

Repetitions (see page 3454)

StartFrame (see page 3457)

StopFrame (see page 3458)

27.1.5.3.11 TAnimate.Reset Method

Clears the values of StartFrame (see page 3457) and StopFrame (see page 3458), and displays the first frame in the animation.

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

Call Reset to restore the animation control to a default state. Reset closes and reopens the animation control, generating OnClose (see page 3461) and OnOpen (see page 3461) events. The animation control is left open but not active.

See Also

Active (see page 3441)

OnClose (see page 3461)

OnOpen (see page 3461)

Open (see page 3452)

StartFrame (see page 3457)

StopFrame (see page 3458)

27.1.5.3.12 TAnimate.Seek Method

Displays a specified frame in the sequence.

Pascal

```
procedure Seek(Frame: Smallint);
```

C++

```
__fastcall Seek(Smallint Frame);
```

Description

Call Seek to move to a particular frame in the animation. The Frame parameter specifies which frame, where 1 is the first frame

in the sequence, 2 is the second frame, and so on. Frame must be a value less than or equal to FrameCount (see page 3451).

If the animation control is not open when Seek is called, Seek sets Open (see page 3452) to true.

See Also

FrameCount (see page 3451)

Open (see page 3452)

27.1.5.3.13 TAnimate.Stop Method

Interrupts the animation control when it is playing.

Pascal

```
procedure Stop;
```

C++

```
__fastcall Stop();
```

Description

Call Stop to halt the sequence of images in an active animation control. Stop does the same thing as setting the Active (see page 3441) property to false.

See Also

Active (see page 3441)

Play (see page 3438)

27.1.5.4 TAnimate Properties

The properties of the TAnimate class are listed here.

Public Properties

	Name	Description
R	FrameCount (see page 3451)	Indicates the total number of frames in the AVI clip.
R	FrameHeight (see page 3451)	Indicates the height, in pixels, of each image in the animation.
R	FrameWidth (see page 3451)	Indicates the width, in pixels, of each image in the animation.
	Open (see page 3452)	Indicates whether the animation is loaded into memory.
	ResHandle (see page 3454)	Specifies the Windows handle for the module that contains the AVI clip as a resource.
	ResId (see page 3455)	Specifies the resource ID of the animation.
	ResName (see page 3455)	Specifies the resource name of the animation.

Published Properties

	Name	Description
	Active (see page 3441)	Indicates whether the animation control is playing the Animation.
	Align (see page 3442)	Determines how the control aligns within its container (parent control).
	Anchors (see page 3446)	Specifies how the control is anchored to its parent.
	AutoSize (see page 3446)	Specifies whether the control sizes itself automatically to fit animation.
	BorderWidth (see page 3447)	Specifies the width of the control's border.
	Center (see page 3447)	Determines whether the frames of the AVI clip are centered in the animation control.
	Color (see page 3447)	Specifies the background color of the control.
	CommonAVI (see page 3448)	Indicates whether the animation control displays a one of the common Windows AVI clips provided in Shell32.dll.

	Constraints (see page 3450)	Specifies the size constraints for the control.
	FileName (see page 3450)	Specifies file containing animation.
	ParentColor (see page 3453)	Determines where a control looks for its color information.
	ParentShowHint (see page 3453)	Determines where a control looks to find out if its Help Hint should be shown.
	Repetitions (see page 3454)	Specifies the number of times to repeat the sequence of frames.
	ShowHint (see page 3456)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	StartFrame (see page 3457)	Specifies the first frame displayed when the animation control is activated.
	StopFrame (see page 3458)	Specifies the last frame displayed when the animation control is activated.
	Timers (see page 3458)	Specifies whether the frames are displayed using a timer.
	Transparent (see page 3459)	Specifies whether the background color of the frame matches the Color (see page 3447) property.
	Visible (see page 3459)	Determines whether the component appears onscreen.

27.1.5.4.1 TAnimate.Active Property

Indicates whether the animation control is playing the Animation.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Set Active to true to cycle through the frames specified by the StartFrame (see page 3457) and StopFrame (see page 3458) properties by the number of iterations specified in the Repetitions (see page 3454) property. Set Active to false to interrupt the animation control when it is playing the animation file.

The animation control must be Open (see page 3452) before it can be Active.

C++ Examples:

```
/*
To run this example, create a new project, place a button on
the form, and insert the example code to the button click
event. Place the button on the bottom of the form to leave
room for the TAnimate component that will be created on the
fly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TForm *TempForm = new TForm(this);
  TAnimate *pAnimate = new TAnimate(TempForm);
  pAnimate->Parent = TempForm;
  pAnimate->CommonAVI = aviFindFile;
  pAnimate->Active = true;
  TempForm->Show();
  // Simulate a lengthy process.  Alter this value
  // to accommodate your machine speed.
  for (int i = 0; i < 90000000; i++)
    Application->ProcessMessages();
  delete TempForm;
}
```

Delphi Examples:

```
{
To run this example, create a new project, place a button on
the form, and insert the example code to the button click
event. Place the button on the bottom of the form to leave
room for the TAnimate component that will be created on the
```

```
fly.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  TempForm: TForm;
  I: Integer;
begin
  TempForm := TForm.Create(Self);
  with TAnimate.Create(TempForm) do
  try
    Parent := TempForm;
    CommonAVI := aviFindFile;
    Active := True;
    TempForm.Show;
    // Simulate a lengthy process.  Alter this value
    // to accommodate your machine speed.
    for I := 0 to 90000000 do Application.ProcessMessages;
  finally
    TempForm.Release;
  end;
end;
```

See Also

OnStart (see page 3462)

OnStop (see page 3462)

Open (see page 3452)

Play (see page 3438)

Repetitions (see page 3454)

StartFrame (see page 3457)

Stop (see page 3440)

StopFrame (see page 3458)

27.1.5.4.2 TAnimate.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
```

```
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
