	SetEnableDropdown (see page 5172)	This is SetEnableDropdown, a member of class TToolButtonActionLink.
	SetImageIndex (see page 5172)	Sets the image index of a tool button control if the client is linked to the action for this event.

27.1.55.3.1 TToolButtonActionLink.AssignClient Method

Assigns a client tool button that is linked to the associated action.

Pascal

```
procedure AssignClient(AClient: TObject); override;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

TToolButtonControlActionLink overrides AssignClient to ensure that the client for the link is a tool button control.

See Also

Action (see page 5797)

TToolButton (see page 5107)

27.1.55.3.2 TToolButtonActionLink.IsCheckedLinked Method

Indicates whether the checked state for the action and the client are linked.

Pascal

```
function IsCheckedLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCheckedLinked();
```

Description

IsCheckedLinked indicates whether the Checked property is linked to the appropriate client property. IsCheckedLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Checked (see page 308)

Down (see page 5128)

SetChecked (see page 5171)

27.1.55.3.3 TToolButtonActionLink.IsDropdownMenuLinked Method

Pascal

```
function IsDropdownMenuLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsDropdownMenuLinked();
```

Description

This is IsDropdownMenuLinked, a member of class TToolButtonActionLink.

27.1.55.3.4 TToolButtonActionLink.IsEnableDropdownLinked Method

Pascal

```
function IsEnableDropdownLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsEnableDropdownLinked();
```

Description

This is IsEnableDropdownLinked, a member of class TToolButtonActionLink.

27.1.55.3.5 TToolButtonActionLink.IsImageIndexLinked Method

Indicates whether the image index for the action and the client are linked.

Pascal

```
function IsImageIndexLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsImageIndexLinked();
```

Description

IsImageIndexLinked indicates whether the ImageIndex property is linked to the appropriate client property. IsImageIndexLinked returns true if the client requests that the action control this property, false otherwise.

See Also

ImageIndex (see page 313)

ImageIndex (see page 5135)

SetImageIndex (see page 5172)

27.1.55.3.6 TToolButtonActionLink.SetChecked Method

Sets the checked state of a tool button control if the client is linked to the action for this event.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked sets the checked state of a tool button control, and is called only if the client is linked for this event. Value specifies whether the checked state should be set.

See Also

Checked (see page 308)

Down (see page 5128)

IsCheckedLinked (see page 5170)

27.1.55.3.7 TToolButtonActionLink.SetDropdownMenu Method

Pascal

```
procedure SetDropdownMenu(Value: TPopupMenu); override;
```

C++

```
virtual __fastcall SetDropdownMenu(TPopupMenu Value);
```

Description

This is SetDropdownMenu, a member of class TToolButtonActionLink.

27.1.55.3.8 TToolButtonActionLink.SetEnableDropdown Method

Pascal

```
procedure SetEnableDropdown(Value: Boolean); override;
```

C++

```
virtual __fastcall SetEnableDropdown(Boolean Value);
```

Description

This is SetEnableDropdown, a member of class TToolButtonActionLink.

27.1.55.3.9 TToolButtonActionLink.SetImageIndex Method

Sets the image index of a tool button control if the client is linked to the action for this event.

Pascal

```
procedure SetImageIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetImageIndex(int Value);
```

Description

SetImageIndex sets the image index of a tool button control, and is called only if the client is linked for this event. Value specifies what the image index should be.

See Also

ImageIndex (see page 313)

ImageIndex (see page 5135)

IsImageIndexLinked (see page 5171)

27.1.56 TTrackBar Class

TTrackBar is a wrapper for a track bar control.

Class Hierarchy

Pascal

```
TTrackBar = class(TWinControl);
```

C++

```
class TTrackBar : public TWinControl;
```

File

ComCtrls

Description

Use TTrackBar to put a track bar on a form. A track bar represents a position along a continuum using a slider and, optionally, tick marks. A track bar can also display a selected range marked by triangular ticks at the starting and ending positions of the selection.

During program execution, the slider can be moved to the desired position by dragging it with the mouse or by clicking the mouse on the bar. To use the keyboard to move the slider, press the arrow keys or the Page Up and Page Down keys.

See Also

TScrollBar (see page 21821)

Specialized Input Controls

Track Bars

27.1.56.1 TTrackBar Members

The following tables list the members exposed by TTrackBar.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5185)	Sends a CM_CHANGED message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.

	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 5185)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 5186)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 5186)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.

	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.

	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.

	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 5184)	Creates and initializes an instance of TTrackBar (see page 5172).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	SetTick (see page 5187)	Adds a tick mark to the track bar at a specified location.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.

	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 5212)	Occurs immediately after the value of Position (see page 5204) changes.
	OnContextPopup (see page 5212)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 5213)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5215)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5217)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5218)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 5219)	Occurs when a control receives the input focus.
	OnExit (see page 5221)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 5223)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 5226)	Occurs when a key is pressed.
	OnKeyUp (see page 5227)	Occurs when the user releases a key that has been pressed.
	OnStartDock (see page 5228)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 5229)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 5188)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 5191)	Specifies how the control is anchored to its parent.
	BorderWidth (see page 5192)	Specifies the width of the control's border.
	Constraints (see page 5192)	Specifies the size constraints for the control.
	Ctl3D (see page 5193)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 5193)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5194)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5194)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 5196)	Controls whether the control responds to mouse, keyboard, and timer events.
	Frequency (see page 5196)	Specifies the increment between tick marks on the track bar.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	LineSize (see page 5196)	Indicates the amount the value of Position (see page 5204) changes when the user presses the arrow keys.
	Margins (see page 5831)	Specifies the margins for the control.
	Max (see page 5197)	Specifies the maximum Position (see page 5204) of a TTrackBar (see page 5172).
	Min (see page 5197)	Specifies the minimum Position (see page 5204) of a TTrackBar (see page 5172).
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Orientation (see page 5198)	Specifies whether the track bar is horizontal or vertical.
	PageSize (see page 5198)	Specifies the amount Position (see page 5204) is changed when the PageUp or PageDown key is pressed, or when the bar is clicked.
	ParentCtl3D (see page 5198)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 5199)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5199)	Identifies the pop-up menu associated with the control.
	Position (see page 5204)	Contains the current position of the slider of a TTrackBar (see page 5172).
	PositionToolTip (see page 5204)	Determines the position of the (optional) tooltip displaying the position of the track bar.
	SelEnd (see page 5205)	Specifies the position of the end point of the selection range.
	SelStart (see page 5205)	Specifies the position of the starting point of the selection range.
	ShowHint (see page 5206)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShowSelRange (see page 5207)	Specifies whether the track bar shows the selection range.
	SliderVisible (see page 5207)	Specifies whether the track bar's slider is visible.
	TabOrder (see page 5208)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5208)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	ThumbLength (see page 5209)	Specifies the length of the track bar's slider.
	TickMarks (see page 5209)	Specifies the location of the tick marks.
	TickStyle (see page 5209)	Specifies how tick marks are placed on the track bar.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

	Visible (see page 5210)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

27.1.56.2 TTrackBar.Create Constructor

Creates and initializes an instance of TTrackBar (see page 5172).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTrackBar(TComponent * AOwner);
```

Description

Call Create to instantiate a TTrackBar (see page 5172) object at runtime. Track bars placed on forms at design time are created automatically.

Create allocates memory and initializes the following properties:

ControlStyle is set to [csCaptureMouse, csClickEvents, csSetCaption].

Frequency (see page 5196) is set to 1.

Height is set to 45 and Width to 150.

LineSize (see page 5196) is set to 1 and PageSize (see page 5198) to 2.

Max (see page 5197) is set to 10 and Min (see page 5197) to 0.

Orientation (see page 5198) is set to trHorizontal.

TickMarks (see page 5209) is set to tbBottomRight and TickStyle (see page 5209) to tsAuto.

TabStop (see page 5208) is set to true.

See Also

ControlStyle (see page 5814)

Frequency (see page 5196)

Height (see page 5825)

LineSize (see page 5196)

Max (see page 5197)

Min (see page 5197)

Orientation (see page 5198)

PageSize (see page 5198)

TabStop (see page 6211)

TickMarks (see page 5209)

TickStyle (see page 5209)

Create (see page 6123)

27.1.56.3 TTrackBar Methods

The methods of the TTrackBar class are listed here.

Protected Methods

	Name	Description
	Changed (see page 5185)	Sends a CM_CHANGED message to the control.
V	CreateParams (see page 5185)	Initializes a window-creation parameter data structure.
V	CreateWnd (see page 5186)	Creates the underlying window.
V	DestroyWnd (see page 5186)	Destroys the control's window.

Public Methods

	Name	Description
	SetTick (see page 5187)	Adds a tick mark to the track bar at a specified location.

27.1.56.3.1 TTrackBar.Changed Method

Sends a CM_CHANGED message to the control.

Pascal

```
procedure Changed; dynamic;
```

C++

```
__fastcall Changed();
```

Description

Call Changed after changing the properties of the control in a way that affects the properties of a parent object. Changed sends a CM_CHANGED message back to the control. If the control is a windowed control, this message is bubbled up to the parent so that it can make any necessary adjustments.

See Also

Parent (see page 5832)

27.1.56.3.2 TTrackBar.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard

controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

27.1.56.3.3 TTrackBar.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

27.1.56.3.4 TTrackBar.DestroyWnd Method

Destroys the control's window.

Pascal

```
procedure DestroyWnd; override;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

DestroyWnd is called when the control needs to replace its window. For example, changing properties that are implemented by window parameter settings require the control to be destroyed and then recreated using the CreateWnd method.

Before the window is destroyed, DestroyWnd saves a copy of the control's text in memory, frees any device contexts, and finally calls DestroyWindowHandle. When the window is recreated, the stored copy of the control's text is assigned to the new window.

See Also

DestroyWindowHandle (see page 6140)

RecreateWnd (see page 6171)

27.1.56.3.5 TTrackBar.SetTick Method

Adds a tick mark to the track bar at a specified location.

Pascal

```
procedure SetTick(Value: Integer);
```

C++

```
__fastcall SetTick(int Value);
```

Description

Use SetTick to place a tick mark on the bar at the position that corresponds to the Value parameter. Tick marks specified in this manner are only displayed when the TickStyle (see page 5209) is set to tsManual.

See Also

Position (see page 5204)

TickStyle (see page 5209)

27.1.56.4 TTrackBar Properties

The properties of the TTrackBar class are listed here.

Published Properties

	Name	Description
	Align (see page 5188)	Determines how the control aligns within its container (parent control).
	Anchors (see page 5191)	Specifies how the control is anchored to its parent.
	BorderWidth (see page 5192)	Specifies the width of the control's border.
	Constraints (see page 5192)	Specifies the size constraints for the control.
	Ctl3D (see page 5193)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 5193)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5194)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5194)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 5196)	Controls whether the control responds to mouse, keyboard, and timer events.
	Frequency (see page 5196)	Specifies the increment between tick marks on the track bar.
	LineSize (see page 5196)	Indicates the amount the value of Position (see page 5204) changes when the user presses the arrow keys.
	Max (see page 5197)	Specifies the maximum Position (see page 5204) of a TTrackBar (see page 5172).
	Min (see page 5197)	Specifies the minimum Position (see page 5204) of a TTrackBar (see page 5172).
	Orientation (see page 5198)	Specifies whether the track bar is horizontal or vertical.
	PageSize (see page 5198)	Specifies the amount Position (see page 5204) is changed when the PageUp or PageDown key is pressed, or when the bar is clicked.
	ParentCtl3D (see page 5198)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 5199)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5199)	Identifies the pop-up menu associated with the control.
	Position (see page 5204)	Contains the current position of the slider of a TTrackBar (see page 5172).
	PositionToolTip (see page 5204)	Determines the position of the (optional) tooltip displaying the position of the track bar.
	SelEnd (see page 5205)	Specifies the position of the end point of the selection range.
	SelStart (see page 5205)	Specifies the position of the starting point of the selection range.

	ShowHint (see page 5206)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShowSelRange (see page 5207)	Specifies whether the track bar shows the selection range.
	SliderVisible (see page 5207)	Specifies whether the track bar's slider is visible.
	TabOrder (see page 5208)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5208)	Determines if the user can tab to a control.
	ThumbLength (see page 5209)	Specifies the length of the track bar's slider.
	TickMarks (see page 5209)	Specifies the location of the tick marks.
	TickStyle (see page 5209)	Specifies how tick marks are placed on the track bar.
	Visible (see page 5210)	Determines whether the component appears onscreen.

27.1.56.4.1 TTrackBar.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{

    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
```

```
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin

    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
```

```
  series of Tab Sheets on the Page Control.
  }
  var
    PageControl1: TPageControl;
    pts: array[0..3] of TTabSheet;
  const
    TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

  procedure TForm1.FormCreate(Sender: TObject);
  const
    colorpalette: Array[0..11] of TColor = (
      clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
      clNavy, clMaroon, clLime, clOlive, clPurple);
  var
    i: Integer;
  begin
    PageControl1 := TPageControl.Create(Self);
    PageControl1.Parent := Self;
    PageControl1.Align := alClient;
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i]:= TTabSheet.Create(PageControl1);
      with pts[i] do
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

27.1.56.4.2 TTrackBar.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control

has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

27.1.56.4.3 TTrackBar.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter (see page 6194)

27.1.56.4.4 TTrackBar.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict,

the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

27.1.56.4.5 TTrackBar.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

27.1.56.4.6 TTrackBar.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

27.1.56.4.7 TTrackBar.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

27.1.56.4.8 TTrackBar.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
```

```
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

EndDrag (see page 5757)

OnDragDrop (see page 5855)

OnDragOver (see page 5857)

OnEndDrag (see page 5860)

OnStartDrag (see page 5871)

DragKind (see page 5819)

Arranging the Order of Persistent Columns

27.1.56.4.9 TTrackBar.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

27.1.56.4.10 TTrackBar.Frequency Property

Specifies the increment between tick marks on the track bar.

Pascal

```
property Frequency: Integer;
```

C++

```
__property int Frequency;
```

Description

Use Frequency to specify the spacing of the tick marks, using the logical units used by the Position (see page 5204) property. For example, a Frequency of 5 sets a tick mark at every fifth possible increment. To provide visual feedback about the units used by the track bar, set Frequency to LineSize (see page 5196) or PageSize (see page 5198).

Note: If the value of the TickStyle (see page 5209) property is not set to tsAuto, the value of Frequency is ignored.

See Also

LineSize (see page 5196)

PageSize (see page 5198)

SetTick (see page 5187)

TickStyle (see page 5209)

27.1.56.4.11 TTrackBar.LineSize Property

Indicates the amount the value of Position (see page 5204) changes when the user presses the arrow keys.

Pascal

```
property LineSize: Integer;
```

C++

```
__property int LineSize;
```

Description

Use LineSize to specify the distance along the slider that represents a single unit. The current Position (see page 5204) is marked by a slider. The right and down arrow keys increment the value of Position (see page 5204) by LineSize, and the left and up arrow keys decrement the value of Position (see page 5204) by LineSize.

Use the PageSize (see page 5198) property to set the number of ticks moved using the Page Up and Page Down keys.

See Also

PageSize (see page 5198)

Position (see page 5204)

27.1.56.4.12 TTrackBar.Max Property

Specifies the maximum Position (see page 5204) of a TTrackBar (see page 5172).

Pascal

```
property Max: Integer;
```

C++

```
__property int Max;
```

Description

Use Max to set an upper limit to the value that can be represented using the track bar. A slider indicates the current Position (see page 5204) in a range between Min (see page 5197) and Max.

See Also

Min (see page 5197)

Position (see page 5204)

27.1.56.4.13 TTrackBar.Min Property

Specifies the minimum Position (see page 5204) of a TTrackBar (see page 5172).

Pascal

```
property Min: Integer;
```

C++

```
__property int Min;
```

Description

Use Min to set a lower limit to the value that can be represented using the track bar. A slider indicates the current Position (see page 5204) in a range between Min and Max (see page 5197).

See Also

Max (see page 5197)

Position (see page 5204)

27.1.56.4.14 TTrackBar.Orientation Property

Specifies whether the track bar is horizontal or vertical.

Pascal

```
property Orientation: TTrackBarOrientation;
```

C++

```
__property TTrackBarOrientation Orientation;
```

Description

Set Orientation to the desired orientation of the track bar. Orientation has these possible values:

Value	Meaning
tbHorizontal	The long edge of the track is parallel to the top of the form. The Min (see page 5197) position is on the left and the Max (see page 5197) position is on the right.
tbVertical	The long edge of the track is parallel to the side of the form. The Min (see page 5197) position is on the top and the Max (see page 5197) position is on the bottom.

See Also

BoundsRect (see page 5803)

27.1.56.4.15 TTrackBar.PageSize Property

Specifies the amount Position (see page 5204) is changed when the PageUp or PageDown key is pressed, or when the bar is clicked.

Pascal

```
property PageSize: Integer;
```

C++

```
__property int PageSize;
```

Description

Set PageSize to the distance along the track bar that corresponds to a single view. A slider marks the current Position (see page 5204). The Page Up key increments the value of Position (see page 5204) by PageSize, and Page Down key decrements the value of Position (see page 5204) by PageSize.

Use the LineSize (see page 5196) property to set the number of ticks moved using the arrow keys.

See Also

LineSize (see page 5196)

Position (see page 5204)

27.1.56.4.16 TTrackBar.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

27.1.56.4.17 TTrackBar.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

27.1.56.4.18 TTrackBar.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup

property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
```

```
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
```

```
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

27.1.56.4.19 TTrackBar.Position Property

Contains the current position of the slider of a TTrackBar (see page 5172).

Pascal

```
property Position: Integer;
```

C++

```
__property int Position;
```

Description

Read Position to determine the current value represented by the track bar. Position is a value in the range between Min (see page 5197) and Max (see page 5197) (inclusive). Set Position to programmatically move the slider of the track bar to a new value.

See Also

Max (see page 5197)

Min (see page 5197)

27.1.56.4.20 TTrackBar.PositionToolTip Property

Determines the position of the (optional) tooltip displaying the position of the track bar.

Pascal

```
property PositionToolTip: TPositionToolTip;
```

C++

```
__property TPositionToolTip PositionToolTip;
```

Description

You can set this property to the following values:

- ptBottom
- ptLeft

- ptNone
- ptRight
- ptLeft

27.1.56.4.21 TTrackBar.SelEnd Property

Specifies the position of the end point of the selection range.

Pascal

```
property SelEnd: Integer;
```

C++

```
__property int SelEnd;
```

Description

Set SelEnd to determine the length of a selection that begins at SelStart (see page 5205). The track bar indicates a selection range on the bar by placing special tick marks at the positions specified by the SelStart (see page 5205) and SelEnd properties and highlighting the selected portion of the bar.

SelEnd must be greater than or equal to Position (see page 5204). If SelEnd is set to a value less than Position (see page 5204), Position (see page 5204) changes to SelEnd. SelEnd must be greater than or equal to SelStart (see page 5205). If SelEnd is the same as SelStart (see page 5205), there is no selection, and the value of Position (see page 5204) is the same as SelStart (see page 5205) and SelEnd.

See Also

Position (see page 5204)

SelStart (see page 5205)

27.1.56.4.22 TTrackBar.SelStart Property

Specifies the position of the starting point of the selection range.

Pascal

```
property SelStart: Integer;
```

C++

```
__property int SelStart;
```

Description

Set SelStart to determine the beginning of a selection that runs to SelEnd (see page 5205). The track bar indicates a selection range on the bar by placing special tick marks at the positions specified by the SelStart and SelEnd (see page 5205) properties and highlighting the selected portion of the bar.

SelStart must be less than or equal to Position (see page 5204). If SelStart is set to a value greater than Position (see page 5204), Position (see page 5204) changes to SelStart. SelStart must be less than or equal to SelEnd (see page 5205). If SelStart is the same as SelEnd (see page 5205), there is no selection, and the value of Position (see page 5204) is the same as SelStart and SelEnd (see page 5205).

See Also

Position (see page 5204)

SelEnd (see page 5205)

27.1.56.4.23 TTrackBar.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

ShowHint (see page 13721)

Displaying Fly-over Help

27.1.56.4.24 TTrackBar.ShowSelRange Property

Specifies whether the track bar shows the selection range.

Pascal

```
property ShowSelRange: Boolean;
```

C++

```
__property Boolean ShowSelRange;
```

Description

If set to True, the selection range on the track bar is displayed. If set to False, the selection range is not displayed.

27.1.56.4.25 TTrackBar.SliderVisible Property

Specifies whether the track bar's slider is visible.

Pascal

```
property SliderVisible: Boolean;
```

C++

```
__property Boolean SliderVisible;
```

Description

Use SliderVisible to get or set whether the track bar's slider is visible.

27.1.56.4.26 TTrackBar.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

27.1.56.4.27 TTrackBar.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

27.1.56.4.28 TTrackBar.ThumbLength Property

Specifies the length of the track bar's slider.

Pascal

```
property ThumbLength: Integer;
```

C++

```
__property int ThumbLength;
```

Description

Use ThumbLength to get or set the length of the track bar's slider.

27.1.56.4.29 TTrackBar.TickMarks Property

Specifies the location of the tick marks.

Pascal

```
property TickMarks: TTickMark;
```

C++

```
__property TTickMark TickMarks;
```

Description

Set TickMarks to specify where the tick marks should be drawn. TickMarks has these possible values:

Value	Meaning
tmBottomRight	Tick marks are on the bottom or right of the track bar, depending of the value of Orientation (see page 5198).
tmTopLeft	Tick marks are on the top or left of the track bar, depending of the value of Orientation (see page 5198).
tmBoth	Tick marks are on both sides of the track bar.

If the TickStyle (see page 5209) property is tsNone, the value of TickMarks is ignored.

See Also

TickStyle (see page 5209)

27.1.56.4.30 TTrackBar.TickStyle Property

Specifies how tick marks are placed on the track bar.

Pascal

```
property TickStyle: TTickStyle;
```

C++

```
__property TTickStyle TickStyle;
```

Description

Set TickStyle to specify whether the track bar should display tick marks, and if so, how those tick marks are set. TickStyle has these possible values:

Value	Meaning
tsAuto	Tick marks are automatically displayed at increments equal to the value of the Frequency (see page 5196) property.
tsManual	Tick marks are displayed at the Min (see page 5197) and Max (see page 5197) values. Additional tick marks can be set using the SetTick (see page 5187) method.
tsNone	No tick marks are displayed.

See Also

Frequency (see page 5196)

Max (see page 5197)

Min (see page 5197)

SetTick (see page 5187)

27.1.56.4.31 TTrackBar.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

27.1.56.5 TTrackBar Events

The events of the TTrackBar class are listed here.

Published Events

	Name	Description
	OnChange (see page 5212)	Occurs immediately after the value of Position (see page 5204) changes.
	OnContextPopup (see page 5212)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDragDrop (see page 5213)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5215)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5217)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5218)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 5219)	Occurs when a control receives the input focus.
	OnExit (see page 5221)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 5223)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 5226)	Occurs when a key is pressed.
	OnKeyUp (see page 5227)	Occurs when the user releases a key that has been pressed.
	OnStartDock (see page 5228)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 5229)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

27.1.56.5.1 TTrackBar.OnChange Event

Occurs immediately after the value of Position (see page 5204) changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the position of the slider may have changed. For example, if the track bar is being used to control another object, update the other object from an OnChange event handler.

See Also

Position (see page 5204)

27.1.56.5.2 TTrackBar.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

27.1.56.5.3 TTrackBar.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
```

```
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

27.1.56.5.4 TTrackBar.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
```

```
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
```

```
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

27.1.56.5.5 TTrackBar.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

27.1.56.5.6 TTrackBar.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
```

```
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;
```

27.1.56.5.7 TTrackBar.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
```

```
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

27.1.56.5.8 TTrackBar.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
```

```
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

OnEnter (see page 6219)

ActiveControl (see page 13896)

27.1.56.5.9 TTrackBar.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
```

```
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
```

```
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
  {
  The following code aborts a print job if the user presses
  Esc. Note that you should set KeyPreview to true to ensure
  that the OnKeyDown event handler of Form1 is called.
  }

  uses Printers;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, X, Y: Integer;
    Memo1 : TMemo;
    r: TRect;
  begin
    Memo1 := TMemo.Create(Form1);
    Memo1.Parent := Form1;
    Memo1.Visible := True;
    Memo1.Width := 700;
    if (OpenDialog1.Execute) then
    begin
      Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
     KeyPreview := True;
  end;

  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
  if (Key=VK_ESCAPE) and Printer.Printing then
    begin
    Printer.Abort;
    MessageDlg('Printing aborted', mtInformation, [mbOK],0);
    end;
  end;

27.1.56.5.10 TTrackBar.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown (see page 6225)

OnKeyUp (see page 6228)

KeyPreview (see page 13918)

27.1.56.5.11 TTrackBar.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
```

```
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
```

OnKeyDown (see page 6225)

OnKeyPress (see page 6227)

27.1.56.5.12 TTrackBar.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

27.1.56.5.13 TTrackBar.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

27.1.57 TTreeNode Class

TTreeNode describes an individual node in a tree view control.

Class Hierarchy

Pascal

```
TTreeNode = class(TPersistent);
```

C++

```
class TTreeNode : public TPersistent;
```

File

ComCtrls

Description

Each node in a tree view control consists of a label and an optional bitmapped image. Each item can be the parent of a list of subitems. By clicking an item, the user can expand or collapse the associated list of subitems.

See Also

TImageList (see page 6078)

TTreeNodes (see page 5266)

TTreeView (see page 5293)

27.1.57.1 TTreeNode Members

The following tables list the members exposed by TTreeNode.

Protected Methods

	Name	Description
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetState (see page 5248)	This is GetState, a member of class TTreeNode.
	SetSelectedBit (see page 5251)	This is SetSelectedBit, a member of class TTreeNode.
	SetState (see page 5251)	This is SetState, a member of class TTreeNode.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AlphaSort (see page 5234)	Sorts tree nodes.
V	Assign (see page 5234)	Copies the properties of another tree view node.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Collapse (see page 5235)	Collapses a node.
	Create (see page 5232)	Creates an instance of TTreeNode (see page 5230).
	CustomSort (see page 5236)	Triggers node sorting.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 5237)	Destroys the node and all its children.
	DeleteChildren (see page 5238)	Deletes all children of the node.
V	Destroy (see page 5233)	Destroys the tree node object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DisplayRect (see page 5238)	Returns the bounding rectangle for a tree node.
	EditText (see page 5240)	Allows editing a tree node.
	EndEdit (see page 5241)	Ends the editing of a node's label.
	Expand (see page 5242)	Expands the node to display all child nodes.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	getFirstChild (see page 5242)	Returns the first child node of a tree node.
	GetHandle (see page 5243)	Returns the Handle (see page 5258) property.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetLastChild (see page 5243)	Returns the last immediate child node of the calling node.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetNext (see page 5243)	Returns the next node after the calling node in the tree view.
	GetNextChild (see page 5244)	Returns the next child node after Value.
	getNextSibling (see page 5245)	Returns the next node in the tree view at the same level as the calling node.
	GetNextVisible (see page 5245)	Returns the next visible node in the tree view after the calling node.
	GetPrev (see page 5246)	Returns the previous node in the tree view before the calling node.
	GetPrevChild (see page 5246)	Returns the previous child node before Value.
	getPrevSibling (see page 5247)	Returns the previous node before the calling node and at the same level.
	GetPrevVisible (see page 5247)	Returns the previous visible node before the calling node.
	HasAsParent (see page 5248)	Returns true if Value is a parent node of the calling node.
	IndexOf (see page 5248)	Returns the position of an immediate child node of the calling node.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsFirstNode (see page 5249)	Indicates whether the tree node is very first.
	MakeVisible (see page 5249)	Makes a node visible.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	MoveTo (see page 5249)	Moves the node to another location in the tree view.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	AbsoluteIndex (see page 5252)	Indicates the index of the tree node relative to the first tree node in a tree node.
R	Count (see page 5253)	Indicates the number of direct descendants of a tree node.
	Cut (see page 5254)	Indicates if the tree node object is drawn as if selected as part of a cut and paste operation.
	Data (see page 5254)	Points to application-defined data associated with the tree node.
R	Deleting (see page 5256)	Indicates whether a node's Destroy (see page 5233) method has been called and the node is in the process of being deleted.
	DropTarget (see page 5257)	Indicates whether the tree node is drawn as a drag and drop target.
	Expanded (see page 5257)	Specifies whether the tree node is expanded.
	Focused (see page 5257)	Indicates whether the node appears to have focus.
R	Handle (see page 5258)	Contains the window Handle of the tree view that contains the node.
	HasChildren (see page 5258)	Indicates whether a node has any children.
	ImageIndex (see page 5259)	Specifies which image is displayed when a node is in its normal state and is not currently selected.
R	Index (see page 5259)	Specifies the position of the node in the list of child nodes maintained by its parent node.
R	IsVisible (see page 5259)	Indicates whether the tree node is currently visible in the tree view image.
	Item (see page 5260)	Provides access to a child node by its position in the list of child nodes.
R	ItemId (see page 5260)	Contains a handle that uniquely identifies each node in a tree view.
R	Level (see page 5260)	Indicates the level of indentation of a node within the tree view control.
	OverlayIndex (see page 5263)	Determines which image from the image list is used as an overlay mask.
R	Owner (see page 5263)	Indicates which tree nodes object contains the tree node.
R	Parent (see page 5263)	Identifies the parent node of the tree node.
	Selected (see page 5264)	Determines whether the node is selected.
	SelectedIndex (see page 5265)	Specifies the index in the tree view's image list of the image displayed for the node when it is selected.
	StateIndex (see page 5265)	Indicates which image from the StateImages list to display for the node.
	Text (see page 5265)	Specifies the label that identifies a tree node.
R	TreeView (see page 5266)	Specifies the tree view that displays the node.

27.1.57.2 TTreeNode.Create Constructor

Creates an instance of TTreeNode (see page 5230).

Pascal

```
constructor Create(AOwner: TTreeNodes);
```

C++

```
__fastcall TTreeNode(TTreeNodes AOwner);
```

Description

Call Create to instantiate a tree node at runtime. Nodes added to a tree view control at design time are created automatically. Use the methods of the TTreeNodes (see page 5266) object instead to create nodes as part of an existing tree view.

After calling the inherited constructor, Create sets the OverlayIndex (see page 5263) and StateIndex (see page 5265) properties to -1 and then sets the Owner (see page 5263) property of the tree node to the AOwner TTreeNodes (see page 5266) object.

See Also

OverlayIndex (see page 5263)

Owner (see page 5263)

StateIndex (see page 5265)

Add (see page 5270)

Insert (see page 5285)

27.1.57.3 TTreeNode.Destroy Destructor

Destroys the tree node object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTreeNode();
```

Description

Do not call Destroy directly in an application. Instead, use the Delete (see page 5237) method. Delete (see page 5237) removes the image of the node and all its children from the tree view window, and guards against recursive deletes.

See Also

Delete (see page 5237)

27.1.57.4 TTreeNode Methods

The methods of the TTreeNode class are listed here.

Protected Methods

	Name	Description
	GetState (see page 5248)	This is GetState, a member of class TTreeNode.
	SetSelectedBit (see page 5251)	This is SetSelectedBit, a member of class TTreeNode.
	SetState (see page 5251)	This is SetState, a member of class TTreeNode.

Public Methods

	Name	Description
	AlphaSort (see page 5234)	Sorts tree nodes.
V	Assign (see page 5234)	Copies the properties of another tree view node.
	Collapse (see page 5235)	Collapses a node.
	CustomSort (see page 5236)	Triggers node sorting.
	Delete (see page 5237)	Destroys the node and all its children.
	DeleteChildren (see page 5238)	Deletes all children of the node.
	DisplayRect (see page 5238)	Returns the bounding rectangle for a tree node.
	EditText (see page 5240)	Allows editing a tree node.
	EndEdit (see page 5241)	Ends the editing of a node's label.
	Expand (see page 5242)	Expands the node to display all child nodes.
	getFirstChild (see page 5242)	Returns the first child node of a tree node.
	GetHandle (see page 5243)	Returns the Handle (see page 5258) property.
	GetLastChild (see page 5243)	Returns the last immediate child node of the calling node.

	GetNext (see page 5243)	Returns the next node after the calling node in the tree view.
	GetNextChild (see page 5244)	Returns the next child node after Value.
	getNextSibling (see page 5245)	Returns the next node in the tree view at the same level as the calling node.
	GetNextVisible (see page 5245)	Returns the next visible node in the tree view after the calling node.
	GetPrev (see page 5246)	Returns the previous node in the tree view before the calling node.
	GetPrevChild (see page 5246)	Returns the previous child node before Value.
	getPrevSibling (see page 5247)	Returns the previous node before the calling node and at the same level.
	GetPrevVisible (see page 5247)	Returns the previous visible node before the calling node.
	HasAsParent (see page 5248)	Returns true if Value is a parent node of the calling node.
	IndexOf (see page 5248)	Returns the position of an immediate child node of the calling node.
	IsFirstNode (see page 5249)	Indicates whether the tree node is very first.
	MakeVisible (see page 5249)	Makes a node visible.
V	MoveTo (see page 5249)	Moves the node to another location in the tree view.

27.1.57.4.1 TTreeNode.AlphaSort Method

Sorts tree nodes.

Pascal

```
function AlphaSort(ARecurse: Boolean = False): Boolean;
```

C++

```
__fastcall Boolean AlphaSort(Boolean ARecurse = False);
```

Description

AlphaSort triggers node sorting or resorting of the node's child nodes. If an OnCompare event handler is defined for the associated TCustomTreeView (see page 3957), that routine determines sort order. If no OnCompare handler is defined, nodes are sorted by a simple case-sensitive compare of their captions.

The optional ARecurse parameter (default false) specifies that sorting should recursively descend the node tree and sort each subtree in turn. By default, only the node's immediate children are sorted.

Calling AlphaSort is equivalent to calling CustomSort (see page 5236) with a nil (Delphi) or NULL (C++) procedure parameter and a data parameter of 0.

To sort the top-level nodes, use the AlphaSort method of TTreeNodes (see page 5266).

See Also

CustomSort (see page 5236)

SortType (see page 4014)

Text (see page 5265)

AlphaSort (see page 3972)

AlphaSort (see page 5279)

27.1.57.4.2 TTreeNode.Assign Method

Copies the properties of another tree view node.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

If the Source parameter is a TTreeNode (see page 5230) object, Assign copies the Text (see page 5265), Data (see page 5254), ImageIndex (see page 5259), SelectedIndex (see page 5265), OverlayIndex (see page 5263), Focused (see page 5257), DropTarget (see page 5257), Cut (see page 5254), and HasChildren (see page 5258) properties from the source node. If Source is any other type of object, Assign calls its inherited method, which copies information from any object that can copy to a tree node in its AssignTo method.

Note: While Assign copies the HasChildren (see page 5258) property, it does not copy the child nodes. Be sure to copy any descendants after assigning the properties of another node that has children.

See Also

Cut (see page 5254)

Data (see page 5254)

DropTarget (see page 5257)

Focused (see page 5257)

HasChildren (see page 5258)

ImageIndex (see page 5259)

OverlayIndex (see page 5263)

SelectedIndex (see page 5265)

Text (see page 5265)

AssignTo (see page 2931)

27.1.57.4.3 TTreeNode.Collapse Method

Collapses a node.

Pascal

```
procedure Collapse(Recurse: Boolean);
```

C++

```
__fastcall Collapse(Boolean Recurse);
```

Description

When a node is collapsed, all of its subnodes are hidden. The plus button may be displayed, depending on whether the tree view's ShowButtons property is set. If Recurse is true, then all subnodes will be collapsed as well. When the node is next expanded the children will still be collapsed. If Recurse is false, the child nodes won't be collapsed and the next time the node is expanded, the children will be in the same state as when Collapse was called.

See Also

Expanded (see page 5257)

OnCollapsed (see page 4018)

OnCollapsing (see page 4018)

FullCollapse (see page 3983)

27.1.57.4.4 TTreeNode.CustomSort Method

Triggers node sorting.

Pascal

```
function CustomSort(SortProc: TTVCompare; Data: Longint; ARecurse: Boolean = False): Boolean;
```

C++

```
__fastcall Boolean CustomSort(TTVCompare SortProc, Longint Data, Boolean ARecurse = False);
```

Description

CustomSort triggers node sorting or resorting of the node's child nodes, using a comparison routine indicated by the SortProc parameter. The Data (see page 5254) parameter is passed to the comparison routine. The optional ARecurse parameter (default false) specifies that sorting should recursively descend the node tree and sort each subtree in turn.

If SortProc is nil (Delphi) or NULL (C++), a default comparison routine is used. The default routine uses the OnCompare event handler for the associated TCustomTreeview object, if defined. If the OnCompare event handler is not defined, the default routine uses a simple case-sensitive compare of node captions.

In the comparison routine, the lParam1 and lParam2 parameters refer to two nodes when cast to TTreeNode (see page 5230). The lParamSort parameter is the value previously passed to the Data (see page 5254) parameter of CustomSort. The return value of the comparison routine indicates the relative sort order of lParam1 and lParam2:

Return Value	Meaning
< 0	lParam1 comes before lParam2
0	lParam1 and lParam2 are equivalent
> 0	lParam2 comes before lParam1

To sort the top-level nodes, use the CustomSort method of TTreeNodes (see page 5266).

C++ Examples:

```
/*
This example shows how to use the CustomSort method to order
a subtree in case-insensitive alphabetical order (either
forward or backward). The callback function CompareFunc
below calls the global AnsiStrIComp function to perform the
actual comparison.  This example requires two buttons and a
populated TreeView.
*/
int CALLBACK CompareFunc(long lParam1, long lParam2, long Reverse)
{
  TTreeNode *Node1 = ((TTreeNode *)lParam1);
  TTreeNode *Node2 = ((TTreeNode *)lParam2);
  if ((Node1 == NULL) || (Node2 == NULL)) return 0;
  int GT = AnsiStrIComp(Node1->Text.c_str(), Node2->Text.c_str());
  if (Reverse)
    return -GT;
  return GT;
}

/*
This procedure can then be used as a parameter to CustomSort
to sort the nodes of the tree view.  To sort in ascending
order, call:
*/

#include <CommCtrl.hpp>
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTreeNode *node = TreeView1->Selected;
  node->CustomSort(CompareFunc, 0); // Sorts in ascending order
}
```

Delphi Examples:

```
{
This example shows how to use the CustomSort method to order
a subtree in case-insensitive alphabetical order (either
forward or backward). The callback function CompareFunc
below calls the global AnsiStrIComp function to perform the
actual comparison.  This example requires two buttons and a
populated TreeView.
}
function CustomSortProc(Node1, Node2: TTreeNode; Data: Longint): Integer; stdcall;
begin
  if Data = 0 then
    Result :=
      AnsiStrIComp(Pchar(Node1.Text), PChar(Node2.Text))
  else
    Result :=
      -AnsiStrIComp(PChar(Node1.Text), PChar(Node2.Text));
end;

{
This procedure can then be used as a parameter to CustomSort
to sort the children of a node:
}

procedure TForm1.Button1Click(Sender: TObject);
var node: TTreeNode;
begin
  node := TreeView1.Selected;
  node.CustomSort(@CustomSortProc, 0);  { Sorts in ascending order }
end;

procedure TForm1.Button2Click(Sender: TObject);
var node: TTreeNode;
begin
  node := TreeView1.Selected;
  node.CustomSort(@CustomSortProc, 1);  { Sorts in descending order }
end;
```

See Also

AlphaSort (see page 5234)

CustomSort (see page 3978)

27.1.57.4.5 TTreeNode.Delete Method

Destroys the node and all its children.

Pascal

```
procedure Delete;
```

C++

```
__fastcall Delete();
```

Description

Use the Delete method to delete a tree node and free all associated memory.

See Also

DeleteChildren (see page 5238)

Deleting (see page 5256)

Destroy (see page 5233)

OnDeletion (see page 4024)

27.1.57.4.6 TTreeNode.DeleteChildren Method

Deletes all children of the node.

Pascal

```
procedure DeleteChildren;
```

C++

```
__fastcall DeleteChildren();
```

Description

Use the DeleteChildren method to delete all children of a tree node, freeing all associated memory.

See Also

Delete (see page 5237)

Deleting (see page 5256)

OnDeletion (see page 4024)

27.1.57.4.7 TTreeNode.DisplayRect Method

Returns the bounding rectangle for a tree node.

Pascal

```
function DisplayRect(TextOnly: Boolean): TRect;
```

C++

```
__fastcall TRect DisplayRect(Boolean TextOnly);
```

Description

If the TextOnly parameter is true, the bounding rectangle includes only the text of the node. Otherwise, it includes the entire line that the node occupies in the tree-view control.

C++ Examples:

```
/*
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
*/
void __fastcall TCustomDrawForm::TVCustomDrawItem(TCustomTreeView *Sender,
      TTreeNode *Node, TCustomDrawState State, bool &DefaultDraw)
{
  TRect NodeRect;
/*
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
```

```
    ignores our font background colors, using instead the
    TreeView's Color property.
*/
    if (State.Contains(cdsSelected))
    {
      TV->Canvas->Font->Assign(SelectedFontDialog->Font);
      TV->Canvas->Brush->Color = SelBkgColorDialog->Color;
    };

    DefaultDraw = FDefaultDrawItem;
/*
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
*/
    if (!DefaultDraw)
    {
      //draw the selection rect.
      if (State.Contains(cdsSelected))
      {
        NodeRect = Node->DisplayRect(True);
        TV->Canvas->FillRect(NodeRect);
      };
      NodeRect = Node->DisplayRect(False);

      if (None1->Checked)
      //no bitmap, so paint in the background color.
      {
        TV->Canvas->Brush->Color = BkgColorDialog->Color;
        TV->Canvas->Brush->Style = FBrushStyle;
        TV->Canvas->FillRect(NodeRect);
      }
      else
        //don't paint over the background bitmap.
        TV->Canvas->Brush->Style = bsClear;

      NodeRect.Left = NodeRect.Left + (Node->Level * TV->Indent);
      // NodeRect.Left now represents the left-most portion
      // of the expand button
      DrawButton(&NodeRect, Node); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + TV->Indent + FButtonSize;
      //NodeRect->Left is now the leftmost portion of the image.
      DrawImage(&NodeRect, Node->ImageIndex); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + ImageList->Width;
      //Now we are finally in a position to draw the text.

      TV->Canvas->TextOut(NodeRect.Left, NodeRect.Top, Node->Text);
    };
}
```

Delphi Examples:

```
{
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
}
procedure TCustomDrawForm.TVCustomDrawItem(Sender: TCustomTreeView; Node: TTreeNode;
  State: TCustomDrawState; var DefaultDraw: Boolean);
var
  NodeRect: TRect;
begin
  with TV.Canvas do
  begin
{
```

```
      If DefaultDraw it is true, any of the node's font
      properties can be changed. Note also that when
      DefaultDraw = True, Windows draws the buttons and
      ignores our font background colors, using instead the
      TreeView's Color property.
  }
      if cdsSelected in State then
      begin
        Font.Assign(SelectedFontDialog.Font);
        Brush.Color := SelBkgColorDialog.Color;
      end;

      DefaultDraw := False; // FDefaultDrawItem;
  {
      DefaultDraw = False means you have to handle all the
      item drawing yourself, including the buttons, lines,
      images, and text.
  }
      if not DefaultDraw then
      begin
        //draw the selection rect.
        if cdsSelected in State then
        begin
          NodeRect := Node.DisplayRect(True);
          FillRect(NodeRect);
        end;
        NodeRect := Node.DisplayRect(False);

        if None1.Checked then
        //no bitmap, so paint in the background color.
        begin
          Brush.Color := BkgColorDialog.Color;
          Brush.Style := FBrushStyle;
          FillRect(NodeRect)
        end
        else
          //don't paint over the background bitmap.
          Brush.Style := bsClear;

        NodeRect.Left := NodeRect.Left + (Node.Level * TV.Indent);
        // NodeRect.Left now represents the left-most portion
        // of the expand button
        DrawButton(NodeRect, Node); // See the CustomDraw demo

        NodeRect.Left := NodeRect.Left + TV.Indent + FButtonSize;
        //NodeRect.Left is now the leftmost portion of the image.
        DrawImage(NodeRect, Node.ImageIndex); // See the CustomDraw demo

        NodeRect.Left := NodeRect.Left + ImageList.Width;
        //Now we are finally in a position to draw the text.

        TextOut(NodeRect.Left, NodeRect.Top, Node.Text);
      end;
    end;
  end;
```

See Also

Text (see page 5265)

27.1.57.4.8 TTreeNode.EditText Method

Allows editing a tree node.

Pascal

```
function EditText: Boolean;
```

C++

```
__fastcall Boolean EditText();
```

Description

Call EditText to allow a user to edit tree node label text.

Delphi Examples:

```
{
This example is an event handler for a popup menu item. The
handler enables editing of the current item in a TListView
control. The example would also work with a TTreeView
control, or with any instance of a control class derived
from TCustomViewControl.
}
procedure TForm1.EditItem1Click(Sender: TObject);
begin
  TreeView1.Selected.EditText;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  MyTreeNode1, MyTreeNode2: TTreeNode;
begin
  with TreeView1.Items do
  begin
    Clear; { remove any existing nodes }
    MyTreeNode1 := Add(nil, 'RootTreeNode1'); { Add a root node }
    { Add a child node to the node just added }
    AddChild(MyTreeNode1,'ChildNode1');

    {Add another root node}
    MyTreeNode2 := Add(MyTreeNode1, 'RootTreeNode2');
    {Give MyTreeNode2 to a child }
    AddChild(MyTreeNode2,'ChildNode2');

    {Change MyTreeNode2 to ChildNode2 }
    { and add a child node to it}
    MyTreeNode2 := TreeView1.Items[3];
    AddChild(MyTreeNode2,'ChildNode2a');

    {Add another child to ChildNode2, after ChildNode2a }
    AddChild(MyTreeNode2,'ChildNode2b');

    {add another root node}
    Add(MyTreeNode1, 'RootTreeNode3');
  end;
end;

procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
begin
  PopupMenu1.Popup(Left + X, Top + Y);
end;
```

27.1.57.4.9 TTreeNode.EndEdit Method

Ends the editing of a node's label.

Pascal

```
procedure EndEdit(Cancel: Boolean);
```

C++

```
__fastcall EndEdit(Boolean Cancel);
```

Description

Call EndEdit to take the node out of edit mode. If the Cancel parameter is true, all changes made by the user are discarded. If Cancel is false, EndEdit updates the node's Text (see page 5265) property and the tree view's OnEdited event occurs.

See Also

Text (see page 5265)

OnEdited (see page 4024)

27.1.57.4.10 TTreeNode.Expand Method

Expands the node to display all child nodes.

Pascal

```
procedure Expand(Recurse: Boolean);
```

C++

```
__fastcall Expand(Boolean Recurse);
```

Description

When a node is expanded, its immediate subnodes are displayed. The minus '-' button may be displayed, depending on whether the tree view's ShowButtons property is set. If Recurse is true, all descendants of the immediate subnodes are expanded as well.

See Also

Collapse (see page 5235)

ShowButtons (see page 4013)

27.1.57.4.11 TTreeNode.getFirstChild Method

Returns the first child node of a tree node.

Pascal

```
function getFirstChild: TTreeNode;
```

C++

```
__fastcall TTreeNode getFirstChild();
```

Description

Call GetFirstChild to access the first child node of the tree view node. If the node has no children, GetFirstChild returns nil (Delphi) or NULL (C++).

Note: GetFirstChild returns the same value as Item (see page 5260)[0].

See Also

GetNextChild (see page 5244)

GetNodeAt (see page 3987)

GetPrevChild (see page 5246)

Item (see page 5260)

27.1.57.4.12 TTreeNode.GetHandle Method

Returns the Handle (see page 5258) property.

Pascal

```
function GetHandle: HWND;
```

C++

```
__fastcall HWND GetHandle();
```

Description

Calling GetHandle is the same as reading the Handle (see page 5258) property.

See Also

Handle (see page 5258)

27.1.57.4.13 TTreeNode.GetLastChild Method

Returns the last immediate child node of the calling node.

Pascal

```
function GetLastChild: TTreeNode;
```

C++

```
__fastcall TTreeNode GetLastChild();
```

Description

Call GetLastChild to find the last immediate child of a node. If the calling node has no children, GetLastChild returns nil (Delphi) or NULL (C++). GetLastChild returns the same value as Item (see page 5260)[Count (see page 5253)-1].

See Also

Count (see page 5253)

GetNext (see page 5243)

GetNodeAt (see page 3987)

Item (see page 5260)

27.1.57.4.14 TTreeNode.GetNext Method

Returns the next node after the calling node in the tree view.

Pascal

```
function GetNext: TTreeNode;
```

C++

```
__fastcall TTreeNode GetNext();
```

Description

If the calling node is the last node, GetNext returns nil (Delphi) or NULL (C++). Otherwise, it returns the next node including nodes that aren't visible and child nodes. To get the next node at the same level as the calling node, use GetNextSibling. To get the next visible node, use GetNextVisible (see page 5245).

C++ Examples:

```
/*
The following example adds the Text for all items in the
tree view to the list box.  This example requires a ListBox
and a populated TreeView.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TTreeNode *CurItem = TreeView1->Items->GetFirstNode();
  while (CurItem)
  {
    ListBox1->Items->Add(CurItem->Text);
    CurItem = CurItem->GetNext();
  }
```

Delphi Examples:

```
{
The following example adds the Text for all items in the
tree view to the list box.  This example requires a ListBox
and a populated TreeView.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  CurItem: TTreeNode;
begin
  CurItem := TreeView1.Items.GetFirstNode;
  while CurItem <> nil do
  begin
    ListBox1.Items.Add(CurItem.Text);
    CurItem := CurItem.GetNext;
  end;
end;
```

See Also

getNextSibling (see page 5245)

GetNextChild (see page 5244)

GetNextVisible (see page 5245)

27.1.57.4.15 TTreeNode.GetNextChild Method

Returns the next child node after Value.

Pascal

```
function GetNextChild(Value: TTreeNode): TTreeNode;
```

C++

```
__fastcall TTreeNode GetNextChild(TTreeNode Value);
```

Description

Call GetNextChild to locate the next node in the list of immediate children of the tree view node. If the calling node has no children or there is no node after Value, GetNextChild returns nil (Delphi) or NULL (C++).

C++ Examples:

```
/*
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
TTreeNode *SelNode = TreeView1->Selected;
TTreeNode *ParentNode = SelNode->Parent;
bool HasSibling = (ParentNode->GetPrevChild(SelNode) ||
                   ParentNode->GetNextChild(SelNode));
  if (HasSibling) Edit1->Text = "True";
  else Edit1->Text = "False";
}
```

Delphi Examples:

```
{
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  HasSibling: Boolean;
  SelNode: TTreeNode;
  ParentNode: TTreeNode;
begin
  SelNode := TreeView1.Selected;
  ParentNode := SelNode.Parent;
  HasSibling := (ParentNode.GetPrevChild(SelNode) <> nil) or
                (ParentNode.GetNextChild(SelNode) <> nil);
  if (HasSibling) then Edit1.Text := 'True'
  else Edit1.Text := 'False';
end;
```

See Also

GetNext (see page 5243)

GetPrevChild (see page 5246)

Item (see page 5260)

27.1.57.4.16 TTreeNode.getNextSibling Method

Returns the next node in the tree view at the same level as the calling node.

Pascal

```
function getNextSibling: TTreeNode;
```

C++

```
__fastcall TTreeNode getNextSibling();
```

Description

GetNextSibling will return the next node, regardless of whether it's visible. To find the next node in the tree view including child nodes, use GetNext (see page 5243).

See Also

GetNext (see page 5243)

27.1.57.4.17 TTreeNode.GetNextVisible Method

Returns the next visible node in the tree view after the calling node.

Pascal

```
function GetNextVisible: TTreeNode;
```

C++

```
__fastcall TTreeNode GetNextVisible();
```

Description

Use GetNextVisible when iterating through all the visible nodes in the tree view. A node is visible if all its parent nodes are expanded.

See Also

GetNext (see page 5243)

IsVisible (see page 5259)

27.1.57.4.18 TTreeNode.GetPrev Method

Returns the previous node in the tree view before the calling node.

Pascal

```
function GetPrev: TTreeNode;
```

C++

```
__fastcall TTreeNode GetPrev();
```

Description

GetPrev will return the previous node whether or not it is visible. To get the previous visible node, use GetPrevVisible (see page 5247).

See Also

GetPrevChild (see page 5246)

getPrevSibling (see page 5247)

GetPrevVisible (see page 5247)

27.1.57.4.19 TTreeNode.GetPrevChild Method

Returns the previous child node before Value.

Pascal

```
function GetPrevChild(Value: TTreeNode): TTreeNode;
```

C++

```
__fastcall TTreeNode GetPrevChild(TTreeNode Value);
```

Description

Call GetPrevChild to locate the previous node in the list of immediate children of the tree view node. If the calling node has no children or there is no node before Value, GetPrevChild returns nil (Delphi) or NULL (C++).

C++ Examples:

```
/*
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
TTreeNode *SelNode = TreeView1->Selected;
TTreeNode *ParentNode = SelNode->Parent;
```

```
bool HasSibling = (ParentNode->GetPrevChild(SelNode) ||
                   ParentNode->GetNextChild(SelNode));
  if (HasSibling) Edit1->Text = "True";
  else Edit1->Text = "False";
}
```

Delphi Examples:

```
{
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  HasSibling: Boolean;
  SelNode: TTreeNode;
  ParentNode: TTreeNode;
begin
  SelNode := TreeView1.Selected;
  ParentNode := SelNode.Parent;
  HasSibling := (ParentNode.GetPrevChild(SelNode) <> nil) or
                (ParentNode.GetNextChild(SelNode) <> nil);
  if (HasSibling) then Edit1.Text := 'True'
  else Edit1.Text := 'False';
end;
```

See Also

GetNextChild (see page 5244)

GetPrev (see page 5246)

27.1.57.4.20 TTreeNode.getPrevSibling Method

Returns the previous node before the calling node and at the same level.

Pascal

```
function getPrevSibling: TTreeNode;
```

C++

```
__fastcall TTreeNode getPrevSibling();
```

Description

GetPrevSibling returns the previous sibling node, regardless of whether it's visible. To find the previous node in the tree view including all levels, use GetPrev (see page 5246).

See Also

GetPrev (see page 5246)

27.1.57.4.21 TTreeNode.GetPrevVisible Method

Returns the previous visible node before the calling node.

Pascal

```
function GetPrevVisible: TTreeNode;
```

C++

```
__fastcall TTreeNode GetPrevVisible();
```

Description

To get the previous node, including non-visible, use GetPrev (see page 5246).

See Also

GetPrev (see page 5246)

27.1.57.4.22 TTreeNode.GetState Method

Pascal

```
function GetState(NodeState: TNodeState): Boolean;
```

C++

```
__fastcall Boolean GetState(TNodeState NodeState);
```

Description

This is GetState, a member of class TTreeNode.

27.1.57.4.23 TTreeNode.HasAsParent Method

Returns true if Value is a parent node of the calling node.

Pascal

```
function HasAsParent(Value: TTreeNode): Boolean;
```

C++

```
__fastcall Boolean HasAsParent(TTreeNode Value);
```

Description

Use the HasAsParent method to determine if a node is a parent to a particular node.

See Also

Parent (see page 5263)

27.1.57.4.24 TTreeNode.IndexOf Method

Returns the position of an immediate child node of the calling node.

Pascal

```
function IndexOf(Value: TTreeNode): Integer;
```

C++

```
__fastcall int IndexOf(TTreeNode Value);
```

Description

Call IndexOf to obtain the position of a child node among the children of the calling node. If Value isn't an immediate child of the calling node, IndexOf returns -1. The first child node has an index on 0, the second an index of 1, and so on.

See Also

HasChildren (see page 5258)

Index (see page 5259)

27.1.57.4.25 TTreeNode.IsFirstNode Method

Indicates whether the tree node is very first.

Pascal

```
function IsFirstNode: Boolean;
```

C++

```
__fastcall Boolean IsFirstNode();
```

Description

IsFirstNode returns true for the first node, with no parent node or previous sibling.

See Also

Expanded (see page 5257)

27.1.57.4.26 TTreeNode.MakeVisible Method

Makes a node visible.

Pascal

```
procedure MakeVisible;
```

C++

```
__fastcall MakeVisible();
```

Description

MakeVisible makes the node visible to the user, expanding parent nodes and scrolling as necessary.

See Also

Expanded (see page 5257)

IsVisible (see page 5259)

27.1.57.4.27 TTreeNode.MoveTo Method

Moves the node to another location in the tree view.

Pascal

```
procedure MoveTo(Destination: TTreeNode; Mode: TNodeAttachMode); virtual;
```

C++

```
virtual __fastcall MoveTo(TTreeNode Destination, TNodeAttachMode Mode);
```

Description

The Destination parameter specifies a node that will be this node's parent or sibling after the move. The Mode parameter specifies the new relationship between this node and the destination node.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
```

```
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;

27.1.57.4.28 TTreeNode.SetSelectedBit Method

Pascal

```
procedure SetSelectedBit(Value: Boolean);
```

C++

```
__fastcall SetSelectedBit(Boolean Value);
```

Description

This is SetSelectedBit, a member of class TTreeNode.

27.1.57.4.29 TTreeNode.SetState Method

Pascal

```
procedure SetState(NodeState: TNodeState; Value: Boolean);
```

C++

```
__fastcall SetState(TNodeState NodeState, Boolean Value);
```

Description

This is SetState, a member of class TTreeNode.

27.1.57.5 TTreeNode Properties

The properties of the TTreeNode class are listed here.

Public Properties

	Name	Description
R	AbsoluteIndex (see page 5252)	Indicates the index of the tree node relative to the first tree node in a tree node.
R	Count (see page 5253)	Indicates the number of direct descendants of a tree node.
	Cut (see page 5254)	Indicates if the tree node object is drawn as if selected as part of a cut and paste operation.
	Data (see page 5254)	Points to application-defined data associated with the tree node.
R	Deleting (see page 5256)	Indicates whether a node's Destroy (see page 5233) method has been called and the node is in the process of being deleted.
	DropTarget (see page 5257)	Indicates whether the tree node is drawn as a drag and drop target.
	Expanded (see page 5257)	Specifies whether the tree node is expanded.
	Focused (see page 5257)	Indicates whether the node appears to have focus.
R	Handle (see page 5258)	Contains the window Handle of the tree view that contains the node.
	HasChildren (see page 5258)	Indicates whether a node has any children.
	ImageIndex (see page 5259)	Specifies which image is displayed when a node is in its normal state and is not currently selected.
R	Index (see page 5259)	Specifies the position of the node in the list of child nodes maintained by its parent node.
R	IsVisible (see page 5259)	Indicates whether the tree node is currently visible in the tree view image.
	Item (see page 5260)	Provides access to a child node by its position in the list of child nodes.
R	ItemId (see page 5260)	Contains a handle that uniquely identifies each node in a tree view.
R	Level (see page 5260)	Indicates the level of indentation of a node within the tree view control.
	OverlayIndex (see page 5263)	Determines which image from the image list is used as an overlay mask.
R	Owner (see page 5263)	Indicates which tree nodes object contains the tree node.
R	Parent (see page 5263)	Identifies the parent node of the tree node.
	Selected (see page 5264)	Determines whether the node is selected.

	SelectedIndex (see page 5265)	Specifies the index in the tree view's image list of the image displayed for the node when it is selected.
	StateIndex (see page 5265)	Indicates which image from the StateImages list to display for the node.
	Text (see page 5265)	Specifies the label that identifies a tree node.
R	TreeView (see page 5266)	Specifies the tree view that displays the node.

27.1.57.5.1 TTreeNode.AbsoluteIndex Property

Indicates the index of the tree node relative to the first tree node in a tree node.

Pascal

```
property AbsoluteIndex: Integer;
```

C++

```
__property int AbsoluteIndex;
```

Description

Use AbsoluteIndex to determine absolute position of a node in a tree nodes object. The first tree node in a tree nodes object has an index of 0 and subsequent nodes are numbered sequentially. If a node has any children, its AbsoluteIndex is one less than the index of its first child.

Delphi Examples:

```
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  type
  PMyRec = ^TMyRec;
  TMyRec = record
    FName: string;
    LName: string;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}
```

```
{
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the selected node.
A TMyRec record is associated with the added item. The FName
and LName fields are obtained from edit boxes Edit1 and
Edit2.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyRecPtr: PMyRec;
  TreeViewIndex: LongInt;
begin
  New(MyRecPtr);
  MyRecPtr^.FName := Edit1.Text;
  MyRecPtr^.LName := Edit2.Text;
  with TreeView1 do
  begin
    TreeViewIndex := Selected.AbsoluteIndex;
    if Items.Count = 0 then
      Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
    else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
      Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
  end;
end;
{
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
    Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                  PMyRec(TreeView1.Selected.Data)^.LName;
end;
procedure TForm1.Button3Click(Sender: TObject);
begin
  Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
end;
```

See Also

Index (see page 5259)

TTreeNodes (see page 5266)

Items (see page 4004)

27.1.57.5.2 TTreeNode.Count Property

Indicates the number of direct descendants of a tree node.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine how many child nodes belong to a tree node. Count includes only immediate children, and not their descendants. Count can be useful when iterating through the children of a tree node.

See Also

HasChildren (see page 5258)

Item (see page 5260)

TTreeNodes (see page 5266)

27.1.57.5.3 TTreeNode.Cut Property

Indicates if the tree node object is drawn as if selected as part of a cut and paste operation.

Pascal

```
property Cut: Boolean;
```

C++

```
__property Boolean Cut;
```

Description

Use Cut to alter the appearance of the tree node when it is selected as part of a cut and paste operation.

See Also

DropTarget (see page 5257)

Focused (see page 5257)

Selected (see page 5264)

27.1.57.5.4 TTreeNode.Data Property

Points to application-defined data associated with the tree node.

Pascal

```
property Data: Pointer;
```

C++

```
__property void * Data;
```

Description

Use the Data property to associate data with a tree node. Data allows applications to quickly access information about the entity represented by the node.

C++ Examples:

```
/*
This example requires two buttons, three TEdits, a label and
a populated TreeView.  The following code defines a record
type of TMyRec and a record pointer type of PMyRec.
*/
typedef struct MyRec
{
  AnsiString FName, LName;
} TMyRec;

typedef TMyRec* PMyRec;
/*
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the node specified
by the Index.  A TMyRec record is associated with the added
```

```
item. The FName and LName fields are obtained from edit
boxes Edit1 and Edit2. The Index parameter is obtained from
edit box Edit3.  The item is added only if the Index is a
valid value.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PMyRec  MyRecPtr;
  int TreeViewIndex;
  TTreeNodes* items;

  MyRecPtr = new TMyRec;
  MyRecPtr->FName = Edit1->Text;
  MyRecPtr->LName = Edit2->Text;
  TreeViewIndex = StrToInt(Edit3->Text);
  items = TreeView1->Items;
  if (items->Count == 0)
    items->AddObject(NULL, "Item" + IntToStr(TreeViewIndex), MyRecPtr);
  else if ((TreeViewIndex < items->Count) && (TreeViewIndex >= 0))
    items->AddObject(items->Item[TreeViewIndex], "Item" + IntToStr(TreeViewIndex) + "after" +
items->Item[TreeViewIndex]->Text, MyRecPtr);
}
/*
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (TreeView1->Selected->Data != NULL)
    Label1->Caption = PMyRec(TreeView1->Selected->Data)->FName + " " +
                  PMyRec(TreeView1->Selected->Data)->LName;
}
```

Delphi Examples:

```
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  type
  PMyRec = ^TMyRec;
  TMyRec = record
    FName: string;
    LName: string;
  end;
```

```
var
  Form1: TForm1;

implementation

{$R *.dfm}

{
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the selected node.
A TMyRec record is associated with the added item. The FName
and LName fields are obtained from edit boxes Edit1 and
Edit2.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyRecPtr: PMyRec;
  TreeViewIndex: LongInt;
begin
  New(MyRecPtr);
  MyRecPtr^.FName := Edit1.Text;
  MyRecPtr^.LName := Edit2.Text;
  with TreeView1 do
  begin
    TreeViewIndex := Selected.AbsoluteIndex;
    if Items.Count = 0 then
      Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
    else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
      Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
  end;
end;
{
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
    Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                  PMyRec(TreeView1.Selected.Data)^.LName;
end;
procedure TForm1.Button3Click(Sender: TObject);
begin
  Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
end;
```

27.1.57.5.5 TTreeNode.Deleting Property

Indicates whether a node's Destroy (see page 5233) method has been called and the node is in the process of being deleted.

Pascal

```
property Deleting: Boolean;
```

C++

```
__property Boolean Deleting;
```

Description

Deleting returns true if the node object is in the process of being deleted. Use Deleting to prevent infinite recursion in event handlers.

See Also

Destroy (see page 5233)

OnDeletion (see page 4024)

27.1.57.5.6 TTreeNode.DropTarget Property

Indicates whether the tree node is drawn as a drag and drop target.

Pascal

```
property DropTarget: Boolean;
```

C++

```
__property Boolean DropTarget;
```

Description

Use DropTarget to indicate that the node is a drag and drop target. When DropTarget is true, the node is drawn in a style used to indicate a drag and drop target.

Note: Setting DropTarget to true does cause the node to automatically accept dragged objects when they are released. The application must still implement the drop behavior.

See Also

Cut (see page 5254)

Selected (see page 5264)

Focused (see page 5257)

MoveTo (see page 5249)

27.1.57.5.7 TTreeNode.Expanded Property

Specifies whether the tree node is expanded.

Pascal

```
property Expanded: Boolean;
```

C++

```
__property Boolean Expanded;
```

Description

When a tree node is expanded, the minus button is shown if the ShowButtons property of the tree view is true and child nodes are displayed. Set Expanded to true to display the children of a node. Set Expanded to false to collapse the node, hiding all of its descendants.

See Also

Expand (see page 5242)

Collapse (see page 5235)

27.1.57.5.8 TTreeNode.Focused Property

Indicates whether the node appears to have focus.

Pascal

```
property Focused: Boolean;
```

C++

```
__property Boolean Focused;
```

Description

Tree view nodes are not windowed controls and so can't receive input focus. However, they can be edited by the user when the tree view control has focus. When Focused is true, the node is surrounded by a standard focus rectangle and the user can edit the label. Use Focused to determine if a particular node in a tree view can currently be edited by the user.

See Also

Selected (see page 5264)

OnChange (see page 4017)

OnChanging (see page 4018)

27.1.57.5.9 TTreeNode.Handle Property

Contains the window Handle of the tree view that contains the node.

Pascal

```
property Handle: HWND;
```

C++

```
__property HWND Handle;
```

Description

Use Handle to obtain the handle of the tree view that owns the node. This handle can be passed as a parameter to Windows API function calls that require a handle to the tree view.

See Also

Handle (see page 6207)

27.1.57.5.10 TTreeNode.HasChildren Property

Indicates whether a node has any children.

Pascal

```
property HasChildren: Boolean;
```

C++

```
__property Boolean HasChildren;
```

Description

HasChildren is true if the node has subnodes, or false if the node has no subnodes. If ShowButtons of the tree view is true, and HasChildren is true, a plus (+) button will appear to the left of the node when it is collapsed, and a minus (-) button will appear when the node is expanded.

Note: If a node has no children, setting HasChildren to true will show a (+) plus button, but will not add any child nodes and the node cannot be expanded.

See Also

Count (see page 5253)

HasAsParent (see page 5248)

getFirstChild (see page 5242)

27.1.57.5.11 TTreeNode.ImageIndex Property

Specifies which image is displayed when a node is in its normal state and is not currently selected.

Pascal

```
property ImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ImageIndex;
```

Description

Use the ImageIndex property with the Images property of the tree view to specify the image for the node in its normal state.

See Also

Images (see page 4001)

27.1.57.5.12 TTreeNode.Index Property

Specifies the position of the node in the list of child nodes maintained by its parent node.

Pascal

```
property Index: Integer;
```

C++

```
__property int Index;
```

Description

Use Index to determine the position of the node relative to its sibling nodes. The first child of the parent node has an Index value of 0, and subsequent children are indexed sequentially.

See Also

AbsoluteIndex (see page 5252)

Item (see page 5260)

27.1.57.5.13 TTreeNode.IsVisible Property

Indicates whether the tree node is currently visible in the tree view image.

Pascal

```
property IsVisible: Boolean;
```

C++

```
__property Boolean IsVisible;
```

Description

A node is visible if it is on level 0 or if all its parents are expanded. IsVisible indicates whether the node is part of the current tree view image. It does not indicate whether or not the node is scrolled into view when the tree view image is larger than the size of the tree view control.

See Also

Expanded (see page 5257)

27.1.57.5.14 TTreeNode.Item Property

Provides access to a child node by its position in the list of child nodes.

Pascal

```
property Item [Index: Integer]: TTreeNode;
```

C++

```
__property TTreeNode Item[int Index];
```

Description

Use Item to access a child node based on its Index (see page 5259) property. The first child node has an index of 0, the second an index of 1, and so on.

See Also

Index (see page 5259)

operator_[]

27.1.57.5.15 TTreeNode.ItemId Property

Contains a handle that uniquely identifies each node in a tree view.

Pascal

```
property ItemId: HTreeItem;
```

C++

```
__property HTreeItem ItemId;
```

Description

Use this property to reference the nodes when making Windows API calls or calling the GetNode method of the TTreeNodes (see page 5266) that owns the item.

See Also

GetNode (see page 5285)

27.1.57.5.16 TTreeNode.Level Property

Indicates the level of indentation of a node within the tree view control.

Pascal

```
property Level: Integer;
```

C++

```
__property int Level;
```

Description

The value of Level is 0 for nodes on the top level. The value of Level is 1 for their children, and so on.

C++ Examples:

```
/*
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
*/
void __fastcall TCustomDrawForm::TVCustomDrawItem(TCustomTreeView *Sender,
      TTreeNode *Node, TCustomDrawState State, bool &DefaultDraw)
{
  TRect NodeRect;
/*
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
*/
    if (State.Contains(cdsSelected))
    {
      TV->Canvas->Font->Assign(SelectedFontDialog->Font);
      TV->Canvas->Brush->Color = SelBkgColorDialog->Color;
    };

    DefaultDraw = FDefaultDrawItem;
/*
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
*/
    if (!DefaultDraw)
    {
      //draw the selection rect.
      if (State.Contains(cdsSelected))
      {
        NodeRect = Node->DisplayRect(True);
        TV->Canvas->FillRect(NodeRect);
      };
      NodeRect = Node->DisplayRect(False);

      if (None1->Checked)
      //no bitmap, so paint in the background color.
      {
        TV->Canvas->Brush->Color = BkgColorDialog->Color;
        TV->Canvas->Brush->Style = FBrushStyle;
        TV->Canvas->FillRect(NodeRect);
      }
      else
        //don't paint over the background bitmap.
        TV->Canvas->Brush->Style = bsClear;

      NodeRect.Left = NodeRect.Left + (Node->Level * TV->Indent);
      // NodeRect.Left now represents the left-most portion
      // of the expand button
      DrawButton(&NodeRect, Node); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + TV->Indent + FButtonSize;
      //NodeRect->Left is now the leftmost portion of the image.
      DrawImage(&NodeRect, Node->ImageIndex); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + ImageList->Width;
      //Now we are finally in a position to draw the text.

      TV->Canvas->TextOut(NodeRect.Left, NodeRect.Top, Node->Text);
    };
}
```

Delphi Examples:

```
{
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
}
procedure TCustomDrawForm.TVCustomDrawItem(Sender: TCustomTreeView; Node: TTreeNode;
  State: TCustomDrawState; var DefaultDraw: Boolean);
var
  NodeRect: TRect;
begin
  with TV.Canvas do
  begin
{
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
}
    if cdsSelected in State then
    begin
      Font.Assign(SelectedFontDialog.Font);
      Brush.Color := SelBkgColorDialog.Color;
    end;

    DefaultDraw := False; // FDefaultDrawItem;
{
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
}
    if not DefaultDraw then
    begin
      //draw the selection rect.
      if cdsSelected in State then
      begin
        NodeRect := Node.DisplayRect(True);
        FillRect(NodeRect);
      end;
      NodeRect := Node.DisplayRect(False);

      if None1.Checked then
      //no bitmap, so paint in the background color.
      begin
        Brush.Color := BkgColorDialog.Color;
        Brush.Style := FBrushStyle;
        FillRect(NodeRect)
      end
      else
        //don't paint over the background bitmap.
        Brush.Style := bsClear;

      NodeRect.Left := NodeRect.Left + (Node.Level * TV.Indent);
      // NodeRect.Left now represents the left-most portion
      // of the expand button
      DrawButton(NodeRect, Node); // See the CustomDraw demo

      NodeRect.Left := NodeRect.Left + TV.Indent + FButtonSize;
      //NodeRect.Left is now the leftmost portion of the image.
      DrawImage(NodeRect, Node.ImageIndex); // See the CustomDraw demo

      NodeRect.Left := NodeRect.Left + ImageList.Width;
      //Now we are finally in a position to draw the text.

      TextOut(NodeRect.Left, NodeRect.Top, Node.Text);
    end;
```

```
  end;
end;
```

See Also

AbsoluteIndex (see page 5252)

27.1.57.5.17 TTreeNode.OverlayIndex Property

Determines which image from the image list is used as an overlay mask.

Pascal

```
property OverlayIndex: Integer;
```

C++

```
__property int OverlayIndex;
```

Description

An overlay mask is an image drawn transparently over another image in the tree view. For example, to indicate that a node is no longer available, use an overlay image that puts an X over the current node's image.

See Also

ImageIndex (see page 5259)

Images (see page 4001)

27.1.57.5.18 TTreeNode.Owner Property

Indicates which tree nodes object contains the tree node.

Pascal

```
property Owner: TTreeNodes;
```

C++

```
__property TTreeNodes Owner;
```

Description

Use the Owner property to determine the owner of the tree node. Do not confuse Owner with the TreeView (see page 5266) property. Owner is the list of nodes used by the tree view to manage its nodes. The TreeView (see page 5266) property is the tree view that uses that list.

See Also

TreeView (see page 5266)

27.1.57.5.19 TTreeNode.Parent Property

Identifies the parent node of the tree node.

Pascal

```
property Parent: TTreeNode;
```

C++

```
__property TTreeNode Parent;
```

Description

A Parent node is one level higher than the node and contains the node as a subnode.

C++ Examples:

```
/*
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
TTreeNode *SelNode = TreeView1->Selected;
TTreeNode *ParentNode = SelNode->Parent;
bool HasSibling = (ParentNode->GetPrevChild(SelNode) ||
                   ParentNode->GetNextChild(SelNode));
  if (HasSibling) Edit1->Text = "True";
  else Edit1->Text = "False";
}
```

Delphi Examples:

```
{
The following code tests to see if the currently selected
item has a sibling; if so, HasSibling will be set to true.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  HasSibling: Boolean;
  SelNode: TTreeNode;
  ParentNode: TTreeNode;
begin
  SelNode := TreeView1.Selected;
  ParentNode := SelNode.Parent;
  HasSibling := (ParentNode.GetPrevChild(SelNode) <> nil) or
                (ParentNode.GetNextChild(SelNode) <> nil);
  if (HasSibling) then Edit1.Text := 'True'
  else Edit1.Text := 'False';
end;
```

See Also

Level (see page 5260)

TopItem (see page 4015)

27.1.57.5.20 TTreeNode.Selected Property

Determines whether the node is selected.

Pascal

```
property Selected: Boolean;
```

C++

```
__property Boolean Selected;
```

Description

Set Selected to true to select the node. The appearance of a selected node depends on whether it has the focus and on whether the system colors are used for selection. When a node becomes selected, the tree view's OnChanging and OnChanged events are triggered.

See Also

Focused (see page 5257)

OnChange (see page 4017)

OnChanging (see page 4018)

27.1.57.5.21 TTreeNode.SelectedIndex Property

Specifies the index in the tree view's image list of the image displayed for the node when it is selected.

Pascal

```
property SelectedIndex: Integer;
```

C++

```
__property int SelectedIndex;
```

Description

Use the SelectedIndex property to specify an image to display when the tree node is selected.

See Also

ImageIndex (see page 5259)

OnGetSelectedIndex (see page 4026)

Selected (see page 5264)

27.1.57.5.22 TTreeNode.StateIndex Property

Indicates which image from the StateImages list to display for the node.

Pascal

```
property StateIndex: Integer;
```

C++

```
__property int StateIndex;
```

Description

Use StateIndex to display an additional image for the node that reflects state information. If StateIndex is -1 then no state image is drawn.

Valid index values are 1..15 only. Values of 0 or -1 mean no state icon.

See Also

ImageIndex (see page 5259)

StateImages (see page 4014)

27.1.57.5.23 TTreeNode.Text Property

Specifies the label that identifies a tree node.

Pascal

```
property Text: string;
```

C++

```
__property AnsiString Text;
```

Description

Use Text to specify the string that is displayed in the tree view. The value of Text can be assigned directly at run-time or can be set within the TreeView (see page 5266) Items Editor while modifying the Items property of the TTreeView (see page 5293) component. If the tree view allows users to edit its nodes, read Text to determine the value given the node by the user.

See Also

Data (see page 5254)

ReadOnly (see page 4006)

27.1.57.5.24 TTreeNode.TreeView Property

Specifies the tree view that displays the node.

Pascal

```
property TreeView: TCustomTreeView;
```

C++

```
__property TCustomTreeView TreeView;
```

Description

Use TreeView to determine the tree view associated with the tree node.

See Also

Owner (see page 5263)

27.1.58 TTreeNodes Class

TTreeNodes maintains a list of tree nodes in a tree view control.

Class Hierarchy

Pascal

```
TTreeNodes = class(TPersistent);
```

C++

```
class TTreeNodes : public TPersistent;
```

File

ComCtrls

Description

The Items property of the tree view control is a TTreeNodes object and maintains the collection of nodes in the tree view. Nodes can be added, deleted, inserted, and moved within the tree view. Access the nodes in the tree view through the Items property of the tree view.

See Also

TTreeView (see page 5293)

TTreeNode (see page 5230)

27.1.58.1 TTreeNodes Members

The following tables list the members exposed by TTreeNodes.

Protected Methods

	Name	Description
	AddItem (see page 5275)	This is AddItem, a member of class TTreeNodes.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CreateItem (see page 5281)	This is CreateItem, a member of class TTreeNodes.
V	DefineProperties (see page 5281)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetCount (see page 5283)	This is GetCount, a member of class TTreeNodes.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetItem (see page 5286)	This is SetItem, a member of class TTreeNodes.
	SetUpdateState (see page 5286)	This is SetUpdateState, a member of class TTreeNodes.

Protected Properties

	Name	Description
R	Reading (see page 5290)	This is Reading, a member of class TTreeNodes.

Public Methods

	Name	Description
	Add (see page 5270)	Adds a new tree node to a tree view control.
	AddChild (see page 5271)	Adds a new tree node to a tree view.
	AddChildFirst (see page 5273)	Adds a new tree node to a tree view.
	AddChildObject (see page 5273)	Adds a new tree node containing data to a tree view.
	AddChildObjectFirst (see page 5274)	Adds a new tree node containing data to a tree view.
	AddFirst (see page 5275)	Adds a new tree node to a tree view.
	AddNode (see page 5276)	Add (see page 5270) a node to a tree view.
	AddObject (see page 5276)	Adds a new node containing data to a tree view.
	AddObjectFirst (see page 5279)	Adds a new node containing data to a tree view.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AlphaSort (see page 5279)	Sort tree nodes.
V	Assign (see page 5279)	Discards any current property information and replaces it with the information from the Source.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 5280)	Prevents the updating of the tree view until the EndUpdate (see page 5283) method is called.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5280)	Deletes all tree nodes contained from the list managed by TTreeNodes (see page 5266).
	Create (see page 5268)	Creates an instance of a TTreeNodes (see page 5266) object
	CustomSort (see page 5281)	Sort tree nodes.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 5282)	Removes a node from the tree view.
V	Destroy (see page 5269)	Destroys an instance of TTreeNodes (see page 5266).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 5283)	Re-enables screen repainting and node reindexing that was turned off with the BeginUpdate (see page 5280) method.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetEnumerator (see page 5283)	This is GetEnumerator, a member of class TTreeNodes.
	GetFirstNode (see page 5284)	Returns the first tree node in the tree view.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetNode (see page 5285)	Returns the tree node given the ItemId of the tree node.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 5285)	Inserts a tree node into the tree view before the node specified by the Node parameter.
	InsertNode (see page 5285)	Inserts a tree node with data.
	InsertObject (see page 5286)	Inserts a tree node containing data into the tree view before the node specified by the Node parameter.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Count (see page 5287)	Indicates the number of nodes maintained by the TTreeNodes (see page 5266) object.
R	Handle (see page 5289)	Contains the window handle of the tree view control that owns the tree nodes object.
R	Item (see page 5289)	Lists all tree nodes managed by the TTreeNodes (see page 5266) object.
R	Owner (see page 5290)	Specifies the tree view control that uses the tree nodes object to implement its Items property.

27.1.58.2 TTreeNodes.Create Constructor

Creates an instance of a TTreeNodes (see page 5266) object

Pascal

```
constructor Create(AOwner: TCustomTreeView);
```

C++

```
__fastcall TTreeNodes(TCustomTreeView AOwner);
```

Description

Call Create to instantiate a TTreeNodes (see page 5266) object at runtime. The TTreeNodes (see page 5266) object used by TTreeView (see page 5293) is created automatically from the constructor of the tree view object.

After calling the inherited constructor, Create sets the Owner (see page 5290) property of the tree nodes object to the value of the AOwner parameter.

See Also

Owner (see page 5290)

TTreeView (see page 5293)

27.1.58.3 TTreeNodes.Destroy Destructor

Destroys an instance of TTreeNodes (see page 5266).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTreeNodes();
```

Description

Do not call Destroy directly in an application. The tree view that owns the TTreeNodes (see page 5266) object destroys the tree nodes object by calling its Free method.

See Also

Free (see page 22300)

27.1.58.4 TTreeNodes Methods

The methods of the TTreeNodes class are listed here.

Protected Methods

	Name	Description
	AddItem (see page 5275)	This is AddItem, a member of class TTreeNodes.
	CreateItem (see page 5281)	This is CreateItem, a member of class TTreeNodes.
V	DefineProperties (see page 5281)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetCount (see page 5283)	This is GetCount, a member of class TTreeNodes.
	SetItem (see page 5286)	This is SetItem, a member of class TTreeNodes.
	SetUpdateState (see page 5286)	This is SetUpdateState, a member of class TTreeNodes.

Public Methods

	Name	Description
	Add (see page 5270)	Adds a new tree node to a tree view control.
	AddChild (see page 5271)	Adds a new tree node to a tree view.
	AddChildFirst (see page 5273)	Adds a new tree node to a tree view.
	AddChildObject (see page 5273)	Adds a new tree node containing data to a tree view.
	AddChildObjectFirst (see page 5274)	Adds a new tree node containing data to a tree view.
	AddFirst (see page 5275)	Adds a new tree node to a tree view.
	AddNode (see page 5276)	Add (see page 5270) a node to a tree view.
	AddObject (see page 5276)	Adds a new node containing data to a tree view.
	AddObjectFirst (see page 5279)	Adds a new node containing data to a tree view.
	AlphaSort (see page 5279)	Sort tree nodes.
V	Assign (see page 5279)	Discards any current property information and replaces it with the information from the Source.
	BeginUpdate (see page 5280)	Prevents the updating of the tree view until the EndUpdate (see page 5283) method is called.
	Clear (see page 5280)	Deletes all tree nodes contained from the list managed by TTreeNodes (see page 5266).
	CustomSort (see page 5281)	Sort tree nodes.
	Delete (see page 5282)	Removes a node from the tree view.
	EndUpdate (see page 5283)	Re-enables screen repainting and node reindexing that was turned off with the BeginUpdate (see page 5280) method.

	GetEnumerator (see page 5283)	This is GetEnumerator, a member of class TTreeNodes.
	GetFirstNode (see page 5284)	Returns the first tree node in the tree view.
	GetNode (see page 5285)	Returns the tree node given the ItemId of the tree node.
	Insert (see page 5285)	Inserts a tree node into the tree view before the node specified by the Node parameter.
	InsertNode (see page 5285)	Inserts a tree node with data.
	InsertObject (see page 5286)	Inserts a tree node containing data into the tree view before the node specified by the Node parameter.

27.1.58.4.1 TTreeNodes.Add Method

Adds a new tree node to a tree view control.

Pascal

```
function Add(Sibling: TTreeNode; const S: string): TTreeNode;
```

C++

```
__fastcall TTreeNode Add(TTreeNode Sibling, const AnsiString S);
```

Description

The node is added as the last sibling of the Node parameter. The S parameter specifies the Text property of the new node. Add returns the node that has been added. If the tree view is sorted, Add inserts the node in the correct sort order position rather than as the last child of the Node parameter's parent.

C++ Examples:

```
/*
The following example demonstrates how to add nodes and
child nodes to a TTreeView control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTreeNode *Node1;
  TreeView1->Items->Clear(); // remove any existing nodes
  // Add a root node
  TreeView1->Items->Add(NULL, "RootNode1");

  /* Set MyTreeNode to first node in tree view and add a child node to it */
  Node1 = TreeView1->Items->Item[0];
  TreeView1->Items->AddChild(Node1,"ChildNode1");

  // Add another root node
  TreeView1->Items->Add(Node1, "RootNode2");

  /* Reset Node1 to RootNode2 and add a child node to it */
  Node1 = TreeView1->Items->Item[2];
  TreeView1->Items->AddChild(Node1,"ChildNode2");

  /* Reset Node1 to ChildNode2 and add a child node to it */
  Node1 = TreeView1->Items->Item[3];
  TreeView1->Items->AddChild(Node1,"ChildNode2a");

   /* Add another child to ChildNode2 following ChildNode2a */
  TreeView1->Items->AddChild(Node1,"ChildNode2b");

  // add another root node
  TreeView1->Items->Add(TreeView1->Items->Item[0], "RootTreeNode3");
}
```

Delphi Examples:

```
{
The following example demonstrates how to add nodes and
```

```
  child nodes to a TTreeView control.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    MyTreeNode1, MyTreeNode2: TTreeNode;
  begin
    with TreeView1.Items do
    begin
      Clear; { remove any existing nodes }
      MyTreeNode1 := Add(nil, 'RootTreeNode1'); { Add a root node }
      { Add a child node to the node just added }
      AddChild(MyTreeNode1,'ChildNode1');

      {Add another root node}
      MyTreeNode2 := Add(MyTreeNode1, 'RootTreeNode2');
      {Give MyTreeNode2 to a child }
      AddChild(MyTreeNode2,'ChildNode2');

      {Change MyTreeNode2 to ChildNode2 }
      { and add a child node to it}
      MyTreeNode2 := TreeView1.Items[3];
      AddChild(MyTreeNode2,'ChildNode2a');

      {Add another child to ChildNode2, after ChildNode2a }
      AddChild(MyTreeNode2,'ChildNode2b');

      {add another root node}
      Add(MyTreeNode1, 'RootTreeNode3');
    end;
  end;
```

See Also

AddChild (see page 5271)

Insert (see page 5285)

27.1.58.4.2 TTreeNodes.AddChild Method

Adds a new tree node to a tree view.

Pascal

```
function AddChild(Parent: TTreeNode; const S: string): TTreeNode;
```

C++

```
__fastcall TTreeNode AddChild(TTreeNode Parent, const AnsiString S);
```

Description

The node is added as a child of the node specified by the Node parameter. It is added to the end of Node's list of child nodes. The S parameter specifies the Text property of the new node. AddChild returns the node that has been added. If the tree view is sorted, AddChild inserts the node in the correct sort order position, rather than as the last child of the Node parameter.

C++ Examples:

```
/*
The following example demonstrates how to add nodes and
child nodes to a TTreeView control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTreeNode *Node1;
  TreeView1->Items->Clear(); // remove any existing nodes
  // Add a root node
  TreeView1->Items->Add(NULL, "RootNode1");
```

```
  /* Set MyTreeNode to first node in tree view and add a child node to it */
  Node1 = TreeView1->Items->Item[0];
  TreeView1->Items->AddChild(Node1,"ChildNode1");

  // Add another root node
  TreeView1->Items->Add(Node1, "RootNode2");

  /* Reset Node1 to RootNode2 and add a child node to it */
  Node1 = TreeView1->Items->Item[2];
  TreeView1->Items->AddChild(Node1,"ChildNode2");

  /* Reset Node1 to ChildNode2 and add a child node to it */
  Node1 = TreeView1->Items->Item[3];
  TreeView1->Items->AddChild(Node1,"ChildNode2a");

   /* Add another child to ChildNode2 following ChildNode2a */
  TreeView1->Items->AddChild(Node1,"ChildNode2b");

  // add another root node
  TreeView1->Items->Add(TreeView1->Items->Item[0], "RootTreeNode3");
}
```

Delphi Examples:

```
{
The following example demonstrates how to add nodes and
child nodes to a TTreeView control.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyTreeNode1, MyTreeNode2: TTreeNode;
begin
  with TreeView1.Items do
  begin
    Clear; { remove any existing nodes }
    MyTreeNode1 := Add(nil, 'RootTreeNode1'); { Add a root node }
    { Add a child node to the node just added }
    AddChild(MyTreeNode1,'ChildNode1');

    {Add another root node}
    MyTreeNode2 := Add(MyTreeNode1, 'RootTreeNode2');
    {Give MyTreeNode2 to a child }
    AddChild(MyTreeNode2,'ChildNode2');

    {Change MyTreeNode2 to ChildNode2 }
    { and add a child node to it}
    MyTreeNode2 := TreeView1.Items[3];
    AddChild(MyTreeNode2,'ChildNode2a');

    {Add another child to ChildNode2, after ChildNode2a }
    AddChild(MyTreeNode2,'ChildNode2b');

    {add another root node}
    Add(MyTreeNode1, 'RootTreeNode3');
  end;
end;
```

See Also

Add (see page 5270)

AddChildFirst (see page 5273)

27.1.58.4.3 TTreeNodes.AddChildFirst Method

Adds a new tree node to a tree view.

Pascal

```
function AddChildFirst(Parent: TTreeNode; const S: string): TTreeNode;
```

C++

```
__fastcall TTreeNode AddChildFirst(TTreeNode Parent, const AnsiString S);
```

Description

Use AddChildFirst to insert a node as the first child of the node specified by the Node parameter. The S parameter specifies the Text property of the new node. Nodes that appear after the added node are moved down one row and reindexed with valid Index values. AddChildFirst returns the node that has been added.

See Also

AddChild (see page 5271)

AddFirst (see page 5275)

27.1.58.4.4 TTreeNodes.AddChildObject Method

Adds a new tree node containing data to a tree view.

Pascal

```
function AddChildObject(Parent: TTreeNode; const S: string; Ptr: Pointer): TTreeNode;
```

C++

```
__fastcall TTreeNode AddChildObject(TTreeNode Parent, const AnsiString S, void * Ptr);
```

Description

The node is added as the last child of the node specified by the Node parameter. The S parameter specifies the Text property of the new node. The Ptr parameter specifies the Data property value of the new node. AddChildObject returns the node that has been added.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

C++ Examples:

```
/*
The following example adds a new child to the selected
item's list of child items in the tree view control. The new
item is identified by the text 'New Item'. The TBitmap
object is attached to the new item.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *MyBitMap =
    new Graphics::TBitmap();
  MyBitMap->LoadFromFile("..\\littleB16.bmp");
  TreeView1->Items->BeginUpdate(); // keep the node from painting until it's built
  TreeView1->Items->AddChildObject(
  TreeView1->Selected, "New Item", MyBitMap);
  TreeView1->Items->EndUpdate();
}
```

Delphi Examples:

```
{
The following example adds a new child to the selected
item's list of child items in the tree view control. The new
item is identified by the text 'New Item'. The TBitmap
object is attached to the new item.
}
procedure TForm1.Button1Click(Sender: TObject);
var MyBitMap : TBitmap;
begin
  MyBitMap := TBitmap.Create;
  MyBitMap.LoadFromFile('littleB16.bmp');
  TreeView1.Items.BeginUpdate;  // keep the node from painting until it's built
  TreeView1.Items.AddChildObject(
    TreeView1.Selected, 'New Item', MyBitMap);
  TreeView1.Items.EndUpdate;
end;
```

See Also

AddObject (see page 5276)

Data (see page 5254)

27.1.58.4.5 TTreeNodes.AddChildObjectFirst Method

Adds a new tree node containing data to a tree view.

Pascal

```
function AddChildObjectFirst(Parent: TTreeNode; const S: string; Ptr: Pointer): TTreeNode;
```

C++

```
__fastcall TTreeNode AddChildObjectFirst(TTreeNode Parent, const AnsiString S, void * Ptr);
```

Description

The node is added as the first child of the node specified by the Node parameter. Nodes that appear after the added node are moved down one row and reindexed with valid Index values. The S parameter specifies the Text property of the new node. The Ptr parameter specifies the Data property value of the new node. AddChildObjectFirst returns the node that has been added.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

C++ Examples:

```
/*
The following example adds a new item to the selected item's
list of child items in the tree view control. The new item
is added first in the list of child items. The new item is
identified by the text 'New Item'. The TBitmap object is
attached to the new item.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *MyBitMap =
    new Graphics::TBitmap();
  MyBitMap->LoadFromFile("..\\littleB.bmp");
  TreeView1->Items->BeginUpdate(); // keep the node from painting until it's built
  TreeView1->Items->AddChildObjectFirst(
    TreeView1->Selected, "New Item", MyBitMap);
  TreeView1->Items->EndUpdate();
}
```

Delphi Examples:

```
{
The following example adds a new item to the selected item's
list of child items in the tree view control. The new item
is added first in the list of child items. The new item is
identified by the text 'New Item'. The TBitmap object is
attached to the new item.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyBitMap : TBitmap;
  node : TTreeNode;
begin
  MyBitMap := TBitmap.Create;
  MyBitMap.LoadFromFile('littleB.bmp');
  TreeView1.Items.BeginUpdate;
  node:= TreeView1.Items.AddChildObjectFirst(
    TreeView1.Selected, 'New Item', MyBitMap);
//  node.ImageIndex:= -1;
  TreeView1.Items.EndUpdate;
end;
```

See Also

AddChildObject (see page 5273)

AddObject (see page 5276)

Data (see page 5254)

27.1.58.4.6 TTreeNodes.AddFirst Method

Adds a new tree node to a tree view.

Pascal

```
function AddFirst(Sibling: TTreeNode; const S: string): TTreeNode;
```

C++

```
__fastcall TTreeNode AddFirst(TTreeNode Sibling, const AnsiString S);
```

Description

The node is added as the first sibling of the node specified by the Node parameter. Nodes that appear after the added node are moved down one row and re-indexed with valid Index values. The S parameter specifies the Text property of the new node. AddFirst returns the node that has been added.

See Also

AddChildFirst (see page 5273)

Add (see page 5270)

27.1.58.4.7 TTreeNodes.AddItem Method

Pascal

```
function AddItem(Parent: HTreeItem; Target: HTreeItem; const Item: TTVItem; AddMode:
TAddMode): HTreeItem;
```

C++

```
__fastcall HTreeItem AddItem(HTreeItem Parent, HTreeItem Target, const TTVItem Item, TAddMode
AddMode);
```

Description

This is AddItem, a member of class TTreeNodes.

27.1.58.4.8 TTreeNodes.AddNode Method

Add (see page 5270) a node to a tree view.

Pascal

```
function AddNode(Node: TTreeNode; Relative: TTreeNode; const S: string; Ptr: Pointer; Method:
TNodeAttachMode): TTreeNode;
```

C++

```
__fastcall TTreeNode AddNode(TTreeNode Node, TTreeNode Relative, const AnsiString S, void *
Ptr, TNodeAttachMode Method);
```

Description

AddNode adds a node object to the collection. AddNode returns the newly-added node, and takes the following parameters.

Node is the node object to be added. If Node is nil, then the tree view's CreateNode method is called to provide one.

The Relative and Method parameters together define the location of the new node. Relative is an existing node that will be either parent or sibling to the new node. Method specifies the precise relationship between the new node and relative, as given by a TNodeAttachMode (see page 5457) constant.

The S parameter specifies the Text property of the new node.

The Ptr parameter specifies the Data property value of the new node.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

See Also

AddChildObject (see page 5273)

Data (see page 5254)

27.1.58.4.9 TTreeNodes.AddObject Method

Adds a new node containing data to a tree view.

Pascal

```
function AddObject(Sibling: TTreeNode; const S: string; Ptr: Pointer): TTreeNode;
```

C++

```
__fastcall TTreeNode AddObject(TTreeNode Sibling, const AnsiString S, void * Ptr);
```

Description

The node is added as the last sibling of the node specified by the Node parameter. The S parameter specifies the Text property of the new node. The Ptr parameter specifies the Data property value of the new node. AddObject returns the node that has been added.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

C++ Examples:

```
/*
This example requires two buttons, three TEdits, a label and
```

```
a populated TreeView.  The following code defines a record
type of TMyRec and a record pointer type of PMyRec.
*/
typedef struct MyRec
{
  AnsiString FName, LName;
} TMyRec;

typedef TMyRec* PMyRec;
/*
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the node specified
by the Index.  A TMyRec record is associated with the added
item. The FName and LName fields are obtained from edit
boxes Edit1 and Edit2. The Index parameter is obtained from
edit box Edit3.  The item is added only if the Index is a
valid value.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PMyRec  MyRecPtr;
  int TreeViewIndex;
  TTreeNodes* items;

  MyRecPtr = new TMyRec;
  MyRecPtr->FName = Edit1->Text;
  MyRecPtr->LName = Edit2->Text;
  TreeViewIndex = StrToInt(Edit3->Text);
  items = TreeView1->Items;
  if (items->Count == 0)
    items->AddObject(NULL, "Item" + IntToStr(TreeViewIndex), MyRecPtr);
  else if ((TreeViewIndex < items->Count) && (TreeViewIndex >= 0))
    items->AddObject(items->Item[TreeViewIndex], "Item" + IntToStr(TreeViewIndex) + "after" +
items->Item[TreeViewIndex]->Text, MyRecPtr);
}
/*
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (TreeView1->Selected->Data != NULL)
    Label1->Caption = PMyRec(TreeView1->Selected->Data)->FName + " " +
                  PMyRec(TreeView1->Selected->Data)->LName;
}
```

Delphi Examples:

```
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
```

```
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  type
  PMyRec = ^TMyRec;
  TMyRec = record
    FName: string;
    LName: string;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

{
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the selected node.
A TMyRec record is associated with the added item. The FName
and LName fields are obtained from edit boxes Edit1 and
Edit2.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyRecPtr: PMyRec;
  TreeViewIndex: LongInt;
begin
  New(MyRecPtr);
  MyRecPtr^.FName := Edit1.Text;
  MyRecPtr^.LName := Edit2.Text;
  with TreeView1 do
  begin
    TreeViewIndex := Selected.AbsoluteIndex;
    if Items.Count = 0 then
      Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
    else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
      Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
  end;
end;
{
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
    Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                  PMyRec(TreeView1.Selected.Data)^.LName;
end;
procedure TForm1.Button3Click(Sender: TObject);
begin
  Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
end;
```

AddChildObject (see page 5273)

Data (see page 5254)

27.1.58.4.10 TTreeNodes.AddObjectFirst Method

Adds a new node containing data to a tree view.

Pascal

```
function AddObjectFirst(Sibling: TTreeNode; const S: string; Ptr: Pointer): TTreeNode;
```

C++

```
__fastcall TTreeNode AddObjectFirst(TTreeNode Sibling, const AnsiString S, void * Ptr);
```

Description

The node is added first to the list to which the node specified by the Node parameter belongs. nodes that appear after the added node are moved down one row and reindexed with valid Index values. The S parameter specifies the Text property of the new node. The Ptr parameter specifies the Data property value of the new node. AddObjectFirst returns the node that has been added.

See Also

AddObject (see page 5276)

AddChildObject (see page 5273)

Data (see page 5254)

27.1.58.4.11 TTreeNodes.AlphaSort Method

Sort tree nodes.

Pascal

```
function AlphaSort(ARecurse: Boolean = False): Boolean;
```

C++

```
__fastcall Boolean AlphaSort(Boolean ARecurse = False);
```

Description

AlphaSort triggers node sorting or resorting. If an OnCompare event handler is defined for the associated TCustomTreeView (see page 3957), that routine determines sort order. If no OnCompare handler is defined, nodes are sorted by a simple case-sensitive compare of their captions.

The optional ARecurse parameter (default false) specifies that sorting should recursively descend the node tree and sort each subtree in turn.

Calling AlphaSort is equivalent to calling CustomSort (see page 5281) with a nil (Delphi) or NULL (C++) procedure parameter and a data parameter of 0.

See Also

AlphaSort (see page 3972)

CustomSort (see page 5281)

OnCompare (see page 4019)

27.1.58.4.12 TTreeNodes.Assign Method

Discards any current property information and replaces it with the information from the Source.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to copy information from one tree nodes object to another. If Source is any other type of object, Assign calls its inherited method, which copies properties from any object that can copy to a TTreeNodes (see page 5266) object in its AssignTo method.

See Also

Assign (see page 2930)

27.1.58.4.13 TTreeNodes.BeginUpdate Method

Prevents the updating of the tree view until the EndUpdate (see page 5283) method is called.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

BeginUpdate prevents the screen from being repainted when new nodes are added, deleted, or inserted. Tree nodes affected by the changes will have invalid Index values until EndUpdate (see page 5283) is called.

Use BeginUpdate to prevent screen repaints and to speed processing time while adding nodes to the tree view.

Note: Calls to BeginUpdate are cumulative; for every call to BeginUpdate there must be a corresponding call to EndUpdate (see page 5283).

See Also

EndUpdate (see page 5283)

27.1.58.4.14 TTreeNodes.Clear Method

Deletes all tree nodes contained from the list managed by TTreeNodes (see page 5266).

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Use the Clear method to remove all the nodes of a tree view.

See Also

Delete (see page 5282)

27.1.58.4.15 TTreeNodes.CreateItem Method

Pascal

```
function CreateItem(Node: TTreeNode): TTVItem;
```

C++

```
__fastcall TTVItem CreateItem(TTreeNode Node);
```

Description

This is CreateItem, a member of class TTreeNodes.

27.1.58.4.16 TTreeNodes.CustomSort Method

Sort tree nodes.

Pascal

```
function CustomSort(SortProc: TTVCompare; Data: Longint; ARecurse: Boolean = False): Boolean;
```

C++

```
__fastcall Boolean CustomSort(TTVCompare SortProc, Longint Data, Boolean ARecurse = False);
```

Description

CustomSort triggers node sorting or resorting, using a comparison routine indicated by the SortProc parameter. The Data parameter is passed to the comparison routine. The optional ARecurse parameter (default false) specifies that sorting should recursively descend the node tree and sort each subtree in turn.

If SortProc is nil (Delphi) or NULL (C++), a default comparison routine is used. The default routine uses the OnCompare event handler for the associated TCustomTreeView (see page 3957) object, if defined. If the OnCompare event handler is not defined, the default routine uses a simple case-sensitive compare of node captions.

In the comparison routine, the lParam1 and lParam2 parameters refer to two nodes when cast to TTreeNode (see page 5230). The lParamSort parameter is the value previously passed to the Data parameter of CustomSort. The return value of the comparison routine indicates the relative sort order of lParam1 and lParam2:

Return Value	Meaning
< 0	lParam1 comes before lParam2
0	lParam1 and lParam2 are equivalent
> 0	lParam2 comes before lParam1

See Also

CustomSort (see page 3978)

27.1.58.4.17 TTreeNodes.DefineProperties Method

Provides an interface for a method that reads and writes otherwise unpublished data.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

Descendants of TPersistent override DefineProperties to designate a method for storing the object's unpublished data to a stream such as a form file. By default, writing an object to a stream writes the values of all its published properties, and reading the object in reads those values and assigns them to the properties. Objects can also specify methods that read and write data other than published properties by overriding the DefineProperties method.

When overriding DefineProperties, consider including some or all of the following:

A call to the inherited method

Calls to the filer object's DefineProperty method

Calls to the filer object's DefineBinaryProperty method

DefineProperties is virtual, so descendant classes can override it as necessary but are not required to do so.

See Also

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

27.1.58.4.18 TTreeNodes.Delete Method

Removes a node from the tree view.

Pascal

```
procedure Delete(Node: TTreeNode);
```

C++

```
__fastcall Delete(TTreeNode Node);
```

Description

Delete removes the tree node specified by the Node parameter and all its children from the tree view.

C++ Examples:

```
/*
The following example deletes an item in the tree view when
the user clicks on it, and if the checkbox is checked. This example
requires a populated TreeView.
*/
void __fastcall TForm1::TVMouseDown(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  THitTests HT;
  if (CheckBox1->Checked && Sender->ClassNameIs("TTreeView"))
  {
    TTreeView *pTV = (TTreeView *)Sender;
    HT = pTV->GetHitTestInfoAt(X,Y);
    if (HT.Contains(htOnItem))
      pTV->Items->Delete(pTV->GetNodeAt(X,Y));
  }
}
```

Delphi Examples:

```
{
The following example deletes an item in the tree view when
the user clicks on it, and if the checkbox is checked. This example
requires a populated TreeView.
```

```
}
procedure TForm1.TVMouseDown(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  HT : THitTests;
begin
if (CheckBox1.Checked) and (Sender is TTreeView) then
  begin
  with Sender as TTreeView do
    begin
    HT := GetHitTestInfoAt(X,Y);
    if (htOnItem in HT) then
      Items.Delete(GetNodeAt(X,Y));
    end;
  end;
end;
```

See Also

OnDeletion (see page 4024)

DeleteChildren (see page 5238)

27.1.58.4.19 TTreeNodes.EndUpdate Method

Re-enables screen repainting and node reindexing that was turned off with the BeginUpdate (see page 5280) method.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Use the EndUpdate method to enable screen updating after BeginUpdate (see page 5280) has been called. Calls to BeginUpdate (see page 5280) are cumulative, so calling EndUpdate will only update the tree view if every other call to BeginUpdate (see page 5280) has already been matched by a call to EndUpdate.

See Also

BeginUpdate (see page 5280)

27.1.58.4.20 TTreeNodes.GetCount Method

Pascal

```
function GetCount: Integer;
```

C++

```
__fastcall int GetCount();
```

Description

This is GetCount, a member of class TTreeNodes.

27.1.58.4.21 TTreeNodes.GetEnumerator Method

Pascal

```
function GetEnumerator: TTreeNodesEnumerator;
```

C++

```
__fastcall TTreeNodesEnumerator GetEnumerator();
```

Description

This is GetEnumerator, a member of class TTreeNodes.

27.1.58.4.22 TTreeNodes.GetFirstNode Method

Returns the first tree node in the tree view.

Pascal

```
function GetFirstNode: TTreeNode;
```

C++

```
__fastcall TTreeNode GetFirstNode();
```

Description

Use the GetFirstNode method to retrieve the first node in the tree view. GetFirstNode returns the value of Item (see page 5289)[0].

C++ Examples:

```
/*
The following example adds the Text for all items in the
tree view to the list box.  This example requires a ListBox
and a populated TreeView.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TTreeNode *CurItem = TreeView1->Items->GetFirstNode();
  while (CurItem)
  {
    ListBox1->Items->Add(CurItem->Text);
    CurItem = CurItem->GetNext();
  }
```

Delphi Examples:

```
{
The following example adds the Text for all items in the
tree view to the list box.  This example requires a ListBox
and a populated TreeView.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  CurItem: TTreeNode;
begin
  CurItem := TreeView1.Items.GetFirstNode;
  while CurItem <> nil do
  begin
    ListBox1.Items.Add(CurItem.Text);
    CurItem := CurItem.GetNext;
  end;
end;
```

See Also

getFirstChild (see page 5242)

GetNode (see page 5285)

Item (see page 5289)

27.1.58.4.23 TTreeNodes.GetNode Method

Returns the tree node given the ItemId of the tree node.

Pascal

```
function GetNode(ItemId: HTreeItem): TTreeNode;
```

C++

```
__fastcall TTreeNode GetNode(HTreeItem ItemId);
```

Description

ItemId is a handle to the node in the tree view.

See Also

GetFirstNode (see page 5284)

ItemId (see page 5260)

27.1.58.4.24 TTreeNodes.Insert Method

Inserts a tree node into the tree view before the node specified by the Node parameter.

Pascal

```
function Insert(Sibling: TTreeNode; const S: string): TTreeNode;
```

C++

```
__fastcall TTreeNode Insert(TTreeNode Sibling, const AnsiString S);
```

Description

Call Insert to add a new sibling to the Node parameter, immediately preceding Node. The S parameter specifies the Text property of the new node. Insert returns the new node.

See Also

Add (see page 5270)

InsertNode (see page 5285)

27.1.58.4.25 TTreeNodes.InsertNode Method

Inserts a tree node with data.

Pascal

```
function InsertNode(Node: TTreeNode; Sibling: TTreeNode; const S: string; Ptr: Pointer):
TTreeNode;
```

C++

```
__fastcall TTreeNode InsertNode(TTreeNode Node, TTreeNode Sibling, const AnsiString S, void *
Ptr);
```

Description

Call InsertNode to add a new sibling to the Node parameter, immediately preceding Node. The S parameter specifies the Text property of the new node. The Ptr parameter specifies data associated with the node. InsertNode returns the new node.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

See Also

Insert (see page 5285)

27.1.58.4.26 TTreeNodes.InsertObject Method

Inserts a tree node containing data into the tree view before the node specified by the Node parameter.

Pascal

```
function InsertObject(Sibling: TTreeNode; const S: string; Ptr: Pointer): TTreeNode;
```

C++

```
__fastcall TTreeNode InsertObject(TTreeNode Sibling, const AnsiString S, void * Ptr);
```

Description

Call InsertObject to add a new sibling to the Node parameter, immediately preceding Node. The S parameter specifies the Text property of the new node and the Ptr parameter specifies the Data property of the new node. InsertObject returns the new node.

Note: The memory referenced by Ptr is not freed when the tree nodes object is freed.

See Also

AddObject (see page 5276)

27.1.58.4.27 TTreeNodes.SetItem Method

Pascal

```
procedure SetItem(Index: Integer; Value: TTreeNode);
```

C++

```
__fastcall SetItem(int Index, TTreeNode Value);
```

Description

This is SetItem, a member of class TTreeNodes.

27.1.58.4.28 TTreeNodes.SetUpdateState Method

Pascal

```
procedure SetUpdateState(Updating: Boolean);
```

C++

```
__fastcall SetUpdateState(Boolean Updating);
```

Description

This is SetUpdateState, a member of class TTreeNodes.

27.1.58.5 TTreeNodes Properties

The properties of the TTreeNodes class are listed here.

Protected Properties

	Name	Description
R	Reading (see page 5290)	This is Reading, a member of class TTreeNodes.

Public Properties

	Name	Description
R	Count (see page 5287)	Indicates the number of nodes maintained by the TTreeNodes (see page 5266) object.
R	Handle (see page 5289)	Contains the window handle of the tree view control that owns the tree nodes object.
R	Item (see page 5289)	Lists all tree nodes managed by the TTreeNodes (see page 5266) object.
R	Owner (see page 5290)	Specifies the tree view control that uses the tree nodes object to implement its Items property.

27.1.58.5.1 TTreeNodes.Count Property

Indicates the number of nodes maintained by the TTreeNodes (see page 5266) object.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Use Count to determine the number of tree nodes in the tree view that owns the tree nodes object. Count provides an upper bound when iterating through the entries in the Item (see page 5289) property array.

C++ Examples:

```
/*
This example requires two buttons, three TEdits, a label and
a populated TreeView.  The following code defines a record
type of TMyRec and a record pointer type of PMyRec.
*/
typedef struct MyRec
{
  AnsiString FName, LName;
} TMyRec;

typedef TMyRec* PMyRec;
/*
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the node specified
by the Index.  A TMyRec record is associated with the added
item. The FName and LName fields are obtained from edit
boxes Edit1 and Edit2. The Index parameter is obtained from
edit box Edit3.  The item is added only if the Index is a
valid value.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PMyRec  MyRecPtr;
  int TreeViewIndex;
  TTreeNodes* items;

  MyRecPtr = new TMyRec;
  MyRecPtr->FName = Edit1->Text;
  MyRecPtr->LName = Edit2->Text;
  TreeViewIndex = StrToInt(Edit3->Text);
  items = TreeView1->Items;
  if (items->Count == 0)
    items->AddObject(NULL, "Item" + IntToStr(TreeViewIndex), MyRecPtr);
  else if ((TreeViewIndex < items->Count) && (TreeViewIndex >= 0))
    items->AddObject(items->Item[TreeViewIndex], "Item" + IntToStr(TreeViewIndex) + "after" +
items->Item[TreeViewIndex]->Text, MyRecPtr);
```

```
}
/*
After an item containing a TMyRec record has been added, the
following code retrieves the FName and LName values
associated with the item and displays the values in a label.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (TreeView1->Selected->Data != NULL)
    Label1->Caption = PMyRec(TreeView1->Selected->Data)->FName + " " +
                  PMyRec(TreeView1->Selected->Data)->LName;
}
```

Delphi Examples:

```
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
  type
  PMyRec = ^TMyRec;
  TMyRec = record
    FName: string;
    LName: string;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

{
Assuming these types are used, the following code adds a
node to TreeView1 as the last sibling of the selected node.
A TMyRec record is associated with the added item. The FName
and LName fields are obtained from edit boxes Edit1 and
Edit2.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyRecPtr: PMyRec;
  TreeViewIndex: LongInt;
begin
```

```
    New(MyRecPtr);
    MyRecPtr^.FName := Edit1.Text;
    MyRecPtr^.LName := Edit2.Text;
    with TreeView1 do
    begin
      TreeViewIndex := Selected.AbsoluteIndex;
      if Items.Count = 0 then
        Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
      else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
        Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
    end;
  end;
  {
  After an item containing a TMyRec record has been added, the
  following code retrieves the FName and LName values
  associated with the item and displays the values in a label.
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
      Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                    PMyRec(TreeView1.Selected.Data)^.LName;
  end;
  procedure TForm1.Button3Click(Sender: TObject);
  begin
    Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
  end;
```

See Also

Owner (see page 5290)

27.1.58.5.2 TTreeNodes.Handle Property

Contains the window handle of the tree view control that owns the tree nodes object.

Pascal

```
property Handle: HWND;
```

C++

```
__property HWND Handle;
```

Description

Use Handle to obtain the handle of the tree view that owns the tree nodes object.

See Also

Owner (see page 5290)

Handle (see page 6207)

27.1.58.5.3 TTreeNodes.Item Property

Lists all tree nodes managed by the TTreeNodes (see page 5266) object.

Pascal

```
property Item [Index: Integer]: TTreeNode;
```

C++

```
__property TTreeNode Item[int Index];
```

Description

Use Item to access to a node by its position in the tree view. The first node has an index of 0, the second an index of 1, and so on.

Note: Item is the default property for TTreeNodes (see page 5266). This means that the name of the Item property can be omitted when indexing into the set of tree nodes. Thus, the line

```
FirstNode := TreeView1.Items.Item[0];
```

Note: can be written

```
FirstNode := TreeView1.Items[0];
```

See Also

AbsoluteIndex (see page 5252)

operator_[]

27.1.58.5.4 TTreeNodes.Owner Property

Specifies the tree view control that uses the tree nodes object to implement its Items property.

Pascal

```
property Owner: TCustomTreeView;
```

C++

```
__property TCustomTreeView Owner;
```

Description

Use the Owner property to access the tree view control that displays the nodes maintained by the TTreeNodes (see page 5266) object.

See Also

Handle (see page 5289)

27.1.58.5.5 TTreeNodes.Reading Property

Pascal

```
property Reading: Boolean;
```

C++

```
__property Boolean Reading;
```

Description

This is Reading, a member of class TTreeNodes.

27.1.59 TTreeNodesEnumerator Class

Class Hierarchy

ComCtrls.TTreeNodesEnumerator

Pascal

```
TTreeNodesEnumerator = class;
```

C++

```
class TTreeNodesEnumerator;
```

File

ComCtrls

Description

This is class ComCtrls.TTreeNodesEnumerator.

27.1.59.1 TTreeNodesEnumerator Members

The following tables list the members exposed by TTreeNodesEnumerator.

Public Methods

	Name	Description
	Create (see page 5291)	This is Create, a member of class TTreeNodesEnumerator.
	GetCurrent (see page 5292)	This is GetCurrent, a member of class TTreeNodesEnumerator.
	MoveNext (see page 5292)	This is MoveNext, a member of class TTreeNodesEnumerator.

Public Properties

	Name	Description
R	Current (see page 5292)	This is Current, a member of class TTreeNodesEnumerator.

27.1.59.2 TTreeNodesEnumerator.Create Constructor

Pascal

```
constructor Create(ATreeNodes: TTreeNodes);
```

C++

```
__fastcall TTreeNodesEnumerator(TTreeNodes ATreeNodes);
```

Description

This is Create, a member of class TTreeNodesEnumerator.

27.1.59.3 TTreeNodesEnumerator Methods

The methods of the TTreeNodesEnumerator class are listed here.

Public Methods

	Name	Description
	GetCurrent (see page 5292)	This is GetCurrent, a member of class TTreeNodesEnumerator.
	MoveNext (see page 5292)	This is MoveNext, a member of class TTreeNodesEnumerator.

27.1.59.3.1 TTreeNodesEnumerator.GetCurrent Method

Pascal

```
function GetCurrent: TTreeNode;
```

C++

```
__fastcall TTreeNode GetCurrent();
```

Description

This is GetCurrent, a member of class TTreeNodesEnumerator.

27.1.59.3.2 TTreeNodesEnumerator.MoveNext Method

Pascal

```
function MoveNext: Boolean;
```

C++

```
__fastcall Boolean MoveNext();
```

Description

This is MoveNext, a member of class TTreeNodesEnumerator.

27.1.59.4 TTreeNodesEnumerator Properties

The properties of the TTreeNodesEnumerator class are listed here.

Public Properties

	Name	Description
R	Current (see page 5292)	This is Current, a member of class TTreeNodesEnumerator.

27.1.59.4.1 TTreeNodesEnumerator.Current Property

Pascal

```
property Current: TTreeNode;
```

C++

```
__property TTreeNode Current;
```

Description

This is Current, a member of class TTreeNodesEnumerator.

27.1.60 TTreeView Class

TTreeView represents a window that displays a hierarchical list of items, such as the headings in a document, the entries in an index, or the files and directories on a disk.

Class Hierarchy

Pascal

```
TTreeView = class(TCustomTreeView);
```

C++

```
class TTreeView : public TCustomTreeView;
```

File

ComCtrls

Description

Use TTreeView to add an expanding and contracting outline to a form. Each node in a tree view control consists of a label and a number of optional bitmapped images. Each node can have a list of subnodes associated with it. By clicking on a node, the user can expand or collapse the associated list of subnodes.

Tree Views

27.1.60.1 TTreeView Members

The following tables list the members exposed by TTreeView.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCancelEdit (see page 4017)	Occurs when user cancels editing of a node's Caption.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.

	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FChangeTimer (see page 3970)	This is FChangeTimer, a member of class TCustomTreeView.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	Added (see page 3972)	This is Added, a member of class TCustomTreeView.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanChange (see page 3972)	Pending node change event dispatcher.
	CanCollapse (see page 3973)	Pending node collapse event dispatcher.
	CanEdit (see page 3973)	Node editing event dispatcher.
	CanExpand (see page 3974)	Node expand event dispatcher.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 3974)	Completed node change event dispatcher.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.

	Click (see page 5743)	Respond to user click.
	Collapse (see page 3975)	Completed node collapse event dispatcher.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateNode (see page 3975)	Creates a new TTreeNode (see page 5230) instance with the TTreeNodes (see page 5266) specified by Items (see page 4004) as its Owner.
V	CreateNodes (see page 3976)	This is CreateNodes, a member of class TCustomTreeView.
V	CreateParams (see page 3976)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 3976)	Creates the window used by the tree view component.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
V	CustomDraw (see page 3977)	Generates an OnCustomDraw (see page 4019) or OnAdvancedCustomDraw (see page 4016) event.
V	CustomDrawItem (see page 3977)	Generates an OnCustomDrawItem (see page 4021) or OnAdvancedCustomDrawItem (see page 4016) event.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	Delete (see page 3979)	Generates an OnDeletion (see page 4024) event.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 3980)	Destroys the control's window.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
V	DoEndDrag (see page 3981)	End drag event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
V	DoEnter (see page 3981)	Respond to receiving input focus.
	DoEnter (see page 6144)	Respond to receiving input focus.
V	DoExit (see page 3981)	Respond to losing input focus
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
V	DoStartDrag (see page 3982)	Drag start event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	Edit (see page 3982)	Edited event dispatcher.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	Expand (see page 3983)	Completed node expansion event dispatcher.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 3984)	Returns the image list to be displayed during drag operations.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetImageIndex (see page 3986)	Obtain image index.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
V	GetSelectedIndex (see page 3988)	Obtain selection index.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.

	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateSelectionsRects (see page 3989)	This is InvalidateSelectionsRects, a member of class TCustomTreeView.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
V	IsCustomDrawn (see page 3989)	Specifies when the control should generate custom draw events.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 3990)	Initializes the tree view after it is loaded from a stream.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 3991)	OnMouseDown event dispatcher.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 3992)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.

	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 3994)	Sets the drag mode for the tree view.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	ValidateSelection (see page 3995)	This is ValidateSelection, a member of class TCustomTreeView.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 3995)	Provides specific message responses for the control.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	CreateWndRestores (see page 4000)	This is CreateWndRestores, a member of class TCustomTreeView.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AlphaSort (see page 3972)	Sort tree nodes.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearSelection (see page 3974)	Deselect (see page 3980) all selected nodes, optionally excluding primary selection.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 3969)	Creates an instance of a TTreeView (see page 5293) control.
	Create (see page 5731)	Creates an instance of TControl (see page 5724).

	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	CustomSort (see page 3978)	Sorts the nodes in the tree view into a customized sort order.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Deselect (see page 3980)	Deselects a specified node.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 3970)	Destroys the tree view control and is called by the Delete (see page 3979) method.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindNextToSelect (see page 3983)	Returns next selectable node.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	FullCollapse (see page 3983)	Collapses all the nodes within a tree view control.
	FullExpand (see page 3984)	Expands all nodes within the tree view control.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetHitTestInfoAt (see page 3985)	Returns information about the location of a point relative to the client area of the tree view control.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.

	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetNodeAt (see page 3987)	Returns the node that is found at the specified position.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetSelections (see page 3989)	Obtain selections list.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsEditing (see page 3990)	Indicates whether a node is currently being edited by the user.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	LoadFromFile (see page 3990)	Reads the file specified in FileName and loads the data into the tree view.
	LoadFromStream (see page 3991)	Reads tree view data from a stream and stores the contents in the tree view.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

	SaveToFile (see page 3992)	Saves a the tree view to the file specified in FileName.
	SaveToStream (see page 3993)	Writes the data in the tree view to the stream passed as the Stream parameter.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
V	Select (see page 3993)	This is the overview for the Select method overload.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Subselect (see page 3994)	Toggle node selection.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 3997)	Provides access to the canvas.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.

	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 4000)	Specifies which item in the tree view appears as the target of a drag and drop operation.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	Selected (see page 4007)	Specifies the selected node in the tree view.
R	SelectionCount (see page 4012)	Returns number of nodes selected.
R	Selections (see page 4012)	Returns nodes selected.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopItem (see page 4015)	Specifies the topmost node that appears in the tree view.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAddition (see page 5342)	Occurs when new node is added.
	OnAdvancedCustomDraw (see page 5342)	Occurs at discrete stages during the painting of the tree view control.
	OnAdvancedCustomDrawItem (see page 5342)	Occurs at discrete stages during the painting of tree view nodes.
	OnChange (see page 5343)	Occurs whenever the selection has changed from one node to another.
	OnChanging (see page 5343)	Occurs when the selection is about to change from one node to another.
	OnClick (see page 5344)	Occurs when the user clicks the control.
	OnCollapsed (see page 5345)	Occurs after a node has been collapsed.
	OnCollapsing (see page 5346)	Occurs when a node is about to be collapsed.
	OnCompare (see page 5346)	Occurs when two nodes must be compared during a sort of the nodes in the tree view.
	OnContextPopup (see page 5347)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreateNodeClass (see page 5347)	Occurs when a node in the treeview is about to be created.
	OnCustomDraw (see page 5348)	Occurs immediately prior to painting the tree view control.
	OnCustomDrawItem (see page 5349)	Occurs immediately prior to painting a node in a tree view control.
	OnDblClick (see page 5352)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeletion (see page 5352)	Occurs when a node in the tree view is deleted.

	OnDragDrop (see page 5352)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5355)	Occurs when the user drags an object over a control.
	OnEdited (see page 5357)	Occurs after the user edits the Text property of a node.
	OnEditing (see page 5357)	Occurs when the user starts to edit the Text property of a node.
	OnEndDock (see page 5358)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5358)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 5359)	Occurs when a control receives the input focus.
	OnExit (see page 5362)	Occurs when the input focus shifts away from one control to another.
	OnExpanded (see page 5363)	Occurs after a node is expanded.
	OnExpanding (see page 5364)	Occurs when a node is about to be expanded.
	OnGetImageIndex (see page 5364)	Occurs when the tree view looks up the ImageIndex of a node.
	OnGetSelectedIndex (see page 5365)	Occurs when the tree view looks up the SelectedIndex of a node.
	OnKeyDown (see page 5365)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 5368)	Occurs when a key is pressed.
	OnKeyUp (see page 5369)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5371)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5372)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5374)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5374)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5375)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5377)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 5379)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 5380)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 5307)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 5310)	Specifies how the control is anchored to its parent.
	AutoExpand (see page 5311)	Specifies whether the nodes in the tree view automatically expand and collapse depending on the selection.
	BevelEdges (see page 5311)	Specifies which edges of the control are beveled.
	BevelInner (see page 5312)	Specifies the cut of the inner bevel.
	BevelKind (see page 5312)	Specifies the control's bevel style.
	BevelOuter (see page 5312)	Specifies the cut of the outer bevel.
	BevelWidth (see page 5313)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 5313)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 5314)	Determines whether the tree view control has a border.
	BorderWidth (see page 5314)	Specifies the width of the control's border.
	ChangeDelay (see page 5315)	Specifies the delay between when a node is selected and when the OnChange event occurs.
	Color (see page 5315)	Specifies the background color of the control.
	Constraints (see page 5316)	Specifies the size constraints for the control.
	Ctl3D (see page 5316)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 5317)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5317)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5318)	Determines how the control initiates drag-and-drop or drag-and-dock operations.

	Enabled (see page 5319)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 5320)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	HideSelection (see page 5321)	Determines whether a selected node appears selected when the focus shifts to another control.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HotTrack (see page 5321)	Specifies whether list items are highlighted when the mouse passes over them.
	Images (see page 5321)	Determines which image list is associated with the tree view.
	Indent (see page 5322)	Specifies the amount of indentation in pixels when a list of child nodes is expanded.
	Items (see page 5324)	Lists the individual nodes that appear in the tree view control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	MultiSelect (see page 5325)	Determines whether the user can select more than one tree node at a time.
	MultiSelectStyle (see page 5326)	Determines how multiple node selections work.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBiDiMode (see page 5326)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 5327)	Determines where a control looks for its color information.
	ParentCtl3D (see page 5327)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5328)	Determines where a control looks for its font information.
	ParentShowHint (see page 5328)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5329)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 5333)	Determines whether the user can edit the node labels.
	RightClickSelect (see page 5333)	Determines whether the Selected property returns nodes that are selected using the right mouse button.
	RowSelect (see page 5334)	Specifies whether the entire row of the selected item is highlighted.
	ShowButtons (see page 5334)	Specifies whether to display plus (+) and minus (-) buttons to the left side of each parent item.
	ShowHint (see page 5335)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShowLines (see page 5336)	Specifies whether to display the lines that link child nodes to their corresponding parent nodes.
	ShowRoot (see page 5336)	Specifies whether lines connecting top-level nodes are displayed.
	SortType (see page 5337)	Determines if and how the nodes in a tree view are automatically sorted.
	StateImages (see page 5337)	Determines which image list to use for state images.
	TabOrder (see page 5338)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5338)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	ToolTips (see page 5339)	Specifies whether the items in the tree view have tool tips.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 5339)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

27.1.60.2 TTreeView Properties

The properties of the TTreeView class are listed here.

Published Properties

	Name	Description
	Align (see page 5307)	Determines how the control aligns within its container (parent control).
	Anchors (see page 5310)	Specifies how the control is anchored to its parent.
	AutoExpand (see page 5311)	Specifies whether the nodes in the tree view automatically expand and collapse depending on the selection.
	BevelEdges (see page 5311)	Specifies which edges of the control are beveled.
	BevelInner (see page 5312)	Specifies the cut of the inner bevel.
	BevelKind (see page 5312)	Specifies the control's bevel style.
	BevelOuter (see page 5312)	Specifies the cut of the outer bevel.
	BevelWidth (see page 5313)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 5313)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 5314)	Determines whether the tree view control has a border.
	BorderWidth (see page 5314)	Specifies the width of the control's border.
	ChangeDelay (see page 5315)	Specifies the delay between when a node is selected and when the OnChange event occurs.
	Color (see page 5315)	Specifies the background color of the control.
	Constraints (see page 5316)	Specifies the size constraints for the control.
	Ctl3D (see page 5316)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 5317)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5317)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5318)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 5319)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 5320)	Controls the attributes of text written on or in the control.
	HideSelection (see page 5321)	Determines whether a selected node appears selected when the focus shifts to another control.
	HotTrack (see page 5321)	Specifies whether list items are highlighted when the mouse passes over them.
	Images (see page 5321)	Determines which image list is associated with the tree view.
	Indent (see page 5322)	Specifies the amount of indentation in pixels when a list of child nodes is expanded.
	Items (see page 5324)	Lists the individual nodes that appear in the tree view control.
	MultiSelect (see page 5325)	Determines whether the user can select more than one tree node at a time.
	MultiSelectStyle (see page 5326)	Determines how multiple node selections work.
	ParentBiDiMode (see page 5326)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 5327)	Determines where a control looks for its color information.
	ParentCtl3D (see page 5327)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5328)	Determines where a control looks for its font information.
	ParentShowHint (see page 5328)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5329)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 5333)	Determines whether the user can edit the node labels.
	RightClickSelect (see page 5333)	Determines whether the Selected property returns nodes that are selected using the right mouse button.
	RowSelect (see page 5334)	Specifies whether the entire row of the selected item is highlighted.
	ShowButtons (see page 5334)	Specifies whether to display plus (+) and minus (-) buttons to the left side of each parent item.
	ShowHint (see page 5335)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShowLines (see page 5336)	Specifies whether to display the lines that link child nodes to their corresponding parent nodes.
	ShowRoot (see page 5336)	Specifies whether lines connecting top-level nodes are displayed.
	SortType (see page 5337)	Determines if and how the nodes in a tree view are automatically sorted.
	StateImages (see page 5337)	Determines which image list to use for state images.
	TabOrder (see page 5338)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5338)	Determines if the user can tab to a control.

	ToolTips (see page 5339)	Specifies whether the items in the tree view have tool tips.
	Visible (see page 5339)	Determines whether the component appears onscreen.

27.1.60.2.1 TTreeView.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;
```

```
  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };

  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

27.1.60.2.2 TTreeView.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other

aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

27.1.60.2.3 TTreeView.AutoExpand Property

Specifies whether the nodes in the tree view automatically expand and collapse depending on the selection.

Pascal

```
property AutoExpand: Boolean;
```

C++

```
__property Boolean AutoExpand;
```

Description

Set AutoExpand to true to cause the selected item to expand and the unselected items to collapse.

See Also

Selected (see page 4007)

Expanded (see page 5257)

Selected (see page 5264)

Expand (see page 5242)

Collapse (see page 5235)

OnExpanded (see page 4025)

OnExpanding (see page 4025)

OnCollapsed (see page 4018)

OnCollapsing (see page 4018)

27.1.60.2.4 TTreeView.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

27.1.60.2.5 TTreeView.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

27.1.60.2.6 TTreeView.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

27.1.60.2.7 TTreeView.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

27.1.60.2.8 TTreeView.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

27.1.60.2.9 TTreeView.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

27.1.60.2.10 TTreeView.BorderStyle Property

Determines whether the tree view control has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to specify whether the tree view control should be outlined with a single-line border. These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

See Also

BoundsRect (see page 5803)

27.1.60.2.11 TTreeView.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter (see page 6194)

27.1.60.2.12 TTreeView.ChangeDelay Property

Specifies the delay between when a node is selected and when the OnChange event occurs.

Pascal

```
property ChangeDelay: Integer;
```

C++

```
__property int ChangeDelay;
```

Description

Use ChangeDelay to get or set the delay, in milliseconds, between when a node is selected and when the OnChange event occurs.

Set the ChangeDelay to 50 milliseconds to emulate the behavior of the tree-view control used in Windows Explorer.

See Also

Selected (see page 4007)

OnChange (see page 4017)

27.1.60.2.13 TTreeView.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
```

```
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

27.1.60.2.14 TTreeView.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

27.1.60.2.15 TTreeView.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

27.1.60.2.16 TTreeView.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

27.1.60.2.17 TTreeView.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

27.1.60.2.18 TTreeView.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
```

```
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

27.1.60.2.19 TTreeView.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

Enabling Mouse

27.1.60.2.20 TTreeView.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

27.1.60.2.21 TTreeView.HideSelection Property

Determines whether a selected node appears selected when the focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Use HideSelection to specify whether the user is given visual feedback about the current selection in the tree view when it does not have focus. If true, the selected node is not visually distinct from other nodes until focus returns to the control. If false, the node always appears selected.

See Also

Selected (see page 4007)

27.1.60.2.22 TTreeView.HotTrack Property

Specifies whether list items are highlighted when the mouse passes over them.

Pascal

```
property HotTrack: Boolean;
```

C++

```
__property Boolean HotTrack;
```

Description

Set HotTrack to true to provide visual feedback about which item is under the mouse. Set HotTrack to false to suppress the visual feedback about which item is under the mouse.

See Also

HideSelection (see page 4000)

RowSelect (see page 4007)

27.1.60.2.23 TTreeView.Images Property

Determines which image list is associated with the tree view.

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

Use Images to provide a customized list of bitmaps that can be displayed to the left of a node's label. Individual nodes specify the image from this list that should appear by setting their ImageIndex property.

See Also

OnGetImageIndex (see page 4026)

StateImages (see page 4014)

ImageIndex (see page 5259)

SelectedIndex (see page 5265)

27.1.60.2.24 TTreeView.Indent Property

Specifies the amount of indentation in pixels when a list of child nodes is expanded.

Pascal

```
property Indent: Integer;
```

C++

```
__property int Indent;
```

Description

Use Indent to determine how far child nodes are indented from their parent nodes when the parent is expanded.

C++ Examples:

```
/*
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
*/
void __fastcall TCustomDrawForm::TVCustomDrawItem(TCustomTreeView *Sender,
      TTreeNode *Node, TCustomDrawState State, bool &DefaultDraw)
{
  TRect NodeRect;
/*
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
*/
    if (State.Contains(cdsSelected))
    {
      TV->Canvas->Font->Assign(SelectedFontDialog->Font);
      TV->Canvas->Brush->Color = SelBkgColorDialog->Color;
    };

    DefaultDraw = FDefaultDrawItem;
/*
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
*/
    if (!DefaultDraw)
    {
      //draw the selection rect.
      if (State.Contains(cdsSelected))
      {
        NodeRect = Node->DisplayRect(True);
        TV->Canvas->FillRect(NodeRect);
      };
      NodeRect = Node->DisplayRect(False);
```

```
        if (None1->Checked)
        //no bitmap, so paint in the background color.
        {
          TV->Canvas->Brush->Color = BkgColorDialog->Color;
          TV->Canvas->Brush->Style = FBrushStyle;
          TV->Canvas->FillRect(NodeRect);
        }
        else
          //don't paint over the background bitmap.
          TV->Canvas->Brush->Style = bsClear;

        NodeRect.Left = NodeRect.Left + (Node->Level * TV->Indent);
        // NodeRect.Left now represents the left-most portion
        // of the expand button
        DrawButton(&NodeRect, Node); // See the CustomDraw demo

        NodeRect.Left = NodeRect.Left + TV->Indent + FButtonSize;
        //NodeRect->Left is now the leftmost portion of the image.
        DrawImage(&NodeRect, Node->ImageIndex); // See the CustomDraw demo

        NodeRect.Left = NodeRect.Left + ImageList->Width;
        //Now we are finally in a position to draw the text.

        TV->Canvas->TextOut(NodeRect.Left, NodeRect.Top, Node->Text);
      };
}
```

Delphi Examples:

```
{
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
}
procedure TCustomDrawForm.TVCustomDrawItem(Sender: TCustomTreeView; Node: TTreeNode;
  State: TCustomDrawState; var DefaultDraw: Boolean);
var
  NodeRect: TRect;
begin
  with TV.Canvas do
  begin
{
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
}
    if cdsSelected in State then
    begin
      Font.Assign(SelectedFontDialog.Font);
      Brush.Color := SelBkgColorDialog.Color;
    end;

    DefaultDraw := False; // FDefaultDrawItem;
{
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
}
    if not DefaultDraw then
    begin
      //draw the selection rect.
      if cdsSelected in State then
      begin
        NodeRect := Node.DisplayRect(True);
        FillRect(NodeRect);
```

```
        end;
        NodeRect := Node.DisplayRect(False);

        if None1.Checked then
        //no bitmap, so paint in the background color.
        begin
          Brush.Color := BkgColorDialog.Color;
          Brush.Style := FBrushStyle;
          FillRect(NodeRect)
        end
        else
          //don't paint over the background bitmap.
          Brush.Style := bsClear;

        NodeRect.Left := NodeRect.Left + (Node.Level * TV.Indent);
        // NodeRect.Left now represents the left-most portion
        // of the expand button
        DrawButton(NodeRect, Node); // See the CustomDraw demo

        NodeRect.Left := NodeRect.Left + TV.Indent + FButtonSize;
        //NodeRect.Left is now the leftmost portion of the image.
        DrawImage(NodeRect, Node.ImageIndex); // See the CustomDraw demo

        NodeRect.Left := NodeRect.Left + ImageList.Width;
        //Now we are finally in a position to draw the text.

        TextOut(NodeRect.Left, NodeRect.Top, Node.Text);
      end;
    end;
  end;
```

See Also

FullExpand (see page 3984)

27.1.60.2.25 TTreeView.Items Property

Lists the individual nodes that appear in the tree view control.

Pascal

```
property Items: TTreeNodes;
```

C++

```
__property TTreeNodes Items;
```

Description

Individual nodes in a tree view are TTreeNode objects. These individual nodes can be accessed by using the Items property along with the item's index into the tree view. For example, to access the second item in the tree view, you could use the following code.

```
MyTreeNode := TreeView1.Items[1];
MyTreeNode = TreeView1->Items[1];
```

When setting this property at design-time in the Object Inspector the Tree View Items Editor appears. Use the New Item and New SubItem buttons to add items to the tree view. Use the Text property to modify what text is displayed in the label of the item.

At run-time nodes can be added and inserted by using the TTreeNodes methods AddChildFirst, AddChild, AddChildObjectFirst, AddChildObject, AddFirst, Add, AddObjectFirst, AddObject, and Insert.

Note: Accessing tree view items by index can be time-intensive, particularly when the tree view contains many items. For optimal performance, try to design your application so that it has as few dependencies on the tree view's item index as possible.

C++ Examples:

```
/*
The following example deletes an item in the tree view when
the user clicks on it, and if the checkbox is checked. This example
requires a populated TreeView.
*/
void __fastcall TForm1::TVMouseDown(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  THitTests HT;
  if (CheckBox1->Checked && Sender->ClassNameIs("TTreeView"))
  {
    TTreeView *pTV = (TTreeView *)Sender;
    HT = pTV->GetHitTestInfoAt(X,Y);
    if (HT.Contains(htOnItem))
      pTV->Items->Delete(pTV->GetNodeAt(X,Y));
  }
}
```

Delphi Examples:

```
{
The following example deletes an item in the tree view when
the user clicks on it, and if the checkbox is checked. This example
requires a populated TreeView.
}
procedure TForm1.TVMouseDown(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  HT : THitTests;
begin
if (CheckBox1.Checked) and (Sender is TTreeView) then
  begin
  with Sender as TTreeView do
    begin
    HT := GetHitTestInfoAt(X,Y);
    if (htOnItem in HT) then
      Items.Delete(GetNodeAt(X,Y));
    end;
  end;
end;
```

AddFirst (see page 5275)

27.1.60.2.26 TTreeView.MultiSelect Property

Determines whether the user can select more than one tree node at a time.

Pascal

```
property MultiSelect: Boolean;
```

C++

```
__property Boolean MultiSelect;
```

Description

Set MultiSelect to specify whether users can select multiple nodes using the Control and Shift keys. A selection style must also be chosen in MultiSelectStyle.

See Also

MultiSelectStyle (see page 4005)

27.1.60.2.27 TTreeView.MultiSelectStyle Property

Determines how multiple node selections work.

Pascal

```
property MultiSelectStyle: TMultiSelectStyle;
```

C++

```
__property TMultiSelectStyle MultiSelectStyle;
```

Description

MultiSelectStyle determines how multiple selections are made when MultiSelect is true. MultiSelectStyle must include at least one of the following values.

Value	Meaning
msControlSelect	Clicking on any node with the Control key pressed toggles the selection of that node.
msShiftSelect	Clicking on any node with the Shift key pressed selects that node, the last single node selected, and the nodes in between. All other nodes are deselected.
msVisibleOnly	Multiple selections with the Shift key do not include child nodes of collapsed nodes.
msSiblingOnly	Selected nodes are restricted to a single set of siblings.

If msControlSelect or msShiftSelect are in effect, the last singly-selected node becomes the primary selection, referenced by Selections[0]. The primary selection is the anchor for extended selections using the Shift key.

See Also

Selections (see page 4012)

27.1.60.2.28 TTreeView.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's

BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

27.1.60.2.29 TTreeView.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

27.1.60.2.30 TTreeView.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

27.1.60.2.31 TTreeView.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

27.1.60.2.32 TTreeView.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

27.1.60.2.33 TTreeView.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
```

```
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
```

```
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type

27.1.60.2.34 TTreeView.ReadOnly Property

Determines whether the user can edit the node labels.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to specify whether the user can edit the nodes of the tree view. If ReadOnly is true, the user can expand and collapse nodes, but can't edit their labels. If ReadOnly is false, the user can edit the labels as well. The default value is false.

See Also

Text (see page 5265)

27.1.60.2.35 TTreeView.RightClickSelect Property

Determines whether the Selected property returns nodes that are selected using the right mouse button.

Pascal

```
property RightClickSelect: Boolean;
```

C++

```
__property Boolean RightClickSelect;
```

Description

Use RightClickSelect to allow the Selected property to indicate nodes the user clicks with the right mouse button. If RightClickSelect is true, the value of Selected is the value of the node last clicked with either the right or left mouse button. If RightClickSelect is false, the value of Selected is the node last clicked using the left mouse button.

RightClickSelect affects only the value of the Selected property. It does not cause the tree view to highlight a new node if the node is selected using the right mouse button.

Note: RightClickSelect must be set to true before the user right-clicks the tree view for it to affect the value of the Selected property.

See Also

Selected (see page 4007)

OnMouseDown (see page 5862)

27.1.60.2.36 TTreeView.RowSelect Property

Specifies whether the entire row of the selected item is highlighted.

Pascal

```
property RowSelect: Boolean;
```

C++

```
__property Boolean RowSelect;
```

Description

Set RowSelect to true to cause the entire row of the selected item to be highlighted.

RowSelect is ignored if ShowLines is true.

See Also

Selected (see page 4007)

ShowLines (see page 4013)

27.1.60.2.37 TTreeView.ShowButtons Property

Specifies whether to display plus (+) and minus (-) buttons to the left side of each parent item.

Pascal

```
property ShowButtons: Boolean;
```

C++

```
__property Boolean ShowButtons;
```

Description

If ShowButtons is true, a button will appear to the left of each parent item. The user can click the button to expand or collapse the child items as an alternative to double-clicking the parent item.

See Also

ShowLines (see page 4013)

ShowRoot (see page 4013)

27.1.60.2.38 TTreeView.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Hint (see page 5827)

ParentShowHint (see page 5835)

ShowHint (see page 13721)

Displaying Fly-over Help

27.1.60.2.39 TTreeView.ShowLines Property

Specifies whether to display the lines that link child nodes to their corresponding parent nodes.

Pascal

```
property ShowLines: Boolean;
```

C++

```
__property Boolean ShowLines;
```

Description

If ShowLines is true, lines linking child nodes to their parent nodes are displayed. Nodes at the root of the hierarchy are not automatically linked. To link nodes at the root, the ShowRoot property must also be set to true.

See Also

ShowButtons (see page 4013)

ShowRoot (see page 4013)

27.1.60.2.40 TTreeView.ShowRoot Property

Specifies whether lines connecting top-level nodes are displayed.

Pascal

```
property ShowRoot: Boolean;
```

C++

```
__property Boolean ShowRoot;
```

Description

To show lines connecting top-level nodes to a single root, set the tree view's ShowRoot and ShowLines properties to true.

See Also

ShowButtons (see page 4013)

ShowLines (see page 4013)

27.1.60.2.41 TTreeView.SortType Property

Determines if and how the nodes in a tree view are automatically sorted.

Pascal

```
property SortType: TSortType;
```

C++

```
__property TSortType SortType;
```

Description

Once a tree view is sorted, the original hierarchy is lost. That is, setting the SortType back to stNone will not restore the original order of items. These are the possible values:

Value	Meaning
stNone	No sorting is done.
stData	The items are sorted when the Data object or SortType is changed.
stText	The items are sorted when the Caption or SortType is changed.
stBoth	The items are sorted when either the Data object, the Caption or SortType is changed

Optionally, the OnCompare event can be hooked to handle comparisons.

See Also

AlphaSort (see page 3972)

OnCompare (see page 4019)

27.1.60.2.42 TTreeView.StateImages Property

Determines which image list to use for state images.

Pascal

```
property StateImages: TCustomImageList;
```

C++

```
__property TCustomImageList StateImages;
```

Description

Use StateImages to provide a set of bitmaps that reflect the state of tree view nodes. The state image appears as an additional

image to the left of the item's icon.

See Also

Images (see page 4001)

StateIndex (see page 5265)

27.1.60.2.43 TTreeView.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

27.1.60.2.44 TTreeView.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the

Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

27.1.60.2.45 TTreeView.ToolTips Property

Specifies whether the items in the tree view have tool tips.

Pascal

```
property ToolTips: Boolean;
```

C++

```
__property Boolean ToolTips;
```

Description

Set ToolTips to true to specify that items in the tree view control have tool tips (Help Hints).

Specify the ToolTip text in an OnHint event handler using the Hint property.

See Also

Hint (see page 5827)

OnHint (see page 13731)

27.1.60.2.46 TTreeView.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

27.1.60.3 TTreeView Events

The events of the TTreeView class are listed here.

Published Events

	Name	Description
	OnAddition (see page 5342)	Occurs when new node is added.
	OnAdvancedCustomDraw (see page 5342)	Occurs at discrete stages during the painting of the tree view control.
	OnAdvancedCustomDrawItem (see page 5342)	Occurs at discrete stages during the painting of tree view nodes.
	OnChange (see page 5343)	Occurs whenever the selection has changed from one node to another.
	OnChanging (see page 5343)	Occurs when the selection is about to change from one node to another.
	OnClick (see page 5344)	Occurs when the user clicks the control.
	OnCollapsed (see page 5345)	Occurs after a node has been collapsed.
	OnCollapsing (see page 5346)	Occurs when a node is about to be collapsed.
	OnCompare (see page 5346)	Occurs when two nodes must be compared during a sort of the nodes in the tree view.
	OnContextPopup (see page 5347)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreateNodeClass (see page 5347)	Occurs when a node in the treeview is about to be created.
	OnCustomDraw (see page 5348)	Occurs immediately prior to painting the tree view control.
	OnCustomDrawItem (see page 5349)	Occurs immediately prior to painting a node in a tree view control.
	OnDblClick (see page 5352)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeletion (see page 5352)	Occurs when a node in the tree view is deleted.
	OnDragDrop (see page 5352)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5355)	Occurs when the user drags an object over a control.
	OnEdited (see page 5357)	Occurs after the user edits the Text property of a node.
	OnEditing (see page 5357)	Occurs when the user starts to edit the Text property of a node.
	OnEndDock (see page 5358)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5358)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 5359)	Occurs when a control receives the input focus.
	OnExit (see page 5362)	Occurs when the input focus shifts away from one control to another.
	OnExpanded (see page 5363)	Occurs after a node is expanded.
	OnExpanding (see page 5364)	Occurs when a node is about to be expanded.
	OnGetImageIndex (see page 5364)	Occurs when the tree view looks up the ImageIndex of a node.
	OnGetSelectedIndex (see page 5365)	Occurs when the tree view looks up the SelectedIndex of a node.
	OnKeyDown (see page 5365)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 5368)	Occurs when a key is pressed.
	OnKeyUp (see page 5369)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5371)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5372)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5374)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5374)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5375)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5377)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 5379)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 5380)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

27.1.60.3.1 TTreeView.OnAddition Event

Occurs when new node is added.

Pascal

```
property OnAddition: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnAddition;
```

Description

OnAddition occurs when a new node is added to the control.

27.1.60.3.2 TTreeView.OnAdvancedCustomDraw Event

Occurs at discrete stages during the painting of the tree view control.

Pascal

```
property OnAdvancedCustomDraw: TTVAdvancedCustomDrawEvent;
```

C++

```
__property TTVAdvancedCustomDrawEvent OnAdvancedCustomDraw;
```

Description

Write an OnAdvancedCustomDraw event handler to paint an owner-drawn tree view. Use the Canvas property as a drawing surface when painting the image of the tree view.

To paint individual items, use the OnAdvancedCustomDrawItem or OnCustomDrawItem event instead.

Note: OnAdvancedCustomDraw occurs at several stages during the paint process, not just immediately prior to the default rendering. If you only need to use the cdPrePaint stage, it is more efficient to use the OnCustomDraw event.

See Also

Canvas (see page 3997)

OnAdvancedCustomDrawItem (see page 4016)

OnCustomDraw (see page 4019)

27.1.60.3.3 TTreeView.OnAdvancedCustomDrawItem Event

Occurs at discrete stages during the painting of tree view nodes.

Pascal

```
property OnAdvancedCustomDrawItem: TTVAdvancedCustomDrawItemEvent;
```

C++

```
__property TTVAdvancedCustomDrawItemEvent OnAdvancedCustomDrawItem;
```

Description

Write an OnAdvancedCustomDrawItem event handler to customize the painting of individual items in the tree view.

Note: OnAdvancedCustomDrawItem occurs at several stages during the paint process and allows you to suppress the default painting of tree node images while still allowing the default painting of the node. If you only need to use the cdPrePaint stage and do not want to suppress only the painting of tree node images, it is more efficient to use the OnCustomDrawItem event.

See Also

Canvas (see page 3997)

OnAdvancedCustomDraw (see page 4016)

OnCustomDrawItem (see page 4021)

27.1.60.3.4 TTreeView.OnChange Event

Occurs whenever the selection has changed from one node to another.

Pascal

```
property OnChange: TTVChangedEvent;
```

C++

```
__property TTVChangedEvent OnChange;
```

Description

Write an OnChange event handler to take specific action when the selected node changes. The Sender parameter is the tree view whose selected node changes, and the Node parameter is the newly selected node.

Note: The OnChange event does not occur for nodes selected using the right mouse button when RightClickSelect is true. To respond to changes in the value of the Selected property when RightClickSelect is true, use the OnMouseUp event.

See Also

OnChanging (see page 4018)

Selected (see page 4007)

RightClickSelect (see page 4006)

ChangeDelay (see page 3999)

OnMouseUp (see page 5867)

27.1.60.3.5 TTreeView.OnChanging Event

Occurs when the selection is about to change from one node to another.

Pascal

```
property OnChanging: TTVChangingEvent;
```

C++

```
__property TTVChangingEvent OnChanging;
```

Description

Write an OnChanging event handler to selectively prevent selection from moving to specific nodes.

The TTVChangingEvent type points to a method that is called when the selection is about to be changed from one node to another. Set AllowChange to false, to prevent selection from moving to a new node. The Node parameter specifies the node that is about to be selected.

See Also

OnChange (see page 4017)

Selected (see page 4007)

27.1.60.3.6 TTreeView.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

27.1.60.3.7 TTreeView.OnCollapsed Event

Occurs after a node has been collapsed.

Pascal

```
property OnCollapsed: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnCollapsed;
```

Description

Write an OnCollapsed event handler to respond after a node in the tree view collapses. The Node parameter is the node whose children are no longer visible.

See Also

Collapse (see page 5235)

FullCollapse (see page 3983)

27.1.60.3.8 TTreeView.OnCollapsing Event

Occurs when a node is about to be collapsed.

Pascal

```
property OnCollapsing: TTVCollapsingEvent;
```

C++

```
__property TTVCollapsingEvent OnCollapsing;
```

Description

The TTVCollapsingEvent type points to a method that is called when a node is about to be collapsed. Set the AllowCollapse parameter to false to prevent the node specified by the Node parameter from being collapsed.

See Also

Collapse (see page 5235)

FullCollapse (see page 3983)

27.1.60.3.9 TTreeView.OnCompare Event

Occurs when two nodes must be compared during a sort of the nodes in the tree view.

Pascal

```
property OnCompare: TTVCompareEvent;
```

C++

```
__property TTVCompareEvent OnCompare;
```

Description

Write an OnCompare event handler to customize the sort order of the nodes in the tree view. Set the Compare parameter to a value less than 0 if Node1 is less than Node2. Set Compare to 0 if Node1 is equivalent to Node2, and set Compare to a value greater than 0 if Node1 is greater than Node2. If an OnCompare event handler is not provided, tree view nodes are sorted alphabetically, based on their labels.

See Also

AlphaSort (see page 3972)

CustomSort (see page 3978)

SortType (see page 4014)

27.1.60.3.10 TTreeView.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

27.1.60.3.11 TTreeView.OnCreateNodeClass Event

Occurs when a node in the treeview is about to be created.

Pascal

```
property OnCreateNodeClass: TTVCreateNodeClassEvent;
```

C++

```
__property TTVCreateNodeClassEvent OnCreateNodeClass;
```

Description

OnCreateNodeClass occurs when a new node object is about to be created.

Sender is the tree view object that is about to add a new node.

NodeClass returns a class reference that is instantiated to create a new node object.

27.1.60.3.12 TTreeView.OnCustomDraw Event

Occurs immediately prior to painting the tree view control.

Pascal

```
property OnCustomDraw: TTVCustomDrawEvent;
```

C++

```
__property TTVCustomDrawEvent OnCustomDraw;
```

Description

Write an OnCustomDraw event handler to paint an owner-drawn tree view. Use the Canvas property as a drawing surface when painting the image of the tree view.

To paint individual items, use the OnCustomDrawItem event instead.

Note: OnCustomDraw only occurs prior to painting the tree view control. To customize the painting at other stages of the paint process (such as after the default drawing), use OnAdvancedCustomDraw instead.

C++ Examples:

```
/*
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
*/
void __fastcall TCustomDrawForm::TVCustomDraw(TCustomTreeView *Sender,
      const TRect &ARect, bool &DefaultDraw)
{
/*
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
subclass the TreeView and handle scrolling messages.
*/
  if (None1 != NULL)
  {
    if (None1->Checked) //no picture
    {
      TV->Canvas->Brush->Color = BkgColorDialog->Color;
      TV->Canvas->Brush->Style = FBrushStyle;
      TV->Canvas->FillRect(ARect);
    }
    else if (Tile1->Checked) //tile bitmap
    {
      TV->Canvas->Brush->Bitmap = Image1->Picture->Bitmap;
      TV->Canvas->FillRect(ARect);
    }
    else //Stretch across the canvas.
      TV->Canvas->StretchDraw(ARect, Image1->Picture->Bitmap);
  };
  DefaultDraw = FDefaultDraw;
  // Setting DefaultDraw to false here prevents all calls to
  // OnCustomDrawItem.
}
```

Delphi Examples:

```
{
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
}
procedure TCustomDrawForm.TVCustomDraw(Sender: TCustomTreeView; const ARect: TRect;
  var DefaultDraw: Boolean);
begin
{
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
subclass the TreeView and handle scrolling messages.
}
  with TV.Canvas do
  begin
    if None1 <> nil then
    begin
      if None1.Checked then //no picture
      begin
        Brush.Color := BkgColorDialog.Color;
        Brush.Style := FBrushStyle;
        FillRect(ARect);
      end else
        if Tile1.Checked then //tile bitmap
        begin
          Brush.Bitmap := Image1.Picture.Bitmap;
            FillRect(ARect);
          end else //Stretch across the canvas.
              StretchDraw(ARect, Image1.Picture.Bitmap);
    end;
  end;
  DefaultDraw := FDefaultDraw;
  // Setting DefaultDraw to false here prevents all calls to
  // OnCustomDrawItem.
end;
```

OnAdvancedCustomDraw (see page 4016)

27.1.60.3.13 TTreeView.OnCustomDrawItem Event

Occurs immediately prior to painting a node in a tree view control.

Pascal

```
property OnCustomDrawItem: TTVCustomDrawItemEvent;
```

C++

```
__property TTVCustomDrawItemEvent OnCustomDrawItem;
```

Description

Write an OnCustomDrawItem event handler to paint individual items in the tree view, or to provide a background to the item before the default rendering of the item.

Note: OnCustomDrawItem only occurs prior to painting individual tree items. To customize the painting of items at other stages

of the paint process (such as after the item is painted), use OnAdvancedCustomDrawItem instead.

C++ Examples:

```
/*
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
*/
void __fastcall TCustomDrawForm::TVCustomDrawItem(TCustomTreeView *Sender,
      TTreeNode *Node, TCustomDrawState State, bool &DefaultDraw)
{
  TRect NodeRect;
/*
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
*/
    if (State.Contains(cdsSelected))
    {
      TV->Canvas->Font->Assign(SelectedFontDialog->Font);
      TV->Canvas->Brush->Color = SelBkgColorDialog->Color;
    };

    DefaultDraw = FDefaultDrawItem;
/*
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
*/
    if (!DefaultDraw)
    {
      //draw the selection rect.
      if (State.Contains(cdsSelected))
      {
        NodeRect = Node->DisplayRect(True);
        TV->Canvas->FillRect(NodeRect);
      };
      NodeRect = Node->DisplayRect(False);

      if (None1->Checked)
      //no bitmap, so paint in the background color.
      {
        TV->Canvas->Brush->Color = BkgColorDialog->Color;
        TV->Canvas->Brush->Style = FBrushStyle;
        TV->Canvas->FillRect(NodeRect);
      }
      else
        //don't paint over the background bitmap.
        TV->Canvas->Brush->Style = bsClear;

      NodeRect.Left = NodeRect.Left + (Node->Level * TV->Indent);
      // NodeRect.Left now represents the left-most portion
      // of the expand button
      DrawButton(&NodeRect, Node); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + TV->Indent + FButtonSize;
      //NodeRect->Left is now the leftmost portion of the image.
      DrawImage(&NodeRect, Node->ImageIndex); // See the CustomDraw demo

      NodeRect.Left = NodeRect.Left + ImageList->Width;
      //Now we are finally in a position to draw the text.
```

```
      TV->Canvas->TextOut(NodeRect.Left, NodeRect.Top, Node->Text);
    };
}
```

Delphi Examples:

```
{
The following example shows how the OnCustomDrawItem event
handler draws items and lines of the tree view after the
OnCustomDraw event handler has filled in the background.
}
procedure TCustomDrawForm.TVCustomDrawItem(Sender: TCustomTreeView; Node: TTreeNode;
  State: TCustomDrawState; var DefaultDraw: Boolean);
var
  NodeRect: TRect;
begin
  with TV.Canvas do
  begin
{
    If DefaultDraw it is true, any of the node's font
    properties can be changed. Note also that when
    DefaultDraw = True, Windows draws the buttons and
    ignores our font background colors, using instead the
    TreeView's Color property.
}
    if cdsSelected in State then
    begin
      Font.Assign(SelectedFontDialog.Font);
      Brush.Color := SelBkgColorDialog.Color;
    end;

    DefaultDraw := False; // FDefaultDrawItem;
{
    DefaultDraw = False means you have to handle all the
    item drawing yourself, including the buttons, lines,
    images, and text.
}
    if not DefaultDraw then
    begin
      //draw the selection rect.
      if cdsSelected in State then
      begin
        NodeRect := Node.DisplayRect(True);
        FillRect(NodeRect);
      end;
      NodeRect := Node.DisplayRect(False);

      if None1.Checked then
      //no bitmap, so paint in the background color.
      begin
        Brush.Color := BkgColorDialog.Color;
        Brush.Style := FBrushStyle;
        FillRect(NodeRect)
      end
      else
        //don't paint over the background bitmap.
        Brush.Style := bsClear;

      NodeRect.Left := NodeRect.Left + (Node.Level * TV.Indent);
      // NodeRect.Left now represents the left-most portion
      // of the expand button
      DrawButton(NodeRect, Node); // See the CustomDraw demo

      NodeRect.Left := NodeRect.Left + TV.Indent + FButtonSize;
      //NodeRect.Left is now the leftmost portion of the image.
      DrawImage(NodeRect, Node.ImageIndex); // See the CustomDraw demo
```

```
        NodeRect.Left := NodeRect.Left + ImageList.Width;
        //Now we are finally in a position to draw the text.

        TextOut(NodeRect.Left, NodeRect.Top, Node.Text);
      end;
    end;
  end;
```

27.1.60.3.14 TTreeView.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

27.1.60.3.15 TTreeView.OnDeletion Event

Occurs when a node in the tree view is deleted.

Pascal

```
property OnDeletion: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnDeletion;
```

Description

Write an OnDeletion event handler to respond when a node is deleted from the tree view control.

See Also

Delete (see page 5237)

27.1.60.3.16 TTreeView.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;
```

```
procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

27.1.60.3.17 TTreeView.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
```

```
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;

  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;
```

```
// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

27.1.60.3.18 TTreeView.OnEdited Event

Occurs after the user edits the Text property of a node.

Pascal

```
property OnEdited: TTVEditedEvent;
```

C++

```
__property TTVEditedEvent OnEdited;
```

Description

Write an OnEdited event handler to respond to changes the user makes to the node labels. The Node parameter is the node whose label was edited. The S parameter is the new value of the node's Text property. The node's label can be changed in an OnEdited event handler before the user's edits are committed. This event can occur only if ReadOnly is set to false.

See Also

OnEditing (see page 4024)

ReadOnly (see page 4006)

Text (see page 5265)

27.1.60.3.19 TTreeView.OnEditing Event

Occurs when the user starts to edit the Text property of a node.

Pascal

```
property OnEditing: TTVEditingEvent;
```

C++

```
__property TTVEditingEvent OnEditing;
```

Description

Write an OnEditing event handler to determine whether the user is allowed to edit the label of a specific node in the tree view. Set the AllowEdit parameter to false to prevent the user from editing the node specified by the Node parameter. To disallow editing of all nodes in the tree view, use the ReadOnly property instead.

OnEdited (see page 4024)

ReadOnly (see page 4006)

27.1.60.3.20 TTreeView.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

27.1.60.3.21 TTreeView.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
```

```
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

27.1.60.3.22 TTreeView.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
```

```
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

27.1.60.3.23 TTreeView.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
```

```
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

27.1.60.3.24 TTreeView.OnExpanded Event

Occurs after a node is expanded.

Pascal

```
property OnExpanded: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnExpanded;
```

Description

Write an OnExpanded event handler to respond when a node in the tree view is expanded. The Node parameter specifies the node whose children are now displayed to the user.

See Also

FullExpand (see page 3984)

OnExpanding (see page 4025)

Expand (see page 5242)

27.1.60.3.25 TTreeView.OnExpanding Event

Occurs when a node is about to be expanded.

Pascal

```
property OnExpanding: TTVExpandingEvent;
```

C++

```
__property TTVExpandingEvent OnExpanding;
```

Description

Write an OnExpanding event handler to determine whether a node can be expanded. Set the AllowExpansion parameter to false to prevent the node from expanding.

See Also

FullExpand (see page 3984)

OnExpanded (see page 4025)

Expand (see page 5242)

27.1.60.3.26 TTreeView.OnGetImageIndex Event

Occurs when the tree view looks up the ImageIndex of a node.

Pascal

```
property OnGetImageIndex: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnGetImageIndex;
```

Description

Write an OnGetImageIndex event handler to change the image index for the particular node before it is drawn. For example, the bitmap of a node can be changed to indicate a different state for the node.

Delphi Examples:

```
{
The following example shows how the OnGetImageIndex event
handler can be used to indicate a different state for the
node.
}
procedure TCustomDrawForm.TVGetImageIndex(Sender: TObject; Node: TTreeNode);
begin
  if Node.HasChildren then
    if Node.Expanded then
      Node.ImageIndex := 3
    else
      Node.ImageIndex := 0
  else
    Node.ImageIndex := 1;
end;

procedure TCustomDrawForm.TVGetSelectedIndex(Sender: TObject; Node: TTreeNode);
begin
  Node.SelectedIndex := Node.ImageIndex;
end;
```

27.1.60.3.27 TTreeView.OnGetSelectedIndex Event

Occurs when the tree view looks up the SelectedIndex of a node.

Pascal

```
property OnGetSelectedIndex: TTVExpandedEvent;
```

C++

```
__property TTVExpandedEvent OnGetSelectedIndex;
```

Description

Write an OnGetSelectedIndex event handler to change the selected image index of a node before it is drawn.

Delphi Examples:

```
{
The following example shows how the OnGetImageIndex event
handler can be used to indicate a different state for the
node.
}
procedure TCustomDrawForm.TVGetImageIndex(Sender: TObject; Node: TTreeNode);
begin
  if Node.HasChildren then
    if Node.Expanded then
      Node.ImageIndex := 3
    else
      Node.ImageIndex := 0
  else
    Node.ImageIndex := 1;
end;

procedure TCustomDrawForm.TVGetSelectedIndex(Sender: TObject; Node: TTreeNode);
begin
  Node.SelectedIndex := Node.ImageIndex;
end;
```

SelectedIndex (see page 5265)

27.1.60.3.28 TTreeView.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);
```

```
      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
     KeyPreview := True;
  end;

  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
  if (Key=VK_ESCAPE) and Printer.Printing then
    begin
    Printer.Abort;
    MessageDlg('Printing aborted', mtInformation, [mbOK],0);
    end;
  end;
```

OnKeyUp (see page 6228)

27.1.60.3.29 TTreeView.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

27.1.60.3.30 TTreeView.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then

27.1.60.3.31 TTreeView.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the

OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

27.1.60.3.32 TTreeView.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
```

```
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

27.1.60.3.33 TTreeView.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

27.1.60.3.34 TTreeView.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

27.1.60.3.35 TTreeView.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

27.1.60.3.36 TTreeView.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

27.1.60.3.37 TTreeView.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

27.1.60.3.38 TTreeView.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

27.1.61 TUpDown Class

TUpDown is a wrapper for a Windows up-down control.

Class Hierarchy

Pascal

```
TUpDown = class(TCustomUpDown);
```

C++

```
class TUpDown : public TCustomUpDown;
```

File

ComCtrls

Description

Use TUpDown to add an up-down control to a form. Up-down controls consist of a pair of arrow buttons, such as the arrows that appear in a spin box. Up-down controls allow users to change the size of a numerical value by clicking on arrow buttons.

See Also

TScrollBar (see page 21821)

27.1.61.1 TUpDown Members

The following tables list the members exposed by TUpDown.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.

	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanChange (see page 4039)	Indicates whether Position (see page 4045) can change.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 4039)	Generates an OnClick (see page 4047) event.
	Click (see page 5743)	Respond to user click.

	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 4039)	Initializes the window creation parameters for the up-down control.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 4040)	Creates the window used by the up-down control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DoCanChange (see page 4040)	Pending change event dispatcher.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.

	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.

	Notification (see page 4041)	Responds to notifications when components are about to be created or destroyed.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.

	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.

	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 4038)	Creates and initializes an instance of TCustomUpDown (see page 4027).
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.

	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.

	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChanging (see page 5409)	Occurs when the position of an up-down control is about to change.
	OnChangingEx (see page 5410)	Occurs when the position of an up-down control is about to change.
	OnClick (see page 5410)	Occurs when the user clicks an arrow button.
	OnContextPopup (see page 5412)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 5412)	Occurs when a control receives the input focus.
	OnExit (see page 5415)	Occurs when the input focus shifts away from one control to another.
	OnMouseActivate (see page 5416)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5417)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5420)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5420)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5420)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5422)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Published Properties

	Name	Description
	AlignButton (see page 5392)	Specifies the position of the up-down control relative to its companion control.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 5393)	Specifies how the control is anchored to its parent.
	ArrowKeys (see page 5393)	Determines whether the up-down control receives input from the Up arrow and Down arrow keys.
	Associate (see page 5394)	Specifies a companion control for the up-down control.
	Constraints (see page 5394)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Enabled (see page 5395)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5395)	Contains the text string that can appear when the user moves the mouse over the control.
	Increment (see page 5397)	Specifies the amount the Position value changes each time the up or down button is pressed.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Max (see page 5397)	Specifies the maximum value of the Position property.
	Min (see page 5398)	Specifies the minimum value of the Position property.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Orientation (see page 5398)	Specifies the direction that the arrow keys point.
	ParentShowHint (see page 5399)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5399)	Identifies the pop-up menu associated with the control.
	Position (see page 5404)	Specifies the current value represented by the up-down control.
	ShowHint (see page 5404)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 5406)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5406)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Thousands (see page 5407)	Determines whether a thousands separator appears between every three digits of a decimal string.

	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 5407)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	Wrap (see page 5408)	Specifies how the up-down control handles attempts to exceed the value of Max or Min.

27.1.61.2 TUpDown Properties

The properties of the TUpDown class are listed here.

Published Properties

	Name	Description
	AlignButton (see page 5392)	Specifies the position of the up-down control relative to its companion control.
	Anchors (see page 5393)	Specifies how the control is anchored to its parent.
	ArrowKeys (see page 5393)	Determines whether the up-down control receives input from the Up arrow and Down arrow keys.
	Associate (see page 5394)	Specifies a companion control for the up-down control.
	Constraints (see page 5394)	Specifies the size constraints for the control.
	Enabled (see page 5395)	Controls whether the control responds to mouse, keyboard, and timer events.
	Hint (see page 5395)	Contains the text string that can appear when the user moves the mouse over the control.
	Increment (see page 5397)	Specifies the amount the Position value changes each time the up or down button is pressed.
	Max (see page 5397)	Specifies the maximum value of the Position property.
	Min (see page 5398)	Specifies the minimum value of the Position property.
	Orientation (see page 5398)	Specifies the direction that the arrow keys point.
	ParentShowHint (see page 5399)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5399)	Identifies the pop-up menu associated with the control.
	Position (see page 5404)	Specifies the current value represented by the up-down control.
	ShowHint (see page 5404)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 5406)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5406)	Determines if the user can tab to a control.
	Thousands (see page 5407)	Determines whether a thousands separator appears between every three digits of a decimal string.
	Visible (see page 5407)	Determines whether the component appears onscreen.
	Wrap (see page 5408)	Specifies how the up-down control handles attempts to exceed the value of Max or Min.

27.1.61.2.1 TUpDown.AlignButton Property

Specifies the position of the up-down control relative to its companion control.

Pascal

```
property AlignButton: TUDAlignButton;
```

C++

```
__property TUDAlignButton AlignButton;
```

Description

Set AlignButton to indicate where to position the up-down control. The up-down control appears attached to the outer edge of the control specified by the Associate property. These are the possible values:

Value	Meaning
udLeft	Position the up-down control on the left edge of the companion control.
udRight	Position the up-down control on the right edge of the companion control.

The up-down control resizes itself to the height of the companion control.

See Also

Associate (see page 4043)

27.1.61.2.2 TUpDown.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

27.1.61.2.3 TUpDown.ArrowKeys Property

Determines whether the up-down control receives input from the Up arrow and Down arrow keys.

Pascal

```
property ArrowKeys: Boolean;
```

C++

```
__property Boolean ArrowKeys;
```

Description

Use ArrowKeys to specify whether the up-down control responds to keyboard input. ArrowKeys is used only when the up-down control is associated with a companion control. When ArrowKeys is true, the up-down control responds to the Up arrow and Down arrow keys, even when its companion control has input focus. When ArrowKeys is false, the user must click the buttons of

the up-down control with the mouse. To set a companion control use the Associate property.

Note: Up-down controls can respond to only the Up and Down arrow keys, even when the value of Orientation is udHorizontal.

See Also

Associate (see page 4043)

Orientation (see page 4044)

27.1.61.2.4 TUpDown.Associate Property

Specifies a companion control for the up-down control.

Pascal

```
property Associate: TWinControl;
```

C++

```
__property TWinControl * Associate;
```

Description

Use Associate to link the up-down control to a companion control (sometimes called a buddy window). The up-down control automatically positions itself on the outer edge of the companion control and adjusts its height to match the companion control.

At design-time the companion control does not move with the up-down control. To keep the up-down control and its companion control together at design time, either multi-select both controls before moving them, or first move the companion control and then reset the Associate property for the up-down control.

See Also

AlignButton (see page 4042)

ArrowKeys (see page 4042)

Position (see page 4045)

27.1.61.2.5 TUpDown.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

27.1.61.2.6 TUpDown.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

27.1.61.2.7 TUpDown.Hint Property

Contains the text string that can appear when the user moves the mouse over the control.

Pascal

```
property Hint: string;
```

C++

```
__property AnsiString Hint;
```

Description

Use the Hint property to provide a string of help text either as a Help Hint, or as help text on a particular location such as a status bar.

A Help Hint is a box containing help text that appears for a control when the user moves the mouse pointer over the control and pauses momentarily. To set up Help Hints:

Specify the Hint property of each control for which a Help Hint should appear.

Set the ShowHint property of each appropriate control to true, or set the ParentShowHint property of all controls to true and set the ShowHint property of the form to true.

At runtime, set the value of the application's ShowHint property to true.

To show the Hint on a status bar or other location, use the OnHint event handler of the application. The application's OnHint event occurs when the mouse pointer moves over the control.

Specify a hint to be used for both a Help Hint box and by an OnHint handler by specifying two values separated by a | character (the vertical bar "or" symbol). For example,

```
Edit1.Hint := 'Name|Enter Name in the edit box';
Edit1->Hint = "Name|Enter Name in the edit box";
```

The "Name" part appears in the Help Hint box and the "Enter full name in the edit box" part can be extracted using the GetLongHint function for use in an OnHint event handler.

If Hint contains only one value, the entire string is used as a Help Hint and returned by the GetLongHint function. If a control has no Hint value specified, but its parent control does, the control uses the Hint value of the parent control (as long as the control's ShowHint property is true).

Note: If the application's ShowHint property is false, the Help Hint does not appear, but the OnHint event handler is still called.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
```

```
    Edit1.Hint := 'Enter your name';
    Edit1.ShowHint := True;
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }
```

27.1.61.2.8 TUpDown.Increment Property

Specifies the amount the Position value changes each time the up or down button is pressed.

Pascal

```
property Increment: Integer;
```

C++

```
__property int Increment;
```

Description

Use Increment to control the granularity of changes the up-down control can make. Set Increment to indicate the number of units between Min and Max the Position moves whenever the user clicks on one of the arrow buttons. Increment represents the mapping between the units used to specify Min, Max, and Position, and the logical units represented by the up-down control.

See Also

Max (see page 4043)

Min (see page 4044)

Position (see page 4045)

27.1.61.2.9 TUpDown.Max Property

Specifies the maximum value of the Position property.

Pascal

```
property Max: SmallInt;
```

C++

```
__property SmallInt Max;
```

Description

Use Max to provide an upper limit to the range of values the Position property can assume.

See Also

Min (see page 4044)

Position (see page 4045)

27.1.61.2.10 TUpDown.Min Property

Specifies the minimum value of the Position property.

Pascal

```
property Min: SmallInt;
```

C++

```
__property SmallInt Min;
```

Description

Use Min to provide a lower limit to the range of values the Position property can assume.

See Also

Max (see page 4043)

Position (see page 4045)

27.1.61.2.11 TUpDown.Orientation Property

Specifies the direction that the arrow keys point.

Pascal

```
property Orientation: TUDOrientation;
```

C++

```
__property TUDOrientation Orientation;
```

Description

Use Orientation to determine the orientation of the arrow buttons. These are the possible values:

Value	Meaning
udHorizontal	The arrow buttons point to the left and right, and appear side by side.
udVertical	The arrow buttons point up and down and are stacked vertically.

Note: Even when the Orientation is udHorizontal, the up-down control can respond only to the Up and Down arrow keys.

See Also

ArrowKeys (see page 4042)

27.1.61.2.12 TUpDown.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

27.1.61.2.13 TUpDown.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
```

```
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
```

```
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type
  TForm1 = class(TForm)

Popup (see page 16174)

OnContextPopup (see page 5854)

27.1.61.2.14 TUpDown.Position Property

Specifies the current value represented by the up-down control.

Pascal

```
property Position: SmallInt;
```

C++

```
__property SmallInt Position;
```

Description

Use Position to get or change the value the up-down control represents. Position must be a value between Min and Max.

When the Associate property specifies an edit control, its text is automatically set to the value of Position. When Position changes, the text of the edit control is updated. If the Associate property is nil (Delphi) or NULL (C++), use the OnClick event to respond to changes in the value of Position.

See Also

Associate (see page 4043)

Max (see page 4043)

Min (see page 4044)

OnChanging (see page 4046)

Thousands (see page 4045)

27.1.61.2.15 TUpDown.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

27.1.61.2.16 TUpDown.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

27.1.61.2.17 TUpDown.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

27.1.61.2.18 TUpDown.Thousands Property

Determines whether a thousands separator appears between every three digits of a decimal string.

Pascal

```
property Thousands: Boolean;
```

C++

```
__property Boolean Thousands;
```

Description

Use Thousands to control the formatting of the text of the companion control of the up-down control. If Thousands is true, a separator appears between every three digits. The numeric value that is displayed by the companion control is given by the Position property.

See Also

Associate (see page 4043)

Position (see page 4045)

27.1.61.2.19 TUpDown.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

See Also

Enabled (see page 5821)

Hide (see page 5769)

Show (see page 5788)

VisibleChanging (see page 5791)

27.1.61.2.20 TUpDown.Wrap Property

Specifies how the up-down control handles attempts to exceed the value of Max or Min.

Pascal

```
property Wrap: Boolean;
```

C++

```
__property Boolean Wrap;
```

Description

Use Wrap to specify whether the up-down control treats the range determined by the Max and Min properties as a continuous loop. If Wrap is true, the value of Position becomes the value of the Min property when the user increments Position beyond the value of Max, and becomes the value of Max when the user decrements Position beyond the value of Min.

Position (see page 4045)

27.1.61.3 TUpDown Events

The events of the TUpDown class are listed here.

Published Events

	Name	Description
	OnChanging (see page 5409)	Occurs when the position of an up-down control is about to change.
	OnChangingEx (see page 5410)	Occurs when the position of an up-down control is about to change.
	OnClick (see page 5410)	Occurs when the user clicks an arrow button.
	OnContextPopup (see page 5412)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 5412)	Occurs when a control receives the input focus.
	OnExit (see page 5415)	Occurs when the input focus shifts away from one control to another.
	OnMouseActivate (see page 5416)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5417)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5420)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5420)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5420)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5422)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

27.1.61.3.1 TUpDown.OnChanging Event

Occurs when the position of an up-down control is about to change.

Pascal

```
property OnChanging: TUDChangingEvent;
```

C++

```
__property TUDChangingEvent OnChanging;
```

Description

Write an OnChanging event handler to conditionally disallow changes to the value of Position. Set the AllowChange parameter to false to prevent a change to the current value of Position.

OnChanging occurs both when the user clicks the arrow buttons of the up-down control and when an attempt is made to change the value of Position programmatically. To determine which button the user clicked, use the OnChangingEx event or the OnClick event, both of which follow the OnChanging event.

CanChange (see page 4039)

OnClick (see page 4047)

OnChangingEx (see page 4047)

Position (see page 4045)

27.1.61.3.2 TUpDown.OnChangingEx Event

Occurs when the position of an up-down control is about to change.

Pascal

```
property OnChangingEx: TUDChangingEventEx;
```

C++

```
__property TUDChangingEventEx OnChangingEx;
```

Description

Write an OnChangingEx event handler to conditionally disallow changes to the value of Position. Set the AllowChange parameter to false to prevent a change to the current value of Position.

Sender is the up-down control that received the event. This may be in response to a user click on the arrow buttons or an attempt to change the value of Position programmatically.

AllowChange returns a value that indicates whether the change is permitted.

NewValue indicates the new value of Position if the change is allowed.

Direction indicates whether the value of Position is to be increased or decreased.

CanChange (see page 4039)

Position (see page 4045)

OnChanging (see page 4046)

27.1.61.3.3 TUpDown.OnClick Event

Occurs when the user clicks an arrow button.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TUDClickEvent OnClick;__property TNotifyEvent OnClick;
```

Description

Write an OnClick event handler to take specific action when the user clicks one of the arrow buttons. If the Associate property is not used to automatically update the text of an edit control when the value of Position changes, use the OnClick event handler to respond to changes just before the value of Position is changed.

The Button parameter specifies how the value of Position is about to change. When Button is btNext, the Up or Right arrow was clicked, and the value of Position is about to increase by Increment. When Button is btPrev, the Down or Left arrow was clicked, and the value of Position is about to decrease by Increment.

C++ Examples:

```
/*
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
const
  TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *page = new TTabSheet(PageControl1);
    page->PageControl = PageControl1;
    page->Caption = AnsiString("Page") + IntToStr(i);
    page->Brush->Color = colorPalette[i];
  }
}

void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  PageControl1->SelectNextPage(Button == btNext);
}
```

Delphi Examples:

```
{
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
const
  colorPalette: Array[0..11] of TColor =
    (clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple);
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet #' + IntToStr(i);
      Brush.Color := colorPalette[i];
    end;

27.1.61.3.4 TUpDown.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

27.1.61.3.5 TUpDown.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,

27.1.61.3.6 TUpDown.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
```

```
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

27.1.61.3.7 TUpDown.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

27.1.61.3.8 TUpDown.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
```

```

27.1.61.3.9 TUpDown.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

27.1.61.3.10 TUpDown.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

27.1.61.3.11 TUpDown.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
```

```
  button, moves the mouse, and releases the mouse button, a
  rectangle is drawn on the form. When the mouse button is
  released, the rectangle appears on the form's canvas. Its
  top-left and bottom-right corners are defined by the
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  }
  procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

MouseCapture (see page 5831)

27.1.61.3.12 TUpDown.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{

27.1.62 TWorkArea Class

TWorkArea represents a rectangular subregion of a list view's client area.

Class Hierarchy

System::TObject → Classes.TPersistent → Classes.TCollectionItem → ComCtrls.TWorkArea

Pascal

```
TWorkArea = class(TCollectionItem);
```

C++

```
class TWorkArea : public TCollectionItem;
```

File

ComCtrls

Description

Use TWorkArea to describe the dimensions and display characteristics of one work area of a list view component. Work areas divide the client area of a list view into logical subregions. The icons of the list view are then arranged within each work area, to provide an additional layer of organization.

Each list item in the list view belongs to a single work area. This association is based on whether the position of the list item falls within the bounding rectangle specified by the work area's Rect (see page 5428) property.

In addition, If the list view's ShowWorkAreas property is true, the list view draws the work area, using its Color (see page 5428) and DisplayName properties.

Note: Work areas are only used when the list view has a ViewStyle of vsIcon or vsSmallIcon.

TCustomListView (see page 3757)

27.1.62.1 TWorkArea Members

The following tables list the members exposed by TWorkArea.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.

	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
V	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
V	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 5427)	Creates an instance of TWorkArea (see page 5425).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2757)	Destroys the TCollectionItem (see page 2755) instance and frees its memory.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
V	GetDisplayName (see page 5427)	Returns the value of the DisplayName property.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SetDisplayName (see page 5427)	Sets the value of the DisplayName property.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	Color (see page 5428)	Specifies the background color of the work area.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.

	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).
	Rect (see page 5428)	Indicates the portion of the list view's client area covered by the work area.

27.1.62.2 TWorkArea.Create Constructor

Creates an instance of TWorkArea (see page 5425).

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TWorkArea(TCollection Collection);
```

Description

It is seldom necessary to call the constructor for TWorkArea (see page 5425) directly. Instead, create TWorkArea (see page 5425) objects indirectly by calling the Add method of TWorkAreas (see page 5429).

See Also

Add (see page 5431)

27.1.62.3 TWorkArea Methods

The methods of the TWorkArea class are listed here.

Public Methods

	Name	Description
	GetDisplayName (see page 5427)	Returns the value of the DisplayName property.
	SetDisplayName (see page 5427)	Sets the value of the DisplayName property.

27.1.62.3.1 TWorkArea.GetDisplayName Method

Returns the value of the DisplayName property.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

GetDisplayName is the read implementer of the DisplayName property. The DisplayName indicates the name that appears as a label for the work area in the list view when the list view's ShowWorkAreas property is true.

See Also

DisplayName (see page 2761)

ShowWorkAreas (see page 3824)

27.1.62.3.2 TWorkArea.SetDisplayName Method

Sets the value of the DisplayName property.

Pascal

```
procedure SetDisplayName(const Value: string); override;
```

C++

```
virtual __fastcall SetDisplayName(const AnsiString Value);
```

Description

SetDisplayName is the write implementer of the DisplayName property. The DisplayName indicates the name that appears as a label for the work area in the list view when the list view's ShowWorkAreas property is true.

See Also

DisplayName (see page 2761)

ShowWorkAreas (see page 3824)

27.1.62.4 TWorkArea Properties

The properties of the TWorkArea class are listed here.

Public Properties

	Name	Description
	Color (see page 5428)	Specifies the background color of the work area.
	Rect (see page 5428)	Indicates the portion of the list view's client area covered by the work area.

27.1.62.4.1 TWorkArea.Color Property

Specifies the background color of the work area.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to specify the color in which the list view paints the portion of its client area circumscribed by the Rect (see page 5428) property. Color is not used unless the list view's ShowWorkAreas property is true.

See Also

Rect (see page 5428)

ShowWorkAreas (see page 3824)

27.1.62.4.2 TWorkArea.Rect Property

Indicates the portion of the list view's client area covered by the work area.

Pascal

```
property Rect: TRect;
```

C++

```
__property TRect Rect;
```

Description

Set Rect to specify the sphere of influence of a work area. Rect is the bounding rectangle of a portion of the list view's client area. If Rect specifies a region larger than the list view's client area, the list view introduces scroll bars to support the logical size specified by Rect.

List items are assigned to the work area when they fall into the region of the list view bounded by Rect. If a list item falls into a region that is contained by more than one work area, it is assigned to the list item with the lowest Index property.

If the list view paints itself to display work areas, it paints the portion of its client area that is outlined by Rect using the color specified by the Color (see page 5428) property.

Color (see page 5428)

ClientRect

WorkArea (see page 4257)

Index (see page 2762)

ShowWorkAreas (see page 3824)

27.1.63 TWorkAreas Class

TWorkAreas is a collection of TWorkArea (see page 5425) objects.

Class Hierarchy

Pascal

```
TWorkAreas = class(TOwnedCollection);
```

C++

```
class TWorkAreas : public TOwnedCollection;
```

File

ComCtrls

Description

Use TWorkAreas to represent the work areas of a list view control. Each work area is represented by a single TWorkArea (see page 5425) object. Most importantly, these work areas define rectangles that cover portions of the list view's client area. List items are associated with a work area when they are placed in the portion of the client area covered by a work area's rectangle. These associations are used to add an extra level of organization to the list view, with list items arranged within each work area.

See Also

TWorkArea (see page 5425)

TCustomListView (see page 3757)

27.1.63.1 TWorkAreas Members

The following tables list the members exposed by TWorkAreas.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 5432)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 2915)	Returns the owner of an object.
	GetOwner (see page 2932)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 5433)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 5431)	Creates a new TWorkArea (see page 5425) object and adds it to the end of the Items (see page 5434) property array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 2734)	Creates and initializes a collection.
	Create (see page 2914)	Creates and initializes a TOwnedCollection (see page 2912) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 5432)	Removes a TWorkArea (see page 5425) object from the Items (see page 5434) property array.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 5433)	Creates a new TWorkArea (see page 5425) object and adds it to the Items (see page 5434) property array in a specified position.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 5434)	Provides indexed access to the TWorkArea (see page 5425) objects.

27.1.63.2 TWorkAreas Methods

The methods of the TWorkAreas class are listed here.

Protected Methods

	Name	Description
	Changed (see page 5432)	Responds when the collection or any of its items changes.
V	Update (see page 5433)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 5431)	Creates a new TWorkArea (see page 5425) object and adds it to the end of the Items (see page 5434) property array.
	Delete (see page 5432)	Removes a TWorkArea (see page 5425) object from the Items (see page 5434) property array.
	Insert (see page 5433)	Creates a new TWorkArea (see page 5425) object and adds it to the Items (see page 5434) property array in a specified position.

27.1.63.2.1 TWorkAreas.Add Method

Creates a new TWorkArea (see page 5425) object and adds it to the end of the Items (see page 5434) property array.

Pascal

```
function Add: TWorkArea;
```

C++

```
__fastcall TWorkArea Add();
```

Description

Call Add to add a new work area to the list view that owns this TWorkAreas (see page 5429) object. Add returns the newly created TWorkArea (see page 5425) object. After adding a new work area, set the work area's Rect property to indicate what portion of the list view's client area it represents.

See Also

Insert (see page 5433)

Items (see page 5434)

Rect (see page 5428)

27.1.63.2.2 TWorkAreas.Changed Method

Responds when the collection or any of its items changes.

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

Changed is called automatically when items in the collection change or when the EndUpdate method signals that an update is complete. It checks the value of UpdateCount, and if it is 0, calls the Update method, which performs any necessary updates.

When writing a TCollection descendant, there is no need to call Changed. Instead, bracket any changes by calls to BeginUpdate and EndUpdate.

See Also

Changed (see page 2758)

Update (see page 2747)

EndUpdate (see page 2742)

UpdateCount (see page 2753)

27.1.63.2.3 TWorkAreas.Delete Method

Removes a TWorkArea (see page 5425) object from the Items (see page 5434) property array.

Pascal

```
procedure Delete(Index: Integer);
```

C++

```
__fastcall Delete(int Index);
```

Description

Call Delete to remove the work area specified by Items (see page 5434)[Index]. Delete removes the work area from the Items

(see page 5434) property array and frees the TWorkArea (see page 5425) object.

See Also

Insert (see page 5433)

Items (see page 5434)

Add (see page 5431)

27.1.63.2.4 TWorkAreas.Insert Method

Creates a new TWorkArea (see page 5425) object and adds it to the Items (see page 5434) property array in a specified position.

Pascal

```
function Insert(Index: Integer): TWorkArea;
```

C++

```
__fastcall TWorkArea Insert(int Index);
```

Description

Call Insert to add a new work area to the list view that owns this TWorkAreas (see page 5429) object. Insert adds a new work area at the position specified by the Index parameter. Existing work areas (starting from the specified position) are moved up in the Items (see page 5434) array. Insert returns the newly created TWorkArea (see page 5425) object. After inserting a new work area, set the work area's Rect property to indicate what portion of the list view's client area it represents.

Note: Usually, there is no meaningful difference between using the Add (see page 5431) method or the Insert method to add work areas. However, if two or more work areas specify overlapping regions, then the order of the work areas in the Items (see page 5434) array determines which work area is associated with list items in the overlapping region. Specifically, list items in the overlapping region are associated with the work area that has the lower index.

See Also

Add (see page 5431)

Items (see page 5434)

Rect (see page 5428)

27.1.63.2.5 TWorkAreas.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary

adjustments.

See Also

Changed (see page 2740)

Changed (see page 2758)

27.1.63.3 TWorkAreas Properties

The properties of the TWorkAreas class are listed here.

Public Properties

	Name	Description
	Items (see page 5434)	Provides indexed access to the TWorkArea (see page 5425) objects.

27.1.63.3.1 TWorkAreas.Items Property

Provides indexed access to the TWorkArea (see page 5425) objects.

Pascal

```
property Items [Index: Integer]: TWorkArea;
```

C++

```
__property TWorkArea Items[int Index];
```

Description

Use Items to access the properties of the TWorkArea (see page 5425) objects maintained by TWorkAreas (see page 5429).

Note: In C++ code, Items is the default property of TWorkAreas (see page 5429), so the name of the Items property can be left off when using this property. Thus the line

```
ListView1.WorkAreas.Items[0].Color := 'clLtGray';
```

Note: can be written

```
ListView1.WorkAreas[0].Color := 'clLtGray';
```

27.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CheckCommonControl (see page 5435)	This is function ComCtrls.CheckCommonControl.
	CheckToolMenuDropdown (see page 5435)	Displays a tool button's dropdown menu.
	GetComCtlVersion (see page 5436)	Indicates which version of ComCtl32.dll is installed.
	InitCommonControl (see page 5437)	This is function ComCtrls.InitCommonControl.

27.2.1 ComCtrls.CheckCommonControl Function

Pascal

```
procedure CheckCommonControl(CC: Integer);
```

C++

```
CheckCommonControl(int CC);
```

File

ComCtrls

Description

This is function ComCtrls.CheckCommonControl.

27.2.2 ComCtrls.CheckToolMenuDropdown Function

Displays a tool button's dropdown menu.

Pascal

```
procedure CheckToolMenuDropdown(ToolButton: TToolButton);
```

C++

```
CheckToolMenuDropdown(TToolButton ToolButton);
```

File

ComCtrls

Description

CallCheckToolMenuDropdown to programmatically display the dropdown menu for a tool button of style tbsDropDown. If the tool button has no associated dropdown menu,CheckToolMenuDropdown does nothing.

Note: CheckToolMenuDropdown is included for backward compatibility. Applications should use the tool button's CheckMenuDropdown method instead.

See Also

TToolButton

TToolButton

27.2.3 ComCtrls.GetComCtlVersion Function

Indicates which version of ComCtl32.dll is installed.

Pascal

```
function GetComCtlVersion: Integer;
```

C++

```
int GetComCtlVersion();
```

File

ComCtrls

Description

The appearance and behavior of some common controls, such as tool bars and cool bars, varies depending on which version of ComCtl32.dll is installed. UseGetComCtlVersion to determine which version is installed. GetComCtlVersion returns an integer that includes the major version number as the high-order word and the minor version number as the low-order word.

Installing Microsoft's Internet Explorer on a system affects which version of ComCtl32.dll is installed. To help determine which version of Internet Explorer is installed, the ComCtrls (see page 3413) unit defines several constants:

ConstantValueMeaning

Constant	Value	Meaning
ComCtlVersionIE3 (see page 5522)	$00040046	The version of ComCtl32.dll installed with Internet Explorer version 3.
ComCtlVersionIE4 (see page 5523)	$00040047	The version of ComCtl32.dll installed with Internet Explorer version 4.
ComCtlVersionIE401 (see page 5523)	$00040048	The version of ComCtl32.dll installed with Internet Explorer version 4.01.
ComCtlVersionIE5 (see page 5523)	$00050050	The version of ComCtl32.dll installed with Internet Explorer version 5.

To quickly determine which version of Internet Explorer is installed, you can compare the return value ofGetComCtlVersion with these constants. For example:

ifGetComCtlVersion >= ComCtlVersionIE4 (see page 5523) then { IE4 is installed }

if (GetComCtlVersion() >= ComCtlVersionIE4 (see page 5523)) // IE4 is installed

See Also

TCoolBar

TToolBar

27.2.4 ComCtrls.InitCommonControl Function

Pascal

```
function InitCommonControl(CC: Integer): Boolean;
```

C++

```
Boolean InitCommonControl(int CC);
```

File

ComCtrls

Description

This is function ComCtrls.InitCommonControl.

27.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAddMode (see page 5439)	This is record ComCtrls.TAddMode.
	TAttributeType (see page 5440)	This is record ComCtrls.TAttributeType.
	TAutoCompleteOption (see page 5440)	TAutoCompleteOption and TAutoCompleteOptions (see page 5480) specify a set of autocomplete options.
	TCalDayOfWeek (see page 5441)	TCalDayOfWeek represents a day of the week.
	TComboBoxExStyle (see page 5442)	TComboBoxExStyle is the type for the Style property of extended combo box controls.
	TComboBoxExStyleEx (see page 5442)	TComboBoxExStyleEx and TComboBoxExStyles (see page 5481) configure the behavior of extended combo box controls.
	TCommonAVI (see page 5443)	This is record ComCtrls.TCommonAVI.
	TConsistentAttribute (see page 5444)	This is record ComCtrls.TConsistentAttribute.
	TCoolBandMaximize (see page 5445)	TCoolBandMaximize specifies the conditions under which a TCoolBand (see page 3584) is maximized.
	TCustomDrawStage (see page 5445)	TCustomDrawStage specifies a stage in the custom drawing process.
	TCustomDrawTarget (see page 5446)	TCustomDrawTarget specifies the target of a custom drawing event.
	TDateTimeKind (see page 5447)	This is record ComCtrls.TDateTimeKind.
	TDisplayCode (see page 5447)	This is record ComCtrls.TDisplayCode.
	TDTCalAlignment (see page 5447)	This is record ComCtrls.TDTCalAlignment.
	TDTDateFormat (see page 5448)	This is record ComCtrls.TDTDateFormat.
	TDTDateMode (see page 5448)	This is record ComCtrls.TDTDateMode.
	THeaderSectionStyle (see page 5449)	This is record ComCtrls.THeaderSectionStyle.
	THeaderStyle (see page 5449)	THeaderStyle specifies the style of a header control.
	THitTest (see page 5450)	THitTest and THitTests (see page 5488) are used in the GetHitTestInfoAt method.
	THKInvalidKey (see page 5451)	This is record ComCtrls.THKInvalidKey.
	THKModifier (see page 5451)	This is record ComCtrls.THKModifier.
	TIconArrangement (see page 5452)	TIconArrangement indicates how the icons for items are arranged.
	TItemChange (see page 5452)	TItemChange describes the type of change a list item undergoes.
	TItemFind (see page 5453)	TItemFind identifies the type of search in an OnDataFind event handler.
	TItemRequests (see page 5454)	This is record ComCtrls.TItemRequests.
	TItemState (see page 5454)	TItemState and TItemStates (see page 5489) specify the state of an item in a list view control.
	TListArrangement (see page 5455)	This is record ComCtrls.TListArrangement.
	TListHotTrackStyle (see page 5456)	TListHotTrackStyle and TListHotTrackStyles (see page 5489) specify hot tracking styles for a list view control.
	TMultiSelectStyles (see page 5456)	This is record ComCtrls.TMultiSelectStyles.
	TNodeAttachMode (see page 5457)	TNodeAttachMode identifies a new or changed tree node relationship.
	TNodeState (see page 5459)	This is record ComCtrls.TNodeState.
	TNumberingStyle (see page 5459)	This is record ComCtrls.TNumberingStyle.
	TPageScrollerButton (see page 5460)	TPageScrollerButton identifies a button on a page scroller.
	TPageScrollerButtonState (see page 5460)	TPageScrollerButtonState indicates the state of a page scroller button.
	TPageScrollerOrientation (see page 5461)	TPageScrollerOrientation indicates the orientation of a page scroller control.
	TPositionToolTip (see page 5462)	Specifies the position of the tool tip.
	TProgressBarOrientation (see page 5462)	TProgressBarOrientation specifies the orientation of a progress bar.
	TSearchDirection (see page 5463)	Indicates the direction in which to search for the nearest item to a specified item or point.
	TSearchType (see page 5464)	Specifies search options.

	TSectionTrackState (see page 5464)	This is record ComCtrls.TSectionTrackState.
	TSortType (see page 5465)	TSortType indicates the criteria to use when sorting items.
	TStatusPanelBevel (see page 5466)	TStatusPanelBevel indicates the type of bevel around a panel in a status bar.
	TStatusPanelStyle (see page 5466)	TStatusPanelStyle indicates the kind of contents in a status bar panel.
	TTabPosition (see page 5467)	This is record ComCtrls.TTabPosition.
	TTabStyle (see page 5467)	TTabStyle indicates whether a TTabSet control is owner-drawn.
	TTBDrawingStyle (see page 5468)	Specifies the drawing style for the tool bar.
	TTickMark (see page 5468)	TTickMark indicates the location of the tick marks on a track bar.
	TTickStyle (see page 5469)	TTickStyle indicates how a track bar determines the increments at which tick marks appear.
	TToolButtonState (see page 5470)	This is record ComCtrls.TToolButtonState.
	TToolButtonStyle (see page 5470)	TToolButtonStyle indicates the type of control a TToolButton (see page 5107) object represents.
	TTrackBarOrientation (see page 5471)	TTrackBarOrientation indicates whether a trackbar is horizontal or vertical.
	TUDAlignButton (see page 5471)	This is record ComCtrls.TUDAlignButton.
	TUDBtnType (see page 5472)	This is record ComCtrls.TUDBtnType.
	TUDOrientation (see page 5472)	This is record ComCtrls.TUDOrientation.
	TUpDownDirection (see page 5473)	TUpDownDirection indicates the direction in which the position of an updown control changes.
	TViewStyle (see page 5473)	TViewStyle indicates how a list view control displays its items.

Records

	Name	Description
	TConversionFormat (see page 5444)	This is record ComCtrls.TConversionFormat.
	TNodeCache (see page 5457)	TNodeCache is the type for a cached tree-view node.
	TNodeDataInfo (see page 5458)	This is record ComCtrls.TNodeDataInfo.
	TNodeInfo (see page 5458)	This is record ComCtrls.TNodeInfo.
	TRichEditStreamInfo (see page 5463)	This is record ComCtrls.TRichEditStreamInfo.

27.3.1 ComCtrls.TAddMode Enumeration

Pascal

```
TAddMode = (
  taAddFirst,
  taAdd,
  taInsert
);
```

C++

```
enum TAddMode {
  taAddFirst,
  taAdd,
  taInsert
};
```

File

ComCtrls

Description

This is record ComCtrls.TAddMode.

27.3.2 ComCtrls.TAttributeType Enumeration

Pascal

```
TAttributeType = (
  atSelected,
  atDefaultText
);
```

C++

```
enum TAttributeType {
  atSelected,
  atDefaultText
};
```

File

ComCtrls

Description

This is record ComCtrls.TAttributeType.

27.3.3 ComCtrls.TAutoCompleteOption Enumeration

TAutoCompleteOption and TAutoCompleteOptions (see page 5480) specify a set of autocomplete options.

Pascal

```
TAutoCompleteOption = (
  acoAutoSuggest,
  acoAutoAppend,
  acoSearch,
  acoFilterPrefixes,
  acoUseTab,
  acoUpDownKeyDropsList,
  acoRtlReading
);
```

C++

```
enum TAutoCompleteOption {
  acoAutoSuggest,
  acoAutoAppend,
  acoSearch,
  acoFilterPrefixes,
  acoUseTab,
  acoUpDownKeyDropsList,
  acoRtlReading
};
```

File

ComCtrls

Description

TAutoCompleteOptions (see page 5480) defines options for controls that support autocompletion. These are:

Value	Meaning
acoAutoSuggest	Enable the autosuggest drop-down list.
acoAutoAppend	Enable autoappend.
acoSearch	Add a search item to the list of completed strings. Selecting this item launches a search engine.
acoFilterPrefixes	Don't match common prefixes, such as "www." and "http://".
acoUseTab	Use the tab key to select items.
acoUpDownKeyDropsList	Use up and down arrow keys to display suggestion list.
acoRtlReading	Text direction is opposite of parent.

27.3.4 ComCtrls.TCalDayOfWeek Enumeration

TCalDayOfWeek represents a day of the week.

Pascal

```
TCalDayOfWeek = (
  dowMonday,
  dowTuesday,
  dowWednesday,
  dowThursday,
  dowFriday,
  dowSaturday,
  dowSunday,
  dowLocaleDefault
);
```

C++

```
enum TCalDayOfWeek {
  dowMonday,
  dowTuesday,
  dowWednesday,
  dowThursday,
  dowFriday,
  dowSaturday,
  dowSunday,
  dowLocaleDefault
};
```

File

ComCtrls

Description

TCalDayOfWeek is used to represent a day of the week for a column in a calendar. It can be any of the following values:

Value	Meaning
dowMonday	Monday
dowTuesday	Tuesday
dowWednesday	Wednesday
dowThursday	Thursday

dowFriday	Friday
dowSaturday	Saturday
dowSunday	Sunday
dowLocaleDefault	The day of the week for the column is determined by the locale in which the application runs.

See Also

TCommonCalendar

27.3.5 ComCtrls.TComboBoxExStyle Enumeration

TComboBoxExStyle is the type for the Style property of extended combo box controls.

Pascal

```
TComboBoxExStyle = (
  csExDropDown,
  csExSimple,
  csExDropDownList
);
```

C++

```
enum TComboBoxExStyle {
  csExDropDown,
  csExSimple,
  csExDropDownList
};
```

File

ComCtrls

Description

These are the values in the TComboBoxExStyle type:

Value	Meaning
csExDropDown	Creates a drop-down list with an edit box for manually entered text.
csExSimple	Creates an edit box with a fixed list (list box) underneath. The length of the list is determined by the Height of the combo box.
csExDropDownList	Creates a drop-down list with no edit box; the user cannot enter text manually.

27.3.6 ComCtrls.TComboBoxExStyleEx Enumeration

TComboBoxExStyleEx and TComboBoxExStyles (see page 5481) configure the behavior of extended combo box controls.

Pascal

```
TComboBoxExStyleEx = (
  csExCaseSensitive,
  csExNoEditImage,
  csExNoEditImageIndent,
```

```
    csExNoSizeLimit,
    csExPathWordBreak
  );
```

C++

```
  enum TComboBoxExStyleEx {
    csExCaseSensitive,
    csExNoEditImage,
    csExNoEditImageIndent,
    csExNoSizeLimit,
    csExPathWordBreak
  };
```

File

ComCtrls

Description

TComboBoxExStyles (see page 5481) is a set of TComboBoxExStyleEx values. These are the values in the TComboBoxExStyleEx type:

Value	Meaning
csExCaseSensitive	Searches against item captions are case sensitive. This includes the automatic location of items in the list as the user types.
csExNoEditImage	The items in the list appear without any corresponding images (The combo box ignores their ImageIndex property).
csExNoEditImageIndent	The items in the list can't appear indented. (The combo box ignores their Indent property).
csExNoSizeLimit	The extended combo box can be resized vertically smaller than the edit region and drop-down button. When resized in this way, the combo box appears clipped.
csExPathWordBreak	The backslash (\), forward slash (/), and period (.) characters are treated as word delimiters for keyboard navigation purposes. This enables keyboard navigation of path names and URLs. (This style is not supported on Windows 9x).

27.3.7 ComCtrls.TCommonAVI Enumeration

Pascal

```
  TCommonAVI = (
    aviNone,
    aviFindFolder,
    aviFindFile,
    aviFindComputer,
    aviCopyFiles,
    aviCopyFile,
    aviRecycleFile,
    aviEmptyRecycle,
    aviDeleteFile
  );
```

C++

```
  enum TCommonAVI {
    aviNone,
    aviFindFolder,
    aviFindFile,
    aviFindComputer,
    aviCopyFiles,
```

```
    aviCopyFile,
    aviRecycleFile,
    aviEmptyRecycle,
    aviDeleteFile
  };
```

File

ComCtrls

Description

This is record ComCtrls.TCommonAVI.

27.3.8 ComCtrls.TConsistentAttribute Enumeration

Pascal

```
  TConsistentAttribute = (
    caBold,
    caColor,
    caFace,
    caItalic,
    caSize,
    caStrikeOut,
    caUnderline,
    caProtected
  );
```

C++

```
  enum TConsistentAttribute {
    caBold,
    caColor,
    caFace,
    caItalic,
    caSize,
    caStrikeOut,
    caUnderline,
    caProtected
  };
```

File

ComCtrls

Description

This is record ComCtrls.TConsistentAttribute.

27.3.9 ComCtrls.TConversionFormat Record

Pascal

```
  TConversionFormat = record
    ConversionClass: TConversionClass;
    Extension: string;
    Next: PConversionFormat;
  end;
```

C++

```
struct TConversionFormat {
  TConversionClass ConversionClass;
  AnsiString Extension;
  PConversionFormat Next;
};
```

File

ComCtrls

Description

This is record ComCtrls.TConversionFormat.

27.3.10 ComCtrls.TCoolBandMaximize Enumeration

TCoolBandMaximize specifies the conditions under which a TCoolBand (see page 3584) is maximized.

Pascal

```
TCoolBandMaximize = (
  bmNone,
  bmClick,
  bmDblClick
);
```

C++

```
enum TCoolBandMaximize {
  bmNone,
  bmClick,
  bmDblClick
};
```

File

ComCtrls

Description

TCoolBandMaximize specifies the conditions under which a TCoolBand (see page 3584) becomes maximized:

Value	Meaning
bmNone	The cool band is never maximized.
bmClick	The cool band is maximized when the user clicks with the left mouse button.
bmDblClick	The cool band is maximized when the user double-clicks with the left mouse button.

27.3.11 ComCtrls.TCustomDrawStage Enumeration

TCustomDrawStage specifies a stage in the custom drawing process.

Pascal

```
TCustomDrawStage = (
  cdPrePaint,
  cdPostPaint,
```

```
    cdPreErase,
    cdPostErase
  );
```

C++

```
  enum TCustomDrawStage {
    cdPrePaint,
    cdPostPaint,
    cdPreErase,
    cdPostErase
  };
```

File

ComCtrls

Description

Use TCustomDrawStage to determine when an advanced custom drawing event occurs:

Value	Meaning
cdPrePaint	Before painting.
cdPostPaint	After painting.
cdPreErase	Before erasing.
cdPostErase	After erasing.

27.3.12 ComCtrls.TCustomDrawTarget Enumeration

TCustomDrawTarget specifies the target of a custom drawing event.

Pascal

```
  TCustomDrawTarget = (
    dtControl,
    dtItem,
    dtSubItem
  );
```

C++

```
  enum TCustomDrawTarget {
    dtControl,
    dtItem,
    dtSubItem
  };
```

File

ComCtrls

Description

TCustomDrawTarget is used to indicate a specific type of custom drawing event. The following table lists the possible values:

Value	Meaning
dtControl	The event occurs when the entire control needs to be painted.
dtItem	The event occurs when an individual item within the control needs to be painted.
dtSubItem	The event occurs when a subitem needs to be painted.

27.3.13 ComCtrls.TDateTimeKind Enumeration

Pascal

```
TDateTimeKind = (
  dtkDate,
  dtkTime
);
```

C++

```
enum TDateTimeKind {
  dtkDate,
  dtkTime
};
```

File

ComCtrls

Description

This is record ComCtrls.TDateTimeKind.

27.3.14 ComCtrls.TDisplayCode Enumeration

Pascal

```
TDisplayCode = (
  drBounds,
  drIcon,
  drLabel,
  drSelectBounds
);
```

C++

```
enum TDisplayCode {
  drBounds,
  drIcon,
  drLabel,
  drSelectBounds
};
```

File

ComCtrls

Description

This is record ComCtrls.TDisplayCode.

27.3.15 ComCtrls.TDTCalAlignment Enumeration

Pascal

```
TDTCalAlignment = (
```

```
    dtaLeft,
    dtaRight
  );
```

C++

```
  enum TDTCalAlignment {
    dtaLeft,
    dtaRight
  };
```

File

ComCtrls

Description

This is record ComCtrls.TDTCalAlignment.

27.3.16 ComCtrls.TDTDateFormat Enumeration

Pascal

```
  TDTDateFormat = (
    dfShort,
    dfLong
  );
```

C++

```
  enum TDTDateFormat {
    dfShort,
    dfLong
  };
```

File

ComCtrls

Description

This is record ComCtrls.TDTDateFormat.

27.3.17 ComCtrls.TDTDateMode Enumeration

Pascal

```
  TDTDateMode = (
    dmComboBox,
    dmUpDown
  );
```

C++

```
  enum TDTDateMode {
    dmComboBox,
    dmUpDown
  };
```

File

ComCtrls

Description

This is record ComCtrls.TDTDateMode.

27.3.18 ComCtrls.THeaderSectionStyle Enumeration

Pascal

```
THeaderSectionStyle = (
  hsText,
  hsOwnerDraw
);
```

C++

```
enum THeaderSectionStyle {
  hsText,
  hsOwnerDraw
};
```

File

ComCtrls

Description

This is record ComCtrls.THeaderSectionStyle.

27.3.19 ComCtrls.THeaderStyle Enumeration

THeaderStyle specifies the style of a header control.

Pascal

```
THeaderStyle = (
  hsButtons,
  hsFlat
);
```

C++

```
enum THeaderStyle {
  hsButtons,
  hsFlat
};
```

File

ComCtrls

Description

THeaderStyle can have one of the following values:

Value	Meaning
hsButtons	The column sections are buttons.
hsFlat	The column sections are flat buttons.

27.3.20 ComCtrls.THitTest Enumeration

THitTest and THitTests (see page 5488) are used in the GetHitTestInfoAt method.

Pascal

```
THitTest = (
  htAbove,
  htBelow,
  htNowhere,
  htOnItem,
  htOnButton,
  htOnIcon,
  htOnIndent,
  htOnLabel,
  htOnRight,
  htOnStateIcon,
  htToLeft,
  htToRight
);
```

C++

```
enum THitTest {
  htAbove,
  htBelow,
  htNowhere,
  htOnItem,
  htOnButton,
  htOnIcon,
  htOnIndent,
  htOnLabel,
  htOnRight,
  htOnStateIcon,
  htToLeft,
  htToRight
};
```

File

ComCtrls

Description

THitTests (see page 5488) is a set of THitTest values. THitTest can have any of the following values:

Value	Means the point is
htAbove	Above the client area.
htBelow	Below the client area.
htNowhere	Inside the control, but not on an item.
htOnItem	On an item, its text, or its bitmap.
htOnButton	On a button.
htOnIcon	On an icon.
htOnIndent	On the indented area of an item.
htOnLabel	On a label.
htOnRight	On the right side of an item.

htOnStateIcon	On a state icon or bitmap associated with an item.
htToLeft	To the left of the client area.
htToRight	To the right of the client area.

27.3.21 ComCtrls.THKInvalidKey Enumeration

Pascal

```
THKInvalidKey = (
  hcNone,
  hcShift,
  hcCtrl,
  hcAlt,
  hcShiftCtrl,
  hcShiftAlt,
  hcCtrlAlt,
  hcShiftCtrlAlt
);
```

C++

```
enum THKInvalidKey {
  hcNone,
  hcShift,
  hcCtrl,
  hcAlt,
  hcShiftCtrl,
  hcShiftAlt,
  hcCtrlAlt,
  hcShiftCtrlAlt
};
```

File

ComCtrls

Description

This is record ComCtrls.THKInvalidKey.

27.3.22 ComCtrls.THKModifier Enumeration

Pascal

```
THKModifier = (
  hkShift,
  hkCtrl,
  hkAlt,
  hkExt
);
```

C++

```
enum THKModifier {
  hkShift,
  hkCtrl,
  hkAlt,
  hkExt
```

```
};
```

File

ComCtrls

Description

This is record ComCtrls.THKModifier.

27.3.23 ComCtrls.TIconArrangement Enumeration

TIconArrangement indicates how the icons for items are arranged.

Pascal

```
TIconArrangement = (
  iaTop,
  iaLeft
);
```

C++

```
enum TIconArrangement {
  iaTop,
  iaLeft
};
```

File

ComCtrls

Description

These are the possible TIconArrangement values:

Value	Meaning
iaTop	Items are aligned left to right in rows at the top of the view control
iaLeft	Items are aligned in columns top to bottom at the left of the view control

27.3.24 ComCtrls.TItemChange Enumeration

TItemChange describes the type of change a list item undergoes.

Pascal

```
TItemChange = (
  ctText,
  ctImage,
  ctState
);
```

C++

```
enum TItemChange {
  ctText,
  ctImage,
  ctState
};
```

File

ComCtrls

Description

TItemChange can have one of the following values:

Value	Meaning
ctText	A change to the Caption property of the list item.
ctImage	A change to the list item's ImageIndex property or the list view's image list.
ctState	A change to the list item's

27.3.25 ComCtrls.TItemFind Enumeration

TItemFind identifies the type of search in an OnDataFind event handler.

Pascal

```
TItemFind = (
  ifData,
  ifPartialString,
  ifExactString,
  ifNearest
);
```

C++

```
enum TItemFind {
  ifData,
  ifPartialString,
  ifExactString,
  ifNearest
};
```

File

ComCtrls

Description

TItemFind can have one of the following values:

Value	Meaning
ifData	Search for matching Data.
ifPartialString	Search for a partial string match.
ifExactString	Search for an exact string match.
ifNearest	Search for the nearest match.

27.3.26 ComCtrls.TItemRequests Enumeration

Pascal

```
TItemRequests = (
  irText,
  irImage,
  irParam,
  irState,
  irIndent
);
```

C++

```
enum TItemRequests {
  irText,
  irImage,
  irParam,
  irState,
  irIndent
};
```

File

ComCtrls

Description

This is record ComCtrls.TItemRequests.

27.3.27 ComCtrls.TItemState Enumeration

TItemState and TItemStates (see page 5489) specify the state of an item in a list view control.

Pascal

```
TItemState = (
  isNone,
  isCut,
  isDropHilited,
  isFocused,
  isSelected,
```

```
  isActivating
);
```

C++

```
enum TItemState {
  isNone,
  isCut,
  isDropHilited,
  isFocused,
  isSelected,
  isActivating
};
```

File

ComCtrls

Description

TItemStates (see page 5489) is a set of TItemState values. TItemState indicates the state of an item in a list view. It can have any of the following values:

Value	Meaning
isNone	Item is in its default state
isCut	Item is cut (for cut and paste operation)
isDropHilited	Item is highlighted as a drag-and-drop target
isFocused	Item is focused
isSelected	Item is selected
isActivating	Item is active

27.3.28 ComCtrls.TListArrangement Enumeration

Pascal

```
TListArrangement = (
  arAlignBottom,
  arAlignLeft,
  arAlignRight,
  arAlignTop,
  arDefault,
  arSnapToGrid
);
```

C++

```
enum TListArrangement {
  arAlignBottom,
  arAlignLeft,
  arAlignRight,
  arAlignTop,
  arDefault,
  arSnapToGrid
};
```

File

ComCtrls

Description

This is record ComCtrls.TListArrangement.

27.3.29 ComCtrls.TListHotTrackStyle Enumeration

TListHotTrackStyle and TListHotTrackStyles (see page 5489) specify hot tracking styles for a list view control.

Pascal

```
TListHotTrackStyle = (
  htHandPoint,
  htUnderlineCold,
  htUnderlineHot
);
```

C++

```
enum TListHotTrackStyle {
  htHandPoint,
  htUnderlineCold,
  htUnderlineHot
};
```

File

ComCtrls

Description

TListHotTrackStyles (see page 5489) describes how hot tracking occurs in a list view control. It can have any of the following values:

Value	Meaning
htHandPoint	The mouse cursor turns into a hand.
htUnderlineCold	An underline is displayed under all untracked items.
htUnderlineHot	An underline is displayed under the tracked item.

27.3.30 ComCtrls.TMultiSelectStyles Enumeration

Pascal

```
TMultiSelectStyles = (
  msControlSelect,
  msShiftSelect,
  msVisibleOnly,
  msSiblingOnly
);
```

C++

```
enum TMultiSelectStyles {
  msControlSelect,
  msShiftSelect,
  msVisibleOnly,
  msSiblingOnly
};
```

File

ComCtrls

Description

This is record ComCtrls.TMultiSelectStyles.

27.3.31 ComCtrls.TNodeAttachMode Enumeration

TNodeAttachMode identifies a new or changed tree node relationship.

Pascal

```
TNodeAttachMode = (
  naAdd,
  naAddFirst,
  naAddChild,
  naAddChildFirst,
  naInsert
);
```

C++

```
enum TNodeAttachMode {
  naAdd,
  naAddFirst,
  naAddChild,
  naAddChildFirst,
  naInsert
};
```

File

ComCtrls

Description

The TNodeAttachMode type specifies the way a new or relocated tree node will be related to some other node.

Value	Meaning
naAdd	The new or relocated node becomes the last sibling of the other node.
naAddFirst	The new or relocated node becomes the first sibling of the other node.
naInsert	The new or relocated node becomes the sibling immediately before the other node.
naAddChild	The new or relocated node becomes the last child of the other node.
naAddChildFirst	The new or relocated node becomes the first child of the other node.

27.3.32 ComCtrls.TNodeCache Record

TNodeCache is the type for a cached tree-view node.

Pascal

```
TNodeCache = record
  CacheNode: TTreeNode;
  CacheIndex: Integer;
```

```
end;
```

C++

```
struct TNodeCache {
  TTreeNode CacheNode;
  int CacheIndex;
};
```

File

ComCtrls

Description

Use TNodeCache to cache a tree-view node.

27.3.33 ComCtrls.TNodeDataInfo Record

Pascal

```
TNodeDataInfo = packed record
  ImageIndex: Integer;
  SelectedIndex: Integer;
  StateIndex: Integer;
  OverlayIndex: Integer;
  Data: Pointer;
  Count: Integer;
  TextLen: Byte;
end;
```

C++

```
struct TNodeDataInfo {
  int ImageIndex;
  int SelectedIndex;
  int StateIndex;
  int OverlayIndex;
  void * Data;
  int Count;
  Byte TextLen;
};
```

File

ComCtrls

Description

This is record ComCtrls.TNodeDataInfo.

27.3.34 ComCtrls.TNodeInfo Record

Pascal

```
TNodeInfo = packed record
  ImageIndex: Integer;
  SelectedIndex: Integer;
  StateIndex: Integer;
  OverlayIndex: Integer;
  Data: Pointer;
  Count: Integer;
```

```
    Text: string[255];
  end;
```

C++

```
  struct TNodeInfo {
    int ImageIndex;
    int SelectedIndex;
    int StateIndex;
    int OverlayIndex;
    void * Data;
    int Count;
    string[255] Text;
  };
```

File

ComCtrls

Description

This is record ComCtrls.TNodeInfo.

27.3.35 ComCtrls.TNodeState Enumeration

Pascal

```
  TNodeState = (
    nsCut,
    nsDropHilited,
    nsFocused,
    nsSelected,
    nsExpanded
  );
```

C++

```
  enum TNodeState {
    nsCut,
    nsDropHilited,
    nsFocused,
    nsSelected,
    nsExpanded
  };
```

File

ComCtrls

Description

This is record ComCtrls.TNodeState.

27.3.36 ComCtrls.TNumberingStyle Enumeration

Pascal

```
  TNumberingStyle = (
    nsNone,
    nsBullet
  );
```

C++

```
enum TNumberingStyle {
  nsNone,
  nsBullet
};
```

File

ComCtrls

Description

This is record ComCtrls.TNumberingStyle.

27.3.37 ComCtrls.TPageScrollerButton Enumeration

TPageScrollerButton identifies a button on a page scroller.

Pascal

```
TPageScrollerButton = (
  sbFirst,
  sbLast
);
```

C++

```
enum TPageScrollerButton {
  sbFirst,
  sbLast
};
```

File

ComCtrls

Description

TPageScrollerButton has one of the following values:

Value	Meaning
sbFirst	The top button (vertical orientation) or the left button (horizontal orientation).
sbLast	The bottom button (vertical orientation) or the right button (horizontal orientation).

27.3.38 ComCtrls.TPageScrollerButtonState Enumeration

TPageScrollerButtonState indicates the state of a page scroller button.

Pascal

```
TPageScrollerButtonState = (
  bsNormal,
  bsInvisible,
  bsGrayed,
  bsDepressed,
  bsHot
);
```

C++

```
enum TPageScrollerButtonState {
  bsNormal,
  bsInvisible,
  bsGrayed,
  bsDepressed,
  bsHot
};
```

File

ComCtrls

Description

TPageScrollerButtonState has one of the following values:

Value	Meaning
bsNormal	The button is in normal state.
bsInvisible	The button is not visible.
bsGrayed	The button is grayed.
bsDepressed	The button is pressed.
bsHot	The button is hot (the mouse is hovering over the button).

27.3.39 ComCtrls.TPageScrollerOrientation Enumeration

TPageScrollerOrientation indicates the orientation of a page scroller control.

Pascal

```
TPageScrollerOrientation = (
  soHorizontal,
  soVertical
);
```

C++

```
enum TPageScrollerOrientation {
  soHorizontal,
  soVertical
};
```

File

ComCtrls

Description

TPageScrollerOrientation has one of the following values:

Value	Meaning
soHorizontal	The page scroller is oriented horizontally.
soVertical	The page scroller is oriented vertically.

27.3.40 ComCtrls.TPositionToolTip Enumeration

Specifies the position of the tool tip.

Pascal

```
TPositionToolTip = (
  ptNone,
  ptTop,
  ptLeft,
  ptBottom,
  ptRight
);
```

C++

```
enum TPositionToolTip {
  ptNone,
  ptTop,
  ptLeft,
  ptBottom,
  ptRight
};
```

File

ComCtrls

Description

Set the position of the tool tip to one of the following values:

- ptNone
- ptTop
- ptLeft
- ptBottom
- ptRight

27.3.41 ComCtrls.TProgressBarOrientation Enumeration

TProgressBarOrientation specifies the orientation of a progress bar.

Pascal

```
TProgressBarOrientation = (
  pbHorizontal,
  pbVertical
);
```

C++

```
enum TProgressBarOrientation {
  pbHorizontal,
  pbVertical
};
```

File

ComCtrls

Description

TProgressBarOrientation has one of the following values:

Value	Meaning
pbHorizontal	The progress bar is oriented horizontally.
pbVertical	The progress bar is oriented vertically.

See Also

TProgressBar

27.3.42 ComCtrls.TRichEditStreamInfo Record

Pascal

```
TRichEditStreamInfo = record
  Converter: TConversion;
  Stream: TStream;
end;
```

C++

```
struct TRichEditStreamInfo {
  TConversion Converter;
  TStream Stream;
};
```

File

ComCtrls

Description

This is record ComCtrls.TRichEditStreamInfo.

27.3.43 ComCtrls.TSearchDirection Enumeration

Indicates the direction in which to search for the nearest item to a specified item or point.

Pascal

```
TSearchDirection = (
  sdLeft,
  sdRight,
  sdAbove,
  sdBelow,
  sdAll
);
```

C++

```
enum TSearchDirection {
  sdLeft,
  sdRight,
  sdAbove,
  sdBelow,
  sdAll
```

```
};
```

File

ComCtrls

Description

TSearchDirection defines the following search directions:

Value	Meaning
sdLeft	Look to the left of a specified item.
sdRight	Look to the right of a specified item.
sdAbove	Look above a specified item.
sdBelow	Look below a specified item.
sdAll	Look in the order that items appear in the Items property.

27.3.44 ComCtrls.TSearchType Enumeration

Specifies search options.

Pascal

```
TSearchType = (
  stWholeWord,
  stMatchCase
);
```

C++

```
enum TSearchType {
  stWholeWord,
  stMatchCase
};
```

File

ComCtrls

Description

The available options are shown in the following table.

Option	Description
stWholeWord	Specifies that the search should find the whole word only, rather than picking out partial search results. For example, if you search for *foo* with this options set, the search result would not include *foobar*.
stMatchCase	Specifies that the search results must match the letter casing of the search term.

27.3.45 ComCtrls.TSectionTrackState Enumeration

Pascal

```
TSectionTrackState = (
  tsTrackBegin,
```

```
    tsTrackMove,
    tsTrackEnd
  );
```

C++

```
  enum TSectionTrackState {
    tsTrackBegin,
    tsTrackMove,
    tsTrackEnd
  };
```

File

ComCtrls

Description

This is record ComCtrls.TSectionTrackState.

27.3.46 ComCtrls.TSortType Enumeration

TSortType indicates the criteria to use when sorting items.

Pascal

```
  TSortType = (
    stNone,
    stData,
    stText,
    stBoth
  );
```

C++

```
  enum TSortType {
    stNone,
    stData,
    stText,
    stBoth
  };
```

File

ComCtrls

Description

Value	Meaning
stNone	No sorting is done.
stData	Items are sorted based on their Data property. An event handler must be provided to compare Data values.
stText	Items are sorted based on their Caption property.
stBoth	Items are sorted based on both the Data and Caption. The Data values are ignored unless an event handler is provided to compare them.

27.3.47 ComCtrls.TStatusPanelBevel Enumeration

TStatusPanelBevel indicates the type of bevel around a panel in a status bar.

Pascal

```
TStatusPanelBevel = (
  pbNone,
  pbLowered,
  pbRaised
);
```

C++

```
enum TStatusPanelBevel {
  pbNone,
  pbLowered,
  pbRaised
};
```

File

ComCtrls

Description

These are the possible TStatusPanelBevel values:

Value	Meaning
pbNone	The panel has no bevel and appears flat.
pbLowered	The panel appears recessed.
pbRaised	The panel appears raised.

27.3.48 ComCtrls.TStatusPanelStyle Enumeration

TStatusPanelStyle indicates the kind of contents in a status bar panel.

Pascal

```
TStatusPanelStyle = (
  psText,
  psOwnerDraw
);
```

C++

```
enum TStatusPanelStyle {
  psText,
  psOwnerDraw
};
```

File

ComCtrls

Description

TStatusPanelStyle enumerates the possible values of the Style property in TStatusPanel (see page 4825):

Value	Meaning
psText	The panel shows the value of the Text property
psOwnerDraw	The panel is drawn by the OnDrawPanel (TStatusBar (see page 4769)) event handler.

See Also

TStatusPanel

TStatusPanel

TStatusBar

27.3.49 ComCtrls.TTabPosition Enumeration

Pascal

```
TTabPosition = (
  tpTop,
  tpBottom,
  tpLeft,
  tpRight
);
```

C++

```
enum TTabPosition {
  tpTop,
  tpBottom,
  tpLeft,
  tpRight
};
```

File

ComCtrls

Description

This is record ComCtrls.TTabPosition.

27.3.50 ComCtrls.TTabStyle Enumeration

TTabStyle indicates whether a TTabSet control is owner-drawn.

Pascal

```
TTabStyle = (
  tsTabs,
  tsButtons,
  tsFlatButtons
);
```

C++

```
enum TTabStyle {
  tsTabs,
  tsButtons,
  tsFlatButtons
```

```
};
```

File

ComCtrls

Description

These are the possible values:

Value	Meaning
tsStandard	Each tab has the standard size and look.
tsOwnerDraw	Each tab has the height specified with the TabHeight property and width needed to hold the text or glyph.

27.3.51 ComCtrls.TTBDrawingStyle Enumeration

Specifies the drawing style for the tool bar.

Pascal

```
TTBDrawingStyle = (
  dsNormal,
  dsGradient
);
```

C++

```
enum TTBDrawingStyle {
  dsNormal,
  dsGradient
};
```

File

ComCtrls

Description

This type allows you to specify one of the following values:

- dsNormal
- dsGradient

27.3.52 ComCtrls.TTickMark Enumeration

TTickMark indicates the location of the tick marks on a track bar.

Pascal

```
TTickMark = (
  tmBottomRight,
  tmTopLeft,
  tmBoth
);
```

C++

```
enum TTickMark {
```

```
  tmBottomRight,
  tmTopLeft,
  tmBoth
};
```

File

ComCtrls

Description

These are the possible values of TTickMark:

Value	Meaning
tmBottomRight	Tick marks are on the bottom or right of the track bar, depending of the value of Orientation.
tmTopLeft	Tick marks are on the top or left of the track bar, depending of the value of Orientation.
tmBoth	Tick marks are on both sides of the track bar.

27.3.53 ComCtrls.TTickStyle Enumeration

TTickStyle indicates how a track bar determines the increments at which tick marks appear.

Pascal

```
TTickStyle = (
  tsNone,
  tsAuto,
  tsManual
);
```

C++

```
enum TTickStyle {
  tsNone,
  tsAuto,
  tsManual
};
```

File

ComCtrls

Description

TTickStyle has these possible values:

Value	Meaning
tsAuto	Tick marks are automatically displayed at increments equal to the value of the Frequency property.
tsManual	Tick marks are displayed at the Min and Max values. Additional tick marks can be set using the SetTick method.
tsNone	No tick marks are displayed.

27.3.54 ComCtrls.TToolButtonState Enumeration

Pascal

```
TToolButtonState = (
  tbsChecked,
  tbsPressed,
  tbsEnabled,
  tbsHidden,
  tbsIndeterminate,
  tbsWrap,
  tbsEllipses,
  tbsMarked
);
```

C++

```
enum TToolButtonState {
  tbsChecked,
  tbsPressed,
  tbsEnabled,
  tbsHidden,
  tbsIndeterminate,
  tbsWrap,
  tbsEllipses,
  tbsMarked
};
```

File

ComCtrls

Description

This is record ComCtrls.TToolButtonState.

27.3.55 ComCtrls.TToolButtonStyle Enumeration

TToolButtonStyle indicates the type of control a TToolButton (see page 5107) object represents.

Pascal

```
TToolButtonStyle = (
  tbsButton,
  tbsCheck,
  tbsDropDown,
  tbsSeparator,
  tbsDivider,
  tbsTextButton
);
```

C++

```
enum TToolButtonStyle {
  tbsButton,
  tbsCheck,
  tbsDropDown,
  tbsSeparator,
  tbsDivider,
  tbsTextButton
};
```

File

ComCtrls

Description

These are the possible values of TToolButtonStyle:

Value	Meaning
tbsButton	The button appears and functions like a normal speed button.
tbsCheck	Clicking the button toggles the Down property. Once selected, the button remains selected until clicked again.
tbsDropDown	The button displays a downward-pointing arrow (suitable for accessing a drop-down menu).
tbsSeparator	The button appears as an empty space on the toolbar (used to separate other controls).
tbsDivider	The button appears as a vertical line on the toolbar (used to separate other controls).

27.3.56 ComCtrls.TTrackBarOrientation Enumeration

TTrackBarOrientation indicates whether a trackbar is horizontal or vertical.

Pascal

```
TTrackBarOrientation = (
  trHorizontal,
  trVertical
);
```

C++

```
enum TTrackBarOrientation {
  trHorizontal,
  trVertical
};
```

File

ComCtrls

Description

These are the possible values of TTrackBarOrientation:

Value	Meaning
trHorizontal	The long edge of the track is parallel to the top of the form. The Min position is on the left and the Max position is on the right.
trVertical	The long edge of the track is parallel to the side of the form. The Min position is on the top and the Max position is on the bottom.

27.3.57 ComCtrls.TUDAlignButton Enumeration

Pascal

```
TUDAlignButton = (
```

```
    udLeft,
    udRight
  );
```

C++

```
  enum TUDAlignButton {
    udLeft,
    udRight
  };
```

File

ComCtrls

Description

This is record ComCtrls.TUDAlignButton.

27.3.58 ComCtrls.TUDBtnType Enumeration

Pascal

```
  TUDBtnType = (
    btNext,
    btPrev
  );
```

C++

```
  enum TUDBtnType {
    btNext,
    btPrev
  };
```

File

ComCtrls

Description

This is record ComCtrls.TUDBtnType.

27.3.59 ComCtrls.TUDOrientation Enumeration

Pascal

```
  TUDOrientation = (
    udHorizontal,
    udVertical
  );
```

C++

```
  enum TUDOrientation {
    udHorizontal,
    udVertical
  };
```

File

ComCtrls

Description

This is record ComCtrls.TUDOrientation.

27.3.60 ComCtrls.TUpDownDirection Enumeration

TUpDownDirection indicates the direction in which the position of an updown control changes.

Pascal

```
TUpDownDirection = (
  updNone,
  updUp,
  updDown
);
```

C++

```
enum TUpDownDirection {
  updNone,
  updUp,
  updDown
};
```

File

ComCtrls

Description

The following table lists the possible values:

Value	Description
updNone	The position is changing to an illegal value (less than the minimum value or greater than the maximum value).
updUp	The position is increasing.
updDown	The position is decreasing.

27.3.61 ComCtrls.TViewStyle Enumeration

TViewStyle indicates how a list view control displays its items.

Pascal

```
TViewStyle = (
  vsIcon,
  vsSmallIcon,
  vsList,
  vsReport
);
```

C++

```
enum TViewStyle {
  vsIcon,
  vsSmallIcon,
  vsList,
```

```
  vsReport
};
```

File

ComCtrls

Description

TViewStyle can have one of the following values:

Value	Meaning
vsIcon	Each item appears as a full-sized icon with a label below it. The user can drag the items to any location in the list view window.
vsSmallIcon	Each item appears as a small icon with the label to the right of it. The user can drag the items to any location.
vsList	Each item appears as a small icon with a label to the right of it. Items are arranged in columns and cannot be dragged by the user.
vsReport	Each item appears on its own line with information arranged in columns. The leftmost column contains the small icon and label, and subsequent columns contain subitems as specified by the application. Unless ShowColumnHeaders is false, each column has a header.

C++ Examples:

```
/*
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {"C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {"Documentation for the C++ icon.", "Borland icon.", "Delphi
icon."};
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  // Add View styles and constants to the Combo Box
```

```
  ComboBox1->Items->AddObject("vsIcon", (TObject *)vsIcon);
  ComboBox1->Items->AddObject("vsList", (TObject *)vsList);
  ComboBox1->Items->AddObject("vsReport", (TObject *)vsReport);
  ComboBox1->Items->AddObject("vsSmallIcon", (TObject *)vsSmallIcon);
  // Display first item in the Combo Box
  ComboBox1->ItemIndex = 0;
}

void __fastcall TForm1::ComboBox1Click(TObject *Sender)
{
  ListView1->ViewStyle = (TViewStyle) ComboBox1->Items->Objects[ComboBox1->ItemIndex];
}
```

Delphi Examples:

```
{
This example requires a TListView, a TImageList and a
TComboBox. You will need to double click the image list and
add several images to the image list prior to running the
project. You can use *.bmp or *.ico files from the
\Images\Icons directory. During the form's OnCreate event
handler, items for the List View control are created for
each image in the Image List and the ImageIndex is assigned
the number of the image within the ImageList. Two columns are
created so that when ViewStyle is vsReport, you will have
columns to view.  Also within the form's OnCreate event
handler assign the ComboBox each of the four TViewStyle
constants to the Items' Objects property. You could also
simply code this within a series of OnClick event handlers
as, for instance, ListView1.->ViewStyle := vsIcon.
}

procedure TComboForm.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
begin
  Col2Array[0]:= 'Documentation for Image0.';
  Col2Array[1]:= 'Documentation for Image1.';
  Col2Array[2]:= 'Documentation for Image2.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
    LargeImages := ImageList1;
    for I := 0 to ImageList1.Count - 1 do
    begin
      ListItem := Items.Add;
      Listitem.Caption := 'Image' + IntToStr(I);
      ListItem.ImageIndex := I;
      Listitem.SubItems.Add(Col2Array[I]);
    end;
    // Create two columns to show during viewing as vsReport
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 1';
    NewColumn.Width := 200;
    NewColumn := Columns.Add;
    NewColumn.Caption := 'Column 2';
    NewColumn.Width := 200;
    // Add View styles and constants to the Combo Box
    ComboBox1.Items.AddObject('vsIcon', TObject(vsIcon));
    ComboBox1.Items.AddObject('vsList', TObject(vsList));
    ComboBox1.Items.AddObject('vsReport', TObject(vsReport));
    ComboBox1.Items.AddObject(
      'vsSmallIcon', TObject(vsSmallIcon));
    // Display first item in the Combo Box
```

```
      ComboBox1.ItemIndex := 0;
    end;
  end;

  procedure TComboForm.ComboBox1Click(Sender: TObject);
  begin
    with ComboBox1 do
      ListView1.ViewStyle := TViewStyle(Items.Objects[ItemIndex]);

  end;
```

27.4 Types

The following table lists types in this documentation.

Types

Name	Description
PConversionFormat (see page 5479)	This is type ComCtrls.PConversionFormat.
PNodeCache (see page 5479)	PNodeCache is a pointer to a TNodeCache (see page 5457) object.
PNodeInfo (see page 5480)	This is type ComCtrls.PNodeInfo.
PRichEditStreamInfo (see page 5480)	This is type ComCtrls.PRichEditStreamInfo.
TAutoCompleteOptions (see page 5480)	TAutoCompleteOptions specify options that control autocompletion.
TComboBoxExStyles (see page 5481)	TComboBoxExStyles is the type for the Style property of extended combo box controls.
TComboExItemClass (see page 5481)	This is type ComCtrls.TComboExItemClass.
TComboExItemsClass (see page 5482)	This is type ComCtrls.TComboExItemsClass.
TConsistentAttributes (see page 5482)	This is type ComCtrls.TConsistentAttributes.
TConversionClass (see page 5482)	This is type ComCtrls.TConversionClass.
TCustomDrawPanelEvent (see page 5483)	TCustomDrawPanelEvent is the type of the OnDrawPanel event handler.
TCustomDrawSectionEvent (see page 5483)	This is type ComCtrls.TCustomDrawSectionEvent.
TCustomDrawState (see page 5483)	TCustomDrawState specifies a custom drawing state.
TCustomHCCreateSectionClassEvent (see page 5484)	This is type ComCtrls.TCustomHCCreateSectionClassEvent.
TCustomSectionNotifyEvent (see page 5484)	This is type ComCtrls.TCustomSectionNotifyEvent.
TCustomSectionTrackEvent (see page 5485)	This is type ComCtrls.TCustomSectionTrackEvent.
TDateTimeColors (see page 5485)	TDateTimeColors specifies colors used in a calendar control.
TDrawPanelEvent (see page 5485)	This is type ComCtrls.TDrawPanelEvent.
TDrawSectionEvent (see page 5486)	This is type ComCtrls.TDrawSectionEvent.
TDrawTabEvent (see page 5486)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet control.
TDTParseInputEvent (see page 5487)	This is type ComCtrls.TDTParseInputEvent.
THCCreateSectionClassEvent (see page 5487)	This is type ComCtrls.THCCreateSectionClassEvent.
THeaderSectionClass (see page 5487)	This is type ComCtrls.THeaderSectionClass.
THitTests (see page 5488)	This is type ComCtrls.THitTests.
THKInvalidKeys (see page 5488)	This is type ComCtrls.THKInvalidKeys.
THKModifiers (see page 5488)	This is type ComCtrls.THKModifiers.
TItemRequest (see page 5489)	This is type ComCtrls.TItemRequest.
TItemStates (see page 5489)	TItemState (see page 5454) and TItemStates specify the state of an item in a list view control.
TListHotTrackStyles (see page 5489)	TListHotTrackStyle (see page 5456) and TListHotTrackStyles specify hot tracking styles for a list view control.
TListItemClass (see page 5490)	This is type ComCtrls.TListItemClass.
TLVAdvancedCustomDrawEvent (see page 5490)	This is type ComCtrls.TLVAdvancedCustomDrawEvent.
TLVAdvancedCustomDrawItemEvent (see page 5491)	This is type ComCtrls.TLVAdvancedCustomDrawItemEvent.
TLVAdvancedCustomDrawSubItemEvent (see page 5491)	This is type ComCtrls.TLVAdvancedCustomDrawSubItemEvent.
TLVChangeEvent (see page 5491)	This is type ComCtrls.TLVChangeEvent.
TLVChangingEvent (see page 5492)	This is type ComCtrls.TLVChangingEvent.
TLVColumnClickEvent (see page 5492)	This is type ComCtrls.TLVColumnClickEvent.
TLVColumnRClickEvent (see page 5492)	This is type ComCtrls.TLVColumnRClickEvent.
TLVCompareEvent (see page 5493)	This is type ComCtrls.TLVCompareEvent.
TLVCreateItemClassEvent (see page 5493)	This is type ComCtrls.TLVCreateItemClassEvent.
TLVCustomDrawEvent (see page 5493)	This is type ComCtrls.TLVCustomDrawEvent.
TLVCustomDrawItemEvent (see page 5494)	This is type ComCtrls.TLVCustomDrawItemEvent.
TLVCustomDrawSubItemEvent (see page 5494)	This is type ComCtrls.TLVCustomDrawSubItemEvent.

TLVDeletedEvent (see page 5494)	TLVDeletedEvent is the type of a list view's OnDeletion event handler.
TLVDrawItemEvent (see page 5495)	TLVDrawItemEvent is the type of the list view OnCustomDrawItem and OnDrawItem event handlers.
TLVEditedEvent (see page 5495)	This is type ComCtrls.TLVEditedEvent.
TLVEditingEvent (see page 5496)	This is type ComCtrls.TLVEditingEvent.
TLVInfoTipEvent (see page 5496)	This is type ComCtrls.TLVInfoTipEvent.
TLVNotifyEvent (see page 5496)	This is type ComCtrls.TLVNotifyEvent.
TLVOwnerDataEvent (see page 5497)	TLVOwnerDataEvent is the type of a list view's OnData event handler.
TLVOwnerDataFindEvent (see page 5497)	TLVOwnerDataFindEvent is the type of a list view's OnDataFind event handler.
TLVOwnerDataHintEvent (see page 5498)	TLVOwnerDataHintEvent is the type of a list view's OnDataHint event handler.
TLVOwnerDataStateChangeEvent (see page 5498)	TLVOwnerDataStateChangeEvent is the type of a list view's OnDataStateChange event handler.
TLVSelectItemEvent (see page 5499)	This is type ComCtrls.TLVSelectItemEvent.
TLVSubItemImageEvent (see page 5499)	This is type ComCtrls.TLVSubItemImageEvent.
TMultiSelectStyle (see page 5499)	This is type ComCtrls.TMultiSelectStyle.
TOnGetMonthInfoEvent (see page 5500)	TOnGetMonthInfoEvent is the type of the TCommonCalendar.OnGetMonthInfo event handler.
TOwnerDrawState (see page 5500)	Indicates state information that can influence how an item is drawn.
TPageScrollEvent (see page 5501)	TPageScrollEvent is the type of a page scroller's OnScroll event handler.
TProgressRange (see page 5502)	This is type ComCtrls.TProgressRange.
TRichEditProtectChange (see page 5502)	This is type ComCtrls.TRichEditProtectChange.
TRichEditResizeEvent (see page 5502)	This is type ComCtrls.TRichEditResizeEvent.
TRichEditSaveClipboard (see page 5503)	This is type ComCtrls.TRichEditSaveClipboard.
TSBCreatePanelClassEvent (see page 5503)	TSBCreatePanelClassEvent is the type of the OnCreatePanelClass event handler.
TSearchTypes (see page 5503)	Set of TSearchType (see page 5464).
TSectionDragEvent (see page 5505)	TSectionDragEvent is the type for event handlers that respond when the user drags a section in a header control.
TSectionNotifyEvent (see page 5506)	This is type ComCtrls.TSectionNotifyEvent.
TSectionTrackEvent (see page 5506)	This is type ComCtrls.TSectionTrackEvent.
TStatusPanelClass (see page 5507)	TStatusPanelClass defines the metaclass for TStatusPanel (see page 4825).
TTabChangingEvent (see page 5507)	This is type ComCtrls.TTabChangingEvent.
TTabGetImageEvent (see page 5507)	This is type ComCtrls.TTabGetImageEvent.
TTBAdvancedCustomDrawBtnEvent (see page 5508)	This is type ComCtrls.TTBAdvancedCustomDrawBtnEvent.
TTBAdvancedCustomDrawEvent (see page 5508)	This is type ComCtrls.TTBAdvancedCustomDrawEvent.
TTBButtonEvent (see page 5508)	TTBButtonEvent is the type of event handlers that respond when the user adds or deletes a tool button in the toolbar customize dialog.
TTBCustomDrawBtnEvent (see page 5509)	This is type ComCtrls.TTBCustomDrawBtnEvent.
TTBCustomDrawEvent (see page 5509)	This is type ComCtrls.TTBCustomDrawEvent.
TTBCustomDrawFlags (see page 5509)	TTBCustomDrawFlags is the type of the OnAdvancedCustomDrawButton event handler.
TTBCustomizeQueryEvent (see page 5510)	TTBCustomizeQueryEvent is the type of event handlers that allow a toolbar to decide whether to allow a user customization.
TTBGradientDrawingOptions (see page 5511)	Specifies the style of the gradient.
TTBNewButtonEvent (see page 5511)	This is type ComCtrls.TTBNewButtonEvent.
TToolButtonActionLinkClass (see page 5511)	This is type ComCtrls.TToolButtonActionLinkClass.
TTreeNodeClass (see page 5512)	This is type ComCtrls.TTreeNodeClass.
TTVAdvancedCustomDrawEvent (see page 5512)	Used in the TCustomTreeView.OnAdvancedCustomDraw event.
TTVAdvancedCustomDrawItemEvent (see page 5513)	Used in the TCustomTreeView.OnAdvancedCustomDrawItem event.
TTVChangedEvent (see page 5513)	Used in the TCustomTreeView.OnChange event.
TTVChangingEvent (see page 5514)	Used in the TCustomTreeView.OnChanging event.
TTVCollapsingEvent (see page 5514)	Used in the TCustomTreeView.OnCollapsing event.
TTVCompareEvent (see page 5515)	Used in the TCustomTreeView.OnCompare event.
TTVCreateNodeClassEvent (see page 5516)	This is type ComCtrls.TTVCreateNodeClassEvent.
TTVCustomDrawEvent (see page 5516)	Used in the TCustomTreeView.OnCustomDraw event.
TTVCustomDrawItemEvent (see page 5516)	Used in the TCustomTreeView.OnCustomDrawItem event.
TTVEditedEvent (see page 5517)	Used in the TCustomTreeView.OnEdited event.

TTVEditingEvent (see page 5518)	Used in the TCustomTreeView.OnEditing event.
TTVExpandedEvent (see page 5518)	Represents the event handler for events that notify a tree view of changes to one of its nodes.
TTVExpandingEvent (see page 5519)	Used in the TCustomTreeView.OnExpanding event.
TUDChangingEvent (see page 5519)	This is type ComCtrls.TUDChangingEvent.
TUDChangingEventEx (see page 5520)	This is type ComCtrls.TUDChangingEventEx.
TUDClickEvent (see page 5520)	This is type ComCtrls.TUDClickEvent.
TWidth (see page 5520)	This is type ComCtrls.TWidth.

27.4.1 ComCtrls.PConversionFormat Type

Pascal

```
PConversionFormat = ^TConversionFormat;
```

C++

```
^TConversionFormat PConversionFormat;
```

File

ComCtrls

Description

This is type ComCtrls.PConversionFormat.

27.4.2 ComCtrls.PNodeCache Type

PNodeCache is a pointer to a TNodeCache (see page 5457) object.

Pascal

```
PNodeCache = ^TNodeCache;
```

C++

```
^TNodeCache PNodeCache;
```

File

ComCtrls

Description

PNodeCache is a pointer to a cached node of an instance of the TTreeView (see page 5293) class defined in the ComCtrls (see page 3413) unit.

See Also

TTreeView

TTreeNodes

27.4.3 ComCtrls.PNodeInfo Type

Pascal

```
PNodeInfo = ^TNodeInfo;
```

C++

```
^TNodeInfo PNodeInfo;
```

File

ComCtrls

Description

This is type ComCtrls.PNodeInfo.

27.4.4 ComCtrls.PRichEditStreamInfo Type

Pascal

```
PRichEditStreamInfo = ^TRichEditStreamInfo;
```

C++

```
^TRichEditStreamInfo PRichEditStreamInfo;
```

File

ComCtrls

Description

This is type ComCtrls.PRichEditStreamInfo.

27.4.5 ComCtrls.TAutoCompleteOptions Type

TAutoCompleteOptions specify options that control autocompletion.

Pascal

```
TAutoCompleteOptions = set of TAutoCompleteOption;
```

C++

```
TAutoCompleteOption TAutoCompleteOptions;
```

File

ComCtrls

Description

TAutoCompleteOptions defines options for controls that support autocompletion. These are:

Value	Meaning
acoAutoSuggest	Enable the autosuggest drop-down list.

acoAutoAppend	Enable autoappend.
acoSearch	Add a search item to the list of completed strings. Selecting this item launches a search engine.
acoFilterPrefixes	Don't match common prefixes, such as "www." and "http://".
acoUseTab	Use the tab key to select items.
acoUpDownKeyDropsList	Use up and down arrow keys to display suggestion list.
acoRtlReading	Text direction is opposite of parent.

27.4.6 ComCtrls.TComboBoxExStyles Type

TComboBoxExStyles is the type for the Style property of extended combo box controls.

Pascal

```
TComboBoxExStyles = set of TComboBoxExStyleEx;
```

C++

```
TComboBoxExStyleEx TComboBoxExStyles;
```

File

ComCtrls

Description

These are the values in the TComboBoxExStyles type:

Value	Meaning
csExDropDown	Creates a drop-down list with an edit box for manually entered text.
csExSimple	Creates an edit box with a fixed list (list box) underneath. The length of the list is determined by the Height of the combo box.
csExDropDownList	Creates a drop-down list with no edit box; the user cannot enter text manually.

27.4.7 ComCtrls.TComboExItemClass Type

Pascal

```
TComboExItemClass = class of TComboExItem;
```

C++

```
TComboExItem TComboExItemClass;
```

File

ComCtrls

Description

This is type ComCtrls.TComboExItemClass.

27.4.8 ComCtrls.TComboExItemsClass Type

Pascal

```
TComboExItemsClass = class of TComboExItems;
```

C++

```
TComboExItems TComboExItemsClass;
```

File

ComCtrls

Description

This is type ComCtrls.TComboExItemsClass.

27.4.9 ComCtrls.TConsistentAttributes Type

Pascal

```
TConsistentAttributes = set of TConsistentAttribute;
```

C++

```
TConsistentAttribute TConsistentAttributes;
```

File

ComCtrls

Description

This is type ComCtrls.TConsistentAttributes.

27.4.10 ComCtrls.TConversionClass Type

Pascal

```
TConversionClass = class of TConversion;
```

C++

```
TConversion TConversionClass;
```

File

ComCtrls

Description

This is type ComCtrls.TConversionClass.

27.4.11 ComCtrls.TCustomDrawPanelEvent Type

TCustomDrawPanelEvent is the type of the OnDrawPanel event handler.

Pascal

```
TCustomDrawPanelEvent = procedure (StatusBar: TCustomStatusBar; Panel: TStatusPanel; const
Rect: TRect) of object;
```

C++

```
(StatusBar: TCustomStatusBar; Panel: TStatusPanel; const Rect: TRect) (
TCustomDrawPanelEvent)();
```

File

ComCtrls

Description

StatusBar is the status bar object that contains the panel.

Panel is the panel that needs to be redrawn.

Rect gives the (new) dimensions of the status panel.

27.4.12 ComCtrls.TCustomDrawSectionEvent Type

Pascal

```
TCustomDrawSectionEvent = procedure (HeaderControl: TCustomHeaderControl; Section:
THeaderSection; const Rect: TRect; Pressed: Boolean) of object;
```

C++

```
(HeaderControl: TCustomHeaderControl; Section: THeaderSection; const Rect: TRect; Pressed:
Boolean) ( TCustomDrawSectionEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TCustomDrawSectionEvent.

27.4.13 ComCtrls.TCustomDrawState Type

TCustomDrawState specifies a custom drawing state.

Pascal

```
TCustomDrawState = set of (cdsSelected, cdsGrayed, cdsDisabled, cdsChecked, cdsFocused,
cdsDefault, cdsHot, cdsMarked, cdsIndeterminate);
```

C++

```
(cdsSelected, cdsGrayed, cdsDisabled, cdsChecked, cdsFocused, cdsDefault, cdsHot, cdsMarked,
```

```
cdsIndeterminate) TCustomDrawState;
```

File

ComCtrls

Description

TCustomDrawState indicates state information that can affect how a control is drawn. It includes a set drawn from the following values:

Value	Meaning
cdsSelected	The control or item is selected.
cdsGrayed	The control or item should appear grayed.
cdsDisabled	The control or item is disabled.
cdsChecked	The item should appear checked.
cdsFocused	The control or item has input focus.
cdsDefault	The item is the default item.
cdsHot	The item is under the mouse and the HotTrack property is True.
cdsMarked	The item is marked (marked items appear shaded by default).
cdsIndeterminate	The item is neither selected nor unselected.

27.4.14 ComCtrls.TCustomHCCreateSectionClassEvent Type

Pascal

```
TCustomHCCreateSectionClassEvent = procedure (Sender: TCustomHeaderControl; var SectionClass:
THeaderSectionClass) of object;
```

C++

```
(Sender: TCustomHeaderControl; var SectionClass: THeaderSectionClass) (
TCustomHCCreateSectionClassEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TCustomHCCreateSectionClassEvent.

27.4.15 ComCtrls.TCustomSectionNotifyEvent Type

Pascal

```
TCustomSectionNotifyEvent = procedure (HeaderControl: TCustomHeaderControl; Section:
THeaderSection) of object;
```

C++

```
(HeaderControl: TCustomHeaderControl; Section: THeaderSection) ( TCustomSectionNotifyEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TCustomSectionNotifyEvent.

27.4.16 ComCtrls.TCustomSectionTrackEvent Type

Pascal

```
TCustomSectionTrackEvent = procedure (HeaderControl: TCustomHeaderControl; Section:
THeaderSection; Width: Integer; State: TSectionTrackState) of object;
```

C++

```
(HeaderControl: TCustomHeaderControl; Section: THeaderSection; Width: Integer; State:
TSectionTrackState) ( TCustomSectionTrackEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TCustomSectionTrackEvent.

27.4.17 ComCtrls.TDateTimeColors Type

TDateTimeColors specifies colors used in a calendar control.

Pascal

```
TDateTimeColors = TMonthCalColors;
```

C++

```
TMonthCalColors TDateTimeColors;
```

File

ComCtrls

Description

TDateTimeColors is provided for backward compatibility on the TDateTimePicker (see page 4049) object.

See Also

TdateTimepicker

27.4.18 ComCtrls.TDrawPanelEvent Type

Pascal

```
TDrawPanelEvent = procedure (StatusBar: TStatusBar; Panel: TStatusPanel; const Rect: TRect) of
object;
```

C++

```
(StatusBar: TStatusBar; Panel: TStatusPanel; const Rect: TRect) ( TDrawPanelEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TDrawPanelEvent.

27.4.19 ComCtrls.TDrawSectionEvent Type

Pascal

```
TDrawSectionEvent = procedure (HeaderControl: THeaderControl; Section: THeaderSection; const
Rect: TRect; Pressed: Boolean) of object;
```

C++

```
(HeaderControl: THeaderControl; Section: THeaderSection; const Rect: TRect; Pressed: Boolean)
( TDrawSectionEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TDrawSectionEvent.

27.4.20 ComCtrls.TDrawTabEvent Type

TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet control.

Pascal

```
TDrawTabEvent = procedure (Control: TCustomTabControl; TabIndex: Integer; const Rect: TRect;
Active: Boolean) of object;
```

C++

```
(Control: TCustomTabControl; TabIndex: Integer; const Rect: TRect; Active: Boolean) (
TDrawTabEvent)();
```

File

ComCtrls

Description

Control is the tab control on which a tab is to be drawn.

TabIndex is the position of the tab that is to be drawn.

Rect is the area in which the tab is to be drawn.

Active indicates whether the tab is active.

Note: The TDrawTabEvent type defined in the tabs unit for the OnDrawTab event handler differs from the TDrawTabEvent type defined in the comctrls unit. Do not use the comctrls unit in source files where you are working with the tab control.

27.4.21 ComCtrls.TDTParseInputEvent Type

Pascal

```
TDTParseInputEvent = procedure (Sender: TObject; const UserString: string; var DateAndTime:
TDateTime; var AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; const UserString: string; var DateAndTime: TDateTime; var AllowChange:
Boolean) ( TDTParseInputEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TDTParseInputEvent.

27.4.22 ComCtrls.THCCreateSectionClassEvent Type

Pascal

```
THCCreateSectionClassEvent = procedure (Sender: THeaderControl; var SectionClass:
THeaderSectionClass) of object;
```

C++

```
(Sender: THeaderControl; var SectionClass: THeaderSectionClass) (
THCCreateSectionClassEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.THCCreateSectionClassEvent.

27.4.23 ComCtrls.THeaderSectionClass Type

Pascal

```
THeaderSectionClass = class of THeaderSection;
```

C++

```
THeaderSection THeaderSectionClass;
```

File

ComCtrls

Description

This is type ComCtrls.THeaderSectionClass.

27.4.24 ComCtrls.THitTests Type

Pascal

```
THitTests = set of THitTest;
```

C++

```
THitTest THitTests;
```

File

ComCtrls

Description

This is type ComCtrls.THitTests.

27.4.25 ComCtrls.THKInvalidKeys Type

Pascal

```
THKInvalidKeys = set of THKInvalidKey;
```

C++

```
THKInvalidKey THKInvalidKeys;
```

File

ComCtrls

Description

This is type ComCtrls.THKInvalidKeys.

27.4.26 ComCtrls.THKModifiers Type

Pascal

```
THKModifiers = set of THKModifier;
```

C++

```
THKModifier THKModifiers;
```

File

ComCtrls

Description

This is type ComCtrls.THKModifiers.

27.4.27 ComCtrls.TItemRequest Type

Pascal

```
TItemRequest = set of TItemRequests;
```

C++

```
TItemRequests TItemRequest;
```

File

ComCtrls

Description

This is type ComCtrls.TItemRequest.

27.4.28 ComCtrls.TItemStates Type

TItemState (see page 5454) and TItemStates specify the state of an item in a list view control.

Pascal

```
TItemStates = set of TItemState;
```

C++

```
TItemState TItemStates;
```

File

ComCtrls

Description

TItemStates is a set of TItemState (see page 5454) values. TItemState (see page 5454) indicates the state of an item in a list view. It can have any of the following values:

Value	Meaning
isNone	Item is in its default state
isCut	Item is cut (for cut and paste operation)
isDropHilited	Item is highlighted as a drag-and-drop target
isFocused	Item is focused
isSelected	Item is selected
isActivating	Item is active

27.4.29 ComCtrls.TListHotTrackStyles Type

TListHotTrackStyle (see page 5456) and TListHotTrackStyles specify hot tracking styles for a list view control.

Pascal

```
TListHotTrackStyles = set of TListHotTrackStyle;
```

C++

```
TListHotTrackStyle TListHotTrackStyles;
```

File

ComCtrls

Description

TListHotTrackStyles describes how hot tracking occurs in a list view control. It can have any of the following values:

Value	Meaning
htHandPoint	The mouse cursor turns into a hand.
htUnderlineCold	An underline is displayed under all untracked items.
htUnderlineHot	An underline is displayed under the tracked item.

27.4.30 ComCtrls.TListItemClass Type

Pascal

```
TListItemClass = class of TListItem;
```

C++

```
TListItem TListItemClass;
```

File

ComCtrls

Description

This is type ComCtrls.TListItemClass.

27.4.31 ComCtrls.TLVAdvancedCustomDrawEvent Type

Pascal

```
TLVAdvancedCustomDrawEvent = procedure (Sender: TCustomListView; const ARect: TRect; Stage:
TCustomDrawStage; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomListView; const ARect: TRect; Stage: TCustomDrawStage; var DefaultDraw:
Boolean) ( TLVAdvancedCustomDrawEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVAdvancedCustomDrawEvent.

27.4.32 ComCtrls.TLVAdvancedCustomDrawItemEvent Type

Pascal

```
TLVAdvancedCustomDrawItemEvent = procedure (Sender: TCustomListView; Item: TListItem; State:
TCustomDrawState; Stage: TCustomDrawStage; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomListView; Item: TListItem; State: TCustomDrawState; Stage: TCustomDrawStage;
var DefaultDraw: Boolean) ( TLVAdvancedCustomDrawItemEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVAdvancedCustomDrawItemEvent.

27.4.33 ComCtrls.TLVAdvancedCustomDrawSubItemEvent Type

Pascal

```
TLVAdvancedCustomDrawSubItemEvent = procedure (Sender: TCustomListView; Item: TListItem;
SubItem: Integer; State: TCustomDrawState; Stage: TCustomDrawStage; var DefaultDraw: Boolean)
of object;
```

C++

```
(Sender: TCustomListView; Item: TListItem; SubItem: Integer; State: TCustomDrawState; Stage:
TCustomDrawStage; var DefaultDraw: Boolean) ( TLVAdvancedCustomDrawSubItemEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVAdvancedCustomDrawSubItemEvent.

27.4.34 ComCtrls.TLVChangeEvent Type

Pascal

```
TLVChangeEvent = procedure (Sender: TObject; Item: TListItem; Change: TItemChange) of object;
```

C++

```
(Sender: TObject; Item: TListItem; Change: TItemChange) ( TLVChangeEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVChangeEvent.

27.4.35 ComCtrls.TLVChangingEvent Type

Pascal

```
TLVChangingEvent = procedure (Sender: TObject; Item: TListItem; Change: TItemChange; var
AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; Item: TListItem; Change: TItemChange; var AllowChange: Boolean) (
TLVChangingEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVChangingEvent.

27.4.36 ComCtrls.TLVColumnClickEvent Type

Pascal

```
TLVColumnClickEvent = procedure (Sender: TObject; Column: TListColumn) of object;
```

C++

```
(Sender: TObject; Column: TListColumn) ( TLVColumnClickEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVColumnClickEvent.

27.4.37 ComCtrls.TLVColumnRClickEvent Type

Pascal

```
TLVColumnRClickEvent = procedure (Sender: TObject; Column: TListColumn; Point: TPoint) of
object;
```

C++

```
(Sender: TObject; Column: TListColumn; Point: TPoint) ( TLVColumnRClickEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVColumnRClickEvent.

27.4.38 ComCtrls.TLVCompareEvent Type

Pascal

```
TLVCompareEvent = procedure (Sender: TObject; Item1, Item2: TListItem; Data: Integer; var
Compare: Integer) of object;
```

C++

```
(Sender: TObject; Item1, Item2: TListItem; Data: Integer; var Compare: Integer) (
TLVCompareEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVCompareEvent.

27.4.39 ComCtrls.TLVCreateItemClassEvent Type

Pascal

```
TLVCreateItemClassEvent = procedure (Sender: TCustomListView; var ItemClass: TListItemClass)
of object;
```

C++

```
(Sender: TCustomListView; var ItemClass: TListItemClass) ( TLVCreateItemClassEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVCreateItemClassEvent.

27.4.40 ComCtrls.TLVCustomDrawEvent Type

Pascal

```
TLVCustomDrawEvent = procedure (Sender: TCustomListView; const ARect: TRect; var DefaultDraw:
Boolean) of object;
```

C++

```
(Sender: TCustomListView; const ARect: TRect; var DefaultDraw: Boolean) (
TLVCustomDrawEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVCustomDrawEvent.

27.4.41 ComCtrls.TLVCustomDrawItemEvent Type

Pascal

```
TLVCustomDrawItemEvent = procedure (Sender: TCustomListView; Item: TListItem; State:
TCustomDrawState; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomListView; Item: TListItem; State: TCustomDrawState; var DefaultDraw: Boolean)
( TLVCustomDrawItemEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVCustomDrawItemEvent.

27.4.42 ComCtrls.TLVCustomDrawSubItemEvent Type

Pascal

```
TLVCustomDrawSubItemEvent = procedure (Sender: TCustomListView; Item: TListItem; SubItem:
Integer; State: TCustomDrawState; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomListView; Item: TListItem; SubItem: Integer; State: TCustomDrawState; var
DefaultDraw: Boolean) ( TLVCustomDrawSubItemEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVCustomDrawSubItemEvent.

27.4.43 ComCtrls.TLVDeletedEvent Type

TLVDeletedEvent is the type of a list view's OnDeletion event handler.

Pascal

```
TLVDeletedEvent = procedure (Sender: TObject; Item: TListItem) of object;
```

C++

```
(Sender: TObject; Item: TListItem) ( TLVDeletedEvent)();
```

File

ComCtrls

Description

Sender is the list view controlthat contains the item that is about to be deleted.

Item is the item that is about to be deleted.

27.4.44 ComCtrls.TLVDrawItemEvent Type

TLVDrawItemEvent is the type of the list view OnCustomDrawItem and OnDrawItem event handlers.

Pascal

```
TLVDrawItemEvent = procedure (Sender: TCustomListView; Item: TListItem; Rect: TRect; State:
TOwnerDrawState) of object;
```

C++

```
(Sender: TCustomListView; Item: TListItem; Rect: TRect; State: TOwnerDrawState) (
TLVDrawItemEvent)();
```

File

ComCtrls

Description

Sender is the list view control in which an item is about to be drawn.

Item is the item that is about to be drawn.

Rect defines the coordinates of the item on the list view's canvas.

State indicates various conditions that can influence how the item is drawn, such as whether it is selected, grayed, or focused.

27.4.45 ComCtrls.TLVEditedEvent Type

Pascal

```
TLVEditedEvent = procedure (Sender: TObject; Item: TListItem; var S: string) of object;
```

C++

```
(Sender: TObject; Item: TListItem; var S: string) ( TLVEditedEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVEditedEvent.

27.4.46 ComCtrls.TLVEditingEvent Type

Pascal

```
TLVEditingEvent = procedure (Sender: TObject; Item: TListItem; var AllowEdit: Boolean) of
object;
```

C++

```
(Sender: TObject; Item: TListItem; var AllowEdit: Boolean) ( TLVEditingEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVEditingEvent.

27.4.47 ComCtrls.TLVInfoTipEvent Type

Pascal

```
TLVInfoTipEvent = procedure (Sender: TObject; Item: TListItem; var InfoTip: string) of object;
```

C++

```
(Sender: TObject; Item: TListItem; var InfoTip: string) ( TLVInfoTipEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVInfoTipEvent.

27.4.48 ComCtrls.TLVNotifyEvent Type

Pascal

```
TLVNotifyEvent = procedure (Sender: TObject; Item: TListItem) of object;
```

C++

```
(Sender: TObject; Item: TListItem) ( TLVNotifyEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVNotifyEvent.

27.4.49 ComCtrls.TLVOwnerDataEvent Type

TLVOwnerDataEvent is the type of a list view's OnData event handler.

Pascal

```
TLVOwnerDataEvent = procedure (Sender: TObject; Item: TListItem) of object;
```

C++

```
(Sender: TObject; Item: TListItem) ( TLVOwnerDataEvent)();
```

File

ComCtrls

Description

Sender is the list view control in which an item is about to be displayed.

Item is the item that is about to be displayed. Any changes that you make to the item will be reflected in the list view control.

27.4.50 ComCtrls.TLVOwnerDataFindEvent Type

TLVOwnerDataFindEvent is the type of a list view's OnDataFind event handler.

Pascal

```
TLVOwnerDataFindEvent = procedure (Sender: TObject; Find: TItemFind; const FindString: string;
const FindPosition: TPoint; FindData: Pointer; StartIndex: Integer; Direction:
TSearchDirection; Wrap: Boolean; var Index: Integer) of object;
```

C++

```
(Sender: TObject; Find: TItemFind; const FindString: string; const FindPosition: TPoint;
FindData: Pointer; StartIndex: Integer; Direction: TSearchDirection; Wrap: Boolean; var Index:
Integer) ( TLVOwnerDataFindEvent)();
```

File

ComCtrls

Description

Sender is the list view control in which a search has been requested.

Find specifies the type of search to perform (any of ifData, ifPartialString, ifExactString, ifNearest).

FindString specifies the item text to search for. FindString is ignored unless Find contains ifPartialString or ifExactString.

FindPosition specifies the point from which to start the search. FindPosition is ignored unless Find contains ifNearest.

FindData specifies the item data to search for. FindData is ignored unless Find contains ifData.

StartIndex specifies the index of the item from which the search should start.

Direction specifies the direction for the search (sdLeft, sdRight, sdAbove, sdBelow, or sdAll).

Wrap specifies whether the search should continue from the start of the list view control if no match is found.

Index is where to store the index of the found item. Set Index to –1 if no item is found.

27.4.51 ComCtrls.TLVOwnerDataHintEvent Type

TLVOwnerDataHintEvent is the type of a list view's OnDataHint event handler.

Pascal

```
TLVOwnerDataHintEvent = procedure (Sender: TObject; StartIndex, EndIndex: Integer) of object;
```

C++

```
(Sender: TObject; StartIndex, EndIndex: Integer) ( TLVOwnerDataHintEvent)();
```

File

ComCtrls

Description

StartIndex is the first item in the range for which the OnData event may occur.

EndIndex is the last item in the range for which the OnData event may occur.

Use the index information to update the items in the range before the OnData event occurs.

See Also

TCustomListView

27.4.52 ComCtrls.TLVOwnerDataStateChangeEvent Type

TLVOwnerDataStateChangeEvent is the type of a list view's OnDataStateChange event handler.

Pascal

```
TLVOwnerDataStateChangeEvent = procedure (Sender: TObject; StartIndex, EndIndex: Integer;
OldState, NewState: TItemStates) of object;
```

C++

```
(Sender: TObject; StartIndex, EndIndex: Integer; OldState, NewState: TItemStates) (
TLVOwnerDataStateChangeEvent)();
```

File

ComCtrls

Description

Sender is the list view control containing the items that have changed.

StartIndex is the index of the first item that has changed.

EndIndex is the index of the last item that has changed.

OldState is the old state of the items.

NewState is the new state of the items.

See Also

TCustomListView

27.4.53 ComCtrls.TLVSelectItemEvent Type

Pascal

```
TLVSelectItemEvent = procedure (Sender: TObject; Item: TListItem; Selected: Boolean) of object;
```

C++

```
(Sender: TObject; Item: TListItem; Selected: Boolean) ( TLVSelectItemEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVSelectItemEvent.

27.4.54 ComCtrls.TLVSubItemImageEvent Type

Pascal

```
TLVSubItemImageEvent = procedure (Sender: TObject; Item: TListItem; SubItem: Integer; var
ImageIndex: Integer) of object;
```

C++

```
(Sender: TObject; Item: TListItem; SubItem: Integer; var ImageIndex: Integer) (
TLVSubItemImageEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TLVSubItemImageEvent.

27.4.55 ComCtrls.TMultiSelectStyle Type

Pascal

```
TMultiSelectStyle = set of TMultiSelectStyles;
```

C++

```
TMultiSelectStyles TMultiSelectStyle;
```

File

ComCtrls

Description

This is type ComCtrls.TMultiSelectStyle.

27.4.56 ComCtrls.TOnGetMonthInfoEvent Type

TOnGetMonthInfoEvent is the type of the TCommonCalendar.OnGetMonthInfo event handler.

Pascal

```
TOnGetMonthInfoEvent = procedure (Sender: TObject; Month: LongWord; var MonthBoldInfo:
LongWord) of object;
```

C++

```
(Sender: TObject; Month: LongWord; var MonthBoldInfo: LongWord) ( TOnGetMonthInfoEvent)();
```

File

ComCtrls

Description

Use TOnGetMonthInfoEvent along with the TCommonCalendar.BoldDays method to set which days are bold in the month that is about to be displayed in the calendar.

Sender is the TObject for the calendar.

Month is a value that corresponds to the month that is about to be displayed in the calendar. If Month is 1, January is about to be displayed, if Month is 2, February is about to be displayed, and so on.

MonthBoldInfo specifies which days of the month should be bold. You should pass MonthBoldInfo to the BoldDays method. You shouldn't work with BoldDays directly.

The first 31 bits of the MonthBoldInfo variable are used to determine whether a particular day of the month should be bold.

See Also

TCommonCalendar (see page 3558)

27.4.57 ComCtrls.TOwnerDrawState Type

Indicates state information that can influence how an item is drawn.

Pascal

```
TOwnerDrawState = Windows.TOwnerDrawState;
```

C++

```
Windows.TOwnerDrawState TOwnerDrawState;
```

File

ComCtrls

Description

TOwnerDrawState is used by event handlers in owner-draw controls to indicate the state of an item about to be drawn. It is a set that includes zero or more of the following:

Value	Meaning
odSelected	The item is selected.

odGrayed	The item should appear grayed.
odDisabled	The item is disabled.
odChecked	The item should appear checked. (This does not apply to all objects)
odFocused	Keyboard input is directed to the item.
odDefault	The item is the default item (This does not apply to all objects)
odHotLight	The item is hot-lighted because under the mouse (only if the operating system supports hot-lighting)
odInactive	The item and its associated menu are inactive
odNoAccel	Any underline of an accelerator character should be skipped when drawing the control
odNoFocusRect	Do not display visual cues that indicate focus
odReserved1	Not currently used.
odReserved2	Not currently used.
odComboBoxEdit	The drawing takes place in the edit box of a combo box control.

27.4.58 ComCtrls.TPageScrollEvent Type

TPageScrollEvent is the type of a page scroller's OnScroll event handler.

Pascal

```
TPageScrollEvent = procedure (Sender: TObject; Shift: TShiftState; X, Y: Integer; Orientation:
TPageScrollerOrientation; var Delta: Integer) of object;
```

C++

```
(Sender: TObject; Shift: TShiftState; X, Y: Integer; Orientation: TPageScrollerOrientation;
var Delta: Integer) ( TPageScrollEvent)();
```

File

ComCtrls

Description

Sender is the page scroller that is being scrolled.

Shift is the state of the Shift, Alt, Ctrl keys and mouse buttons.

X is the horizontal position of the page scroller.

Y is the vertical position of the page scroller.

Orientation is the direction for the scroll.

Delta is the amount of the scroll.

See Also

TPageScroller (see page 4548)

27.4.59 ComCtrls.TProgressRange Type

Pascal

```
TProgressRange = Integer;
```

C++

```
int TProgressRange;
```

File

ComCtrls

Description

This is type ComCtrls.TProgressRange.

27.4.60 ComCtrls.TRichEditProtectChange Type

Pascal

```
TRichEditProtectChange = procedure (Sender: TObject; StartPos, EndPos: Integer; var
AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; StartPos, EndPos: Integer; var AllowChange: Boolean) (
TRichEditProtectChange)();
```

File

ComCtrls

Description

This is type ComCtrls.TRichEditProtectChange.

27.4.61 ComCtrls.TRichEditResizeEvent Type

Pascal

```
TRichEditResizeEvent = procedure (Sender: TObject; Rect: TRect) of object;
```

C++

```
(Sender: TObject; Rect: TRect) ( TRichEditResizeEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TRichEditResizeEvent.

27.4.62 ComCtrls.TRichEditSaveClipboard Type

Pascal

```
TRichEditSaveClipboard = procedure (Sender: TObject; NumObjects, NumChars: Integer; var
SaveClipboard: Boolean) of object;
```

C++

```
(Sender: TObject; NumObjects, NumChars: Integer; var SaveClipboard: Boolean) (
TRichEditSaveClipboard)();
```

File

ComCtrls

Description

This is type ComCtrls.TRichEditSaveClipboard.

27.4.63 ComCtrls.TSBCreatePanelClassEvent Type

TSBCreatePanelClassEvent is the type of the OnCreatePanelClass event handler.

Pascal

```
TSBCreatePanelClassEvent = procedure (Sender: TCustomStatusBar; var PanelClass:
TStatusPanelClass) of object;
```

C++

```
(Sender: TCustomStatusBar; var PanelClass: TStatusPanelClass) ( TSBCreatePanelClassEvent)();
```

File

ComCtrls

Description

Sender is the status bar object that needs to add a new panel.

PanelClass returns a class reference to the TStatusPanel (see page 4825) descendant that should be used to implement the new panel.

27.4.64 ComCtrls.TSearchTypes Type

Set of TSearchType (see page 5464).

Pascal

```
TSearchTypes = set of TSearchType;
```

C++

```
TSearchType TSearchTypes;
```

File

ComCtrls

Description

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button click will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FindDialog1->Position = Point(RichEdit1->Left + RichEdit1->Width, RichEdit1->Top);
  FindDialog1->Execute();
}

void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  int FoundAt, StartPos, ToEnd;
  TSearchTypes mySearchTypes;
  // begin the search after the current selection
  // if there is one
  // otherwise, begin at the start of the text
  if (FindDialog1->Options.Contains(frMatchCase))
    mySearchTypes << stMatchCase;
  if (FindDialog1->Options.Contains(frWholeWord))
    mySearchTypes << stWholeWord;
  if (RichEdit1->SelLength)
    StartPos = RichEdit1->SelStart + RichEdit1->SelLength;
  else
    StartPos = 0;
  // ToEnd is the length from StartPos
  // to the end of the text in the rich edit control
  ToEnd = RichEdit1->Text.Length() - StartPos;
  FoundAt = RichEdit1->FindText(FindDialog1->FindText, StartPos, ToEnd, mySearchTypes);
  if (FoundAt != -1)
  {
    RichEdit1->SetFocus();
    RichEdit1->SelStart = FoundAt;
    RichEdit1->SelLength = FindDialog1->FindText.Length();
  }
  else Beep();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("../Overview.RTF");  // starts in Debug
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button click will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FindDialog1.Position :=
```

```
      Point(RichEdit1.Left + RichEdit1.Width, RichEdit1.Top);
    FindDialog1.Execute;
  end;

  procedure TForm1.FindDialog1Find(Sender: TObject);
  var
    FoundAt: LongInt;
    StartPos, ToEnd: Integer;
    mySearchTypes : TSearchTypes;
    myFindOptions : TFindOptions;
  begin
    with RichEdit1 do
    begin
      if frMatchCase in FindDialog1.Options then
         mySearchTypes := mySearchTypes + [stMatchCase];
      if frWholeWord in FindDialog1.Options then
         mySearchTypes := mySearchTypes + [stWholeWord];
      { begin the search after the current selection if there is one }
      { otherwise, begin at the start of the text }
      if SelLength <> 0 then
        StartPos := SelStart + SelLength
      else
        StartPos := 0;
      { ToEnd is the length from StartPos to the end of the
        text in the rich edit control }
      ToEnd := Length(Text) - StartPos;
      FoundAt :=
        FindText(FindDialog1.FindText, StartPos, ToEnd, mySearchTypes);
      if FoundAt <> -1 then
      begin
        SetFocus;
        SelStart := FoundAt;
        SelLength := Length(FindDialog1.FindText);
      end
      else Beep;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
```

27.4.65 ComCtrls.TSectionDragEvent Type

TSectionDragEvent is the type for event handlers that respond when the user drags a section in a header control.

Pascal

```
TSectionDragEvent = procedure (Sender: TObject; FromSection, ToSection: THeaderSection; var
AllowDrag: Boolean) of object;
```

C++

```
(Sender: TObject; FromSection, ToSection: THeaderSection; var AllowDrag: Boolean) (
TSectionDragEvent)();
```

File

ComCtrls

Description

Sender is the header control that includes the dragged section.

FromSection is the header section that the user is dragging.

ToSection is the header section currently in the position where the user dragged FromSection.

AllowDrag returns a value that indicates whether the header control repositions the headers to accommodate the user's drag. If AllowDrag is false on exit from the event handler, the headers remain in their original positions, as if the user had not tried a drag operation.

See Also

THeaderControl (see page 4118)

27.4.66 ComCtrls.TSectionNotifyEvent Type

Pascal

```
TSectionNotifyEvent = procedure (HeaderControl: THeaderControl; Section: THeaderSection) of
object;
```

C++

```
(HeaderControl: THeaderControl; Section: THeaderSection) ( TSectionNotifyEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TSectionNotifyEvent.

27.4.67 ComCtrls.TSectionTrackEvent Type

Pascal

```
TSectionTrackEvent = procedure (HeaderControl: THeaderControl; Section: THeaderSection; Width:
Integer; State: TSectionTrackState) of object;
```

C++

```
(HeaderControl: THeaderControl; Section: THeaderSection; Width: Integer; State:
TSectionTrackState) ( TSectionTrackEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TSectionTrackEvent.

27.4.68 ComCtrls.TStatusPanelClass Type

TStatusPanelClass defines the metaclass for TStatusPanel (see page 4825).

Pascal

```
TStatusPanelClass = class of TStatusPanel;
```

C++

```
TStatusPanel TStatusPanelClass;
```

File

ComCtrls

Description

TStatusPanelClass is the metaclass for TStatusPanel (see page 4825). Its value is the class reference for TStatusPanel (see page 4825) or for one of its descendants.

27.4.69 ComCtrls.TTabChangingEvent Type

Pascal

```
TTabChangingEvent = procedure (Sender: TObject; var AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; var AllowChange: Boolean) ( TTabChangingEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTabChangingEvent.

27.4.70 ComCtrls.TTabGetImageEvent Type

Pascal

```
TTabGetImageEvent = procedure (Sender: TObject; TabIndex: Integer; var ImageIndex: Integer) of
object;
```

C++

```
(Sender: TObject; TabIndex: Integer; var ImageIndex: Integer) ( TTabGetImageEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTabGetImageEvent.

27.4.71 ComCtrls.TTBAdvancedCustomDrawBtnEvent Type

Pascal

```
TTBAdvancedCustomDrawBtnEvent = procedure (Sender: TToolBar; Button: TToolButton; State:
TCustomDrawState; Stage: TCustomDrawStage; var Flags: TTBCustomDrawFlags; var DefaultDraw:
Boolean) of object;
```

C++

```
(Sender: TToolBar; Button: TToolButton; State: TCustomDrawState; Stage: TCustomDrawStage; var
Flags: TTBCustomDrawFlags; var DefaultDraw: Boolean) ( TTBAdvancedCustomDrawBtnEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTBAdvancedCustomDrawBtnEvent.

27.4.72 ComCtrls.TTBAdvancedCustomDrawEvent Type

Pascal

```
TTBAdvancedCustomDrawEvent = procedure (Sender: TToolBar; const ARect: TRect; Stage:
TCustomDrawStage; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TToolBar; const ARect: TRect; Stage: TCustomDrawStage; var DefaultDraw: Boolean) (
TTBAdvancedCustomDrawEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTBAdvancedCustomDrawEvent.

27.4.73 ComCtrls.TTBButtonEvent Type

TTBButtonEvent is the type of event handlers that respond when the user adds or deletes a tool button in the toolbar customize dialog.

Pascal

```
TTBButtonEvent = procedure (Sender: TToolbar; Button: TToolButton) of object;
```

C++

```
(Sender: TToolbar; Button: TToolButton) ( TTBButtonEvent)();
```

File

ComCtrls

Description

TTBButtonEvent is the type for the OnCustomizeAdded and OnCustomizeDelete events. It allows a toolbar to respond to notifications of changes that the user makes to the items in the toolbar.

Sender is the toolbar whose button was just added or deleted.

Button is the button that was just added or deleted.

See Also

TToolBar (see page 4994)

27.4.74 ComCtrls.TTBCustomDrawBtnEvent Type

Pascal

```
TTBCustomDrawBtnEvent = procedure (Sender: TToolBar; Button: TToolButton; State:
TCustomDrawState; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TToolBar; Button: TToolButton; State: TCustomDrawState; var DefaultDraw: Boolean) (
TTBCustomDrawBtnEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTBCustomDrawBtnEvent.

27.4.75 ComCtrls.TTBCustomDrawEvent Type

Pascal

```
TTBCustomDrawEvent = procedure (Sender: TToolBar; const ARect: TRect; var DefaultDraw:
Boolean) of object;
```

C++

```
(Sender: TToolBar; const ARect: TRect; var DefaultDraw: Boolean) ( TTBCustomDrawEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTBCustomDrawEvent.

27.4.76 ComCtrls.TTBCustomDrawFlags Type

TTBCustomDrawFlags is the type of the OnAdvancedCustomDrawButton event handler.

Pascal

```
TTBCustomDrawFlags = set of (tbNoEdges, tbHiliteHotTrack, tbNoOffset, tbNoMark,
tbNoEtchedEffect);
```

C++

```
(tbNoEdges, tbHiliteHotTrack, tbNoOffset, tbNoMark, tbNoEtchedEffect) TTBCustomDrawFlags;
```

File

ComCtrls

Description

TTBCustomDrawFlags influences the subsequent painting of a tool button following an OnAdvancedCustomDrawButton event in the cdPrePaint stage:

Value	Meaning
tbNoEdges	The button is drawn without edges to distinguish it from the tool bar.
tbHiliteHotTrack	Enables the change in background color when the button is hot tracked. If this is not included in the set, the background color does not change for hot tracking.
tbNoOffset	The button is not offset when in the "down" position.
tbNoMark	Disables the default change in background color on buttons with the Marked property set to Truetrue.
tbNoEtchedEffect	Disables the etched effect that appears by default on disabled tool buttons.

See Also

TToolBar

27.4.77 ComCtrls.TTBCustomizeQueryEvent Type

TTBCustomizeQueryEvent is the type of event handlers that allow a toolbar to decide whether to allow a user customization.

Pascal

```
TTBCustomizeQueryEvent = procedure (Sender: TToolbar; Index: Integer; var Allow: Boolean) of
object;
```

C++

```
(Sender: TToolbar; Index: Integer; var Allow: Boolean) ( TTBCustomizeQueryEvent)();
```

File

ComCtrls

Description

TTBCustomizeQueryEvent is the type for the OnCustomizeCanInsert and OnCustomizeCanDelete events. It allows a toolbar to approve or block the insertion or deletion of a button by the user.

Sender is the customizable toolbar that the user is trying to modify.

Index is the index of the button to be deleted or the index where a new button is to be inserted.

Allow returns an indication of whether the user can proceed with the operation. On entry, Allow is T t rue, indicating that the user can add or delete the button. The event handler can change Allow to F f alse to block the change to the toolbar.

See Also

TToolBar (see page 4994)

27.4.78 ComCtrls.TTBGradientDrawingOptions Type

Specifies the style of the gradient.

Pascal

```
TTBGradientDrawingOptions = set of (gdoHotTrack, gdoGradient);
```

C++

```
(gdoHotTrack, gdoGradient) TTBGradientDrawingOptions;
```

File

ComCtrls

Description

This type allows you to use one of the following options:

- gdoHotTrack
- gdoGradient

27.4.79 ComCtrls.TTBNewButtonEvent Type

Pascal

```
TTBNewButtonEvent = procedure (Sender: TToolbar; Index: Integer; var Button: TToolButton) of
object;
```

C++

```
(Sender: TToolbar; Index: Integer; var Button: TToolButton) ( TTBNewButtonEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTBNewButtonEvent.

27.4.80 ComCtrls.TToolButtonActionLinkClass Type

Pascal

```
TToolButtonActionLinkClass = class of TToolButtonActionLink;
```

C++

```
TToolButtonActionLink TToolButtonActionLinkClass;
```

File

ComCtrls

Description

This is type ComCtrls.TToolButtonActionLinkClass.

27.4.81 ComCtrls.TTreeNodeClass Type

Pascal

```
TTreeNodeClass = class of TTreeNode;
```

C++

```
TTreeNode TTreeNodeClass;
```

File

ComCtrls

Description

This is type ComCtrls.TTreeNodeClass.

27.4.82 ComCtrls.TTVAdvancedCustomDrawEvent Type

Used in the TCustomTreeView.OnAdvancedCustomDraw event.

Pascal

```
TTVAdvancedCustomDrawEvent = procedure (Sender: TCustomTreeView; const ARect: TRect; Stage:
TCustomDrawStage; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomTreeView; const ARect: TRect; Stage: TCustomDrawStage; var DefaultDraw:
Boolean) ( TTVAdvancedCustomDrawEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnAdvancedCustomDraw event when a tree-view control is being painted.

Sender is the tree-view control that is being painted.

ARect is the rectangle that defines the boundaries of the tree-view control on its canvas.

Stage indicates the current stage of the painting process.

DefaultDraw specifies whether the control should paint itself after the event handler exits. This parameter is only used when **Stage** is **cdPrePaint**.

See Also

OnAdvancedCustomDraw (see page 4016)

27.4.83 ComCtrls.TTVAdvancedCustomDrawItemEvent Type

Used in the TCustomTreeView.OnAdvancedCustomDrawItem event.

Pascal

```
TTVAdvancedCustomDrawItemEvent = procedure (Sender: TCustomTreeView; Node: TTreeNode; State:
TCustomDrawState; Stage: TCustomDrawStage; var PaintImages, DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomTreeView; Node: TTreeNode; State: TCustomDrawState; Stage: TCustomDrawStage;
var PaintImages, DefaultDraw: Boolean) ( TTVAdvancedCustomDrawItemEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnAdvancedCustomDrawItem event when an item is about to be painted.

Sender is the tree-view control in which an item is about to be painted.

Node is the item that is about to be painted.

State is the item's current state, which is a TCustomDrawState (see page 5483) type: one or more of **cdsSelected**, **cdsGrayed**, **cdsDisabled**, **cdsChecked**, **cdsFocused**, **csDefault**, **cdsHot**, **cdsMarked**, **cdsIndeterminate**.

Stage is a TCustomDrawStage (see page 5445) type that indicates the current stage of the painting process.

PaintImages specifies whether the control should paint the images associated with the control. This parameter is only used when **Stage** is **cdPrePaint**.

DefaultDraw specifies whether the control should paint the text of the item after the event handler exits. This parameter is only used when **Stage** is **cdPrePaint**.

See Also

OnAdvancedCustomDrawItem (see page 4016)

TCustomDrawState (see page 5483)

TCustomDrawStage (see page 5445)

27.4.84 ComCtrls.TTVChangedEvent Type

Used in the TCustomTreeView.OnChange event.

Pascal

```
TTVChangedEvent = procedure (Sender: TObject; Node: TTreeNode) of object;
```

C++

```
(Sender: TObject; Node: TTreeNode) ( TTVChangedEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnChange event whenever the selection has changed from one node to another.

The **Sender** parameter is the tree view whose selected node changes, and the **Node** parameter is the newly selected node.

See Also

ChangeDelay (see page 3999)

RightClickSelect (see page 4006)

Selected (see page 4007)

OnChange (see page 4017)

OnChanging (see page 4018)

OnMouseUp (see page 5867)

27.4.85 ComCtrls.TTVChangingEvent Type

Used in the TCustomTreeView.OnChanging event.

Pascal

```
TTVChangingEvent = procedure (Sender: TObject; Node: TTreeNode; var AllowChange: Boolean) of
object;
```

C++

```
(Sender: TObject; Node: TTreeNode; var AllowChange: Boolean) ( TTVChangingEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnChanging event when the selection is about to change from one node to another.

The **Sender** parameter is the tree view whose selected node changes, and the **Node** parameter specifies the node that is about to be selected. **AllowChange** indicates whether the node can be selected or not.

See Also

Selected (see page 4007)

OnChanging (see page 4018)

OnChange (see page 4017)

27.4.86 ComCtrls.TTVCollapsingEvent Type

Used in the TCustomTreeView.OnCollapsing event.

Pascal

```
TTVCollapsingEvent = procedure (Sender: TObject; Node: TTreeNode; var AllowCollapse: Boolean)
of object;
```

C++

```
(Sender: TObject; Node: TTreeNode; var AllowCollapse: Boolean) ( TTVCollapsingEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnCollapsing event when a node is about to be collapsed.

The **Sender** parameter is the tree view whose selected node collapses, and the **Node** parameter specifies the node that is about to be collapsed. **AllowCollapse** indicates whether the node can collapse or not.

See Also

FullCollapse (see page 3983)

Collapse (see page 5235)

OnCollapsing (see page 4018)

27.4.87 ComCtrls.TTVCompareEvent Type

Used in the TCustomTreeView.OnCompare event.

Pascal

```
TTVCompareEvent = procedure (Sender: TObject; Node1, Node2: TTreeNode; Data: Integer; var
Compare: Integer) of object;
```

C++

```
(Sender: TObject; Node1, Node2: TTreeNode; Data: Integer; var Compare: Integer) (
TTVCompareEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnCompare event when two nodes must be compared during a sort of the nodes in the tree view.

The **Sender** parameter is the tree view whose nodes are compared.

Node1 and **Node2** are the nodes being compared.

Compare parameter is less than 0 if **Node1** is less than **Node2**. **Compare** is 0 if **Node1** is equivalent to **Node2**, and **Compare** is greater than 0 if **Node1** is greater than **Node2**.

See Also

SortType (see page 4014)

AlphaSort (see page 3972)

CustomSort (see page 3978)

OnCompare (see page 4019)

27.4.88 ComCtrls.TTVCreateNodeClassEvent Type

Pascal

```
TTVCreateNodeClassEvent = procedure (Sender: TCustomTreeView; var NodeClass: TTreeNodeClass)
of object;
```

C++

```
(Sender: TCustomTreeView; var NodeClass: TTreeNodeClass) ( TTVCreateNodeClassEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TTVCreateNodeClassEvent.

27.4.89 ComCtrls.TTVCustomDrawEvent Type

Used in the TCustomTreeView.OnCustomDraw event.

Pascal

```
TTVCustomDrawEvent = procedure (Sender: TCustomTreeView; const ARect: TRect; var DefaultDraw:
Boolean) of object;
```

C++

```
(Sender: TCustomTreeView; const ARect: TRect; var DefaultDraw: Boolean) (
TTVCustomDrawEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnCustomDraw event.

Sender is the tree-view control that is about to be painted.

ARect is the rectangle that defines the boundaries of the tree-view control.

DefaultDraw specifies whether the control should paint itself after the event handler exits.

See Also

OnCustomDraw (see page 4019)

27.4.90 ComCtrls.TTVCustomDrawItemEvent Type

Used in the TCustomTreeView.OnCustomDrawItem event.

Pascal

```
TTVCustomDrawItemEvent = procedure (Sender: TCustomTreeView; Node: TTreeNode; State:
```

```
TCustomDrawState; var DefaultDraw: Boolean) of object;
```

C++

```
(Sender: TCustomTreeView; Node: TTreeNode; State: TCustomDrawState; var DefaultDraw: Boolean)
( TTVCustomDrawItemEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnCustomDrawItem event.

Sender is the tree-view control in which an item is about to be drawn.

Node is the item that is about to be drawn.

State is the item's current state, which is a TCustomDrawState (see page 5483) type: one or more of **cdsSelected**, **cdsGrayed**, **cdsDisabled**, **cdsChecked**, **cdsFocused**, **cdsDefault**, **cdsHot**, **cdsMarked**, **cdsIndeterminate**.

DefaultDraw specifies whether the control should paint the item after the event handler exits.

See Also

OnCustomDrawItem (see page 4021)

TCustomDrawState (see page 5483)

27.4.91 ComCtrls.TTVEditedEvent Type

Used in the TCustomTreeView.OnEdited event.

Pascal

```
TTVEditedEvent = procedure (Sender: TObject; Node: TTreeNode; var S: string) of object;
```

C++

```
(Sender: TObject; Node: TTreeNode; var S: string) ( TTVEditedEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnEdited event after the user edits the Text property of a node.

Sender is the tree-view control in which a node's label was edited.

Node is the item whose label was edited.

The **S** parameter is the new value of the node’s Text property.

See Also

ReadOnly (see page 4006)

Text (see page 5265)

OnEdited (see page 4024)

OnEditing (see page 4024)

27.4.92 ComCtrls.TTVEditingEvent Type

Used in the TCustomTreeView.OnEditing event.

Pascal

```
TTVEditingEvent = procedure (Sender: TObject; Node: TTreeNode; var AllowEdit: Boolean) of
object;
```

C++

```
(Sender: TObject; Node: TTreeNode; var AllowEdit: Boolean) ( TTVEditingEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnEditing event when the user starts to edit the Text property of a node.

Sender is the tree-view control in which an item is about to be edited.

Node is the item whose label is about to be edited.

AllowEdit indicates whether the user is allowed to edit the label of the node specified by the **Node** parameter.

See Also

ReadOnly (see page 4006)

OnEdited (see page 4024)

OnEditing (see page 4024)

27.4.93 ComCtrls.TTVExpandedEvent Type

Represents the event handler for events that notify a tree view of changes to one of its nodes.

Pascal

```
TTVExpandedEvent = procedure (Sender: TObject; Node: TTreeNode) of object;
```

C++

```
(Sender: TObject; Node: TTreeNode) ( TTVExpandedEvent)();
```

File

ComCtrls

Description

TTVExpandedEvent is used to respond to notifications of events that occur to the nodes of a tree view control. It is a generic event handler for various events that notify the tree view of something that happened to a node.

Sender is the tree-view control that contains the node that is the focus of the notification.

Node is the item that has been expanded, collapsed, deleted, or which is about to be drawn.

See Also

OnCollapsed (see page 4018)

OnDeletion (see page 4024)

OnExpanded (see page 4025)

OnGetImageIndex (see page 4026)

OnGetSelectedIndex (see page 4026)

27.4.94 ComCtrls.TTVExpandingEvent Type

Used in the TCustomTreeView.OnExpanding event.

Pascal

```
TTVExpandingEvent = procedure (Sender: TObject; Node: TTreeNode; var AllowExpansion: Boolean)
of object;
```

C++

```
(Sender: TObject; Node: TTreeNode; var AllowExpansion: Boolean) ( TTVExpandingEvent)();
```

File

ComCtrls

Description

This event is used in the TCustomTreeView.OnExpanding event when a node is about to be expanded.

Sender is the tree-view control in which a node is about to be expanded.

Node is the node about to be expanded.

AllowExpansion indicates whether the node can be expanded.

See Also

FullExpand (see page 3984)

Expand (see page 5242)

OnExpanding (see page 4025)

OnExpanded (see page 4025)

27.4.95 ComCtrls.TUDChangingEvent Type

Pascal

```
TUDChangingEvent = procedure (Sender: TObject; var AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; var AllowChange: Boolean) ( TUDChangingEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TUDChangingEvent.

27.4.96 ComCtrls.TUDChangingEventEx Type

Pascal

```
TUDChangingEventEx = procedure (Sender: TObject; var AllowChange: Boolean; NewValue: SmallInt;
Direction: TUpDownDirection) of object;
```

C++

```
(Sender: TObject; var AllowChange: Boolean; NewValue: SmallInt; Direction: TUpDownDirection) (
TUDChangingEventEx)();
```

File

ComCtrls

Description

This is type ComCtrls.TUDChangingEventEx.

27.4.97 ComCtrls.TUDClickEvent Type

Pascal

```
TUDClickEvent = procedure (Sender: TObject; Button: TUDBtnType) of object;
```

C++

```
(Sender: TObject; Button: TUDBtnType) ( TUDClickEvent)();
```

File

ComCtrls

Description

This is type ComCtrls.TUDClickEvent.

27.4.98 ComCtrls.TWidth Type

Pascal

```
TWidth = ColumnHeaderWidth..MaxInt;
```

C++

```
ColumnHeaderWidth..MaxInt TWidth;
```

File

ComCtrls

Description

This is type ComCtrls.TWidth.

27.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CN_BANDCHANGE (see page 5521)	This is constant ComCtrls.CN_BANDCHANGE.
CN_DROPDOWNCLOSED (see page 5521)	This is constant ComCtrls.CN_DROPDOWNCLOSED.
ColumnHeaderWidth (see page 5522)	This is constant ComCtrls.ColumnHeaderWidth.
ColumnTextWidth (see page 5522)	This is constant ComCtrls.ColumnTextWidth.
ComCtlVersionIE3 (see page 5522)	This is constant ComCtrls.ComCtlVersionIE3.
ComCtlVersionIE4 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE4.
ComCtlVersionIE401 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE401.
ComCtlVersionIE5 (see page 5523)	This is constant ComCtrls.ComCtlVersionIE5.
ComCtlVersionIE501 (see page 5524)	This is constant ComCtrls.ComCtlVersionIE501.
ComCtlVersionIE6 (see page 5524)	This is constant ComCtrls.ComCtlVersionIE6.

27.5.1 ComCtrls.CN_BANDCHANGE Constant

Pascal

```
CN_BANDCHANGE = WM_USER + $1000;
```

C++

```
CN_BANDCHANGE = WM_USER + $1000;
```

File

ComCtrls

Description

This is constant ComCtrls.CN_BANDCHANGE.

27.5.2 ComCtrls.CN_DROPDOWNCLOSED Constant

Pascal

```
CN_DROPDOWNCLOSED = WM_USER + $1000;
```

C++

```
CN_DROPDOWNCLOSED = WM_USER + $1000;
```

File

ComCtrls

Description

This is constant ComCtrls.CN_DROPDOWNCLOSED.

27.5.3 ComCtrls.ColumnHeaderWidth Constant

Pascal

```
ColumnHeaderWidth = LVSCW_AUTOSIZE_USEHEADER;
```

C++

```
ColumnHeaderWidth = LVSCW_AUTOSIZE_USEHEADER;
```

File

ComCtrls

Description

This is constant ComCtrls.ColumnHeaderWidth.

27.5.4 ComCtrls.ColumnTextWidth Constant

Pascal

```
ColumnTextWidth = LVSCW_AUTOSIZE;
```

C++

```
ColumnTextWidth = LVSCW_AUTOSIZE;
```

File

ComCtrls

Description

This is constant ComCtrls.ColumnTextWidth.

27.5.5 ComCtrls.ComCtlVersionIE3 Constant

Pascal

```
ComCtlVersionIE3 = $00040046;
```

C++

```
ComCtlVersionIE3 = 0x00040046;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE3.

27.5.6 ComCtrls.ComCtlVersionIE4 Constant

Pascal

```
ComCtlVersionIE4 = $00040047;
```

C++

```
ComCtlVersionIE4 = 0x00040047;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE4.

27.5.7 ComCtrls.ComCtlVersionIE401 Constant

Pascal

```
ComCtlVersionIE401 = $00040048;
```

C++

```
ComCtlVersionIE401 = 0x00040048;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE401.

27.5.8 ComCtrls.ComCtlVersionIE5 Constant

Pascal

```
ComCtlVersionIE5 = $00050050;
```

C++

```
ComCtlVersionIE5 = 0x00050050;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE5.

27.5.9 ComCtrls.ComCtlVersionIE501 Constant

Pascal

```
ComCtlVersionIE501 = $00050051;
```

C++

```
ComCtlVersionIE501 = 0x00050051;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE501.

27.5.10 ComCtrls.ComCtlVersionIE6 Constant

Pascal

```
ComCtlVersionIE6 = $00060000;
```

C++

```
ComCtlVersionIE6 = 0x00060000;
```

File

ComCtrls

Description

This is constant ComCtrls.ComCtlVersionIE6.

28 ComObj Namespace

This is namespace ComObj.

Topics

Name	Description
Classes (see page 5528)	The following table lists classes in this documentation.
Interfaces (see page 5588)	The following table lists interfaces in this documentation.
Functions (see page 5590)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5604)	The following table lists structs, records, enums in this documentation.
Types (see page 5606)	The following table lists types in this documentation.
Variables (see page 5610)	The following table lists variables in this documentation.

Classes

	Name	Description
	EOleError (see page 5528)	EOleError is the exception class for low-level OLE errors.
	EOleException (see page 5529)	EOleException is the exception class for OLE automation errors that occur in methods or properties of an object.
	EOleRegistrationError (see page 5531)	EOleRegistrationError is the exception class for errors that occur when registering an OLE object.
	EOleSysError (see page 5532)	EOleSysError is the exception class for errors specific to the OLE IDispatch interface.
	TAutoIntfObject (see page 5534)	TAutoIntfObject implements the IDispatch and ISupportErrorInfo interfaces.
	TAutoObject (see page 5540)	TAutoObject is a CoClass that supports the IDispatch interface, and that can be used as a base class for ActiveX Automation servers.
	TAutoObjectFactory (see page 5545)	TAutoObjectFactory is the class factory for TAutoObject (see page 5540).
	TComClassManager (see page 5550)	TComClassManager is the class type of the ComClassManager (see page 5591) variable in the ComObj unit.
	TComObject (see page 5553)	TComObject is the base class for creating simple COM classes, such as those used for creating Shell extensions.
	TComObjectFactory (see page 5563)	TComObjectFactory is the type of the class factory object used to instantiate a TComObject (see page 5553) class.
	TComServerObject (see page 5575)	TComServerObject is the abstract base class for TComServer.
	TTypedComObject (see page 5581)	TTypedComObject supports the IProvideClassInfo interface and is the class type for COM objects that can provide the type information without requiring a type library to be loaded.
	TTypedComObjectFactory (see page 5583)	TTypedComObjectFactory is the type of the class factory object used to instantiate a TypedComObject class.

Functions

	Name	Description
	ClassIDToProgID (see page 5590)	Returns the programmatic ID for a specified class given its class ID (CLSID).
	ComClassManager (see page 5591)	Returns a TComClassManager (see page 5550) object.
	CreateClassID (see page 5591)	CreateClassID generates a new GUID and returns it as a string.
	CreateComObject (see page 5592)	Instantiates a single instance of a COM object.
	CreateOleObject (see page 5592)	Instantiates an Automation object.
	CreateRegKey (see page 5593)	Creates or opens a registry key that is a subkey of HKEY_CLASSES_ROOT.
	CreateRemoteComObject (see page 5594)	Creates a Com object on another machine and returns an IUnknown interface for it.
	DeleteRegKey (see page 5595)	Deletes a single key that is a subkey of HKEY_CLASSES_ROOT from the system registry.
	DispatchInvoke (see page 5595)	This is function ComObj.DispatchInvoke.
	DispatchInvokeError (see page 5596)	This is function ComObj.DispatchInvokeError.
	GetActiveOleObject (see page 5596)	Retrieves a reference to an IDispatch interface to a currently running, registered COM object.
	GetDispatchPropValue (see page 5596)	Returns the value of a property on an IDispatch interface.
	GetDispatchPropValue (see page 5596)	Returns the value of a property on an IDispatch interface.
	GetRegStringValue (see page 5597)	Retrieves a value stored under a subkey of HKEY_CLASSES_ROOT from the system registry.
	GUIDToString (see page 5597)	This is function ComObj.GUIDToString.
	HandleSafeCallException (see page 5598)	This is function ComObj.HandleSafeCallException.
	InterfaceConnect (see page 5598)	Connects an IConnectionPoint interface.
	InterfaceDisconnect (see page 5599)	Disconnects an IConnectionPoint interface connection that was previously made by the InterfaceConnect (see page 5598) procedure.
	OleCheck (see page 5600)	Throws an EOleSysError (see page 5532) exception if the result code indicates an error.
	OleError (see page 5600)	Raises an EOleSysError (see page 5532) exception.
	ProgIDToClassID (see page 5601)	Returns the class ID (CLSID) GUID that corresponds to the string specified as the ProgID parameter.
	RegisterAsService (see page 5601)	Registers a COM object as an NT service.
	RegisterComServer (see page 5602)	Registers an in-process COM server with the operating system.
	SetDispatchPropValue (see page 5602)	Sets the value of a property on an IDispatch interface.
	SetDispatchPropValue (see page 5602)	Sets the value of a property on an IDispatch interface.
	StringToGUID (see page 5603)	This is function ComObj.StringToGUID.
	StringToLPOLESTR (see page 5603)	This is function ComObj.StringToLPOLESTR.

Interfaces

	Name	Description
	IServerExceptionHandler (see page 5588)	This is class ComObj.IServerExceptionHandler.

Structs, Records, Enums

	Name	Description
	TClassInstancing (see page 5604)	This is record ComObj.TClassInstancing.
	TThreadingModel (see page 5604)	This is record ComObj.TThreadingModel.

Types

Name	Description
TAutoClass (see page 5606)	This is type ComObj.TAutoClass.
TCoAddRefServerProcessProc (see page 5606)	This is type ComObj.TCoAddRefServerProcessProc.
TCoCreateInstanceExProc (see page 5607)	This is type ComObj.TCoCreateInstanceExProc.
TCoInitializeExProc (see page 5607)	This is type ComObj.TCoInitializeExProc.
TComClass (see page 5607)	This is type ComObj.TComClass.
TConnectEvent (see page 5608)	This is type ComObj.TConnectEvent.
TCoReleaseServerProcessProc (see page 5608)	This is type ComObj.TCoReleaseServerProcessProc.
TCoResumeClassObjectsProc (see page 5608)	This is type ComObj.TCoResumeClassObjectsProc.

TCoSuspendClassObjectsProc (see page 5609)	This is type ComObj.TCoSuspendClassObjectsProc.
TFactoryProc (see page 5609)	This is type ComObj.TFactoryProc.
TTypedComClass (see page 5609)	This is type ComObj.TTypedComClass.

Variables

Name	Description
CoAddRefServerProcess (see page 5610)	This is variable ComObj.CoAddRefServerProcess.
CoCreateInstanceEx (see page 5610)	This is variable ComObj.CoCreateInstanceEx.
CoInitFlags (see page 5611)	Specifies the level of threading support requested for a COM server .EXE.
CoInitializeEx (see page 5611)	This is variable ComObj.CoInitializeEx.
CoReleaseServerProcess (see page 5612)	This is variable ComObj.CoReleaseServerProcess.
CoResumeClassObjects (see page 5612)	This is variable ComObj.CoResumeClassObjects.
CoSuspendClassObjects (see page 5612)	This is variable ComObj.CoSuspendClassObjects.

28.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EOleError (see page 5528)	EOleError is the exception class for low-level OLE errors.
	EOleException (see page 5529)	EOleException is the exception class for OLE automation errors that occur in methods or properties of an object.
	EOleRegistrationError (see page 5531)	EOleRegistrationError is the exception class for errors that occur when registering an OLE object.
	EOleSysError (see page 5532)	EOleSysError is the exception class for errors specific to the OLE IDispatch interface.
	TAutoIntfObject (see page 5534)	TAutoIntfObject implements the IDispatch and ISupportErrorInfo interfaces.
	TAutoObject (see page 5540)	TAutoObject is a CoClass that supports the IDispatch interface, and that can be used as a base class for ActiveX Automation servers.
	TAutoObjectFactory (see page 5545)	TAutoObjectFactory is the class factory for TAutoObject (see page 5540).
	TComClassManager (see page 5550)	TComClassManager is the class type of the ComClassManager (see page 5591) variable in the ComObj (see page 5525) unit.
	TComObject (see page 5553)	TComObject is the base class for creating simple COM classes, such as those used for creating Shell extensions.
	TComObjectFactory (see page 5563)	TComObjectFactory is the type of the class factory object used to instantiate a TComObject (see page 5553) class.
	TComServerObject (see page 5575)	TComServerObject is the abstract base class for TComServer.
	TTypedComObject (see page 5581)	TTypedComObject supports the IProvideClassInfo interface and is the class type for COM objects that can provide the type information without requiring a type library to be loaded.
	TTypedComObjectFactory (see page 5583)	TTypedComObjectFactory is the type of the class factory object used to instantiate a TypedComObject class.

28.1.1 EOleError Class

EOleError is the exception class for low-level OLE errors.

Class Hierarchy

Pascal

```
EOleError = class(Exception);
```

C++

```
class EOleError : public Exception;
```

File

ComObj

Description

EOleError is raised when the system returns a non-zero HRESULT involving low-level OLE errors or and old OLE 2 errors. The library checks for, but does not generate, these exceptions.

See Also

EOleException (see page 5529)

EOleSysError (see page 5532)

TObject (see page 22285)

TComObject (see page 5553)

28.1.2 EOleException Class

EOleException is the exception class for OLE automation errors that occur in methods or properties of an object.

Class Hierarchy

Pascal

```
EOleException = class(EOleSysError);
```

C++

```
class EOleException : public EOleSysError;
```

File

ComObj

Description

EOleException is the exception class for errors specific to the OLE IDispatch interface. EOleException is raised when an error occurs in the middle of a method call from IDispatch. EOleException is generated when a server receives a failure return value from a property or method that was called with the IDispatch interface Invoke method.

When an error occurs, objects invoked through IDispatch can return essential information about the exception, including the source of the error, error code, description, help file, and ID number for context-sensitive help. EOleException captures this information, and the error description and ID number (if available) are included in a message generated by the constructor; the other information is stored in the Source (see page 5531) and HelpFile (see page 5531) properties defined for EOleException and the ErrorCode (see page 5534) property inherited from EOleSysError (see page 5532).

Invoke

28.1.2.1 EOleException Members

The following tables list the members exposed by EOleException.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.

	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5530)	Creates an ole exception object.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	ErrorCode (see page 5534)	The status code returned by the failed method call, indicating the reason for the failure.
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	HelpFile (see page 5531)	Specifies the name and location of the help file that contains information about the error that occurred.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.
	Source (see page 5531)	Designates the application program in which the exception occurred.

28.1.2.2 EOleException.Create Constructor

Creates an ole exception object.

Pascal

```
constructor Create(const Message: string; ErrorCode: HRESULT; const Source: string; const
HelpFile: string; HelpContext: Integer);
```

C++

```
__fastcall EOleException(const AnsiString Message, HRESULT ErrorCode, const AnsiString Source,
```

```
const AnsiString HelpFile, int HelpContext);
```

Description

Create instantiates an EOleException (see page 5529) object.

Create allocates memory for the exception and initializes the ErrorCode (see page 5534), HelpFile (see page 5531), and Source (see page 5531) properties using information passed in the OLE EXCEPINFO structure. It then calls the inherited CreateHelp method to display the error description and ID number from EXCEPINFO.

See Also

Create (see page 5533)

28.1.2.3 EOleException Properties

The properties of the EOleException class are listed here.

Public Properties

	Name	Description
	HelpFile (see page 5531)	Specifies the name and location of the help file that contains information about the error that occurred.
	Source (see page 5531)	Designates the application program in which the exception occurred.

28.1.2.3.1 EOleException.HelpFile Property

Specifies the name and location of the help file that contains information about the error that occurred.

Pascal

```
property HelpFile: string;
```

C++

```
__property AnsiString HelpFile;
```

Description

HelpFile lists the name and complete directory path of the help file that contains information about the error.

28.1.2.3.2 EOleException.Source Property

Designates the application program in which the exception occurred.

Pascal

```
property Source: string;
```

C++

```
__property AnsiString Source;
```

Description

Source gives the source of the exception. Usually, this is the name of an application program.

28.1.3 EOleRegistrationError Class

EOleRegistrationError is the exception class for errors that occur when registering an OLE object.

Class Hierarchy

System::TObject → SysUtils.Exception → ComObj.EOleError → ComObj.EOleRegistrationError

Pascal

```
EOleRegistrationError = class(EOleError);
```

C++

```
class EOleRegistrationError : public EOleError;
```

File

ComObj

Description

EOleRegistrationError is raised by the CreateRegKey (see page 5593) method when it encounters an error while trying to register a COM class with the system registry.

28.1.4 EOleSysError Class

EOleSysError is the exception class for errors specific to the OLE IDispatch interface.

Class Hierarchy

System::TObject → SysUtils.Exception → ComObj.EOleError → ComObj.EOleSysError

Pascal

```
EOleSysError = class(EOleError);
```

C++

```
class EOleSysError : public EOleError;
```

File

ComObj

Description

EOleSysError is the exception class for errors that occur during an attempt to invoke a method or property of an OLE automation object. When the IDispatch Invoke method fails, EOleSysError is raised. Objects invoked through IDispatch can return the error code—an OLE status code or SCODE—indicating the reason for the error.

28.1.4.1 EOleSysError Members

The following tables list the members exposed by EOleSysError.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5533)	Creates an EOleSysError (see page 5532) object.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	ErrorCode (see page 5534)	The status code returned by the failed method call, indicating the reason for the failure.
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

28.1.4.2 EOleSysError.Create Constructor

Creates an EOleSysError (see page 5532) object.

Pascal

```
constructor Create(const Message: string; ErrorCode: HRESULT; HelpContext: Integer);
```

C++

```
__fastcall EOleSysError(const AnsiString Message, HRESULT ErrorCode, int HelpContext);
```

Description

Create calls SysErrorMessage to turn the OLE error code, ErrorCode (see page 5534), into a message string that it passes to the inherited constructor. EOleSysError (see page 5532) initializes the ErrorCode (see page 5534) property to the

ErrorCode (see page 5534) string.

See Also

CreateHelp (see page 22755)

ErrorCode (see page 5534)

28.1.4.3 EOleSysError Properties

The properties of the EOleSysError class are listed here.

Public Properties

	Name	Description
	ErrorCode (see page 5534)	The status code returned by the failed method call, indicating the reason for the failure.

28.1.4.3.1 EOleSysError.ErrorCode Property

The status code returned by the failed method call, indicating the reason for the failure.

Pascal

```
property ErrorCode: HRESULT;
```

C++

```
__property HRESULT ErrorCode;
```

Description

ErrorCode is the numerical error code returned by a failed call to an OLE automation object's method or property.

ErrorCode is initialized in the constructor.

See Also

Create (see page 5533)

28.1.5 TAutoIntfObject Class

TAutoIntfObject implements the IDispatch and ISupportErrorInfo interfaces.

Class Hierarchy

Pascal

```
TAutoIntfObject = class(TInterfacedObject, IDispatch, ISupportErrorInfo);
```

C++

```
class TAutoIntfObject : public TInterfacedObject, public IDispatch, public ISupportErrorInfo;
```

File

ComObj

Description

TAutoIntfObject is used internally by objects that support dispatch interfaces. By implementing the IDispatch interface, TAutoIntfObject encapsulates the functionality of an Automation object.

TAutoIntfObject does not have a class factory, so it can only be instantiated by calling the constructor. Objects that are externally instantiated typically have a class factory so that they can be instantiated in a standard way.

TAutoIntfObject supports OLE exception handling through its implementation of the ISupportErrorInfo interface.

TAutoIntfObject is similar to TAutoObject (see page 5540) in that both classes implement the IDispatch and (directly or indirectly) ISupportErrorInfo interfaces and both require a type library to support dual interfaces. TAutoIntfObject differs from TAutoObject (see page 5540) in that it does not have a class factory.

GetIDsOfNames (see page 5537), GetTypeInfo (see page 5537), GetTypeInfoCount (see page 5537), Invoke (see page 5538).

See Also

TAutoObject (see page 5540)

TAutoObjectFactory (see page 5545)

28.1.5.1 TAutoIntfObject Members

The following tables list the members exposed by TAutoIntfObject.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	GetIDsOfNames (see page 5537)	This is GetIDsOfNames, a member of class TAutoIntfObject.
	GetTypeInfo (see page 5537)	This is GetTypeInfo, a member of class TAutoIntfObject.
	GetTypeInfoCount (see page 5537)	This is GetTypeInfoCount, a member of class TAutoIntfObject.
	InterfaceSupportsErrorInfo (see page 5538)	This is InterfaceSupportsErrorInfo, a member of class TAutoIntfObject.
	Invoke (see page 5538)	This is Invoke, a member of class TAutoIntfObject.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5536)	Create instantiates an automation interface object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 5538)	SafeCallException is used for OLE exception handling.

Public Properties

	Name	Description
R	DispIID (see page 5539)	DispIID is the dispatch identifier.
R	DispIntfEntry (see page 5539)	DispIntfEntry contains the entry for the dispatch interface implemented by the automation object.
R	DispTypeInfo (see page 5539)	DispTypeInfo returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the automation object.
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

28.1.5.2 TAutoIntfObject.Create Constructor

Create instantiates an automation interface object.

Pascal

```
constructor Create(const TypeLib: ITypeLib; const DispIntf: TGUID);
```

C++

```
__fastcall TAutoIntfObject(const ITypeLib TypeLib, const TGUID DispIntf);
```

Description

You must use the constructor to instantiate TAutoIntfObject (see page 5534) descendants because there is no built-in class factory support.

TypeLib is an ITypeLib interface that can return the type information for DispIntf.

DispIntf is the GUID for the object you are creating.

Create allocates memory for an automation interface object, uses TypeLib to access the type information for DispIntf, and initializes the DispIntfEntry (see page 5539) property.

28.1.5.3 TAutoIntfObject Methods

The methods of the TAutoIntfObject class are listed here.

Protected Methods

	Name	Description
	GetIDsOfNames (see page 5537)	This is GetIDsOfNames, a member of class TAutoIntfObject.
	GetTypeInfo (see page 5537)	This is GetTypeInfo, a member of class TAutoIntfObject.
	GetTypeInfoCount (see page 5537)	This is GetTypeInfoCount, a member of class TAutoIntfObject.
	InterfaceSupportsErrorInfo (see page 5538)	This is InterfaceSupportsErrorInfo, a member of class TAutoIntfObject.
	Invoke (see page 5538)	This is Invoke, a member of class TAutoIntfObject.

Public Methods

	Name	Description
	SafeCallException (see page 5538)	SafeCallException is used for OLE exception handling.

28.1.5.3.1 TAutoIntfObject.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TAutoIntfObject.

28.1.5.3.2 TAutoIntfObject.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TAutoIntfObject.

28.1.5.3.3 TAutoIntfObject.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TAutoIntfObject.

28.1.5.3.4 TAutoIntfObject.InterfaceSupportsErrorInfo Method

Pascal

```
function InterfaceSupportsErrorInfo(const iid: TIID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT InterfaceSupportsErrorInfo(const TIID iid);
```

Description

This is InterfaceSupportsErrorInfo, a member of class TAutoIntfObject.

28.1.5.3.5 TAutoIntfObject.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TAutoIntfObject.

28.1.5.3.6 TAutoIntfObject.SafeCallException Method

SafeCallException is used for OLE exception handling.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException prevents an exception from escaping its scope. Any exceptions raised must also be handled within the method.

The implementation of a safecall method guarantees that no exceptions escape by enclosing the body of the method in an implied exception block.

Note: SafeCallException calls the global routine HandleSafeCallException (see page 5598), which provides a standard way of handling this behavior. Methods of a CoClass that supports OLE exception handling (that implements the ISupportErrorInfo interface) are affected by this function. If those CoClass methods use the safecall calling convention, they are modified to return an HRESULT. Procedures will return an HRESULT, and functions will pass their usual result value as the last (out) parameter, and will return an HRESULT instead. The method is enclosed in an exception block, after which the HRESULT is returned, and the environment is set up so that the ISupportErrorInfo implementation will work correctly.

28.1.5.4 TAutoIntfObject Properties

The properties of the TAutoIntfObject class are listed here.

Public Properties

	Name	Description
R	DispIID (see page 5539)	DispIID is the dispatch identifier.
R	DispIntfEntry (see page 5539)	DispIntfEntry contains the entry for the dispatch interface implemented by the automation object.
R	DispTypeInfo (see page 5539)	DispTypeInfo returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the automation object.

28.1.5.4.1 TAutoIntfObject.DispIID Property

DispIID is the dispatch identifier.

Pascal

```
property DispIID: TGUID;
```

C++

```
__property TGUID DispIID;
```

Description

DispIID is used for exception handling.

28.1.5.4.2 TAutoIntfObject.DispIntfEntry Property

DispIntfEntry contains the entry for the dispatch interface implemented by the automation object.

Pascal

```
property DispIntfEntry: PInterfaceEntry;
```

C++

```
__property PInterfaceEntry DispIntfEntry;
```

Description

DispIntfEntry is initialized in the constructor. DispIntfEntry returns the entry for a dispatch interface.

See Also

Create (see page 5536)

28.1.5.4.3 TAutoIntfObject.DispTypeInfo Property

DispTypeInfo returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the automation object.

Pascal

```
property DispTypeInfo: ITypeInfo;
```

C++

```
__property ITypeInfo DispTypeInfo;
```

Description

DispTypeInfo is used to provide type information on the automation object.

28.1.6 TAutoObject Class

TAutoObject is a CoClass that supports the IDispatch interface, and that can be used as a base class for ActiveX Automation servers.

Class Hierarchy

Pascal

```
TAutoObject = class(TTypedComObject, IDispatch);
```

C++

```
class TAutoObject : public TTypedComObject, public IDispatch;
```

File

ComObj

Description

TAutoObject is used as a base class for ActiveX control classes and provides support for ActiveX Automation objects.

To create a new Automation object, use the Automation wizard. The steps for creating an Automation object are covered in depth in the Developer's Guide or in the online document, Developing COM-based applications.

By implementing the IDispatch interface, TAutoObject encapsulates the following functionality:

Provides access to properties and methods exposed by an object by calling a method or by accessing a property of a specified dispatch interface (dispinterface), given any necessary parameters.

Converts text names of properties and methods (including their arguments) to their corresponding DISPIDs which identify them.

Determines whether there is type information available for this dispatch interface.

Retrieves the type information for a specified dispatch interface.

TAutoObject requires a type library because it supports dual interfaces, and because it inherits the IProvideClassInfo interface support which requires a type library. TAutoObject has a class factory. For creating automation objects that are used internally and do not need a class factory, use TAutoIntfObject (see page 5534) as a base class.

GetIDsOfNames (see page 5543), GetTypeInfo (see page 5543), GetTypeInfoCount (see page 5544), and Invoke (see page 5544).

28.1.6.1 TAutoObject Members

The following tables list the members exposed by TAutoObject.

Protected Methods

	Name	Description
	_AddRef (see page 5558)	This is _AddRef, a member of class TComObject.
	_Release (see page 5558)	This is _Release, a member of class TComObject.
	EventConnect (see page 5542)	This is EventConnect, a member of class TAutoObject.
V	EventSinkChanged (see page 5543)	This is EventSinkChanged, a member of class TAutoObject.
	GetClassInfo (see page 5583)	Returns a pointer to a TTypedComObject (see page 5581)'s type information.
V	GetIDsOfNames (see page 5543)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetTypeInfo (see page 5543)	Retrieves the type information for an object.
V	GetTypeInfoCount (see page 5544)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InterfaceSupportsErrorInfo (see page 5559)	This is InterfaceSupportsErrorInfo, a member of class TComObject.
V	Invoke (see page 5544)	Provides access to Automation properties and methods exposed by an object that supports the IDispatch interface.
	QueryInterface (see page 5560)	This is QueryInterface, a member of class TComObject.

Protected Properties

	Name	Description
R	AutoFactory (see page 5545)	The class factory that created this TAutoObject (see page 5540).
	EventSink (see page 5545)	This is EventSink, a member of class TAutoObject.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5555)	Instantiates a COM object that is not part of an aggregate.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateAggregated (see page 5556)	Instantiates a COM object that is part of an aggregate.
	CreateFromFactory (see page 5556)	Instantiates a COM object and initializes its values.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5557)	Disposes of an instance of a COM object.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	Initialize (see page 5544)	Provides an interface to a method that initializes the Automation object.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	ObjAddRef (see page 5559)	Implements the AddRef method of the IUnknown interface.
V	ObjQueryInterface (see page 5559)	Implements the QueryInterface (see page 5560) method of the IUnknown interface.
V	ObjRelease (see page 5559)	Implements the Release method of the IUnknown interface.
V	SafeCallException (see page 5560)	Handles OLE exceptions.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Controller (see page 5561)	Specifies the controlling IUnknown interface that controls interfaces within an aggregate object.
R	Factory (see page 5561)	Specifies the class factory object for the TComObject (see page 5553) class.
R	RefCount (see page 5562)	Indicates the number of references to the COM object that are currently in use.
	ServerExceptionHandler (see page 5562)	Provides access to the SafeCall exception notification process.

28.1.6.2 TAutoObject Methods

The methods of the TAutoObject class are listed here.

Protected Methods

	Name	Description
	EventConnect (see page 5542)	This is EventConnect, a member of class TAutoObject.
V	EventSinkChanged (see page 5543)	This is EventSinkChanged, a member of class TAutoObject.
V	GetIDsOfNames (see page 5543)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetTypeInfo (see page 5543)	Retrieves the type information for an object.
V	GetTypeInfoCount (see page 5544)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	Invoke (see page 5544)	Provides access to Automation properties and methods exposed by an object that supports the IDispatch interface.

Public Methods

	Name	Description
V	Initialize (see page 5544)	Provides an interface to a method that initializes the Automation object.

28.1.6.2.1 TAutoObject.EventConnect Method

Pascal

```
procedure EventConnect(const Sink: IUnknown; Connecting: Boolean);
```

C++

```
__fastcall EventConnect(const IUnknown Sink, Boolean Connecting);
```

Description

This is EventConnect, a member of class TAutoObject.

28.1.6.2.2 TAutoObject.EventSinkChanged Method

Pascal

```
procedure EventSinkChanged(const EventSink: IUnknown); virtual;
```

C++

```
virtual __fastcall EventSinkChanged(const IUnknown EventSink);
```

Description

This is EventSinkChanged, a member of class TAutoObject.

28.1.6.2.3 TAutoObject.GetIDsOfNames Method

Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int
NameCount, int LocaleID, void * DispIDs);
```

Description

GetIDsOfNames implements the IDispatch interface GetIDsOfNames method. GetIDsOfNames calls this method for the interface represented by the TAutoObject (see page 5540), passing the specified parameters. The returned value can be used on subsequent calls to the Invoke (see page 5544) method.

See Also

GetTypeInfo (see page 5543)

GetTypeInfoCount (see page 5544)

Invoke (see page 5544)

28.1.6.2.4 TAutoObject.GetTypeInfo Method

Retrieves the type information for an object.

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; virtual;
stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

GetTypeInfo implements the IDispatch interface GetTypeInfo method. GetTypeInfo calls the GetTypeInfo method for the interface for the interface represented by the TAutoObject (see page 5540), passing it the specified parameters. Use the returned value to get the type information for an interface implemented by the component.

See Also

GetIDsOfNames (see page 5543)

GetTypeInfoCount (see page 5544)

Invoke (see page 5544)

28.1.6.2.5 TAutoObject.GetTypeInfoCount Method

Returns the number of type information interfaces that an object provides (either 0 or 1).

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

GetTypeInfoCount implements the IDispatch interface GetTypeInfoCount method. GetTypeInfoCount calls this method for the interface represented by the TAutoObject (see page 5540). The out parameter points to a location that receives the number of type information interfaces provided by the object. If the object provides type information, this number is 1; otherwise the number is 0.

See Also

GetIDsOfNames (see page 5543)

GetTypeInfo (see page 5543)

Invoke (see page 5544)

28.1.6.2.6 TAutoObject.Initialize Method

Provides an interface to a method that initializes the Automation object.

Pascal

```
procedure Initialize; override;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize currently does nothing. Descendant Automation objects can override Initialize to provide some post-creation initialization of the object.

28.1.6.2.7 TAutoObject.Invoke Method

Provides access to Automation properties and methods exposed by an object that supports the IDispatch interface.

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word
Flags,  Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

Invoke implements the IDispatch interface Invoke method. Invoke is the standard mechanism for accessing the exposed properties and methods of an Automation object. Invoke calls the Invoke method for the interface represented by the TAutoObject (see page 5540), passing it the parameters specified by the function.

See Also

GetIDsOfNames (see page 5543)

GetTypeInfo (see page 5543)

GetTypeInfoCount (see page 5544)

28.1.6.3 TAutoObject Properties

The properties of the TAutoObject class are listed here.

Protected Properties

	Name	Description
R	AutoFactory (see page 5545)	The class factory that created this TAutoObject (see page 5540).
	EventSink (see page 5545)	This is EventSink, a member of class TAutoObject.

28.1.6.3.1 TAutoObject.AutoFactory Property

The class factory that created this TAutoObject (see page 5540).

Pascal

```
property AutoFactory: TAutoObjectFactory;
```

C++

```
__property TAutoObjectFactory AutoFactory;
```

Description

Factory (see page 5561) is the class factory that is used to instantiate a TAutoObject (see page 5540) instance.

28.1.6.3.2 TAutoObject.EventSink Property

Pascal

```
property EventSink: IUnknown;
```

C++

```
__property IUnknown EventSink;
```

Description

This is EventSink, a member of class TAutoObject.

28.1.7 TAutoObjectFactory Class

TAutoObjectFactory is the class factory for TAutoObject (see page 5540).

Class Hierarchy

Pascal

```
TAutoObjectFactory = class(TTypedComObjectFactory);
```

C++

```
class TAutoObjectFactory : public TTypedComObjectFactory;
```

File

ComObj

Description

TAutoObjectFactory creates instances of the TAutoObject (see page 5540) class, and has methods that manage the functionality of all of the instances of the automation objects it creates.

TAutoObjectFactory inherits support for the IClassFactory and IClassFactory2 interfaces.

Note: In Delphi applications, an Automation object is a COM object, which means that the module in which it is implemented must provide a factory object so that the system can create the Automation object. To add an Automation object factory to your program, create the factory object in the initialization section of the unit that defines the Automation object. For more information about COM factories, see TComObjectFactory (see page 5563).

See Also

TAutoObject (see page 5540)

TComObjectFactory (see page 5563)

28.1.7.1 TAutoObjectFactory Members

The following tables list the members exposed by TAutoObjectFactory.

Protected Methods

	Name	Description
	_AddRef (see page 5567)	This is _AddRef, a member of class TComObjectFactory.
	_Release (see page 5567)	This is _Release, a member of class TComObjectFactory.
	CreateInstance (see page 5568)	This is CreateInstance, a member of class TComObjectFactory.
	CreateInstanceLic (see page 5568)	This is CreateInstanceLic, a member of class TComObjectFactory.
V	GetLicenseString (see page 5568)	This is GetLicenseString, a member of class TComObjectFactory.
	GetLicInfo (see page 5568)	This is GetLicInfo, a member of class TComObjectFactory.
V	GetProgID (see page 5569)	This is GetProgID, a member of class TComObjectFactory.
V	HasMachineLicense (see page 5569)	This is HasMachineLicense, a member of class TComObjectFactory.
	LockServer (see page 5569)	This is LockServer, a member of class TComObjectFactory.
	QueryInterface (see page 5569)	This is QueryInterface, a member of class TComObjectFactory.
	RequestLicKey (see page 5570)	This is RequestLicKey, a member of class TComObjectFactory.
V	ValidateUserLicense (see page 5571)	This is ValidateUserLicense, a member of class TComObjectFactory.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.

	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5548)	This is Create, a member of class TAutoObjectFactory.
V	CreateComObject (see page 5567)	Instantiates a TComObject (see page 5553) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5566)	Disposes of an instance of a class factory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetInterfaceTypeInfo (see page 5586)	Retrieves the type information for the typed COM object created by the factory.
V	GetIntfEntry (see page 5548)	Returns the entry for a specific interface implemented in a class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RegisterClassObject (see page 5569)	Registers the COM class associated with the factory object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	UpdateRegistry (see page 5570)	Registers COM objects created by the factory.
V	UpdateRegistry (see page 5586)	Registers the typed COM object class.

Public Properties

	Name	Description
R	ClassID (see page 5571)	This is ClassID, a member of class TComObjectFactory.
R	ClassInfo (see page 5587)	Specifies an interface reference that provides type information without having to load a type library.
R	ClassName (see page 5572)	Specifies the name of the class that the class factory instantiates.
R	ComClass (see page 5572)	This is ComClass, a member of class TComObjectFactory.
R	ComServer (see page 5572)	This is ComServer, a member of class TComObjectFactory.
R	Description (see page 5572)	Describes the class object.
R	DispIntfEntry (see page 5549)	Contains the entry for the dispatch interface implemented by the OLE Automation object created by the factory.
R	DispTypeInfo (see page 5549)	Returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the OLE Automation object.
	ErrorIID (see page 5573)	Indicates the interface of the CoClass in which an error occurred.
R	EventIID (see page 5549)	This is EventIID, a member of class TAutoObjectFactory.
R	EventTypeInfo (see page 5550)	This is EventTypeInfo, a member of class TAutoObjectFactory.
R	Instancing (see page 5573)	Indicates the process space of COM object instances.
	LicString (see page 5573)	Contains licensing information about the object.
R	ProgID (see page 5574)	Specifies the name of the class factory.
	ShowErrors (see page 5574)	Indicates whether the COM object factory displays a message box when exceptions are raised.
	SupportsLicensing (see page 5574)	Indicates whether the object being instantiated supports licensing.
R	ThreadingModel (see page 5575)	Indicates the type of thread support provided by objects that the factory creates.

28.1.7.2 TAutoObjectFactory.Create Constructor

Pascal

```
constructor Create(ComServer: TComServerObject; AutoClass: TAutoClass; const ClassID: TGUID;
Instancing: TClassInstancing; ThreadingModel: TThreadingModel = tmSingle);
```

C++

```
__fastcall TAutoObjectFactory(TComServerObject ComServer, TAutoClass AutoClass, const TGUID
ClassID, TClassInstancing Instancing, TThreadingModel ThreadingModel = tmSingle);
```

Description

This is Create, a member of class TAutoObjectFactory.

28.1.7.3 TAutoObjectFactory Methods

The methods of the TAutoObjectFactory class are listed here.

Public Methods

	Name	Description
	GetIntfEntry (see page 5548)	Returns the entry for a specific interface implemented in a class.

28.1.7.3.1 TAutoObjectFactory.GetIntfEntry Method

Returns the entry for a specific interface implemented in a class.

Pascal

```
function GetIntfEntry(Guid: TGUID): PInterfaceEntry; virtual;
```

C++

```
virtual __fastcall PInterfaceEntry GetIntfEntry(TGUID Guid);
```

Description

GetIntfEntry calls the GetInterfaceEntry method for the CoClass associated with the class factory.

GetIntfEntry returns the entry for the interface, specified by the IID parameter, in the class. GetIntfEntry is used internally. It is rarely called directly.

One use for this method is to describe to OLE how to automatically dispatch calls to a dual-IDispatch interface. An interface type name, such as IUnknown, can be supplied as the IID parameter since the compiler will replace the interface with the associated GUID.

See Also

GetInterfaceEntry

28.1.7.4 TAutoObjectFactory Properties

The properties of the TAutoObjectFactory class are listed here.

Public Properties

	Name	Description
R	DispIntfEntry (see page 5549)	Contains the entry for the dispatch interface implemented by the OLE Automation object created by the factory.
R	DispTypeInfo (see page 5549)	Returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the OLE Automation object.
R	EventIID (see page 5549)	This is EventIID, a member of class TAutoObjectFactory.
R	EventTypeInfo (see page 5550)	This is EventTypeInfo, a member of class TAutoObjectFactory.

28.1.7.4.1 TAutoObjectFactory.DispIntfEntry Property

Contains the entry for the dispatch interface implemented by the OLE Automation object created by the factory.

Pascal

```
property DispIntfEntry: PInterfaceEntry;
```

C++

```
__property PInterfaceEntry DispIntfEntry;
```

Description

DispIntfEntry is initialized in the constructor. It indicates the entry for a dispatch interface.

See Also

Create

28.1.7.4.2 TAutoObjectFactory.DispTypeInfo Property

Returns an ITypeInfo interface reference to the type information for the dispinterface implemented by the OLE Automation object.

Pascal

```
property DispTypeInfo: ITypeInfo;
```

C++

```
__property ITypeInfo DispTypeInfo;
```

Description

DispTypeInfo is used to provide type information on the OLE Automation object created by the factory.

28.1.7.4.3 TAutoObjectFactory.EventIID Property

Pascal

```
property EventIID: TGUID;
```

C++

```
__property TGUID EventIID;
```

Description

This is EventIID, a member of class TAutoObjectFactory.

28.1.7.4.4 TAutoObjectFactory.EventTypeInfo Property

Pascal

```
property EventTypeInfo: ITypeInfo;
```

C++

```
__property ITypeInfo EventTypeInfo;
```

Description

This is EventTypeInfo, a member of class TAutoObjectFactory.

28.1.8 TComClassManager Class

TComClassManager is the class type of the ComClassManager (see page 5591) variable in the ComObj (see page 5525) unit.

Class Hierarchy

Pascal

```
TComClassManager = class(TObject);
```

C++

```
class TComClassManager : public TObject;
```

File

ComObj

Description

An instance of TComClassManager is returned by the ComClassManager (see page 5591) function in the ComObj (see page 5525) unit. This instance of TComClassManager manages the class factory objects owned by COM servers.

TComClassManager is a class designed for internal use to keep track of class factories.

For all servers linked to the module containing this unit, the manager returned by ComClassManager (see page 5591) maintains a list of pointers to the class factory objects. This list is updated by the individual COM servers, which add class factories objects when they are created and delete them when they are destroyed. The ComClass manager has methods that are used to manipulate class factories based upon their associated servers. These methods process iterative actions on factories or return factories based upon the class object type they create.

28.1.8.1 TComClassManager Members

The following tables list the members exposed by TComClassManager.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5551)	Creates an instance of the TComClassManager (see page 5550) class.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5552)	Destroys an instance of TComClassManager (see page 5550).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	ForEachFactory (see page 5552)	Processes iterative actions on factories associated with a given server.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetFactoryFromClass (see page 5553)	Returns the class factory for a given COM class.
	GetFactoryFromClassID (see page 5553)	Returns the class factory for a given COM class identifier.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

28.1.8.2 TComClassManager.Create Constructor

Creates an instance of the TComClassManager (see page 5550) class.

Pascal

```
constructor Create;
```

C++

```
__fastcall TComClassManager();
```

Description

Do not create instances of TComClassManager (see page 5550). Instead, use the ComClassManager (see page 5591) function to obtain a reference to the global COM class manager.

See Also

comclassmanager

28.1.8.3 TComClassManager.Destroy Destructor

Destroys an instance of TComClassManager (see page 5550).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComClassManager();
```

Description

Do not destroy the COM class manager. This is a global instance that is managed by Delphi.

See Also

Free (see page 22300)

28.1.8.4 TComClassManager Methods

The methods of the TComClassManager class are listed here.

Public Methods

	Name	Description
	ForEachFactory (see page 5552)	Processes iterative actions on factories associated with a given server.
	GetFactoryFromClass (see page 5553)	Returns the class factory for a given COM class.
	GetFactoryFromClassID (see page 5553)	Returns the class factory for a given COM class identifier.

28.1.8.4.1 TComClassManager.ForEachFactory Method

Processes iterative actions on factories associated with a given server.

Pascal

```
procedure ForEachFactory(ComServer: TComServerObject; FactoryProc: TFactoryProc);
```

C++

```
__fastcall ForEachFactory(TComServerObject ComServer, TFactoryProc FactoryProc);
```

Description

ForEachFactory is used to process an action, specified by the FactoryProc parameter, on all class factories in the factory list that are owned by the ComServer specified by the ComServer parameter.

ForEachFactory is used internally by the COM server to:

Destroy (see page 5552) factories when the associated COM server unloads.

Have factories register their class objects in the system registry, when the associated COM server initializes.

Have the factories update the system registry when necessary.

TFactoryProc (see page 5609) is the method-pointer type of the FactoryProc parameter of ForEachProperty. TFactoryProc (see page 5609) defines a method that takes a class factory as a parameter.

See Also

TComObjectFactory (see page 5563)

TComServerObject (see page 5575)

28.1.8.4.2 TComClassManager.GetFactoryFromClass Method

Returns the class factory for a given COM class.

Pascal

```
function GetFactoryFromClass(ComClass: TClass): TComObjectFactory;
```

C++

```
__fastcall TComObjectFactory GetFactoryFromClass(TClass ComClass);
```

Description

GetFactoryFromClass returns the class factory associated with the COM class specified by the ComClass parameter. If no such class factory is found in the list maintained by the ComClass manager, an EOleError (see page 5528) exception is raised indicating that the class factory for the specified COM class is not in the current list.

See Also

EOleError (see page 5528)

28.1.8.4.3 TComClassManager.GetFactoryFromClassID Method

Returns the class factory for a given COM class identifier.

Pascal

```
function GetFactoryFromClassID(const ClassID: TGUID): TComObjectFactory;
```

C++

```
__fastcall TComObjectFactory GetFactoryFromClassID(const TGUID ClassID);
```

Description

GetFactoryFromClassID is used internally by DllGetClassObject to obtain a reference to the IClassFactory interface of the corresponding class factory object for a given class object specified by the ClassID parameter.

GetFactoryFromClassID returns the class factory associated with the COM class specified by the ClassID parameter. If the class cannot be found, GetFactoryFromClassID returns nil (Delphi) or NULL (C++).

See Also

DllGetClassObject

28.1.9 TComObject Class

TComObject is the base class for creating simple COM classes, such as those used for creating Shell extensions.

Class Hierarchy

Pascal

```
TComObject = class(TObject, IUnknown, ISupportErrorInfo);
```

C++

```
class TComObject : public TObject, public IUnknown, public ISupportErrorInfo;
```

File

ComObj

Description

TComObject is a COM object that supports the IUnknown and ISupportErrorInfo interfaces. TComObject provides the implementation for simple COM objects that have:

A class identifier (CLSID) for external instantiation using a class factory.

Optional support for aggregation implemented through the IUnknown methods.

Support for the SafeCall calling convention and OLE exception-handling by implementing IProvideErrorInfo.

Support for the the IErrorInfo mechanism.

TComObject can be used as a base class for creating classes for COM objects that must have a class identifier (CLSID). CLSIDs are used to register the class in the database registry and to externally instantiate the class using a class factory. The class factory for TComObject is TComObjectFactory (see page 5563). The class factory properties provide information about TComObject class, such as its name, description, CLSID, and so on. The TComObjectFactory (see page 5563) methods are used to register the TComObject class in the registry and to instantiate it.

TComObject can be instantiated either as a single COM object, or as part of an aggregate. The IUnknown methods are implemented in TComObject to support aggregation by appropriately delegating to the controlling IUnknown interface when the instantiated COM object is the inner object of an aggregate. Consequently, for all interfaces that are implemented by the inner COM object, its reference count will not be directly affected when an interface reference is created.

TComObject supports the ISupportErrorInfo interface which allows OLE Automation controllers to query whether an error object will be available, and ensures that error information can be propagated correctly up the call chain. By implementing the ISupportErrorInfo interface method, InterfaceSupportsErrorInfo (see page 5559), TComObject supports the IErrorInfo mechanism, thereby providing support for OLE exception-handling and the safecall calling convention. The information available through the IErrorInfo interface is used for SafeCall error handling.

Using TComObject will not require the instantiated object to have a type library.

InterfaceSupportsErrorInfo (see page 5559) method

See Also

TComObjectFactory (see page 5563)

28.1.9.1 TComObject Members

The following tables list the members exposed by TComObject.

Protected Methods

	Name	Description
	_AddRef (see page 5558)	This is _AddRef, a member of class TComObject.
	_Release (see page 5558)	This is _Release, a member of class TComObject.
	InterfaceSupportsErrorInfo (see page 5559)	This is InterfaceSupportsErrorInfo, a member of class TComObject.
	QueryInterface (see page 5560)	This is QueryInterface, a member of class TComObject.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5555)	Instantiates a COM object that is not part of an aggregate.
	CreateAggregated (see page 5556)	Instantiates a COM object that is part of an aggregate.
	CreateFromFactory (see page 5556)	Instantiates a COM object and initializes its values.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5557)	Disposes of an instance of a COM object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	Initialize (see page 5558)	Provides an interface to a method that initializes the COM object.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	ObjAddRef (see page 5559)	Implements the AddRef method of the IUnknown interface.
V	ObjQueryInterface (see page 5559)	Implements the QueryInterface (see page 5560) method of the IUnknown interface.
V	ObjRelease (see page 5559)	Implements the Release method of the IUnknown interface.
V	SafeCallException (see page 5560)	Handles OLE exceptions.

Public Properties

	Name	Description
R	Controller (see page 5561)	Specifies the controlling IUnknown interface that controls interfaces within an aggregate object.
R	Factory (see page 5561)	Specifies the class factory object for the TComObject (see page 5553) class.
R	RefCount (see page 5562)	Indicates the number of references to the COM object that are currently in use.
	ServerExceptionHandler (see page 5562)	Provides access to the SafeCall exception notification process.

28.1.9.2 TComObject.Create Constructor

Instantiates a COM object that is not part of an aggregate.

Pascal

```
constructor Create;
```

C++

```
__fastcall TComObject();
```

Description

Call Create to instantiate a COM object that is not part of an aggregate, at runtime.

Create allocates memory for a COM object, and then directly calls the CreateFromFactory (see page 5556) constructor, passing it nil as the Controller (see page 5561) parameter to indicate that the COM object is not being created as part of an aggregate.

See Also

Controller (see page 5561)

CreateFromFactory (see page 5556)

28.1.9.3 TComObject.CreateAggregated Constructor

Instantiates a COM object that is part of an aggregate.

Pascal

```
constructor CreateAggregated(const Controller: IUnknown);
```

C++

```
__fastcall TComObject(const IUnknown Controller);
```

Description

Call CreateAggregated to instantiate a COM object that is part of an aggregate by passing it the IUnknown control object as the Controller (see page 5561) parameter.

CreateAggregated allocates memory for a COM object and then calls the CreateFromFactory (see page 5556) constructor. Because the newly instantiated COM object is part of an aggregate, CreateAggregated passes Controller (see page 5561) to CreateFromFactory (see page 5556) as its Controller (see page 5561) parameter. Controller (see page 5561) also becomes the value of the Controller (see page 5561) property of the COM object.

See Also

Controller (see page 5561)

CreateFromFactory (see page 5556)

28.1.9.4 TComObject.CreateFromFactory Constructor

Instantiates a COM object and initializes its values.

Pascal

```
constructor CreateFromFactory(Factory: TComObjectFactory; const Controller: IUnknown);
```

C++

```
__fastcall TComObject(TComObjectFactory Factory, const IUnknown Controller);
```

Description

Call Create (see page 5555) to instantiate a COM object that is not part of an aggregate, at runtime.

Create (see page 5555) allocates memory for a COM object, and then initializes the following properties:

Sets RefCount (see page 5562) to 1, as a means of artificial reference counting in the case that the newly created object has a zero reference count and is passed as a parameter.

Sets Factory (see page 5561) to the Factory (see page 5561) parameter, which is the instance of the class factory responsible for creating the object.

Sets Controller (see page 5561) to the Controller (see page 5561) parameter, which is either a control object, if the object is part of an aggregate, or nil if it is not.

Calls on the COM server to increment the reference count of objects dependent on it.

Calls Initialize (see page 5558).

Decrements the RefCount (see page 5562) that was artificially incremented.

See Also

Controller (see page 5561)

Factory (see page 5561)

Initialize (see page 5558)

RefCount (see page 5562)

comserver (see page 5572)

TComServerObject (see page 5575)

ObjectCount (see page 5631)

28.1.9.5 TComObject.Destroy Destructor

Disposes of an instance of a COM object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComObject();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the COM object is not nil before it calls Destroy.

Destroy checks to see if the Factory (see page 5561) property is nil. If it is nil, then Destroy passes False to the CountObject method of the Factory (see page 5561) object's ComServer, allowing the DLL (server) to be unloaded if no more objects are dependent upon the server.

See Also

Factory (see page 5561)

comserver (see page 5572)

ObjectCount (see page 5631)

Free (see page 22300)

28.1.9.6 TComObject Methods

The methods of the TComObject class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 5558)	This is _AddRef, a member of class TComObject.
	_Release (see page 5558)	This is _Release, a member of class TComObject.
	InterfaceSupportsErrorInfo (see page 5559)	This is InterfaceSupportsErrorInfo, a member of class TComObject.
	QueryInterface (see page 5560)	This is QueryInterface, a member of class TComObject.

Public Methods

	Name	Description
V	Initialize (see page 5558)	Provides an interface to a method that initializes the COM object.
V	ObjAddRef (see page 5559)	Implements the AddRef method of the IUnknown interface.
V	ObjQueryInterface (see page 5559)	Implements the QueryInterface (see page 5560) method of the IUnknown interface.
V	ObjRelease (see page 5559)	Implements the Release method of the IUnknown interface.
V	SafeCallException (see page 5560)	Handles OLE exceptions.

28.1.9.6.1 TComObject._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TComObject.

28.1.9.6.2 TComObject._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TComObject.

28.1.9.6.3 TComObject.Initialize Method

Provides an interface to a method that initializes the COM object.

Pascal

```
procedure Initialize; virtual;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize currently does nothing. Descendant COM objects can override Initialize to provide some post-creation initialization of the object.

See Also

Create_c

CreateFromFactory (see page 5556)

28.1.9.6.4 TComObject.InterfaceSupportsErrorInfo Method

Pascal

```
function InterfaceSupportsErrorInfo(const iid: TIID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT InterfaceSupportsErrorInfo(const TIID iid);
```

Description

This is InterfaceSupportsErrorInfo, a member of class TComObject.

28.1.9.6.5 TComObject.ObjAddRef Method

Implements the AddRef method of the IUnknown interface.

Pascal

```
function ObjAddRef: Integer; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall int ObjAddRef();
```

Description

ObjAddRef is used as the implementation of the IUnknown AddRef method, incrementing the reference count for the object.

28.1.9.6.6 TComObject.ObjQueryInterface Method

Implements the QueryInterface (see page 5560) method of the IUnknown interface.

Pascal

```
function ObjQueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT ObjQueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface (see page 5560) queries whether the COM object supports a given interface specified by the IID parameter. QueryInterface (see page 5560) is used as the implementation of the IUnknown QueryInterface (see page 5560) method when the COM object (TComObject (see page 5553)) is not part of an aggregate.

28.1.9.6.7 TComObject.ObjRelease Method

Implements the Release method of the IUnknown interface.

Pascal

```
function ObjRelease: Integer; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall int ObjRelease();
```

Description

ObjRelease is used as the implementation of the IUnknown Release method. It decrements the reference count for the object. If the reference count reaches 0, it automatically frees the object.

28.1.9.6.8 TComObject.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TComObject.

28.1.9.6.9 TComObject.SafeCallException Method

Handles OLE exceptions.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException prevents an exception from being raised to escape its scope. Any exceptions raised must also be handled within the method.

The implementation of a safecall method guarantees that no exceptions are raised by enclosing the statement part of the method in an implied exception block.

Note: SafeCallException calls the global routine HandleSafeCallException (see page 5598), which provides a standard way of handling this behavior. Methods of a CoClass that supports OLE exception handling (that implements the ISupportErrorInfo interface) are affected by this function. If those CoClass methods use the safecall calling convention, they are modified to return an HRESULT. Procedures will return an HRESULT, and functions will pass their usual result value as the last (out) parameter, and will return an HRESULT instead. The method is enclosed in a exception block, after which the HRESULT is returned, and the environment is set up so that the ISupportErrorInfo implementation will work correctly.

28.1.9.7 TComObject Properties

The properties of the TComObject class are listed here.

Public Properties

	Name	Description
R	Controller (see page 5561)	Specifies the controlling IUnknown interface that controls interfaces within an aggregate object.
R	Factory (see page 5561)	Specifies the class factory object for the TComObject (see page 5553) class.
R	RefCount (see page 5562)	Indicates the number of references to the COM object that are currently in use.
	ServerExceptionHandler (see page 5562)	Provides access to the SafeCall exception notification process.

28.1.9.7.1 TComObject.Controller Property

Specifies the controlling IUnknown interface that controls interfaces within an aggregate object.

Pascal

```
property Controller: IUnknown;
```

C++

```
__property IUnknown Controller;
```

Description

Controller is the controlling IUnknown interface for the inner object in an aggregate. The QueryInterface (see page 5560), AddRef, and Release methods of all other interfaces of the inner object (except IUnknown) must delegate to the controlling IUnknown. Because of this delegation, the inner object's reference count is not affected when these methods are called.

Controller is nil (Delphi) or NULL (C++) if the object is not part of an aggregate. If Controller is not nil (Delphi) or NULL (C++), the object is part of an aggregate, and Controller is the controlling interface.

Create_c

CreateAggregated (see page 5556)

TAggregatedObject (see page 22248)

TComObjectFactory (see page 5563)

TContainedObject (see page 22253)

28.1.9.7.2 TComObject.Factory Property

Specifies the class factory object for the TComObject (see page 5553) class.

Pascal

```
property Factory: TComObjectFactory;
```

C++

```
__property TComObjectFactory Factory;
```

Description

Factory is the class factory which is used to instantiate a TComObject (see page 5553).

See Also

TComClassManager (see page 5550)

TComObjectFactory (see page 5563)

28.1.9.7.3 TComObject.RefCount Property

Indicates the number of references to the COM object that are currently in use.

Pascal

```
property RefCount: Integer;
```

C++

```
__property int RefCount;
```

Description

RefCount is used to determine when the object can be destroyed. RefCount is the number of references to interfaces implemented by the COM object. When RefCount is zero, the object can be is destroyed.

RefCount is automatically incremented when references to interfaces implemented by the COM object are created, and is automatically decremented when those references are destroyed. RefCount is usually incremented by the IUnknown AddRef method and decremented by the IUnknown method, Release.

RefCount can be artificially incremented when a new object is created which may be passed as a function parameter. In this case, RefCount should not be zero, and should be incremented prior to the function call and decremented when the function returns.

Note: In Delphi code, the CreateFromFactory (see page 5556) method artificially increment and decrements RefCount.

Note: In C++ code, if you pass a class factory to the constructor as the first parameter, the constructor artificially increments and decrements RefCount.

See Also

CreateFromFactory (see page 5556)

Create_c

AddRef

Release

28.1.9.7.4 TComObject.ServerExceptionHandler Property

Provides access to the SafeCall exception notification process.

Pascal

```
property ServerExceptionHandler: IServerExceptionHandler;
```

C++

```
__property IServerExceptionHandler ServerExceptionHandler;
```

Description

The ServerExceptionHandler property provides a way for you to access the SafeCall exception notification process so that you can log or reroute those notifications to an external monitor. The monitor can be another object within the same COM server module, or it could be on a different machine entirely.

For example, server exception handlers could be implemented to:

Log COM server exceptions to the NT system event log

Write exceptions to a text file

Send email to an administrator

Alert support personnel through a pager

The ServerExceptionHandler property is useful for administering remote servers, particularly if a server is physically unreachable. For example, when an exception is raised in a COM object, if the server application is a VCL forms-based application (not just a DLL), then the VCL default exception handler may show a message box on the server. No client requests on that COM object instance can be serviced until the message box is closed. By reporting the exception to an event log, others can see the information from any remote location, as long as the remote users have access rights on the server.

Tip: The ServerExceptionHandler property would be particularly useful for COM objects (either stand-alone or those running in the MTS environment), that are used in active server pages. You can use the ServerExceptionHandler property to write exception information in HTML or in any other format you desire.

28.1.10 TComObjectFactory Class

TComObjectFactory is the type of the class factory object used to instantiate a TComObject (see page 5553) class.

Class Hierarchy

Pascal

```
TComObjectFactory = class(TObject, IUnknown, IClassFactory, IClassFactory2);
```

C++

```
class TComObjectFactory : public TObject, public IUnknown, public IClassFactory, public
IClassFactory2;
```

File

ComObj

Description

TComObjectFactory supports the IUnknown, IClassFactory, and IClassFactory2 interfaces. The IClassFactory interface is implemented by class objects associated with class identifiers (CLSIDs) for the classes that they instantiate. IClassFactory must be implemented for every object definition, so that objects of that type can be created. The IClassFactory2 interface is implemented by class factories for classes that need support for licensing.

Class factories instantiate the COM classes specified by a registered class identifier (CLSID). Class factory objects are created automatically by the COM servers that contain the code for the class objects and their associated classes. When a class factory is created, the CLSID is specified in a parameter to the constructor of the class factory object. This CLSID indicates the type of object for which the class factory creates instances.

Class factory objects can also be externally instantiated by directly calling the Windows API function CoCreateClassObject. The functions CreateComObject (see page 5567) or CreateOleObject (see page 5592) can also be called to instantiate a COM class. These functions indirectly use class factories to instantiate the classes. When creating multiple instances of a class that has a CLSID, however, it is more efficient to instantiate a class factory, obtain a pointer to its IClassFactory interface, and use its methods as needed.

Class factories are managed on the server by a global class manager accessed using the ComClassManager (see page 5591) function. This class manager maintains a list of class factories through which the factories are manipulated, usually according to the COM server that owns them.

28.1.10.1 TComObjectFactory Members

The following tables list the members exposed by TComObjectFactory.

Protected Methods

	Name	Description
	_AddRef (see page 5567)	This is _AddRef, a member of class TComObjectFactory.
	_Release (see page 5567)	This is _Release, a member of class TComObjectFactory.
	CreateInstance (see page 5568)	This is CreateInstance, a member of class TComObjectFactory.
	CreateInstanceLic (see page 5568)	This is CreateInstanceLic, a member of class TComObjectFactory.
V	GetLicenseString (see page 5568)	This is GetLicenseString, a member of class TComObjectFactory.
	GetLicInfo (see page 5568)	This is GetLicInfo, a member of class TComObjectFactory.
V	GetProgID (see page 5569)	This is GetProgID, a member of class TComObjectFactory.
V	HasMachineLicense (see page 5569)	This is HasMachineLicense, a member of class TComObjectFactory.
	LockServer (see page 5569)	This is LockServer, a member of class TComObjectFactory.
	QueryInterface (see page 5569)	This is QueryInterface, a member of class TComObjectFactory.
	RequestLicKey (see page 5570)	This is RequestLicKey, a member of class TComObjectFactory.
V	ValidateUserLicense (see page 5571)	This is ValidateUserLicense, a member of class TComObjectFactory.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5565)	Instantiates a class factory object.
V	CreateComObject (see page 5567)	Instantiates a TComObject (see page 5553) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5566)	Disposes of an instance of a class factory.

V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RegisterClassObject (see page 5569)	Registers the COM class associated with the factory object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	UpdateRegistry (see page 5570)	Registers COM objects created by the factory.

Public Properties

	Name	Description
R	ClassID (see page 5571)	This is ClassID, a member of class TComObjectFactory.
R	ClassName (see page 5572)	Specifies the name of the class that the class factory instantiates.
R	ComClass (see page 5572)	This is ComClass, a member of class TComObjectFactory.
R	ComServer (see page 5572)	This is ComServer, a member of class TComObjectFactory.
R	Description (see page 5572)	Describes the class object.
	ErrorIID (see page 5573)	Indicates the interface of the CoClass in which an error occurred.
R	Instancing (see page 5573)	Indicates the process space of COM object instances.
	LicString (see page 5573)	Contains licensing information about the object.
R	ProgID (see page 5574)	Specifies the name of the class factory.
	ShowErrors (see page 5574)	Indicates whether the COM object factory displays a message box when exceptions are raised.
	SupportsLicensing (see page 5574)	Indicates whether the object being instantiated supports licensing.
R	ThreadingModel (see page 5575)	Indicates the type of thread support provided by objects that the factory creates.

28.1.10.2 TComObjectFactory.Create Constructor

Instantiates a class factory object.

Pascal

```
constructor Create(ComServer: TComServerObject; ComClass: TComClass; const ClassID: TGUID;
const ClassName: string; const Description: string; Instancing: TClassInstancing;
ThreadingModel: TThreadingModel = tmSingle);
```

C++

```
__fastcall TComObjectFactory(TComServerObject ComServer, TComClass ComClass, const TGUID
ClassID, const AnsiString ClassName, const AnsiString Description, TClassInstancing
Instancing, TThreadingModel ThreadingModel = tmSingle);
```

Description

Create instantiates a class factory, usually when the server is loaded. Class factories should be instantiated in the initialization section of the unit that includes their associated server, so that they are automatically available when the server is loaded.

Create allocates memory for a class factory object, and adds the object to the class factory list managed by the

ComClassManager (see page 5591). Then Create initializes the following properties with values passed to it:

Sets ComServer (see page 5572) to the ComServer (see page 5572) parameter.

Sets ComClass (see page 5572) to the ComClass (see page 5572) parameter.

Sets ClassID (see page 5571) to the ClassID (see page 5571) parameter.

Sets ClassName (see page 5572) to the ClassName (see page 5572) parameter.

Sets Description (see page 5572) to the Description (see page 5572) parameter.

Sets Instancing (see page 5573) to the Instancing (see page 5573) parameter.

Sets ThreadingModel (see page 5575) to the ThreadingModel (see page 5575) parameter.

Sets ErrorIID (see page 5573) to IUnknown.

See Also

ComClassManager

Instancing (see page 5573)

ThreadingModel (see page 5575)

28.1.10.3 TComObjectFactory.Destroy Destructor

Disposes of an instance of a class factory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComObjectFactory();
```

Description

Do not call Destroy directly in an application. Class factories are automatically destroyed when their corresponding servers are unloaded.

Free (see page 22300)

28.1.10.4 TComObjectFactory Methods

The methods of the TComObjectFactory class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 5567)	This is _AddRef, a member of class TComObjectFactory.
	_Release (see page 5567)	This is _Release, a member of class TComObjectFactory.
	CreateInstance (see page 5568)	This is CreateInstance, a member of class TComObjectFactory.
	CreateInstanceLic (see page 5568)	This is CreateInstanceLic, a member of class TComObjectFactory.
V	GetLicenseString (see page 5568)	This is GetLicenseString, a member of class TComObjectFactory.
	GetLicInfo (see page 5568)	This is GetLicInfo, a member of class TComObjectFactory.
V	GetProgID (see page 5569)	This is GetProgID, a member of class TComObjectFactory.
V	HasMachineLicense (see page 5569)	This is HasMachineLicense, a member of class TComObjectFactory.

	LockServer (see page 5569)	This is LockServer, a member of class TComObjectFactory.
	QueryInterface (see page 5569)	This is QueryInterface, a member of class TComObjectFactory.
	RequestLicKey (see page 5570)	This is RequestLicKey, a member of class TComObjectFactory.
V	ValidateUserLicense (see page 5571)	This is ValidateUserLicense, a member of class TComObjectFactory.

Public Methods

	Name	Description
V	CreateComObject (see page 5567)	Instantiates a TComObject (see page 5553) object.
	RegisterClassObject (see page 5569)	Registers the COM class associated with the factory object.
V	UpdateRegistry (see page 5570)	Registers COM objects created by the factory.

28.1.10.4.1 TComObjectFactory._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TComObjectFactory.

28.1.10.4.2 TComObjectFactory._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TComObjectFactory.

28.1.10.4.3 TComObjectFactory.CreateComObject Method

Instantiates a TComObject (see page 5553) object.

Pascal

```
function CreateComObject(const Controller: IUnknown): TComObject; virtual;
```

C++

```
virtual __fastcall TComObject CreateComObject(const IUnknown Controller);
```

Description

CreateComObject is the method that instantiates the class type for which TComObjectFactory (see page 5563) is the class factory. CreateComObject calls the CreateFromFactory constructor of the TComObject (see page 5553) class to create a COM object. CreateComObject passes itself as the Factory parameter to CreateFromFactory.

CreateComClass creates a COM object based upon the value of the ComClass (see page 5572) property. ComClass (see page 5572) is the class identifier (CLSID) used by other applications to identify the COM class for which they request an object instance.

See Also

comclass (see page 5572)

CreateFromFactory (see page 5556)

TComObject (see page 5553)

28.1.10.4.4 TComObjectFactory.CreateInstance Method

Pascal

```
function CreateInstance(const UnkOuter: IUnknown; const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CreateInstance(const IUnknown UnkOuter, const TGUID IID,  Obj);
```

Description

This is CreateInstance, a member of class TComObjectFactory.

28.1.10.4.5 TComObjectFactory.CreateInstanceLic Method

Pascal

```
function CreateInstanceLic(const unkOuter: IUnknown; const unkReserved: IUnknown; const iid:
TIID; const bstrKey: WideString; out vObject): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CreateInstanceLic(const IUnknown unkOuter, const IUnknown
unkReserved, const TIID iid, const BSTR bstrKey,  vObject);
```

Description

This is CreateInstanceLic, a member of class TComObjectFactory.

28.1.10.4.6 TComObjectFactory.GetLicenseString Method

Pascal

```
function GetLicenseString: WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetLicenseString();
```

Description

This is GetLicenseString, a member of class TComObjectFactory.

28.1.10.4.7 TComObjectFactory.GetLicInfo Method

Pascal

```
function GetLicInfo(var licInfo: TLicInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetLicInfo(TLicInfo licInfo);
```

Description

This is GetLicInfo, a member of class TComObjectFactory.

28.1.10.4.8 TComObjectFactory.GetProgID Method

Pascal

```
function GetProgID: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetProgID();
```

Description

This is GetProgID, a member of class TComObjectFactory.

28.1.10.4.9 TComObjectFactory.HasMachineLicense Method

Pascal

```
function HasMachineLicense: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean HasMachineLicense();
```

Description

This is HasMachineLicense, a member of class TComObjectFactory.

28.1.10.4.10 TComObjectFactory.LockServer Method

Pascal

```
function LockServer(fLock: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT LockServer(BOOL fLock);
```

Description

This is LockServer, a member of class TComObjectFactory.

28.1.10.4.11 TComObjectFactory.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TComObjectFactory.

28.1.10.4.12 TComObjectFactory.RegisterClassObject Method

Registers the COM class associated with the factory object.

Pascal

```
procedure RegisterClassObject;
```

C++

```
__fastcall RegisterClassObject();
```

Description

RegisterClassObject registers an EXE class object with OLE so other applications can connect to it. EXE object applications should call RegisterClassObject on startup. It can also be used to register internal objects for use by the same EXE or other code (such as DLLs) that the EXE uses.

If RegisterClassObject is not successful, an EOleSysError (see page 5532) is raised with the following error code possibilities:

Value	Meaning
E_INVALIDARG	One or more the arguments are invalid.
E_OUTOFMEMORY	Not enough memory.
E_UNEXPECTED	An unexpected error occurred.
CO_E_OBJISREG	The class was already registered in the class object table.

Only EXE object applications call RegisterClassObject. Object handlers or DLL object applications do not call this function. Instead, they must implement and export the DllGetClassObject function.

At startup, a multiple-use EXE object application must create a class object (with the IClassFactory interface on it), and call RegisterClassObject to register the class object. Object applications that support several different classes (such as multiple types of embeddable objects) must allocate and register a different class object for each.

Multiple registrations of the same class object are independent and do not produce an error. Each subsequent registration yields a unique key.

See Also

DllGetClassObject

28.1.10.4.13 TComObjectFactory.RequestLicKey Method

Pascal

```
function RequestLicKey(dwResrved: Longint; out bstrKey: WideString): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT RequestLicKey(Longint dwResrved, BSTR bstrKey);
```

Description

This is RequestLicKey, a member of class TComObjectFactory.

28.1.10.4.14 TComObjectFactory.UpdateRegistry Method

Registers COM objects created by the factory.

Pascal

```
procedure UpdateRegistry(Register: Boolean); virtual;
```

C++

```
virtual __fastcall UpdateRegistry(Boolean Register);
```

Description

UpdateRegistry is called for EXEs when the EXE is run, and for DLLs or EXEs when the routines are called to specifically

register or unregister the server.

See Also

DLLRegisterServer

DLLUnregisterServer

RegisterClassObject (see page 5569)

28.1.10.4.15 TComObjectFactory.ValidateUserLicense Method

Pascal

```
function ValidateUserLicense(const LicStr: WideString): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ValidateUserLicense(const BSTR LicStr);
```

Description

This is ValidateUserLicense, a member of class TComObjectFactory.

28.1.10.5 TComObjectFactory Properties

The properties of the TComObjectFactory class are listed here.

Public Properties

	Name	Description
R	ClassID (see page 5571)	This is ClassID, a member of class TComObjectFactory.
R	ClassName (see page 5572)	Specifies the name of the class that the class factory instantiates.
R	ComClass (see page 5572)	This is ComClass, a member of class TComObjectFactory.
R	ComServer (see page 5572)	This is ComServer, a member of class TComObjectFactory.
R	Description (see page 5572)	Describes the class object.
	ErrorIID (see page 5573)	Indicates the interface of the CoClass in which an error occurred.
R	Instancing (see page 5573)	Indicates the process space of COM object instances.
	LicString (see page 5573)	Contains licensing information about the object.
R	ProgID (see page 5574)	Specifies the name of the class factory.
	ShowErrors (see page 5574)	Indicates whether the COM object factory displays a message box when exceptions are raised.
	SupportsLicensing (see page 5574)	Indicates whether the object being instantiated supports licensing.
R	ThreadingModel (see page 5575)	Indicates the type of thread support provided by objects that the factory creates.

28.1.10.5.1 TComObjectFactory.ClassID Property

Pascal

```
property ClassID: TGUID;
```

C++

```
__property TGUID ClassID;
```

Description

This is ClassID, a member of class TComObjectFactory.

28.1.10.5.2 TComObjectFactory.ClassName Property

Specifies the name of the class that the class factory instantiates.

Pascal

```
property ClassName: string;
```

C++

```
__property AnsiString ClassName;
```

Description

ClassName is the name identifying the COM class that the class factory instantiates.

ClassName is initialized, in the class factory constructor, to the class name that is passed to the constructor.

See Also

ClassIDToProgID

Create (see page 5565)

ProgIDToClassID

Create (see page 5565)

28.1.10.5.3 TComObjectFactory.ComClass Property

Pascal

```
property ComClass: TClass;
```

C++

```
__property TClass ComClass;
```

Description

This is ComClass, a member of class TComObjectFactory.

28.1.10.5.4 TComObjectFactory.ComServer Property

Pascal

```
property ComServer: TComServerObject;
```

C++

```
__property TComServerObject ComServer;
```

Description

This is ComServer, a member of class TComObjectFactory.

28.1.10.5.5 TComObjectFactory.Description Property

Describes the class object.

Pascal

```
property Description: string;
```

C++

```
__property AnsiString Description;
```

Description

Description is used in the registration database, when the class factory is registered, to describe the class object.

Description is initialized, in the class factory constructor, to the Description parameter that is passed to the constructor. This description is retrieved from the type library.

See Also

Create (see page 5565)

28.1.10.5.6 TComObjectFactory.ErrorIID Property

Indicates the interface of the CoClass in which an error occurred.

Pascal

```
property ErrorIID: TGUID;
```

C++

```
__property TGUID ErrorIID;
```

Description

Use ErrorIID to determine the interface in which an error occurred. For most CoClasses, this is the primary interface for that CoClass, as indicated in the type library.

See Also

Create (see page 5565)

28.1.10.5.7 TComObjectFactory.Instancing Property

Indicates the process space of COM object instances.

Pascal

```
property Instancing: TClassInstancing;
```

C++

```
__property TClassInstancing Instancing;
```

Description

Instancing determines the process space in which the factory can create COM objects and whether the factory can create multiple instances within a single process space. Instancing is initialized in the class factory constructor to the Instancing parameter that is passed to the constructor.

See Also

Create (see page 5565)

28.1.10.5.8 TComObjectFactory.LicString Property

Contains licensing information about the object.

Pascal

```
property LicString: WideString;
```

C++

```
__property BSTR LicString;
```

Description

LicString is used to verify the user has valid access to the object for development. LicString can be any string defined by the developer who is optionally licensing the object.

28.1.10.5.9 TComObjectFactory.ProgID Property

Specifies the name of the class factory.

Pascal

```
property ProgID: string;
```

C++

```
__property AnsiString ProgID;
```

Description

ProgID is the programmatic identifier that specifies the vendor, component, and version of the class factory object.

Every object class that can be inserted into an OLE container has ProgID.

See Also

ClassIDToProgID

ProgIDToClassID

28.1.10.5.10 TComObjectFactory.ShowErrors Property

Indicates whether the COM object factory displays a message box when exceptions are raised.

Pascal

```
property ShowErrors: Boolean;
```

C++

```
__property Boolean ShowErrors;
```

Description

When ShowErrors is true, exceptions that are raised when trying to create a COM object are caught and a message box appears to describe the error. When ShowErrors is false, the exception is not caught by the COM object factory.

28.1.10.5.11 TComObjectFactory.SupportsLicensing Property

Indicates whether the object being instantiated supports licensing.

Pascal

```
property SupportsLicensing: Boolean;
```

C++

```
__property Boolean SupportsLicensing;
```

Description

SupportsLicensing is used to determine whether a user has valid access to the object.

28.1.10.5.12 TComObjectFactory.ThreadingModel Property

Indicates the type of thread support provided by objects that the factory creates.

Pascal

```
property ThreadingModel: TThreadingModel;
```

C++

```
__property TThreadingModel ThreadingModel;
```

Description

The threading model of a factory is initialized in the constructor. The factory uses this value to indicate how COM should serialize calls to the objects that it creates. Use this value to determine the type of thread support you must provide in the implementation of the associated COM object.

See Also

Create (see page 5565)

28.1.11 TComServerObject Class

TComServerObject is the abstract base class for TComServer.

Class Hierarchy

Pascal

```
TComServerObject = class(TObject);
```

C++

```
class TComServerObject : public TObject;
```

File

ComObj

Description

TComServerObject is used as a base class for the TComServer class. All of its methods are abstract and protected. The TComServerObject introduces protected abstract methods that are overridden in descendant classes as accessor functions for its properties. These methods are implemented in the TComServer class. All of the properties of TComServerObject are read-only.

To use a COM server object, include the ComServ (see page 5621) unit in the project. This unit automatically instantiates the descendant TComServer class and assigns that object to the ComServ (see page 5621) variable in the ComServ (see page 5621) unit.

See Also

ComServer

TComServer (see page 5623)

28.1.11.1 TComServerObject Members

The following tables list the members exposed by TComServerObject.

Protected Methods

	Name	Description
	CountFactory (see page 5577)	This is CountFactory, a member of class TComServerObject.
	CountObject (see page 5577)	This is CountObject, a member of class TComServerObject.
	GetHelpFileName (see page 5577)	This is GetHelpFileName, a member of class TComServerObject.
	GetServerFileName (see page 5578)	This is GetServerFileName, a member of class TComServerObject.
	GetServerKey (see page 5578)	This is GetServerKey, a member of class TComServerObject.
	GetServerName (see page 5578)	This is GetServerName, a member of class TComServerObject.
	GetStartSuspended (see page 5578)	This is GetStartSuspended, a member of class TComServerObject.
	GetTypeLib (see page 5579)	This is GetTypeLib, a member of class TComServerObject.
	SetHelpFileName (see page 5579)	This is SetHelpFileName, a member of class TComServerObject.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpFileName (see page 5579)	Specifies the name of the Help file associated with the module.
	ServerFileName (see page 5580)	Specifies the complete path and filename of the COM server.

R	ServerKey (see page 5580)	Indicates whether the COM server is an in-process server or whether it is a local server.
R	ServerName (see page 5580)	Specifies the name of the executable file for the server.
R	StartSuspended (see page 5580)	Specifies whether the server started in a suspended state.
R	TypeLib (see page 5581)	Provides access to the type library associated with the COM server.

28.1.11.2 TComServerObject Methods

The methods of the TComServerObject class are listed here.

Protected Methods

	Name	Description
A	CountFactory (see page 5577)	This is CountFactory, a member of class TComServerObject.
A	CountObject (see page 5577)	This is CountObject, a member of class TComServerObject.
A	GetHelpFileName (see page 5577)	This is GetHelpFileName, a member of class TComServerObject.
A	GetServerFileName (see page 5578)	This is GetServerFileName, a member of class TComServerObject.
A	GetServerKey (see page 5578)	This is GetServerKey, a member of class TComServerObject.
A	GetServerName (see page 5578)	This is GetServerName, a member of class TComServerObject.
A	GetStartSuspended (see page 5578)	This is GetStartSuspended, a member of class TComServerObject.
A	GetTypeLib (see page 5579)	This is GetTypeLib, a member of class TComServerObject.
A	SetHelpFileName (see page 5579)	This is SetHelpFileName, a member of class TComServerObject.

28.1.11.2.1 TComServerObject.CountFactory Method

Pascal

```
function CountFactory(Created: Boolean): Integer; virtual; abstract;
```

C++

```
virtual __fastcall int CountFactory(Boolean Created) = 0;
```

Description

This is CountFactory, a member of class TComServerObject.

28.1.11.2.2 TComServerObject.CountObject Method

Pascal

```
function CountObject(Created: Boolean): Integer; virtual; abstract;
```

C++

```
virtual __fastcall int CountObject(Boolean Created) = 0;
```

Description

This is CountObject, a member of class TComServerObject.

28.1.11.2.3 TComServerObject.GetHelpFileName Method

Pascal

```
function GetHelpFileName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetHelpFileName() = 0;
```

Description

This is GetHelpFileName, a member of class TComServerObject.

28.1.11.2.4 TComServerObject.GetServerFileName Method

Pascal

```
function GetServerFileName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetServerFileName() = 0;
```

Description

This is GetServerFileName, a member of class TComServerObject.

28.1.11.2.5 TComServerObject.GetServerKey Method

Pascal

```
function GetServerKey: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetServerKey() = 0;
```

Description

This is GetServerKey, a member of class TComServerObject.

28.1.11.2.6 TComServerObject.GetServerName Method

Pascal

```
function GetServerName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetServerName() = 0;
```

Description

This is GetServerName, a member of class TComServerObject.

28.1.11.2.7 TComServerObject.GetStartSuspended Method

Pascal

```
function GetStartSuspended: Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean GetStartSuspended() = 0;
```

Description

This is GetStartSuspended, a member of class TComServerObject.

28.1.11.2.8 TComServerObject.GetTypeLib Method

Pascal

```
function GetTypeLib: ITypeLib; virtual; abstract;
```

C++

```
virtual __fastcall ITypeLib GetTypeLib() = 0;
```

Description

This is GetTypeLib, a member of class TComServerObject.

28.1.11.2.9 TComServerObject.SetHelpFileName Method

Pascal

```
procedure SetHelpFileName(const Value: string); virtual; abstract;
```

C++

```
virtual __fastcall SetHelpFileName(const AnsiString Value) = 0;
```

Description

This is SetHelpFileName, a member of class TComServerObject.

28.1.11.3 TComServerObject Properties

The properties of the TComServerObject class are listed here.

Public Properties

	Name	Description
	HelpFileName (see page 5579)	Specifies the name of the Help file associated with the module.
R	ServerFileName (see page 5580)	Specifies the complete path and filename of the COM server.
R	ServerKey (see page 5580)	Indicates whether the COM server is an in-process server or whether it is a local server.
R	ServerName (see page 5580)	Specifies the name of the executable file for the server.
R	StartSuspended (see page 5580)	Specifies whether the server started in a suspended state.
R	TypeLib (see page 5581)	Provides access to the type library associated with the COM server.

28.1.11.3.1 TComServerObject.HelpFileName Property

Specifies the name of the Help file associated with the module.

Pascal

```
property HelpFileName: string;
```

C++

```
__property AnsiString HelpFileName;
```

Description

The abstract accessor methods for HelpFileName are overridden in descendant classes.

28.1.11.3.2 TComServerObject.ServerFileName Property

Specifies the complete path and filename of the COM server.

Pascal

```
property ServerFileName: string;
```

C++

```
__property AnsiString ServerFileName;
```

Description

The abstract accessor methods for ServerFileName are overridden in descendant classes.

See Also

ServerName (see page 5580)

28.1.11.3.3 TComServerObject.ServerKey Property

Indicates whether the COM server is an in-process server or whether it is a local server.

Pascal

```
property ServerKey: string;
```

C++

```
__property AnsiString ServerKey;
```

Description

The abstract accessor methods for ServerKey are overridden in descendant classes.

28.1.11.3.4 TComServerObject.ServerName Property

Specifies the name of the executable file for the server.

Pascal

```
property ServerName: string;
```

C++

```
__property AnsiString ServerName;
```

Description

The abstract accessor methods for ServerName are overridden in descendant classes.

See Also

ServerFileName (see page 5580)

28.1.11.3.5 TComServerObject.StartSuspended Property

Specifies whether the server started in a suspended state.

Pascal

```
property StartSuspended: Boolean;
```

C++

```
__property Boolean StartSuspended;
```

Description

StartSuspended specifies whether the server started in a suspended state.

See Also

ServerName (see page 5580)

28.1.11.3.6 TComServerObject.TypeLib Property

Provides access to the type library associated with the COM server.

Pascal

```
property TypeLib: ITypeLib;
```

C++

```
__property ITypeLib TypeLib;
```

Description

The abstract accessor methods for TypeLib are overridden in descendant classes.

28.1.12 TTypedComObject Class

TTypedComObject supports the IProvideClassInfo interface and is the class type for COM objects that can provide the type information without requiring a type library to be loaded.

Class Hierarchy

Pascal

```
TTypedComObject = class(TComObject, IProvideClassInfo);
```

C++

```
class TTypedComObject : public TComObject, public IProvideClassInfo;
```

File

ComObj

Description

TTypedComObject supports the IProvideClassInfo interface which gives an object the ability to describe its interfaces and types when everything else about it, such as its class identifier (CLSID), is unknown. TTypedComObject requires a type library for the IProvideClassInfo interface. This class is designed to require a type library so that it can support dual interfaces, which are created by default.

IProvideClassInfo has a single method, GetClassInfo (see page 5583), which is implemented in TTypedComObject to provide access to the type information for the object's CoClass entry in its type library. This means that if the TTypedComObject has a

running instance, a client can query for the IProvideClassInfo interface and retrieve this information without having to load and navigate a type library to find the ITypeInfo pointer for the object's CoClass.

Use TTypedComObject as a base class for objects that can conveniently provide type information without having to load a type library, such as an unknown object received through a drag-and-drop operation. The only objects that must implement IProvideClassInfo are those with custom events such as ActiveX controls.

Note: There is no support for type information in a particular language. Type information appropriate to the user's international settings on the current machine is assumed to have been loaded.

GetClassClassInfo.

28.1.12.1 TTypedComObject Members

The following tables list the members exposed by TTypedComObject.

Protected Methods

	Name	Description
	_AddRef (see page 5558)	This is _AddRef, a member of class TComObject.
	_Release (see page 5558)	This is _Release, a member of class TComObject.
	GetClassInfo (see page 5583)	Returns a pointer to a TTypedComObject (see page 5581)'s type information.
	InterfaceSupportsErrorInfo (see page 5559)	This is InterfaceSupportsErrorInfo, a member of class TComObject.
	QueryInterface (see page 5560)	This is QueryInterface, a member of class TComObject.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5555)	Instantiates a COM object that is not part of an aggregate.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateAggregated (see page 5556)	Instantiates a COM object that is part of an aggregate.
	CreateFromFactory (see page 5556)	Instantiates a COM object and initializes its values.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5557)	Disposes of an instance of a COM object.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.

	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	Initialize (see page 5558)	Provides an interface to a method that initializes the COM object.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	ObjAddRef (see page 5559)	Implements the AddRef method of the IUnknown interface.
V	ObjQueryInterface (see page 5559)	Implements the QueryInterface (see page 5560) method of the IUnknown interface.
V	ObjRelease (see page 5559)	Implements the Release method of the IUnknown interface.
V	SafeCallException (see page 5560)	Handles OLE exceptions.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Controller (see page 5561)	Specifies the controlling IUnknown interface that controls interfaces within an aggregate object.
R	Factory (see page 5561)	Specifies the class factory object for the TComObject (see page 5553) class.
R	RefCount (see page 5562)	Indicates the number of references to the COM object that are currently in use.
	ServerExceptionHandler (see page 5562)	Provides access to the SafeCall exception notification process.

28.1.12.2 TTypedComObject Methods

The methods of the TTypedComObject class are listed here.

Protected Methods

	Name	Description
	GetClassInfo (see page 5583)	Returns a pointer to a TTypedComObject (see page 5581)'s type information.

28.1.12.2.1 TTypedComObject.GetClassInfo Method

Returns a pointer to a TTypedComObject (see page 5581)'s type information.

Pascal

```
function GetClassInfo(out TypeInfo: ITypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetClassInfo(ITypeInfo TypeInfo);
```

Description

The GetClassInfo method returns a pointer to a type information object that describes the incoming and outgoing interfaces to the ActiveX control. The method gets a pointer to the control's type library, and through it, uses the ITypeLib interface to retrieve the type information.

28.1.13 TTypedComObjectFactory Class

TTypedComObjectFactory is the type of the class factory object used to instantiate a TypedComObject class.

Class Hierarchy

Pascal

```
TTypedComObjectFactory = class(TComObjectFactory);
```

C++

```
class TTypedComObjectFactory : public TComObjectFactory;
```

File

ComObj

Description

TTypedComObjectFactory inherits support for the IUnknown, IClassFactory, and IClassFactory2 interfaces. TTypedComObjectFactory is used to instantiate the TTypedComObject (see page 5581) class.

28.1.13.1 TTypedComObjectFactory Members

The following tables list the members exposed by TTypedComObjectFactory.

Protected Methods

	Name	Description
	_AddRef (see page 5567)	This is _AddRef, a member of class TComObjectFactory.
	_Release (see page 5567)	This is _Release, a member of class TComObjectFactory.
	CreateInstance (see page 5568)	This is CreateInstance, a member of class TComObjectFactory.
	CreateInstanceLic (see page 5568)	This is CreateInstanceLic, a member of class TComObjectFactory.
V	GetLicenseString (see page 5568)	This is GetLicenseString, a member of class TComObjectFactory.
	GetLicInfo (see page 5568)	This is GetLicInfo, a member of class TComObjectFactory.
V	GetProgID (see page 5569)	This is GetProgID, a member of class TComObjectFactory.
V	HasMachineLicense (see page 5569)	This is HasMachineLicense, a member of class TComObjectFactory.
	LockServer (see page 5569)	This is LockServer, a member of class TComObjectFactory.
	QueryInterface (see page 5569)	This is QueryInterface, a member of class TComObjectFactory.
	RequestLicKey (see page 5570)	This is RequestLicKey, a member of class TComObjectFactory.
V	ValidateUserLicense (see page 5571)	This is ValidateUserLicense, a member of class TComObjectFactory.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5585)	Instantiates a TTypedComObjectFactory (see page 5583) object.
V	CreateComObject (see page 5567)	Instantiates a TComObject (see page 5553) object.

V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5566)	Disposes of an instance of a class factory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetInterfaceTypeInfo (see page 5586)	Retrieves the type information for the typed COM object created by the factory.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RegisterClassObject (see page 5569)	Registers the COM class associated with the factory object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	UpdateRegistry (see page 5586)	Registers the typed COM object class.

Public Properties

	Name	Description
R	ClassID (see page 5571)	This is ClassID, a member of class TComObjectFactory.
R	ClassInfo (see page 5587)	Specifies an interface reference that provides type information without having to load a type library.
R	ClassName (see page 5572)	Specifies the name of the class that the class factory instantiates.
R	ComClass (see page 5572)	This is ComClass, a member of class TComObjectFactory.
R	ComServer (see page 5572)	This is ComServer, a member of class TComObjectFactory.
R	Description (see page 5572)	Describes the class object.
	ErrorIID (see page 5573)	Indicates the interface of the CoClass in which an error occurred.
R	Instancing (see page 5573)	Indicates the process space of COM object instances.
	LicString (see page 5573)	Contains licensing information about the object.
R	ProgID (see page 5574)	Specifies the name of the class factory.
	ShowErrors (see page 5574)	Indicates whether the COM object factory displays a message box when exceptions are raised.
	SupportsLicensing (see page 5574)	Indicates whether the object being instantiated supports licensing.
R	ThreadingModel (see page 5575)	Indicates the type of thread support provided by objects that the factory creates.

28.1.13.2 TTypedComObjectFactory.Create Constructor

Instantiates a TTypedComObjectFactory (see page 5583) object.

Pascal

```
constructor Create(ComServer: TComServerObject; TypedComClass: TTypedComClass; const ClassID:
TGUID; Instancing: TClassInstancing; ThreadingModel: TThreadingModel = tmSingle);
```

C++

```
__fastcall TTypedComObjectFactory(TComServerObject ComServer, TTypedComClass TypedComClass,
const TGUID ClassID, TClassInstancing Instancing, TThreadingModel ThreadingModel = tmSingle);
```

Description

Create is used to instantiate a TTypedComObjectFactory (see page 5583). Create is automatically called when the COM server that contains the class definition for a TTypedComObject (see page 5581) is loaded. Class factories should be instantiated in the initialization section of the unit that includes their associated server.

Create allocates memory for a TTypedComObjectFactory (see page 5583), and verifies that a type library exists and is available, before calling the inherited Create. If the type library is not available, an EOleSysError (see page 5532) exception is raised.

See Also

EOleSysError (see page 5532)

Create (see page 5565)

28.1.13.3 TTypedComObjectFactory Methods

The methods of the TTypedComObjectFactory class are listed here.

Public Methods

	Name	Description
	GetInterfaceTypeInfo (see page 5586)	Retrieves the type information for the typed COM object created by the factory.
V	UpdateRegistry (see page 5586)	Registers the typed COM object class.

28.1.13.3.1 TTypedComObjectFactory.GetInterfaceTypeInfo Method

Retrieves the type information for the typed COM object created by the factory.

Pascal

```
function GetInterfaceTypeInfo(TypeFlags: Integer): ITypeInfo;
```

C++

```
__fastcall ITypeInfo GetInterfaceTypeInfo(int TypeFlags);
```

Description

GetInterfaceTypeInfo is called to retrieve type information on the TTypedComObject (see page 5581) instances that are created by the factory.

28.1.13.3.2 TTypedComObjectFactory.UpdateRegistry Method

Registers the typed COM object class.

Pascal

```
procedure UpdateRegistry(Register: Boolean); override;
```

C++

```
virtual __fastcall UpdateRegistry(Boolean Register);
```

Description

UpdateRegistry is called for EXEs when the EXE is run, and for DLLs or EXEs when the routines are called to specifically register or unregister the server.

DLLRegisterServer

DLLUnregisterServer

RegisterClassObject (see page 5569)

28.1.13.4 TTypedComObjectFactory Properties

The properties of the TTypedComObjectFactory class are listed here.

Public Properties

	Name	Description
	ClassInfo (see page 5587)	Specifies an interface reference that provides type information without having to load a type library.

28.1.13.4.1 TTypedComObjectFactory.ClassInfo Property

Specifies an interface reference that provides type information without having to load a type library.

Pascal

```
property ClassInfo: ITypeInfo;
```

C++

```
__property ITypeInfo ClassInfo;
```

Description

ClassInfo is of type ITypeInfo, which is an interface usually used for reading information about objects. Use ITypeInfo to extract information about the characteristics and capabilities of objects from type libraries.

Type information interfaces are intended to describe the parts of the application that can be called by outside clients, rather than those that might be used internally to build an application.

The ITypeInfo interface provides access to the following:

The set of function descriptions associated with the type; for interfaces, this contains the set of member functions in the interface.

The set of data member descriptions associated with the type; for structures, this contains the set of fields of the type.

The general attributes of the type, such as whether it describes a structure, an interface, and so on.

An ITypeInfo instance provides various information about a type, and is used in different ways. A compiler can use an ITypeInfo to compile references to members of the type. A type interface browser can use it to find information about each member of the type.

Note: An IDispatch implementer can use it to provide automatic delegation of IDispatch calls to an interface.

Note: A type library is a container for type descriptions. A type library contains descriptions of one or more objects, and is accessed through the ITypeLib interface. The ITypeLib interface provides access to information about the type description in a type library. The descriptions of individual objects are accessed through the ITypeInfo interface.

28.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IServerExceptionHandler (see page 5588)	This is class ComObj.IServerExceptionHandler.

28.2.1 IServerExceptionHandler Interface

Class Hierarchy

ComObj.IServerExceptionHandler

Pascal

```
IServerExceptionHandler = interface;
```

C++

```
__interface IServerExceptionHandler;
```

File

ComObj

Description

This is class ComObj.IServerExceptionHandler.

28.2.1.1 IServerExceptionHandler Members

The following tables list the members exposed by IServerExceptionHandler.

Public Methods

	Name	Description
	OnException (see page 5589)	This is OnException, a member of class IServerExceptionHandler.

28.2.1.2 IServerExceptionHandler Methods

The methods of the IServerExceptionHandler class are listed here.

Public Methods

	Name	Description
	OnException (see page 5589)	This is OnException, a member of class IServerExceptionHandler.

28.2.1.2.1 IServerExceptionHandler.OnException Method

Pascal

```
procedure OnException(const ServerClass: WideString; const ExceptionClass: WideString; const
ErrorMessage: WideString; ExceptAddr: Integer; const ErrorIID: WideString; const ProgID:
WideString; var Handled: Integer; var Result: HResult);
```

C++

```
__fastcall OnException(const BSTR ServerClass, const BSTR ExceptionClass, const BSTR
ErrorMessage, int ExceptAddr, const BSTR ErrorIID, const BSTR ProgID, int Handled, HRESULT
Result);
```

Description

This is OnException, a member of class IServerExceptionHandler.

28.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	ClassIDToProgID (see page 5590)	Returns the programmatic ID for a specified class given its class ID (CLSID).
	ComClassManager (see page 5591)	Returns a TComClassManager (see page 5550) object.
	CreateClassID (see page 5591)	CreateClassID generates a new GUID and returns it as a string.
	CreateComObject (see page 5592)	Instantiates a single instance of a COM object.
	CreateOleObject (see page 5592)	Instantiates an Automation object.
	CreateRegKey (see page 5593)	Creates or opens a registry key that is a subkey of HKEY_CLASSES_ROOT.
	CreateRemoteComObject (see page 5594)	Creates a Com object on another machine and returns an IUnknown interface for it.
	DeleteRegKey (see page 5595)	Deletes a single key that is a subkey of HKEY_CLASSES_ROOT from the system registry.
	DispatchInvoke (see page 5595)	This is function ComObj.DispatchInvoke.
	DispatchInvokeError (see page 5596)	This is function ComObj.DispatchInvokeError.
	GetActiveOleObject (see page 5596)	Retrieves a reference to an IDispatch interface to a currently running, registered COM object.
	GetDispatchPropValue (see page 5596)	Returns the value of a property on an IDispatch interface.
	GetDispatchPropValue (see page 5596)	Returns the value of a property on an IDispatch interface.
	GetRegStringValue (see page 5597)	Retrieves a value stored under a subkey of HKEY_CLASSES_ROOT from the system registry.
	GUIDToString (see page 5597)	This is function ComObj.GUIDToString.
	HandleSafeCallException (see page 5598)	This is function ComObj.HandleSafeCallException.
	InterfaceConnect (see page 5598)	Connects an IConnectionPoint interface.
	InterfaceDisconnect (see page 5599)	Disconnects an IConnectionPoint interface connection that was previously made by the InterfaceConnect (see page 5598) procedure.
	OleCheck (see page 5600)	Throws an EOleSysError (see page 5532) exception if the result code indicates an error.
	OleError (see page 5600)	Raises an EOleSysError (see page 5532) exception.
	ProgIDToClassID (see page 5601)	Returns the class ID (CLSID) GUID that corresponds to the string specified as the ProgID parameter.
	RegisterAsService (see page 5601)	Registers a COM object as an NT service.
	RegisterComServer (see page 5602)	Registers an in-process COM server with the operating system.
	SetDispatchPropValue (see page 5602)	Sets the value of a property on an IDispatch interface.
	SetDispatchPropValue (see page 5602)	Sets the value of a property on an IDispatch interface.
	StringToGUID (see page 5603)	This is function ComObj.StringToGUID.
	StringToLPOLESTR (see page 5603)	This is function ComObj.StringToLPOLESTR.

28.3.1 ComObj.ClassIDToProgID Function

Returns the programmatic ID for a specified class given its class ID (CLSID).

Pascal

```
function ClassIDToProgID(const ClassID: TGUID): string;
```

C++

```
AnsiString ClassIDToProgID(const TGUID ClassID);
```

File

ComObj

Description

ClassIDToProgID retrieves the programmatic ID for the CLSID specified by the ClassID parameter.

If ClassIDToProgID succeeds, it returns the requested ProgID. If ClassIDToProgID fails an EOleSysError (see page 5532) exception is raised with an error code indicating the cause of the error. The possible error codes are as follows:

Error code	Meaning
REGDB_E_CLASSNOTREG	Class not registered in the registry.
REGDB_E_READREGDB	Error reading registry.

See Also

EOleSysError (see page 5532)

OleError (see page 5600)

28.3.2 ComObj.ComClassManager Function

Returns a TComClassManager (see page 5550) object.

Pascal

```
function ComClassManager: TComClassManager;
```

C++

```
TComClassManager ComClassManager();
```

File

ComObj

Description

Use ComClassManager to obtain a reference to the global COM class manager. This COM class manager manages the class factory objects owned by COM servers.

See Also

TComServer

ComServer

28.3.3 ComObj.CreateClassID Function

CreateClassID generates a new GUID and returns it as a string.

Pascal

```
function CreateClassID: string;
```

C++

```
AnsiString CreateClassID();
```

File

ComObj

Description

Use CreateClassID to create a new GUID and access it as a string. A Delphi demo of the CreateClassID function is available in the Demos area.

See Also

CreateOleObject (see page 5592)

CreateRemoteComObject (see page 5594)

28.3.4 ComObj.CreateComObject Function

Instantiates a single instance of a COM object.

Pascal

```
function CreateComObject(const ClassID: TGUID): IUnknown;
```

C++

```
IUnknown CreateComObject(const TGUID ClassID);
```

File

ComObj

Description

CreateComObject creates a single uninitialized object of the class associated with the CLSID specified by the ClassID parameter. CreateComObject is used to create an object of a specified type when the CLSID is known, and when the object is on a local or in-proc server.

Note: In Delphi code, CreateComObject is called once to create each new single instance of a class. To create multiple instance of the same class it is recommended to use a class factory.

CreateComObject returns a reference to the interface to be used to communicate with the object. For CreateComObject this interface is of type IUnknown. To create OLE objects that return references to the IDispatch interface, use CreateOleObject (see page 5592).

Tip: If the interface returned by CreateCOMObject is assigned to a Variant, you can release the interface by assigning the Unassigned constant to that Variant.

See Also

CreateOleObject (see page 5592)

CreateRemoteComObject (see page 5594)

Unassigned

28.3.5 ComObj.CreateOleObject Function

Instantiates an Automation object.

Pascal

```
function CreateOleObject(const ClassName: string): IDispatch;
```

C++

```
IDispatch CreateOleObject(const AnsiString ClassName);
```

File

ComObj

Description

CreateOleObject creates a single uninitialized object of the class specified by the ClassName parameter. ClassName specifies the string representation of the Class ID (CLSID). CreateOleObject is used to create an object of a specified type when the CLSID is known, and when the object is on a local or in-proc server. Only objects that are not part of an aggregate are created using CreateOleObject.

Note: In Delphi code, CreateOleObject is called once to create each new single instance of a class. To create multiple instance of the same class, using a class factory is recommended.

CreateOleObject returns a reference to the interface that can be used to communicate with the object. For CreateOleObject this interface is of type IDispatch. To create a COM object that does not support an IDispatch interface, use CreateComObject (see page 5592).

Tip: As shown in the example, if the interface returned by CreateOleObject is assigned to a Variant, you can release the interface by assigning the Unassigned constant to that Variant.

See Also

CreateComObject (see page 5592)

Unassigned

Connecting to a Server

Controlling an Automation Server Using a Dispatch Interface

28.3.6 ComObj.CreateRegKey Function

Creates or opens a registry key that is a subkey of HKEY_CLASSES_ROOT.

Pascal

```
procedure CreateRegKey(const Key: string; const ValueName: string; const Value: string;
RootKey: DWord = HKEY_CLASSES_ROOT);
```

C++

```
CreateRegKey(const AnsiString Key, const AnsiString ValueName, const AnsiString Value, DWord
RootKey = HKEY_CLASSES_ROOT);
```

File

ComObj

Description

CreateRegKey creates or opens the key specified by the Key parameter. If the key does not already exist in the registry, CreateRegKey creates it, otherwise CreateRegKey opens it.

Note: CreateRegKey is useful for implementing the UpdateRegistry method of a class factory.

Key specifies a string that cannot begin with the backslash character ('\'). It must be a subkey of RootKey.

When the key is created, additional value and type information for the specified key can be set from the parameters passed to CreateRegKey.

ValueName points to a string that specifies the name of the subkey associated with value.

Value specifies the data to be stored with the specified value name.

RootKey is the top-level registry key under which the new key is created or opened. If omitted, it is HKEY_CLASSES_ROOT.

If CreateRegKey is not successful, an EOleRegistrationError (see page 5531) exception is raised.

See Also

EOleRegistrationError (see page 5531)

TRegistry

TRegistryIniFile

28.3.7 ComObj.CreateRemoteComObject Function

Creates a Com object on another machine and returns an IUnknown interface for it.

Pascal

```
function CreateRemoteComObject(const MachineName: WideString; const ClassID: TGUID): IUnknown;
```

C++

```
IUnknown CreateRemoteComObject(const BSTR MachineName, const TGUID ClassID);
```

File

ComObj

Description

Use CreateRemoteComObject to create an object on a remote server. CreateRemoteComObject creates a single uninitialized object of the class associated with the CLSID specified by the ClassID parameter. The MachineName parameter specifies the machine that lists the ClassID in its type library.

Usually, MachineName is the UNC name of the machine, which can be obtained by looking up its Machine Name under the Network settings in the Windows control panel. However, under some configurations of COM, MachineName is the IP address or Host name of the remote system.

CreateRemoteComObject returns a reference to the IUnknown interface for the object. Use this interface to obtain information about other interfaces supported by the object.

Tip: If the interface returned by CreateRemoteComObject is assigned to a Variant, you can release the interface by assigning the Unassigned constant to that Variant.

See Also

CreateComObject (see page 5592)

Unassigned

28.3.8 ComObj.DeleteRegKey Function

Deletes a single key that is a subkey of HKEY_CLASSES_ROOT from the system registry.

Pascal

```
procedure DeleteRegKey(const Key: string; RootKey: DWord = HKEY_CLASSES_ROOT);
```

C++

```
DeleteRegKey(const AnsiString Key, DWord RootKey = HKEY_CLASSES_ROOT);
```

File

ComObj

Description

Use DeleteRegKey to update the system registry.

Note: DeleteRegKey is useful for implementing the UpdateRegistry method of a class factory.

DeleteRegKey deletes the subkey of RootKey that is passed in as the Key parameter.

Key must specify a null-terminated string, which is the name of the key to delete. It cannot be NULL. The Key to delete must not have subkeys.

RootKey is the top-level key under which the key to delete appears. It defaults to HKEY_CLASSES_ROOT.

If DeleteRegKey succeeds it removes the entire specified key from the registry, including all of its values. An exception is raised if it fails.

See Also

CreateRegKey (see page 5593)

TRegistry

TRegistryIniFile

GetRegStringValue (see page 5597)

28.3.9 ComObj.DispatchInvoke Function

Pascal

```
procedure DispatchInvoke(const Dispatch: IDispatch; CallDesc: PCallDesc; DispIDs: PDispIDList;
Params: Pointer; Result: PVariant);
```

C++

```
DispatchInvoke(const IDispatch Dispatch, PCallDesc CallDesc, PDispIDList DispIDs, void *
Params, PVariant Result);
```

File

ComObj

Description

This is function ComObj.DispatchInvoke.

28.3.10 ComObj.DispatchInvokeError Function

Pascal

```
procedure DispatchInvokeError(Status: Integer; const ExcepInfo: TExcepInfo);
```

C++

```
DispatchInvokeError(int Status, const TExcepInfo ExcepInfo);
```

File

ComObj

Description

This is function ComObj.DispatchInvokeError.

28.3.11 ComObj.GetActiveOleObject Function

Retrieves a reference to an IDispatch interface to a currently running, registered COM object.

Pascal

```
function GetActiveOleObject(const ClassName: string): IDispatch;
```

C++

```
IDispatch GetActiveOleObject(const AnsiString ClassName);
```

File

ComObj

Description

GetActiveOleObject returns a reference to the IDispatch interface of the active object for the given class indicated by ClassName. ClassName is the programmatic ID for the class of the active object from the OLE running object table. GetActiveOleObject is used to access the OLE running object table. To add an object to this table, use the RegisterActiveObject API.

If either the the class object or the IDispatch interface are not successfully returned, an EOleSysError (see page 5532) exception is raised.

See Also

EOleSysError (see page 5532)

OleCheck (see page 5600)

28.3.12 ComObj.GetDispatchPropValue Function

Returns the value of a property on an IDispatch interface.

Pascal

```
function GetDispatchPropValue(Disp: IDispatch; DispID: Integer): OleVariant; overload;
```

```
function GetDispatchPropValue(Disp: IDispatch; Name: WideString): OleVariant; overload;
```

C++

```
OleVariant GetDispatchPropValue(IDispatch Disp, int DispID);
OleVariant GetDispatchPropValue(IDispatch Disp, BSTR Name);
```

File

ComObj

Description

Call GetDispatchPropValue to read the value of the property with the dispatch ID specified by DispID from the IDispatch interface given by Disp.

See Also

EnumDispatchProperties

SetDispatchPropValue (see page 5602)

28.3.13 ComObj.GetRegStringValue Function

Retrieves a value stored under a subkey of HKEY_CLASSES_ROOT from the system registry.

Pascal

```
function GetRegStringValue(const Key: string; const ValueName: string; RootKey: DWord =
HKEY_CLASSES_ROOT): string;
```

C++

```
AnsiString GetRegStringValue(const AnsiString Key, const AnsiString ValueName, DWord RootKey =
HKEY_CLASSES_ROOT);
```

File

ComObj

Description

GetRegStringValue returns the value specified by the ValueName property that is stored under the key specified by Key. Key must be a subkey of RootKey, which defaults to HKEY_CLASSES_ROOT. If there is no such value stored in the system registry, GetRegStringValue returns an empty string.

See Also

CreateRegKey (see page 5593)

TRegistry

TRegistryIniFile

28.3.14 ComObj.GUIDToString Function

Pascal

```
function GUIDToString(const ClassID: TGUID): string;
```

C++

```
AnsiString GUIDToString(const TGUID ClassID);
```

File

ComObj

Description

This is function ComObj.GUIDToString.

28.3.15 ComObj.HandleSafeCallException Function

Pascal

```
function HandleSafeCallException(ExceptObject: TObject; ExceptAddr: Pointer; const ErrorIID:
TGUID; const ProgID: WideString; const HelpFileName: WideString): HResult;
```

C++

```
HRESULT HandleSafeCallException(TObject * ExceptObject, void * ExceptAddr, const TGUID
ErrorIID, const BSTR ProgID, const BSTR HelpFileName);
```

File

ComObj

Description

This is function ComObj.HandleSafeCallException.

28.3.16 ComObj.InterfaceConnect Function

Connects an IConnectionPoint interface.

Pascal

```
procedure InterfaceConnect(const Source: IUnknown; const IID: TIID; const Sink: IUnknown; var
Connection: Longint);
```

C++

```
InterfaceConnect(const IUnknown Source, const TIID IID, const IUnknown Sink, Longint
Connection);
```

File

ComObj

Description

Call InterfaceConnect from a client application to register an object that implements an outgoing server connection. Typically, this object is an event sink that a client uses to respond to server events. When an event occurs, the server (event source) calls its outgoing interface for the event, and the client, which implements the interface as an event sink, receives the call

InterfaceConnect obtains an IConnectionPoint interface from a COM server advising on a particular connection point. IConnectionPoint lets the server expose an outgoing interface for an object, typically an event sink. IConnectionPointContainer enumerates the connection points supported by the server, so that a caller can find the right connection point. The IConnectionPointContainer and IConnectionPoint interfaces comprise the standard COM event-handling mechanism.

Source is an IUnknown interface for the server object that defines and calls the outgoing interface.

IID is the GUID of the outgoing interface.

Sink is the IUnknown interface of the client object that implements the outgoing interface.

Connection returns a token that represents the connection. It must be saved for use by the InterfaceDisconnect (see page 5599) procedure that is called to terminate the connection established by calling InterfaceConnect.

Note: A demo containing this procedure resides in Demos/ActiveX directory.

See Also

InterfaceDisconnect (see page 5599)

Handling Events in an Automation Controller

28.3.17 ComObj.InterfaceDisconnect Function

Disconnects an IConnectionPoint interface connection that was previously made by the InterfaceConnect (see page 5598) procedure.

Pascal

```
procedure InterfaceDisconnect(const Source: IUnknown; const IID: TIID; var Connection:
Longint);
```

C++

```
InterfaceDisconnect(const IUnknown Source, const TIID IID, Longint Connection);
```

File

ComObj

Description

Call InterfaceDisconnect from a client application to tell the server to stop calling its sink interface. InterfaceDisconnect disconnects an IConnectionPoint interface connection that was previously made by the InterfaceConnect (see page 5598) procedure. These procedures are wrappers for the COM event-handling mechanism, which is based on the IConnectionPointContainer and IConnectionPoint interfaces.

Source is an IUnknown interface for the server object that defines and calls the outgoing interface.

IID is the GUID of the outgoing interface.

Connection is the token that represents the connection, which was returned by the InterfaceConnect (see page 5598) procedure.

Note: A demo containing this procedure resides in Demos/ActiveX directory.

See Also

InterfaceConnect (see page 5598)

Handling Events in an Automation Controller

28.3.18 ComObj.OleCheck Function

Throws an EOleSysError (see page 5532) exception if the result code indicates an error.

Pascal

```
procedure OleCheck(Result: HResult);
```

C++

```
OleCheck(HRESULT Result);
```

File

ComObj

Description

OleCheck is used to wrap many COM routines, so that if that routine fails, users will have an opportunity to handle it in the resulting exception that is raised.

If ECode is a value less than zero, OleCheck raises an EOleSysError (see page 5532) exception that specifies the error code.

Delphi Examples:

```
{
OleCheck, GuidToString example
The following example manufactures a GUID and displays it in a dialog box after translating it
to a string.
}
uses ActiveX, ComObj;
procedure TForm1.Button1Click(Sender: TObject);
var
  G: TGUID;
begin
  OleCheck(CoCreateGuid(G));
  ShowMessage(SysUtils.GuidToString(G));
end;
```

See Also

EOleSysError (see page 5532)

OleError (see page 5600)

28.3.19 ComObj.OleError Function

Raises an EOleSysError (see page 5532) exception.

Pascal

```
procedure OleError(ErrorCode: HResult);
```

C++

```
OleError(HRESULT ErrorCode);
```

File

ComObj

Description

OleError raises an EOleSysError (see page 5532) exception from an error code passed in as the ErrorCode parameter.

OleError is used internally to catch failed function calls by throwing an EOleSysError (see page 5532) exception that indicates the cause of the failure as an error code. Unlike the OleCheck (see page 5600) procedure, which checks its parameter to determine whether it represents an error, OleError always raises an exception.

See Also

EOleSysError (see page 5532)

OleCheck (see page 5600)

28.3.20 ComObj.ProgIDToClassID Function

Returns the class ID (CLSID) GUID that corresponds to the string specified as the ProgID parameter.

Pascal

```
function ProgIDToClassID(const ProgID: string): TGUID;
```

C++

```
TGUID ProgIDToClassID(const AnsiString ProgID);
```

File

ComObj

Description

ProgIDToClassID retrieves, from the registry, the CLSID for a given programmatic ID. The ProgID parameter specifies the programmatic ID for which the CLSID is requested. A programmatic ID is a string that is associated with the CLSID in the registry.

If ProgIDToClassID succeeds it returns the requested CLSID. If ProgIDToClassID fails an EOleSysError (see page 5532) exception is raised with an error code indicating the cause of the error. The error code possibilities are as follows:

Error code	Meaning
CO_E_CLASSSTRING	The registered CLSID for the ProgID is invalid.
REGDB_E_WRITEREGDB	An error occurred writing the CLSID to the registry.

Note: If the ProgID cannot be found in the registry, ProgIDToClassID creates an OLE 1 CLSID for the ProgID and a CLSID entry in the registry.

See Also

EOleSysError (see page 5532)

OleError (see page 5600)

28.3.21 ComObj.RegisterAsService Function

Registers a COM object as an NT service.

Pascal

```
procedure RegisterAsService(const ClassID: string; const ServiceName: string);
```

C++

```
RegisterAsService(const AnsiString ClassID, const AnsiString ServiceName);
```

File

ComObj

Description

Use RegisterAsService to register a service given a classID. ClassID specifies the classID of the COM object that implements the service. ServiceName specifies the name under which the object is registered.

See Also

TService

28.3.22 ComObj.RegisterComServer Function

Registers an in-process COM server with the operating system.

Pascal

```
procedure RegisterComServer(const DLLName: string);
```

C++

```
RegisterComServer(const AnsiString DLLName);
```

File

ComObj

Description

COM servers are always registered as dynamic link libraries, DLLs. The DLLName parameter specifies the name of the DLL that implements the COM controls.

28.3.23 ComObj.SetDispatchPropValue Function

Sets the value of a property on an IDispatch interface.

Pascal

```
procedure SetDispatchPropValue(Disp: IDispatch; DispID: Integer; const Value: OleVariant);
overload;
procedure SetDispatchPropValue(Disp: IDispatch; Name: WideString; const Value: OleVariant);
overload;
```

C++

```
SetDispatchPropValue(IDispatch Disp, int DispID, const OleVariant Value);
SetDispatchPropValue(IDispatch Disp, BSTR Name, const OleVariant Value);
```

File

ComObj

Description

Call SetDispatchPropValue to assign the value specified by the Value parameter to the specified property of the IDispatch interface given by the Disp parameter. The DispID parameter gives the dispatch ID of the property to set.

See Also

EnumDispatchProperties

GetDispatchPropValue (see page 5596)

28.3.24 ComObj.StringToGUID Function

Pascal

```
function StringToGUID(const S: string): TGUID;
```

C++

```
TGUID StringToGUID(const AnsiString S);
```

File

ComObj

Description

This is function ComObj.StringToGUID.

28.3.25 ComObj.StringToLPOLESTR Function

Pascal

```
function StringToLPOLESTR(const Source: string): POleStr;
```

C++

```
POleStr StringToLPOLESTR(const AnsiString Source);
```

File

ComObj

Description

This is function ComObj.StringToLPOLESTR.

28.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TClassInstancing (see page 5604)	This is record ComObj.TClassInstancing.
	TThreadingModel (see page 5604)	This is record ComObj.TThreadingModel.

28.4.1 ComObj.TClassInstancing Enumeration

Pascal

```
TClassInstancing = (
  ciInternal,
  ciSingleInstance,
  ciMultiInstance
);
```

C++

```
enum TClassInstancing {
  ciInternal,
  ciSingleInstance,
  ciMultiInstance
};
```

File

ComObj

Description

This is record ComObj.TClassInstancing.

28.4.2 ComObj.TThreadingModel Enumeration

Pascal

```
TThreadingModel = (
  tmSingle,
  tmApartment,
  tmFree,
  tmBoth,
  tmNeutral
);
```

C++

```
enum TThreadingModel {
  tmSingle,
  tmApartment,
  tmFree,
  tmBoth,
```

```
    tmNeutral
  };
```

File

ComObj

Description

This is record ComObj.TThreadingModel.

28.5 Types

The following table lists types in this documentation.

Types

Name	Description
TAutoClass (see page 5606)	This is type ComObj.TAutoClass.
TCoAddRefServerProcessProc (see page 5606)	This is type ComObj.TCoAddRefServerProcessProc.
TCoCreateInstanceExProc (see page 5607)	This is type ComObj.TCoCreateInstanceExProc.
TCoInitializeExProc (see page 5607)	This is type ComObj.TCoInitializeExProc.
TComClass (see page 5607)	This is type ComObj.TComClass.
TConnectEvent (see page 5608)	This is type ComObj.TConnectEvent.
TCoReleaseServerProcessProc (see page 5608)	This is type ComObj.TCoReleaseServerProcessProc.
TCoResumeClassObjectsProc (see page 5608)	This is type ComObj.TCoResumeClassObjectsProc.
TCoSuspendClassObjectsProc (see page 5609)	This is type ComObj.TCoSuspendClassObjectsProc.
TFactoryProc (see page 5609)	This is type ComObj.TFactoryProc.
TTypedComClass (see page 5609)	This is type ComObj.TTypedComClass.

28.5.1 ComObj.TAutoClass Type

Pascal

```
TAutoClass = class of TAutoObject;
```

C++

```
TAutoObject TAutoClass;
```

File

ComObj

Description

This is type ComObj.TAutoClass.

28.5.2 ComObj.TCoAddRefServerProcessProc Type

Pascal

```
TCoAddRefServerProcessProc = function :Longint;
```

C++

```
:Longint ( TCoAddRefServerProcessProc)();
```

File

ComObj

Description

This is type ComObj.TCoAddRefServerProcessProc.

28.5.3 ComObj.TCoCreateInstanceExProc Type

Pascal

```
TCoCreateInstanceExProc = function (const clsid: TCLSID; unkOuter: IUnknown; dwClsCtx:
Longint; ServerInfo: PCoServerInfo; dwCount: Longint; rgmqResults: PMultiQIArray): HResult
stdcall;
```

C++

```
(const clsid: TCLSID; unkOuter: IUnknown; dwClsCtx: Longint; ServerInfo: PCoServerInfo;
dwCount: Longint; rgmqResults: PMultiQIArray): HResult stdcall ( TCoCreateInstanceExProc)();
```

File

ComObj

Description

This is type ComObj.TCoCreateInstanceExProc.

28.5.4 ComObj.TCoInitializeExProc Type

Pascal

```
TCoInitializeExProc = function (pvReserved: Pointer; coInit: Longint): HResult;
```

C++

```
(pvReserved: Pointer; coInit: Longint): HResult ( TCoInitializeExProc)();
```

File

ComObj

Description

This is type ComObj.TCoInitializeExProc.

28.5.5 ComObj.TComClass Type

Pascal

```
TComClass = class of TComObject;
```

C++

```
TComObject TComClass;
```

File

ComObj

Description

This is type ComObj.TComClass.

28.5.6 ComObj.TConnectEvent Type

Pascal

```
TConnectEvent = procedure (const Sink: IUnknown; Connecting: Boolean) of object;
```

C++

```
(const Sink: IUnknown; Connecting: Boolean) ( TConnectEvent)();
```

File

ComObj

Description

This is type ComObj.TConnectEvent.

28.5.7 ComObj.TCoReleaseServerProcessProc Type

Pascal

```
TCoReleaseServerProcessProc = function :Longint;
```

C++

```
:Longint ( TCoReleaseServerProcessProc)();
```

File

ComObj

Description

This is type ComObj.TCoReleaseServerProcessProc.

28.5.8 ComObj.TCoResumeClassObjectsProc Type

Pascal

```
TCoResumeClassObjectsProc = function :HResult;
```

C++

```
:HResult ( TCoResumeClassObjectsProc)();
```

File

ComObj

Description

This is type ComObj.TCoResumeClassObjectsProc.

28.5.9 ComObj.TCoSuspendClassObjectsProc Type

Pascal

```
TCoSuspendClassObjectsProc = function :HResult;
```

C++

```
:HResult ( TCoSuspendClassObjectsProc)();
```

File

ComObj

Description

This is type ComObj.TCoSuspendClassObjectsProc.

28.5.10 ComObj.TFactoryProc Type

Pascal

```
TFactoryProc = procedure (Factory: TComObjectFactory) of object;
```

C++

```
(Factory: TComObjectFactory) ( TFactoryProc)();
```

File

ComObj

Description

This is type ComObj.TFactoryProc.

28.5.11 ComObj.TTypedComClass Type

Pascal

```
TTypedComClass = class of TTypedComObject;
```

C++

```
TTypedComObject TTypedComClass;
```

File

ComObj

Description

This is type ComObj.TTypedComClass.

28.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CoAddRefServerProcess (see page 5610)	This is variable ComObj.CoAddRefServerProcess.
CoCreateInstanceEx (see page 5610)	This is variable ComObj.CoCreateInstanceEx.
CoInitFlags (see page 5611)	Specifies the level of threading support requested for a COM server .EXE.
CoInitializeEx (see page 5611)	This is variable ComObj.CoInitializeEx.
CoReleaseServerProcess (see page 5612)	This is variable ComObj.CoReleaseServerProcess.
CoResumeClassObjects (see page 5612)	This is variable ComObj.CoResumeClassObjects.
CoSuspendClassObjects (see page 5612)	This is variable ComObj.CoSuspendClassObjects.

28.6.1 ComObj.CoAddRefServerProcess Variable

Pascal

```
CoAddRefServerProcess: TCoAddRefServerProcessProc = nil;
```

C++

```
TCoAddRefServerProcessProc CoAddRefServerProcess = nil;
```

File

ComObj

Description

This is variable ComObj.CoAddRefServerProcess.

28.6.2 ComObj.CoCreateInstanceEx Variable

Pascal

```
CoCreateInstanceEx: TCoCreateInstanceExProc = nil;
```

C++

```
TCoCreateInstanceExProc CoCreateInstanceEx = nil;
```

File

ComObj

Description

This is variable ComObj.CoCreateInstanceEx.

28.6.3 ComObj.CoInitFlags Variable

Specifies the level of threading support requested for a COM server .EXE.

Pascal

```
CoInitFlags: Integer = -1;
```

C++

```
int CoInitFlags = -1;
```

File

ComObj

Description

CoInitFlags controls the way COM is initialized for threading support. This variable only affects executables (.EXEs), not in-process servers (.DLLs and .OCXs).

Typically, code to initialize the level of threading support is added automatically by the wizard that creates the COM object in your application. In applications containing multiple COM objects, COM is initialized for the highest level of support, where single threading is lowest and free threading is highest. To manually set the level of COM threading support, assign a value to CoInitFlags in the program's main source file before the call to Application.Initialize.

The following table lists the constants (defined in the ActiveX unit) that can be or'ed together to create a value for CoInitFlags.

ConstantValueMeaning

Constant	Value	Meaning
COINIT_MULTITHREADED	0	COM calls objects on any thread (free threading)
COINIT_APARTMENTTHREADED	2	Each object has its own thread (apartment model)
COINIT_DISABLE_OLE1DDE	4	Don't use DDE for Ole1 support.
COINIT_SPEED_OVER_MEMORY	8	Optimize for speed rather than memory.

The value of CoInitFlags is –1 for single threading.

IsMultiThread

28.6.4 ComObj.CoInitializeEx Variable

Pascal

```
CoInitializeEx: TCoInitializeExProc = nil;
```

C++

```
TCoInitializeExProc CoInitializeEx = nil;
```

File

ComObj

Description

This is variable ComObj.CoInitializeEx.

28.6.5 ComObj.CoReleaseServerProcess Variable

Pascal

```
CoReleaseServerProcess: TCoReleaseServerProcessProc = nil;
```

C++

```
TCoReleaseServerProcessProc CoReleaseServerProcess = nil;
```

File

ComObj

Description

This is variable ComObj.CoReleaseServerProcess.

28.6.6 ComObj.CoResumeClassObjects Variable

Pascal

```
CoResumeClassObjects: TCoResumeClassObjectsProc = nil;
```

C++

```
TCoResumeClassObjectsProc CoResumeClassObjects = nil;
```

File

ComObj

Description

This is variable ComObj.CoResumeClassObjects.

28.6.7 ComObj.CoSuspendClassObjects Variable

Pascal

```
CoSuspendClassObjects: TCoSuspendClassObjectsProc = nil;
```

C++

```
TCoSuspendClassObjectsProc CoSuspendClassObjects = nil;
```

File

ComObj

Description

This is variable ComObj.CoSuspendClassObjects.

29 CompProd Namespace

This is namespace CompProd.

Topics

Name	Description
Classes (see page 5614)	The following table lists classes in this documentation.

Classes

	Name	Description
	TComponentsPageProducer (see page 5614)	TComponentsPageProducer produces a string of HTML commands based on an input template.

29.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TComponentsPageProducer (see page 5614)	TComponentsPageProducer produces a string of HTML commands based on an input template.

29.1.1 TComponentsPageProducer Class

TComponentsPageProducer produces a string of HTML commands based on an input template.

Class Hierarchy

Pascal

```
TComponentsPageProducer = class(TBasePageProducer);
```

C++

```
class TComponentsPageProducer : public TBasePageProducer;
```

File

CompProd

Description

Use TComponentsPageProducer to convert an HTML template that includes content generated by other components into a string of HTML commands that can be interpreted by a client application such as a Web browser. HTML templates include HTML commands and HTML-transparent tags that are replaced with customized content by the components page producer in an OnHTMLTag (see page 5620) event handler.

Components page producers differ from other page producer components in that they replace special HTML-transparent tags of the format

```
<#COMPONENT Name=WebContentComponent>
```

with the HTML produced by the component named WebContentComponent. WebContentComponent must have the same Owner as the components page producer and support the IWebContent interface, which the components page producer uses to obtain the replacement HTML for the COMPONENT tag.

See Also

IWebContent (see page 24792)

TPageItemsProducer (see page 18383)

TInetXPageProducer (see page 17145)

29.1.1.1 TComponentsPageProducer Members

The following tables list the members exposed by TComponentsPageProducer.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DoTagEvent (see page 5618)	This is DoTagEvent, a member of class TComponentsPageProducer.
	FindComponent (see page 5619)	This is FindComponent, a member of class TComponentsPageProducer.
	FindComponentName (see page 5619)	This is FindComponentName, a member of class TComponentsPageProducer.
	GetAppDispatcher (see page 15108)	This is GetAppDispatcher, a member of class TCustomContentProducer.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetComponentContent (see page 5619)	This is GetComponentContent, a member of class TComponentsPageProducer.
	GetContentOptions (see page 5619)	This is GetContentOptions, a member of class TComponentsPageProducer.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetProducerTemplateFileName (see page 15276)	This is GetProducerTemplateFileName, a member of class TBasePageProducer.
	GetProducerTemplateStream (see page 15276)	This is GetProducerTemplateStream, a member of class TBasePageProducer.
	GetScriptEngine (see page 15277)	This is GetScriptEngine, a member of class TBasePageProducer.
	GetTagID (see page 15277)	This is GetTagID, a member of class TBasePageProducer.
	GetTemplateFileName (see page 15277)	This is GetTemplateFileName, a member of class TBasePageProducer.
	GetTemplateStream (see page 15277)	This is GetTemplateStream, a member of class TBasePageProducer.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleScriptTag (see page 15277)	This is HandleScriptTag, a member of class TBasePageProducer.
	HandleTag (see page 5620)	This is HandleTag, a member of class TComponentsPageProducer.
	ImplHandleTag (see page 15278)	This is ImplHandleTag, a member of class TBasePageProducer.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.

	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 15108)	Overrides the inherited method to respond to messages that the dispatcher is going away.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	ProduceContent (see page 15108)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15109)	This is ProduceContentFromStream, a member of class TCustomContentProducer.
	ProduceContentFromString (see page 15109)	This is ProduceContentFromString, a member of class TCustomContentProducer.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ServerScriptFromStream (see page 15278)	This is ServerScriptFromStream, a member of class TBasePageProducer.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAppDispatcher (see page 15109)	This is SetAppDispatcher, a member of class TCustomContentProducer.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	UseScriptEngine (see page 15278)	This is UseScriptEngine, a member of class TBasePageProducer.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Content (see page 15106)	Returns the content produced by the content producer.
	Content (see page 15274)	Returns the content produced by the content producer.
	ContentFromStream (see page 15107)	Returns the content produced in response to input read from a stream.
	ContentFromStream (see page 15275)	Returns the content produced in response to input read from a stream.
	ContentFromString (see page 15107)	Returns the content produced in response to an input string.
	ContentFromString (see page 15275)	Returns the content produced in response to an input string.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.

	Create (see page 15274)	Creates an instance of TBasePageProducer (see page 15269).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetAppDispatcher (see page 15220)	This is GetAppDispatcher, a member of class IGetAppDispatcher.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetProducerTemplateFileName (see page 15320)	This is GetProducerTemplateFileName, a member of class IGetProducerTemplate.
	GetProducerTemplateStream (see page 15320)	This is GetProducerTemplateStream, a member of class IGetProducerTemplate.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ProduceContent (see page 15224)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15225)	This is ProduceContentFromStream, a member of class IProduceContentFrom.
	ProduceContentFromString (see page 15226)	This is ProduceContentFromString, a member of class IProduceContentFrom.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetAppDispatcher (see page 15227)	This is SetAppDispatcher, a member of class ISetAppDispatcher.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Dispatcher (see page 15109)	Provides access to the dispatcher for the Web server application that includes the TCustomContentProducer (see page 15102) object.
R	DispatcherComponent (see page 15110)	Provides access to the dispatcher component.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ScriptEngine (see page 15279)	Names the script engine that generates or interprets script embedded in the documents that this producer creates.
	StripParamQuotes (see page 15279)	Specifies whether to strip quotation marks when extracting the parameters from an HTML-transparent tag.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	WebModuleContext (see page 15279)	Provides access to the Web module context object.

Published Events

	Name	Description
	OnHTMLTag (see page 5620)	Occurs when the page producer needs to interpret the value of an HTML-transparent tag in the HTML template.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

29.1.1.2 TComponentsPageProducer Methods

The methods of the TComponentsPageProducer class are listed here.

Protected Methods

	Name	Description
V	DoTagEvent (see page 5618)	This is DoTagEvent, a member of class TComponentsPageProducer.
V	FindComponent (see page 5619)	This is FindComponent, a member of class TComponentsPageProducer.
	FindComponentName (see page 5619)	This is FindComponentName, a member of class TComponentsPageProducer.
V	GetComponentContent (see page 5619)	This is GetComponentContent, a member of class TComponentsPageProducer.
V	GetContentOptions (see page 5619)	This is GetContentOptions, a member of class TComponentsPageProducer.
V	HandleTag (see page 5620)	This is HandleTag, a member of class TComponentsPageProducer.

29.1.1.2.1 TComponentsPageProducer.DoTagEvent Method

Pascal

```
procedure DoTagEvent(Tag: TTag; const TagString: string; TagParams: TStrings; var ReplaceText:
string); override;
```

C++

```
virtual __fastcall DoTagEvent(TTag Tag, const AnsiString TagString, TStrings TagParams,
AnsiString ReplaceText);
```

Description

This is DoTagEvent, a member of class TComponentsPageProducer.

29.1.1.2.2 TComponentsPageProducer.FindComponent Method

Pascal

```
function FindComponent(TagParams: TStrings): TComponent; virtual;
```

C++

```
virtual __fastcall TComponent * FindComponent(TStrings TagParams);
```

Description

This is FindComponent, a member of class TComponentsPageProducer.

29.1.1.2.3 TComponentsPageProducer.FindComponentName Method

Pascal

```
function FindComponentName(TagParams: TStrings): string;
```

C++

```
__fastcall AnsiString FindComponentName(TStrings TagParams);
```

Description

This is FindComponentName, a member of class TComponentsPageProducer.

29.1.1.2.4 TComponentsPageProducer.GetComponentContent Method

Pascal

```
function GetComponentContent(TagParams: TStrings): string; virtual;
```

C++

```
virtual __fastcall AnsiString GetComponentContent(TStrings TagParams);
```

Description

This is GetComponentContent, a member of class TComponentsPageProducer.

29.1.1.2.5 TComponentsPageProducer.GetContentOptions Method

Pascal

```
function GetContentOptions(var Owned: Boolean): TWebContentOptions; virtual;
```

C++

```
virtual __fastcall TWebContentOptions GetContentOptions(Boolean Owned);
```

Description

This is GetContentOptions, a member of class TComponentsPageProducer.

29.1.1.2.6 TComponentsPageProducer.HandleTag Method

Pascal

```
function HandleTag(const TagString: string; TagParams: TStrings): string; override;
```

C++

```
virtual __fastcall AnsiString HandleTag(const AnsiString TagString, TStrings TagParams);
```

Description

This is HandleTag, a member of class TComponentsPageProducer.

29.1.1.3 TComponentsPageProducer Events

The events of the TComponentsPageProducer class are listed here.

Published Events

	Name	Description
	OnHTMLTag (see page 5620)	Occurs when the page producer needs to interpret the value of an HTML-transparent tag in the HTML template.

29.1.1.3.1 TComponentsPageProducer.OnHTMLTag Event

Occurs when the page producer needs to interpret the value of an HTML-transparent tag in the HTML template.

Pascal

```
property OnHTMLTag: THTMLTagEvent;
```

C++

```
__property THTMLTagEvent OnHTMLTag;
```

Description

Write an OnHTMLTag event handler to convert an HTML-transparent tag into the corresponding HTML commands that can be interpreted by a Web browser. If an OnHTMLTag event is not supplied, the HTML-transparent tags in the HTML template will be replaced by empty strings.

Note: The sequence of HTML that the event handler produces for an HTML-transparent tag can contain HTML-transparent tags for another page producer to convert. For example, one page producer might have a template that represents the format of the final HTTP response. It could read the HTTP request and for each section in the request assemble a set of HTML-transparent tags with parameters based on the request. Another page producer might take the content of the first page producer, and interpret those parameters.

30 ComServ Namespace

This is namespace ComServ.

Topics

Name	Description
Classes (see page 5623)	The following table lists classes in this documentation.
Functions (see page 5634)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5638)	The following table lists structs, records, enums in this documentation.
Types (see page 5639)	The following table lists types in this documentation.
Variables (see page 5640)	The following table lists variables in this documentation.

Classes

	Name	Description
	TComServer (see page 5623)	TComServer is the class type of the ComServ variable that is declared and instantiated in the ComServ unit.

Functions

	Name	Description
	DllCanUnloadNow (see page 5634)	Tells Windows whether it can unload the in-process server exporting this function.
	DllGetClassObject (see page 5635)	Obtains a class factory for an ActiveX object when the ActiveX object resides in an in-process ActiveX server (DLL).
	DllRegisterServer (see page 5636)	Registers an in-process ActiveX server in the current module within the system registry.
	DllUnregisterServer (see page 5636)	Unregisters an OLE automation server in the current module with the system registry.
	LoadTypeLibrary (see page 5637)	This is function ComServ.LoadTypeLibrary.

Structs, Records, Enums

	Name	Description
	TStartMode (see page 5638)	This is record ComServ.TStartMode.

Types

Name	Description
TLastReleaseEvent (see page 5639)	This is type ComServ.TLastReleaseEvent.

Variables

Name	Description
ComServer (see page 5640)	Provides class and registry information about server objects.

30.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TComServer (see page 5623)	TComServer is the class type of the ComServ (see page 5621) variable that is declared and instantiated in the ComServ (see page 5621) unit.

30.1.1 TComServer Class

TComServer is the class type of the ComServ (see page 5621) variable that is declared and instantiated in the ComServ (see page 5621) unit.

Class Hierarchy

System::TObject → ComObj.TComServerObject → ComServ.TComServer

Pascal

```
TComServer = class(TComServerObject);
```

C++

```
class TComServer : public TComServerObject;
```

File

ComServ

Description

TComServer is the class type used for a COM server, which is a module that contains COM or OLE class definitions. That module can be either an in-process server (DLL) or a local server (EXE).

TComServer properties contain all necessary information about the server, such as its type library, name, Help file, and so on. They also indicate when and how the server should be loaded and unloaded.

TComServer methods are used

To access TComServer properties.

To create associated class factories to instantiate the COM and OLE classes based upon their class identifier (CLSID).

To update the registry database with information about the COM and OLE classes.

TComServer is the type of the ComServ (see page 5621) variable that is automatically instantiated in the ComServ (see page 5621) unit. Each module that is created as a server for COM objects has its own instance of ComServ (see page 5621).

To manage its class factories, the ComServer (see page 5640) uses a TComClassManager object, which is accessed using the ComClassManager function in the ComObj (see page 5525) unit. The class factories are used primarily by calls to TComClassManager methods.

Note: The ComServ (see page 5621) unit declares and implements global routines that must be exported by each in-process server. These routines automatically handle the registering, unregistering, and unloading of the COM server.

30.1.1.1 TComServer Members

The following tables list the members exposed by TComServer.

Protected Methods

	Name	Description
	CountFactory (see page 5626)	This is CountFactory, a member of class TComServer.
	CountObject (see page 5627)	This is CountObject, a member of class TComServer.
	GetHelpFileName (see page 5627)	This is GetHelpFileName, a member of class TComServer.
	GetServerFileName (see page 5627)	This is GetServerFileName, a member of class TComServer.
	GetServerKey (see page 5627)	This is GetServerKey, a member of class TComServer.
	GetServerName (see page 5628)	This is GetServerName, a member of class TComServer.
	GetStartSuspended (see page 5628)	This is GetStartSuspended, a member of class TComServer.
	GetTypeLib (see page 5628)	This is GetTypeLib, a member of class TComServer.
	SetHelpFileName (see page 5629)	This is SetHelpFileName, a member of class TComServer.

Public Events

	Name	Description
	OnLastRelease (see page 5632)	Occurs when the last object using the server is released.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5625)	Creates a COM server object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5626)	Destroys an instance of a COM server object.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	Initialize (see page 5628)	Updates the registry and registers the class objects.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadTypeLib (see page 5629)	Loads the type library for the server.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetServerName (see page 5629)	Sets the ServerName property.
	UpdateRegistry (see page 5630)	Registers information on classes implemented in the COM server.

Public Properties

	Name	Description
	HelpFileName (see page 5579)	Specifies the name of the Help file associated with the module.
	IsInprocServer (see page 5630)	Indicates whether the COM server is an in-process server.
R	ObjectCount (see page 5631)	Indicates how many objects are currently dependent upon the server being loaded.
R	ServerFileName (see page 5580)	Specifies the complete path and filename of the COM server.
R	ServerKey (see page 5580)	Indicates whether the COM server is an in-process server or whether it is a local server.
R	ServerName (see page 5580)	Specifies the name of the executable file for the server.
R	StartMode (see page 5631)	Indicates why the COM server was started.
R	StartSuspended (see page 5580)	Specifies whether the server started in a suspended state.
R	TypeLib (see page 5581)	Provides access to the type library associated with the COM server.
	UIInteractive (see page 5632)	Controls (see page 5711) whether the server displays error messages to the user.

30.1.1.2 TComServer.Create Constructor

Creates a COM server object.

Pascal

```
constructor Create;
```

C++

```
__fastcall TComServer();
```

Description

Applications do not need to call the constructor for TComServer (see page 5623). An instance of TComServer (see page 5623) is automatically created as the ComServ (see page 5621) variable in modules that are servers for COM objects.

Create allocates memory for a COM server object, and initializes its IsInprocServer (see page 5630) and StartMode (see page 5631) properties. It is not necessary to directly call the constructor to create a COM server object. A global ComServer (see page 5640) variable is declared in the ComServ (see page 5621) unit and is instantiated in the initialization section.

See Also

ComServer

IsInprocServer (see page 5630)

StartMode (see page 5631)

30.1.1.3 TComServer.Destroy Destructor

Destroys an instance of a COM server object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComServer();
```

Description

It is not necessary to directly call Free (or Destroy) to destroy a COM server object. The global ComServ (see page 5621) variable, declared in the ComServ (see page 5621) unit, is automatically created and destroyed in the initialization and finalization sections.

Destroy destroys the COM server object and calls the ComClassManager to free, from the list it maintains, each of the class factories that the server owns.

See Also

Free (see page 22300)

30.1.1.4 TComServer Methods

The methods of the TComServer class are listed here.

Protected Methods

	Name	Description
	CountFactory (see page 5626)	This is CountFactory, a member of class TComServer.
	CountObject (see page 5627)	This is CountObject, a member of class TComServer.
	GetHelpFileName (see page 5627)	This is GetHelpFileName, a member of class TComServer.
	GetServerFileName (see page 5627)	This is GetServerFileName, a member of class TComServer.
	GetServerKey (see page 5627)	This is GetServerKey, a member of class TComServer.
	GetServerName (see page 5628)	This is GetServerName, a member of class TComServer.
	GetStartSuspended (see page 5628)	This is GetStartSuspended, a member of class TComServer.
	GetTypeLib (see page 5628)	This is GetTypeLib, a member of class TComServer.
	SetHelpFileName (see page 5629)	This is SetHelpFileName, a member of class TComServer.

Public Methods

	Name	Description
	Initialize (see page 5628)	Updates the registry and registers the class objects.
	LoadTypeLib (see page 5629)	Loads the type library for the server.
	SetServerName (see page 5629)	Sets the ServerName property.
	UpdateRegistry (see page 5630)	Registers information on classes implemented in the COM server.

30.1.1.4.1 TComServer.CountFactory Method

Pascal

```
function CountFactory(Created: Boolean): Integer; override;
```

C++

```
virtual __fastcall int CountFactory(Boolean Created);
```

Description

This is CountFactory, a member of class TComServer.

30.1.1.4.2 TComServer.CountObject Method

Pascal

```
function CountObject(Created: Boolean): Integer; override;
```

C++

```
virtual __fastcall int CountObject(Boolean Created);
```

Description

This is CountObject, a member of class TComServer.

30.1.1.4.3 TComServer.GetHelpFileName Method

Pascal

```
function GetHelpFileName: string; override;
```

C++

```
virtual __fastcall AnsiString GetHelpFileName();
```

Description

This is GetHelpFileName, a member of class TComServer.

30.1.1.4.4 TComServer.GetServerFileName Method

Pascal

```
function GetServerFileName: string; override;
```

C++

```
virtual __fastcall AnsiString GetServerFileName();
```

Description

This is GetServerFileName, a member of class TComServer.

30.1.1.4.5 TComServer.GetServerKey Method

Pascal

```
function GetServerKey: string; override;
```

C++

```
virtual __fastcall AnsiString GetServerKey();
```

Description

This is GetServerKey, a member of class TComServer.

30.1.1.4.6 TComServer.GetServerName Method

Pascal

```
function GetServerName: string; override;
```

C++

```
virtual __fastcall AnsiString GetServerName();
```

Description

This is GetServerName, a member of class TComServer.

30.1.1.4.7 TComServer.GetStartSuspended Method

Pascal

```
function GetStartSuspended: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetStartSuspended();
```

Description

This is GetStartSuspended, a member of class TComServer.

30.1.1.4.8 TComServer.GetTypeLib Method

Pascal

```
function GetTypeLib: ITypeLib; override;
```

C++

```
virtual __fastcall ITypeLib GetTypeLib();
```

Description

This is GetTypeLib, a member of class TComServer.

30.1.1.4.9 TComServer.Initialize Method

Updates the registry and registers the class objects.

Pascal

```
procedure Initialize;
```

C++

```
__fastcall Initialize();
```

Description

Initialize updates the registry if the server was not started only to remove the server from the system registry. Then, if the server was started as an interactive stand-alone application, or in response to a request from an automation controller, Initialize calls on each class factory, owned by the server, to register its class object in the system registry.

See Also

RegisterClassObject (see page 5569)

UpdateRegistry (see page 5630)

30.1.1.4.10 TComServer.LoadTypeLib Method

Loads the type library for the server.

Pascal

```
procedure LoadTypeLib;
```

C++

```
__fastcall LoadTypeLib();
```

Description

LoadTypeLib loads the type library for the server. If the type library is not already loaded when LoadTypeLib is called, it also registers the type library.

If LoadTypeLib is not successful, it raises an EOleSysError indicating the error code. The possible error codes are as follows:

Error code	Meaning
E_OUTOFMEMORY	Out of memory.
E_INVALIDARG	One or more of the arguments is invalid.
TYPE_E_IOERROR	The function could not write to the file.
TYPE_E_INVALIDSTATE	The type library could not be opened.
TYPE_E_INVDATAREAD	The function could not read from the file.
TYPE_E_UNSUPFORMAT	The type library has an older format.
TYPE_E_UNKNOWNLCID	The LCID could not be found in the OLE support DLLs.
TYPE_E_CANTLOADLIBRARY	The type library or DLL could not be loaded.
Other return codes	All FACILITY_STORAGE errors may be returned.

See Also

EOleSysError (see page 5532)

TypeLib

30.1.1.4.11 TComServer.SetHelpFileName Method

Pascal

```
procedure SetHelpFileName(const Value: string); override;
```

C++

```
virtual __fastcall SetHelpFileName(const AnsiString Value);
```

Description

This is SetHelpFileName, a member of class TComServer.

30.1.1.4.12 TComServer.SetServerName Method

Sets the ServerName property.

Pascal

```
procedure SetServerName(const Name: string);
```

C++

```
__fastcall SetServerName(const AnsiString Name);
```

Description

Call SetServerName to provide a name for the server. If the server has an associated type library (the TypeLib property is nil for Delphi or NULL for C++), SetServerName does nothing, because the name for the server must match the name specified in the type library.

See Also

ServerName

TypeLib

30.1.1.4.13 TComServer.UpdateRegistry Method

Registers information on classes implemented in the COM server.

Pascal

```
procedure UpdateRegistry(Register: Boolean);
```

C++

```
__fastcall UpdateRegistry(Boolean Register);
```

Description

UpdateRegistry updates the registry to reflect the current status of the COM server. Accordingly, UpdateRegistry either registers or unregisters the type library information and the CLSIDs associated with the class factories instantiated by the COM server.

The global functions that register and unregister the server call UpdateRegistry. UpdateRegistry is also called by the Initialize (see page 5628) method.

See Also

DLLRegisterServer

DLLUnregisterServer

Initialize (see page 5628)

30.1.1.5 TComServer Properties

The properties of the TComServer class are listed here.

Public Properties

	Name	Description
	IsInprocServer (see page 5630)	Indicates whether the COM server is an in-process server.
R	ObjectCount (see page 5631)	Indicates how many objects are currently dependent upon the server being loaded.
R	StartMode (see page 5631)	Indicates why the COM server was started.
	UIInteractive (see page 5632)	Controls (see page 5711) whether the server displays error messages to the user.

30.1.1.5.1 TComServer.IsInprocServer Property

Indicates whether the COM server is an in-process server.

Pascal

```
property IsInprocServer: Boolean;
```

C++

```
__property Boolean IsInprocServer;
```

Description

InProcServer indicates whether the COM server is an in-process server, meaning that it is running the same process space as the object's container. The value of this property is set in the COM server's constructor and is determined by the IsLibrary variable.

The library assumes that all OLE automation servers in DLLs are in-process servers, and that those in applications are not.

See Also

IsLibrary (see page 22648)

30.1.1.5.2 TComServer.ObjectCount Property

Indicates how many objects are currently dependent upon the server being loaded.

Pascal

```
property ObjectCount: Integer;
```

C++

```
__property int ObjectCount;
```

Description

ObjectCount indicates when the server can be unloaded. ObjectCount contains the number of objects that are currently dependent upon the server.

ObjectCount is incremented when new objects are created from class factories, and is decremented when objects are destroyed.

When ObjectCount is zero the server can be unloaded. At this time, code written for the OnLastRelease (see page 5632) event handler can process special actions after the last object is released and before the server shuts down.

See Also

OnLastRelease (see page 5632)

30.1.1.5.3 TComServer.StartMode Property

Indicates why the COM server was started.

Pascal

```
property StartMode: TStartMode;
```

C++

```
__property TStartMode StartMode;
```

Description

StartMode indicates the reason a COM server was started. It can be started as a stand-alone application, as an interactive application, as an embedded object, or for registration or unregistration with the system Registry (see page 18633).

TStartMode (see page 5638) is the type of the StartMode property, indicating the different reasons why an OLE automation server can be started.

The following table explains each of the possible start-mode values and the command-line switch that corresponds to each.

Start mode	Switch	Meaning
smAutomation	embedding	The application was started by Windows in response to a request from an automation controller.
smRegServer	regserver	The application was started only to add the server to the system registry.
smStandalone	-	The user started the application as a stand-alone, interactive application.
smUnregServer	unregserver	The application was started only to remove the server from the system registry.

See Also

OnLastRelease (see page 5632)

30.1.1.5.4 TComServer.UIInteractive Property

Controls (see page 5711) whether the server displays error messages to the user.

Pascal

```
property UIInteractive: Boolean;
```

C++

```
__property Boolean UIInteractive;
```

Description

Use UIInteractive to determine whether the server has a user interface. Set UIInteractive to False to suppress error messages that appear when there are server errors. For example, UIInteractive should be False for COM servers running as a service

30.1.1.6 TComServer Events

The events of the TComServer class are listed here.

Public Events

	Name	Description
	OnLastRelease (see page 5632)	Occurs when the last object using the server is released.

30.1.1.6.1 TComServer.OnLastRelease Event

Occurs when the last object using the server is released.

Pascal

```
property OnLastRelease: TLastReleaseEvent;
```

C++

```
__property TLastReleaseEvent OnLastRelease;
```

Description

Use OnLastRelease to write a handler to process some action after the last object using the server is released, and just before the server shuts down. ShutDown indicates whether the server should be unloaded.

TLastReleaseEvent (see page 5639) is the type of the OnLastRelease event. Shutdown indicates whether the server will shut down after processing the OnLastRelease event.

See Also

StartMode (see page 5631)

30.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DllCanUnloadNow (see page 5634)	Tells Windows whether it can unload the in-process server exporting this function.
	DllGetClassObject (see page 5635)	Obtains a class factory for an ActiveX object when the ActiveX object resides in an in-process ActiveX server (DLL).
	DllRegisterServer (see page 5636)	Registers an in-process ActiveX server in the current module within the system registry.
	DllUnregisterServer (see page 5636)	Unregisters an OLE automation server in the current module with the system registry.
	LoadTypeLibrary (see page 5637)	This is function ComServ.LoadTypeLibrary.

30.2.1 ComServ.DllCanUnloadNow Function

Tells Windows whether it can unload the in-process server exporting this function.

Pascal

```
function DllCanUnloadNow: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllCanUnloadNow();
```

File

ComServ

Description

Do not call DllCanUnloadNow directly. DllCanUnloadNow is exported by ActiveX servers (DLLs) and is called by the operating system to indicate whether the server can be unloaded from memory because it is no longer in use. A DLL is no longer in use when it is not managing any existing objects (the reference count on all of its objects is 0).

The return values for DllCanUnloadNow are as follows:

Value	Meaning
S_OK	The DLL can be unloaded.
S_FALSE	The DLL cannot be unloaded now.

Note: DllCanUnloadNow is one of four functions in the ComServ (see page 5621) unit that every in-process ActiveX server must export so that Windows can manage the server resources properly. The others are DllGetClassObject (see page 5635), DllRegisterServer (see page 5636), and DllUnregisterServer (see page 5636).

See Also

DllGetClassObject

DllRegisterServer

DllUnregisterServer

30.2.2 ComServ.DllGetClassObject Function

Obtains a class factory for an ActiveX object when the ActiveX object resides in an in-process ActiveX server (DLL).

Pascal

```
function DllGetClassObject(const CLSID: TGUID; const IID: TGUID; var Obj): HResult; stdcall;
```

C++

```
__stdcall HRESULT DllGetClassObject(const TGUID CLSID, const TGUID IID,  Obj);
```

File

ComServ

Description

Do not call DllGetClassObject directly. DllGetClassObject is exported by all ActiveX server DLLs, and it is called internally by the operating system. When a user calls CoGetClassObject (or CoCreateInstance, which internally calls CoGetClassObject) to obtain a class factory for an ActiveX object, the OLE engine loads the ActiveX server DLL into memory and calls its DllGetClassObject function.

The parameters to DllGetClassObject are:

CLSID is the class identifier for the ActiveX object to be created by the class factory.

IID is the interface indentifier for the interface through which the caller will communicate with the class factory object to create instances of the object referenced by CLSID. This parameter is nearly always IID_IClassFactory or IID_IClassFactory2.

Obj will hold a pointer to the resulting class factory interface upon successful completion of the function. If an error occurs, Obj will be set to nil.

The return values for DLLGetClassObject are as follows:

Value	Meaning
S_OK	The object was retrieved successfully.
E_NOINTERFACE	The object referenced by Obj doesn't support the interface passed in the IID parameter.
CLASS_E_CLASSNOTAVAILABLE	The DLL does not support the class type referenced by the CLSID parameter.

Note: DllGetClassObject is one of four functions in the ComServ (see page 5621) unit that every in-process server must export so that Windows can manage the server resources properly. The others are DllCanUnloadNow (see page 5634), DllRegisterServer (see page 5636), and DllUnregisterServer (see page 5636).

See Also

DllCanUnloadNow

DllRegisterServer

DllUnregisterServer

TComClassManager

Requirements for Transactional Objects

30.2.3 ComServ.DllRegisterServer Function

Registers an in-process ActiveX server in the current module within the system registry.

Pascal

```
function DllRegisterServer: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllRegisterServer();
```

File

ComServ

Description

Do not call DllRegisterServer directly. DllRegisterServer is exported by in-process ActiveX servers (DLLs) and instructs the DLL to create its registry entries for the type library and all classes supported in that server module. DLLRegisterServer is usually called when the ActiveX server is installed on a user's system.

If this function fails, the state of the registry for its type library and its classes is indeterminate.

The return values for DllRegisterServer are as follows:

Value	Meaning
S_OK	The registry entries were created successfully.
E_FAIL	The registry entries were not completed.

Note: DllRegisterServer is one of four functions in the ComServ (see page 5621) unit that every in-process server must export so that Windows can manage the server resources properly. The others are DllCanUnloadNow (see page 5634), DllGetClassObject (see page 5635), and DllUnregisterServer (see page 5636).

See Also

DllCanUnloadNow

DllGetClassObject

DllUnregisterServer

Requirements for Transactional Objects

30.2.4 ComServ.DllUnregisterServer Function

Unregisters an OLE automation server in the current module with the system registry.

Pascal

```
function DllUnregisterServer: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllUnregisterServer();
```

File

ComServ

Description

Do not call DllUnregisterServer directly. DllUnregisterServer is exported by in-process automation servers (DLLs) and instructs the DLL to remove entries created through DllRegisterServer (see page 5636). DLLRegisterServer is called when a server is uninstalled.

The return values for DllUnregisterServer are as follows:

Value	Meaning
S_OK	The registry entries were successfully removed.
S_FALSE	Some or all registry entries were not removed.

Note: DllUnregisterServer is one of four functions in the ComServ (see page 5621) unit that every in-process server must export so that Windows can manage the server resources properly. The others are DllCanUnloadNow (see page 5634), DllGetClassObject (see page 5635), and DllRegisterServer (see page 5636). It should never be necessary for users to directly call or alter any of these functions.

See Also

DllCanUnloadNow

DllGetClassObject

DllRegisterServer

30.2.5 ComServ.LoadTypeLibrary Function

Pascal

```
function LoadTypeLibrary(const ModuleName: string): ITypeLib;
```

C++

```
ITypeLib LoadTypeLibrary(const AnsiString ModuleName);
```

File

ComServ

Description

This is function ComServ.LoadTypeLibrary.

30.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TStartMode (see page 5638)	This is record ComServ.TStartMode.

30.3.1 ComServ.TStartMode Enumeration

Pascal

```
TStartMode = (
  smStandalone,
  smAutomation,
  smRegServer,
  smUnregServer
);
```

C++

```
enum TStartMode {
  smStandalone,
  smAutomation,
  smRegServer,
  smUnregServer
};
```

File

ComServ

Description

This is record ComServ.TStartMode.

30.4 Types

The following table lists types in this documentation.

Types

Name	Description
TLastReleaseEvent (see page 5639)	This is type ComServ.TLastReleaseEvent.

30.4.1 ComServ.TLastReleaseEvent Type

Pascal

```
TLastReleaseEvent = procedure (var Shutdown: Boolean) of object;
```

C++

```
(var Shutdown: Boolean) ( TLastReleaseEvent)();
```

File

ComServ

Description

This is type ComServ.TLastReleaseEvent.

30.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ComServer (see page 5640)	Provides class and registry information about server objects.

30.5.1 ComServ.ComServer Variable

Provides class and registry information about server objects.

Pascal

```
ComServer: TComServer;
```

C++

```
TComServer ComServer;
```

File

ComServ

Description

ComServ (see page 5621) declares an instance of COM server. By default, when the ComServ (see page 5621) unit is included in a project, Delphi constructs a COM server object and assigns it to ComServ (see page 5621). ComServ (see page 5621) has several properties and methods that provide class and registry information about the objects loaded on the server. See TComServer (see page 5623) object for a list of properties and methods.

31 Contnrs Namespace

This is namespace Contnrs.

Topics

Name	Description
Classes (see page 5643)	The following table lists classes in this documentation.
Functions (see page 5705)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5706)	The following table lists structs, records, enums in this documentation.
Types (see page 5709)	The following table lists types in this documentation.

Classes

	Name	Description
	TBucketList (see page 5643)	TBucketList is a simple hash table that stores pointers indexed by pointers.
	TClassList (see page 5646)	TClassList maintains a list of classes.
	TComponentList (see page 5653)	TComponentList maintains a list of components, updating itself when a component is freed.
	TCustomBucketList (see page 5661)	TCustomBucketList is the base class for lists that store items under a limited number of categories.
	TIntegerBucketList (see page 5670)	This is class Contnrs.TIntegerBucketList.
	TObjectBucketList (see page 5673)	TObjectBucketList is a simple hash table that stores objects that are identified by other objects.
	TObjectList (see page 5677)	TObjectList maintains a list of (owned) objects.
	TObjectQueue (see page 5687)	TObjectQueue maintains a first-in first-out list of objects.
	TObjectStack (see page 5690)	TObjectStack maintains a last-in first-out list of objects.
	TOrderedList (see page 5693)	TOrderedList maintains an array of pointers that must be accessed in serial order.
	TQueue (see page 5699)	TQueue maintains a first-in first-out array of pointers.
	TStack (see page 5701)	TStack maintains a last-in first-out array of pointers.

Functions

	Name	Description
	RaiseListError (see page 5705)	This is function Contnrs.RaiseListError.

Structs, Records, Enums

	Name	Description
	TBucket (see page 5706)	TBucketArray (see page 5709) and TBucket represent a list of buckets that each store an array of items.

	TBucketItem (see page 5707)	TBucketItemArray (see page 5710) and TBucketItem represent the items in a TBucket (see page 5706) record (Delphi) or structure (C++).
	TBucketListSizes (see page 5707)	TBucketListSizes indicates the number of distinct buckets in a TBucketList (see page 5643) object.

Types

Name	Description
TBucketArray (see page 5709)	This is type Contnrs.TBucketArray.
TBucketEvent (see page 5709)	This is type Contnrs.TBucketEvent.
TBucketItemArray (see page 5710)	This is type Contnrs.TBucketItemArray.
TBucketProc (see page 5710)	This is type Contnrs.TBucketProc.

31.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TBucketList (see page 5643)	TBucketList is a simple hash table that stores pointers indexed by pointers.
	TClassList (see page 5646)	TClassList maintains a list of classes.
	TComponentList (see page 5653)	TComponentList maintains a list of components, updating itself when a component is freed.
	TCustomBucketList (see page 5661)	TCustomBucketList is the base class for lists that store items under a limited number of categories.
	TIntegerBucketList (see page 5670)	This is class Contnrs.TIntegerBucketList.
	TObjectBucketList (see page 5673)	TObjectBucketList is a simple hash table that stores objects that are identified by other objects.
	TObjectList (see page 5677)	TObjectList maintains a list of (owned) objects.
	TObjectQueue (see page 5687)	TObjectQueue maintains a first-in first-out list of objects.
	TObjectStack (see page 5690)	TObjectStack maintains a last-in first-out list of objects.
	TOrderedList (see page 5693)	TOrderedList maintains an array of pointers that must be accessed in serial order.
	TQueue (see page 5699)	TQueue maintains a first-in first-out array of pointers.
	TStack (see page 5701)	TStack maintains a last-in first-out array of pointers.

31.1.1 TBucketList Class

TBucketList is a simple hash table that stores pointers indexed by pointers.

Class Hierarchy

Pascal

```
TBucketList = class(TCustomBucketList);
```

C++

```
class TBucketList : public TCustomBucketList;
```

File

Contnrs

Description

Use TBucketList as a simple hash table to store data pointers using identifiers represented as pointers. TBucketList includes methods to add, remove, and locate items in the list, as well as a method that executes a callback for every item in the list.

See Also

Working with Lists

31.1.1.1 TBucketList Members

The following tables list the members exposed by TBucketList.

Protected Methods

	Name	Description
V	AddItem (see page 5664)	Inserts an item and its associated data into a specified bucket.
V	BucketFor (see page 5645)	Returns the index of the bucket in which a specified item belongs.
V	DeleteItem (see page 5666)	Deletes an item from a bucket in the bucket list.
V	FindItem (see page 5667)	Returns the location of an item in the bucket list.

Protected Properties

	Name	Description
	BucketCount (see page 5668)	Indicates the number of buckets in the bucket list.
R	Buckets (see page 5669)	Lists the buckets in the bucket list

Public Methods

	Name	Description
	Add (see page 5664)	Inserts an item and its associated data into the bucket list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5665)	Replaces all the items in this list with the items from another bucket list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5665)	Empties the bucket list of all its items.
	Create (see page 5645)	Creates and initializes a TBucketList (see page 5643) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5663)	Destroys an instance of TCustomBucketList (see page 5661).
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Exists (see page 5666)	Indicates whether the bucket list contains a specified item.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 5666)	Returns the data associated with a specified item.
	ForEach (see page 5667)	This is the overview for the ForEach method overload.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Remove (see page 5668)	Removes a specified item from the list and returns its data.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Data (see page 5669)	Represents the data associated with a specified item in the bucket list.

31.1.1.2 TBucketList.Create Constructor

Creates and initializes a TBucketList (see page 5643) object.

Pascal

```
constructor Create(ABuckets: TBucketListSizes = bl16);
```

C++

```
__fastcall TBucketList(TBucketListSizes ABuckets = bl16);
```

Description

Call Create to create a bucket list at runtime.

31.1.1.3 TBucketList Methods

The methods of the TBucketList class are listed here.

Protected Methods

	Name	Description
	BucketFor (see page 5645)	Returns the index of the bucket in which a specified item belongs.

31.1.1.3.1 TBucketList.BucketFor Method

Returns the index of the bucket in which a specified item belongs.

Pascal

```
function BucketFor(AItem: Pointer): Integer; override;
```

C++

```
virtual __fastcall int BucketFor(void * AItem);
```

Description

TBucketList (see page 5643) uses BucketFor internally to determine the bucket into which an arbitrary item belongs.

AItem is the identifier of the item for which you want to find a bucket.

BucketFor returns the index of the bucket in the Buckets (see page 5669) property array.

See Also

Buckets (see page 5669)

31.1.2 TClassList Class

TClassList maintains a list of classes.

Class Hierarchy

Pascal

```
TClassList = class(TList);
```

C++

```
class TClassList : public TList;
```

File

Contnrs

Description

Use a TClassList object to store and maintain a list of classes.

See Also

TList (see page 2868)

TCollection (see page 2731)

TStrings (see page 3029)

TComponent (see page 2762)

TObjectList (see page 5677)

TComponentList (see page 5653)

TStack (see page 5701)

Working with Lists

31.1.2.1 TClassList Members

The following tables list the members exposed by TClassList.

Protected Methods

	Name	Description
	Get (see page 2878)	This is Get, a member of class TList.
	GetItems (see page 5649)	This is GetItems, a member of class TClassList.
V	Grow (see page 2879)	This is Grow, a member of class TList.
V	Notify (see page 2884)	Responds when items are added, removed, or extracted from the list.
	Put (see page 2887)	This is Put, a member of class TList.
	SetCapacity (see page 2891)	This is SetCapacity, a member of class TList.
	SetCount (see page 2892)	This is SetCount, a member of class TList.
	SetItems (see page 5652)	This is SetItems, a member of class TClassList.

Public Methods

	Name	Description
	Add (see page 5648)	Inserts a new class at the end of the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2874)	Copies elements of one list to another.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 2874)	Deletes all items from the list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2874)	Removes the item at the position given by the Index parameter.
V	Destroy (see page 2870)	Destroys an instance of TList (see page 2868).
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Error (see page 2875)	This is the overview for the Error method overload.
	Exchange (see page 2876)	Swaps the position of two items in the Items (see page 2898) array.
	Expand (see page 2877)	Increases the Capacity (see page 2895) of the list.
	Extract (see page 5649)	Removes a class from the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	First (see page 5649)	Returns Items (see page 5652)[0].
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2878)	Returns a TList (see page 2868) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 5650)	Returns the index of the first occurrence in the list of a specified class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 5650)	Firsts a class to the list at a specified position.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Last (see page 5651)	Returns the last class listed in the Items (see page 5652) array.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 2884)	Changes the position of an item in the Items (see page 2898) array.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pack (see page 2885)	Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.
	Remove (see page 5651)	Removes the first occurrence of a specified class from the list.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Sort (see page 2892)	Performs a QuickSort on the list based on the comparison function Compare.

Public Properties

	Name	Description
	Capacity (see page 2895)	Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.
	Count (see page 2896)	Indicates the number of entries in the list that are in use.
	Items (see page 5652)	Lists the classes in the TClassList (see page 5646).
R	List (see page 2900)	Specifies the array of pointers that make up the Items (see page 2898) array.

31.1.2.2 TClassList Methods

The methods of the TClassList class are listed here.

Protected Methods

	Name	Description
	GetItems (see page 5649)	This is GetItems, a member of class TClassList.
	SetItems (see page 5652)	This is SetItems, a member of class TClassList.

Public Methods

	Name	Description
	Add (see page 5648)	Inserts a new class at the end of the list.
	Extract (see page 5649)	Removes a class from the list.
	First (see page 5649)	Returns Items (see page 5652)[0].
	IndexOf (see page 5650)	Returns the index of the first occurrence in the list of a specified class.
	Insert (see page 5650)	Firsts a class to the list at a specified position.
	Last (see page 5651)	Returns the last class listed in the Items (see page 5652) array.
	Remove (see page 5651)	Removes the first occurrence of a specified class from the list.

31.1.2.2.1 TClassList.Add Method

Inserts a new class at the end of the list.

Pascal

```
function Add(AClass: TClass): Integer;
```

C++

```
__fastcall int Add(TClass AClass);
```

Description

Call Add to insert a new class at the end of the Items (see page 5652) array. Add returns the index of the new class, where the first class in the list has an index of 0.

Add increments Count and, if necessary, allocates memory by increasing the value of Capacity.

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 2882)

Items (see page 5652)

Remove (see page 2887)

Clear (see page 2874)

Pack (see page 2885)

31.1.2.2.2 TClassList.Extract Method

Removes a class from the list.

Pascal

```
function Extract(Item: TClass): TClass;
```

C++

```
__fastcall TClass Extract(TClass Item);
```

Description

Call Extract to remove a class from the list. After the class is removed, all the classes that follow it are moved up in index position and Count is decremented.

In TClassList (see page 5646), Extract does the same thing as the Delete method, except that it returns the class that was removed from the list.

To remove the reference to a class without deleting the entry from the Items (see page 5652) array and changing the Count, set the Items (see page 5652) property for Index to nil (Delphi) or NULL (C++).

See Also

Items (see page 5652)

Remove (see page 5651)

Count (see page 2896)

Delete (see page 2874)

31.1.2.2.3 TClassList.First Method

Returns Items (see page 5652)[0].

Pascal

```
function First: TClass;
```

C++

```
__fastcall TClass First();
```

Description

Call First to retrieve the first class in the Items (see page 5652) array.

See Also

Items (see page 5652)

Last (see page 5651)

31.1.2.2.4 TClassList.GetItems Method

Pascal

```
function GetItems(Index: Integer): TClass;
```

C++

```
__fastcall TClass GetItems(int Index);
```

Description

This is GetItems, a member of class TClassList.

31.1.2.2.5 TClassList.IndexOf Method

Returns the index of the first occurrence in the list of a specified class.

Pascal

```
function IndexOf(AClass: TClass): Integer;
```

C++

```
__fastcall int IndexOf(TClass AClass);
```

Description

Call IndexOf to get the index for a class in the Items (see page 5652) array. The first class in the array has index 0, the second class has index 1, and so on.

If a class is not in the list, IndexOf returns -1. If a class appears more than once in the list, IndexOf returns the index of the first appearance.

See Also

Delete (see page 2874)

Items (see page 5652)

31.1.2.2.6 TClassList.Insert Method

Firsts a class to the list at a specified position.

Pascal

```
procedure Insert(Index: Integer; AClass: TClass);
```

C++

```
__fastcall Insert(int Index, TClass AClass);
```

Description

Call Insert to First (see page 5649) a class at a specified position in the list, shifting the item that previously occupied that position (and all subsequent items) up. Insert increments Count and, if necessary, allocates memory by increasing the value of Capacity.

The Index parameter is zero-based, so the first position in the list has an index of 0.

To replace an empty reference with a new class without growing the array, set the Items (see page 5652) property directly.

See Also

First (see page 5649)

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 5652)

Remove (see page 5651)

Pack (see page 2885)

Clear (see page 2874)

31.1.2.2.7 TClassList.Last Method

Returns the last class listed in the Items (see page 5652) array.

Pascal

```
function Last: TClass;
```

C++

```
__fastcall TClass Last();
```

Description

Call Last to retrieve the last class in the Items (see page 5652) array.

See Also

Items (see page 5652)

First (see page 5649)

31.1.2.2.8 TClassList.Remove Method

Removes the first occurrence of a specified class from the list.

Pascal

```
function Remove(AClass: TClass): Integer;
```

C++

```
__fastcall int Remove(TClass AClass);
```

Description

Call Remove to delete a specific class from the list when its index is unknown. The value returned is the index of the class in the Items (see page 5652) array before it was removed. If the specified object is not found on the list, Remove returns –1.

After a class is deleted, all the classes that follow it are moved up in index position and Count is decremented. If a class appears more than once on the list, Remove deletes only the first appearance.

To use an index position (rather than an object reference) to specify the class to be removed, call Delete.

See Also

First (see page 5649)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 5650)

Items (see page 5652)

Pack (see page 2885)

Extract (see page 5649)

31.1.2.2.9 TClassList.SetItems Method

Pascal

```
procedure SetItems(Index: Integer; AClass: TClass);
```

C++

```
__fastcall SetItems(int Index, TClass AClass);
```

Description

This is SetItems, a member of class TClassList.

31.1.2.3 TClassList Properties

The properties of the TClassList class are listed here.

Public Properties

	Name	Description
	Items (see page 5652)	Lists the classes in the TClassList (see page 5646).

31.1.2.3.1 TClassList.Items Property

Lists the classes in the TClassList (see page 5646).

Pascal

```
property Items [Index: Integer]: TClass;
```

C++

```
__property TClass Items[int Index];
```

Description

Use Items to access classes in the list. Items is a zero-based array: The first class is indexed as 0, the second class is indexed as 1, and so forth. You can read or change the value at a specific index, or use Items with the Count property to iterate through the list.

Items can contain empty class references. To remove empty references and reduce the size of the array, call the Pack method.

Note: In Delphi, Items is the default property for TClassList (see page 5646). This means that the property name can be omitted in code. Thus, the following two lines are both acceptable and do the same thing:

```
RegisterClass(ClassList1.Items[i]);
RegisterClass(ClassList1[i]);
```

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

Count (see page 2896)

List (see page 2900)

Pack (see page 2885)

Delete (see page 2874)

Remove (see page 2887)

Clear (see page 2874)

Add (see page 5648)

Insert (see page 5650)

operator_sb

31.1.3 TComponentList Class

TComponentList maintains a list of components, updating itself when a component is freed.

Class Hierarchy

Pascal

```
TComponentList = class(TObjectList);
```

C++

```
class TComponentList : public TObjectList;
```

File

Contnrs

Description

Use TComponentList to store and maintain a list of components. TComponentList provides properties and methods to add, delete, rearrange, locate, access, and sort components. Like TObjectList (see page 5677), TComponentList controls the memory of its components; unless the OwnsObjects (see page 5686) property is set to false (or the components are removed with the Extract (see page 5656) method). TComponentList frees its components when they are removed from the list or when the TComponentList instance is itself destroyed.

In addition, TComponentList tracks its components. When a component is freed, TComponentList automatically updates itself by deleting the reference to the freed component and packing the list.

See Also

Working with Lists

31.1.3.1 TComponentList Members

The following tables list the members exposed by TComponentList.

Protected Methods

	Name	Description
	Get (see page 2878)	This is Get, a member of class TList.
	GetItem (see page 5682)	This is GetItem, a member of class TObjectList.
	GetItems (see page 5657)	This is GetItems, a member of class TComponentList.
V	Grow (see page 2879)	This is Grow, a member of class TList.
	HandleFreeNotify (see page 5657)	This is HandleFreeNotify, a member of class TComponentList.
V	Notify (see page 5659)	Responds when items are added, removed, or extracted from the list.
	Put (see page 2887)	This is Put, a member of class TList.
	SetCapacity (see page 2891)	This is SetCapacity, a member of class TList.
	SetCount (see page 2892)	This is SetCount, a member of class TList.

	SetItem (see page 5685)	This is SetItem, a member of class TObjectList.
	SetItems (see page 5660)	This is SetItems, a member of class TComponentList.

Public Methods

	Name	Description
	Add (see page 5656)	Inserts a component at the end of the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2874)	Copies elements of one list to another.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 2874)	Deletes all items from the list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 5679)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2874)	Removes the item at the position given by the Index parameter.
V	Destroy (see page 5655)	Destroys an instance of TComponentList (see page 5653).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Error (see page 2875)	This is the overview for the Error method overload.
	Exchange (see page 2876)	Swaps the position of two items in the Items (see page 2898) array.
	Expand (see page 2877)	Increases the Capacity (see page 2895) of the list.
	Extract (see page 5656)	Removes a component from the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindInstanceOf (see page 5682)	Finds the first instance of a specified class in the list.
	First (see page 5657)	Returns Items (see page 5660)[0].
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2878)	Returns a TList (see page 2868) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 5658)	Returns the index of the first component in the list with a specified value.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 5658)	Adds a component to the list at a specified position.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Last (see page 5659)	Returns the component at the end of the Items (see page 5660) array.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 2884)	Changes the position of an item in the Items (see page 2898) array.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pack (see page 2885)	Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.
	Remove (see page 5659)	Removes a specified component from the list and (if OwnsObjects (see page 5686) is true) frees the component.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

	Sort (see page 2892)	Performs a QuickSort on the list based on the comparison function Compare.

Public Properties

	Name	Description
	Capacity (see page 2895)	Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.
	Count (see page 2896)	Indicates the number of entries in the list that are in use.
	Items (see page 5660)	Lists the component references.
R	List (see page 2900)	Specifies the array of pointers that make up the Items (see page 2898) array.
	OwnsObjects (see page 5686)	Allows TObjectList (see page 5677) to free objects when they are deleted from the list or the list is destroyed.

31.1.3.2 TComponentList.Destroy Destructor

Destroys an instance of TComponentList (see page 5653).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TComponentList();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the component list is not nil before calling Destroy.

Before destroying the TComponentList (see page 5653), Destroy calls Clear, which frees the components in the list if OwnsObjects (see page 5686) is true.

See Also

Items (see page 5660)

OwnsObjects (see page 5686)

Clear (see page 2874)

31.1.3.3 TComponentList Methods

The methods of the TComponentList class are listed here.

Protected Methods

	Name	Description
	GetItems (see page 5657)	This is GetItems, a member of class TComponentList.
	HandleFreeNotify (see page 5657)	This is HandleFreeNotify, a member of class TComponentList.
V	Notify (see page 5659)	Responds when items are added, removed, or extracted from the list.
	SetItems (see page 5660)	This is SetItems, a member of class TComponentList.

Public Methods

	Name	Description
	Add (see page 5656)	Inserts a component at the end of the list.
	Extract (see page 5656)	Removes a component from the list.
	First (see page 5657)	Returns Items (see page 5660)[0].
	IndexOf (see page 5658)	Returns the index of the first component in the list with a specified value.
	Insert (see page 5658)	Adds a component to the list at a specified position.
	Last (see page 5659)	Returns the component at the end of the Items (see page 5660) array.

	Remove (see page 5659)	Removes a specified component from the list and (if OwnsObjects (see page 5686) is true) frees the component.

31.1.3.3.1 TComponentList.Add Method

Inserts a component at the end of the list.

Pascal

```
function Add(AComponent: TComponent): Integer;
```

C++

```
__fastcall int Add(TComponent * AComponent);
```

Description

Call Add to insert a component at the end of the list. Add places the component after the last item, even if the array contains nil (Delphi) or NULL (C++) references, and returns the index of the inserted component. (The first component in the list has an index of 0.)

Add increments Count and, if necessary, allocates memory by increasing the value of Capacity.

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 5658)

Items (see page 5660)

Remove (see page 5659)

Extract (see page 2877)

Extract (see page 5656)

Clear (see page 2874)

Pack (see page 2885)

31.1.3.3.2 TComponentList.Extract Method

Removes a component from the list.

Pascal

```
function Extract(Item: TComponent): TComponent;
```

C++

```
__fastcall TComponent * Extract(TComponent * Item);
```

Description

Call Extract to remove a component from the list. After the component is removed, all the components that follow it are moved up in index position and Count is decremented.

Extract does not free the component when it is removed from the list. This differs, for example, from the Delete method, which frees the component unless OwnsObjects (see page 5686) is set to false.

To remove the reference to a component without deleting the entry from the Items (see page 5660) array and changing the

Count, set the Items (see page 5660) property for Index to nil (Delphi) or NULL (C++).

See Also

Items (see page 5660)

Remove (see page 5659)

Count (see page 2896)

Delete (see page 2874)

OwnsObjects (see page 5686)

31.1.3.3.3 TComponentList.First Method

Returns Items (see page 5660)[0].

Pascal

```
function First: TComponent;
```

C++

```
__fastcall TComponent * First();
```

Description

Call First to retrieve the first component in the Items (see page 5660) array.

See Also

Items (see page 5660)

Last (see page 5659)

31.1.3.3.4 TComponentList.GetItems Method

Pascal

```
function GetItems(Index: Integer): TComponent;
```

C++

```
__fastcall TComponent * GetItems(int Index);
```

Description

This is GetItems, a member of class TComponentList.

31.1.3.3.5 TComponentList.HandleFreeNotify Method

Pascal

```
procedure HandleFreeNotify(Sender: TObject; AComponent: TComponent);
```

C++

```
__fastcall HandleFreeNotify(TObject * Sender, TComponent * AComponent);
```

Description

This is HandleFreeNotify, a member of class TComponentList.

31.1.3.3.6 TComponentList.IndexOf Method

Returns the index of the first component in the list with a specified value.

Pascal

```
function IndexOf(AComponent: TComponent): Integer;
```

C++

```
__fastcall int IndexOf(TComponent * AComponent);
```

Description

Call IndexOf to get the index for a specified component in the list.

AComponent is the component to locate in the list.

Index of returns the index of AComponent, where the first component has index 0, the second component has index 1, and so on. If a component is not in the list, IndexOf returns -1. If a component appears more than once, IndexOf returns the index of the first appearance.

See Also

Delete (see page 2874)

Items (see page 5660)

FindInstanceOf (see page 5682)

31.1.3.3.7 TComponentList.Insert Method

Adds a component to the list at a specified position.

Pascal

```
procedure Insert(Index: Integer; AComponent: TComponent);
```

C++

```
__fastcall Insert(int Index, TComponent * AComponent);
```

Description

Call Insert to add a component at a specified position in the list, shifting the item that previously occupied that position (and all subsequent items) up. Insert increments Count and, if necessary, allocates memory by increasing the value of Capacity.

The Index parameter is zero-based, so the first position in the list has an index of 0.

To replace a nil (Delphi) or NULL (C++) reference with a new component without growing the array, set the Items (see page 5660) property directly.

See Also

Add (see page 5656)

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 5660)

Remove (see page 5659)

Pack (see page 2885)

Clear (see page 2874)

Extract (see page 5656)

31.1.3.3.8 TComponentList.Last Method

Returns the component at the end of the Items (see page 5660) array.

Pascal

```
function Last: TComponent;
```

C++

```
__fastcall TComponent * Last();
```

Description

Call Last to retrieve the last component in the Items (see page 5660) array.

See Also

Items (see page 5660)

First (see page 5657)

31.1.3.3.9 TComponentList.Notify Method

Responds when items are added, removed, or extracted from the list.

Pascal

```
procedure Notify(Ptr: Pointer; Action: TListNotification); override;
```

C++

```
virtual __fastcall Notify(void * Ptr, TListNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Ptr points to item affected by the change.

Action indicates the change.

As implemented in TList, Notify does nothing. Descendant classes can override Notify in order to implement an appropriate response to the change notification.

31.1.3.3.10 TComponentList.Remove Method

Removes a specified component from the list and (if OwnsObjects (see page 5686) is true) frees the component.

Pascal

```
function Remove(AComponent: TComponent): Integer;
```

C++

```
__fastcall int Remove(TComponent * AComponent);
```

Description

Call Remove to delete a specific component from the list when its index is unknown. The value returned is the index of the component in the Items (see page 5660) array before it was removed. If the specified component is not found on the list, Remove returns –1. If OwnsObjects (see page 5686) is true, Remove frees the component in addition to removing it from the

list.

After a component is deleted, all the components that follow it are moved up in index position and Count is decremented. If a component appears more than once on the list, Remove deletes only the first appearance. Hence, if OwnsObjects (see page 5686) is true, removing a component that appears more than once results in empty references later in the list.

To use an index position (rather than an object reference) to specify the component to be removed, call Delete.

To remove a component from the list without freeing it, call Extract (see page 5656).

See Also

Add (see page 5656)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 5658)

Items (see page 5660)

OwnsObjects (see page 5686)

Extract (see page 5656)

Pack (see page 2885)

31.1.3.3.11 TComponentList.SetItems Method

Pascal

```
procedure SetItems(Index: Integer; AComponent: TComponent);
```

C++

```
__fastcall SetItems(int Index, TComponent * AComponent);
```

Description

This is SetItems, a member of class TComponentList.

31.1.3.4 TComponentList Properties

The properties of the TComponentList class are listed here.

Public Properties

	Name	Description
	Items (see page 5660)	Lists the component references.

31.1.3.4.1 TComponentList.Items Property

Lists the component references.

Pascal

```
property Items [Index: Integer]: TComponent;
```

C++

```
__property TComponent * Items[int Index];
```

Description

Use Items to access components in the list. Items is a zero-based array: The first component is indexed as 0, the second component is indexed as 1, and so forth. You can read or change the value at a specific index, or use Items with the Count property to iterate through the list.

If OwnsObjects (see page 5686) is true, reassigning an Items value frees the component that previously occupied that position in the list.

Items can contain nil (Delphi) or NULL (C++) references. To remove nil (Delphi) or NULL (C++) references and reduce the size of the array, call the Pack method.

Note: In Delphi, Items is the default property of TComponentList (see page 5653). This means that the property name can be eliminated in code that uses this property. Thus, the following two lines are both acceptable and do the same thing:

```
ComponentList1->Items[i] := Screen.CustomForms[i];
ComponentList1[i] := Screen.CustomForms[i];
```

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

OwnsObjects (see page 5686)

Add (see page 5656)

Insert (see page 5658)

Delete (see page 2874)

Remove (see page 5659)

List (see page 2900)

Extract (see page 2877)

Extract (see page 5656)

Count (see page 2896)

Clear (see page 2874)

Pack (see page 2885)

operator_sb

31.1.4 TCustomBucketList Class

TCustomBucketList is the base class for lists that store items under a limited number of categories.

Class Hierarchy

Pascal

```
TCustomBucketList = class(TObject);
```

C++

```
class TCustomBucketList : public TObject;
```

File

Contnrs

Description

Use TCustomBucketList as a base class for lists of items that fit into a limited number of categories (or buckets). Each bucket can contain multiple items, and there is a well-defined function (the protected BucketFor (see page 5665) method) that determines the bucket into which an item belongs. TCustomBucketList descendants can include lists of items that fall into natural categories, or implementations of a hash table.

Do not create instances of TCustomBucketList. In TCustomBucketList, the BucketFor (see page 5665) method is abstract (pure virtual), meaning that descendant classes must override it and provide an implementation.

31.1.4.1 TCustomBucketList Members

The following tables list the members exposed by TCustomBucketList.

Protected Methods

	Name	Description
V	AddItem (see page 5664)	Inserts an item and its associated data into a specified bucket.
A	BucketFor (see page 5665)	Returns the index of the bucket in which a specified item belongs.
V	DeleteItem (see page 5666)	Deletes an item from a bucket in the bucket list.
V	FindItem (see page 5667)	Returns the location of an item in the bucket list.

Protected Properties

	Name	Description
	BucketCount (see page 5668)	Indicates the number of buckets in the bucket list.
R	Buckets (see page 5669)	Lists the buckets in the bucket list

Public Methods

	Name	Description
	Add (see page 5664)	Inserts an item and its associated data into the bucket list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5665)	Replaces all the items in this list with the items from another bucket list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5665)	Empties the bucket list of all its items.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5663)	Destroys an instance of TCustomBucketList (see page 5661).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Exists (see page 5666)	Indicates whether the bucket list contains a specified item.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 5666)	Returns the data associated with a specified item.
	ForEach (see page 5667)	This is the overview for the ForEach method overload.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Remove (see page 5668)	Removes a specified item from the list and returns its data.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Data (see page 5669)	Represents the data associated with a specified item in the bucket list.

31.1.4.2 TCustomBucketList.Destroy Destructor

Destroys an instance of TCustomBucketList (see page 5661).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomBucketList();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the component list is not nil before calling Destroy.

Before destroying the TCustomBucketList (see page 5661), Destroy calls Clear (see page 5665), which deletes all of the items from all of the buckets in the list.

See Also

Clear (see page 5665)

31.1.4.3 TCustomBucketList Methods

The methods of the TCustomBucketList class are listed here.

Protected Methods

	Name	Description
	AddItem (see page 5664)	Inserts an item and its associated data into a specified bucket.
	BucketFor (see page 5665)	Returns the index of the bucket in which a specified item belongs.
	DeleteItem (see page 5666)	Deletes an item from a bucket in the bucket list.
	FindItem (see page 5667)	Returns the location of an item in the bucket list.

Public Methods

	Name	Description
	Add (see page 5664)	Inserts an item and its associated data into the bucket list.

	Assign (see page 5665)	Replaces all the items in this list with the items from another bucket list.
	Clear (see page 5665)	Empties the bucket list of all its items.
	Exists (see page 5666)	Indicates whether the bucket list contains a specified item.
	Find (see page 5666)	Returns the data associated with a specified item.
	ForEach (see page 5667)	This is the overview for the ForEach method overload.
	Remove (see page 5668)	Removes a specified item from the list and returns its data.

31.1.4.3.1 TCustomBucketList.Add Method

Inserts an item and its associated data into the bucket list.

Pascal

```
function Add(AItem: Pointer; AData: Pointer): Pointer;
```

C++

```
__fastcall void * Add(void * AItem, void * AData);
```

Description

Call Add to add an item and its associated data into the bucket list. Add locates the bucket into which the specified item belongs. If the item is already in the bucket, Add raises an EListError exception. Otherwise, it adds the item to the correct bucket and returns AData.

See Also

BucketFor (see page 5665)

EListError (see page 2701)

31.1.4.3.2 TCustomBucketList.AddItem Method

Inserts an item and its associated data into a specified bucket.

Pascal

```
function AddItem(ABucket: Integer; AItem: Pointer; AData: Pointer): Pointer; virtual;
```

C++

```
virtual __fastcall void * AddItem(int ABucket, void * AItem, void * AData);
```

Description

TCustomBucketList (see page 5661) uses AddItem internally to add items into buckets. AddItem does not check whether the specified item correctly belongs in the specified bucket; it simply handles the mechanics of adding the item into the bucket. If you need to determine the bucket in which an item belongs, use the Add (see page 5664) method instead.

ABucket is the index of the bucket in which the item belongs.

AItem is the item to add to ABucket.

AData is the data to associate with AItem.

AddItem returns the value of AData.

See Also

Add (see page 5664)

31.1.4.3.3 TCustomBucketList.Assign Method

Replaces all the items in this list with the items from another bucket list.

Pascal

```
procedure Assign(AList: TCustomBucketList);
```

C++

```
__fastcall Assign(TCustomBucketList AList);
```

Description

Assign empties the bucket list of any items it currently holds and then adds in all the items in the bucket list specified by the AList parameter.

Note: Assign merely copies the items from another bucket list, not the organization of the bucket list. Thus, the items may end up in entirely different buckets.

31.1.4.3.4 TCustomBucketList.BucketFor Method

Returns the index of the bucket in which a specified item belongs.

Pascal

```
function BucketFor(AItem: Pointer): Integer; virtual; abstract;
```

C++

```
virtual __fastcall int BucketFor(void * AItem) = 0;
```

Description

TCustomBucketList (see page 5661) uses BucketFor internally to determine the bucket into which an arbitrary item belongs. TCustomBucketList (see page 5661) introduces BucketFor as an abstract (pure virtual) method, which means it has no implementation. Descendant classes must override BucketFor to provide an implementation that determines the bucket for an arbitrary item.

AItem is the item for which you want to find a bucket.

BucketFor returns the index of the bucket in the Buckets (see page 5669) property array.

See Also

Buckets (see page 5669)

31.1.4.3.5 TCustomBucketList.Clear Method

Empties the bucket list of all its items.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the bucket list. Clear deletes all of the items from all of the buckets in the bucket list.

Note: Clearing the bucket list does not free any of the items in the list, it merely removes them from the bucket list.

See Also

Remove (see page 5668)

31.1.4.3.6 TCustomBucketList.DeleteItem Method

Deletes an item from a bucket in the bucket list.

Pascal

```
function DeleteItem(ABucket: Integer; AIndex: Integer): Pointer; virtual;
```

C++

```
virtual __fastcall void * DeleteItem(int ABucket, int AIndex);
```

Description

TCustomBucketList (see page 5661) uses DeleteItem to remove items from the bucket list. DeleteItem removes the specified item from the specified bucket and moves all items that came after the deleted item up by one position within the bucket.

ABucket is the bucket that contains the item to delete.

AIndex is the index of the item to delete within the bucket specified by ABucket.

DeleteItem returns the data associated with the deleted item.

See Also

Remove (see page 5668)

Clear (see page 5665)

31.1.4.3.7 TCustomBucketList.Exists Method

Indicates whether the bucket list contains a specified item.

Pascal

```
function Exists(AItem: Pointer): Boolean;
```

C++

```
__fastcall Boolean Exists(void * AItem);
```

Description

Call Exists to determine whether the item specified by AItem is already in the bucket list. Exists returns true if the bucket list contains AItem, false if AItem is not in the list.

See Also

Find (see page 5666)

31.1.4.3.8 TCustomBucketList.Find Method

Returns the data associated with a specified item.

Pascal

```
function Find(AItem: Pointer; out AData: Pointer): Boolean;
```

C++

```
__fastcall Boolean Find(void * AItem, void * AData);
```

Description

Call Find to retrieve the data associated with an item in the list. Calling the Find method differs from reading the Data (see page 5669) property in that it does not raise an exception if the item is not in the bucket list.

AItem is the item to find in the bucket list.

AData returns the data associated with AItem.

Find returns true if AItem is in the bucket list, false otherwise. The value of AData is not set if Find returns false.

See Also

Exists (see page 5666)

Data (see page 5669)

31.1.4.3.9 TCustomBucketList.FindItem Method

Returns the location of an item in the bucket list.

Pascal

```
function FindItem(AItem: Pointer; out ABucket: Integer; out AIndex: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean FindItem(void * AItem, int ABucket, int AIndex);
```

Description

TCustomBucketList (see page 5661) uses FindItem internally to locate items in the bucket list.

AItem is the item to find in the bucket list.

ABucket returns the index of the bucket that contains the item.

AIndex returns the index of the item in the bucket specified by ABucket.

FindItem returns true if AItem is in the bucket list, false otherwise.

See Also

Find (see page 5666)

Buckets (see page 5669)

31.1.4.3.10 ForEach Method

This is the overview for the ForEach method overload.

Overload List

	Name	Description
	TCustomBucketList.ForEach (TBucketEvent) (see page 5667)	Executes a callback for every item in the bucket list.
	TCustomBucketList.ForEach (TBucketProc, Pointer) (see page 5667)	Executes a callback for every item in the bucket list.

31.1.4.3.10.1 TCustomBucketList.ForEach Method (TBucketEvent)

Executes a callback for every item in the bucket list.

Pascal

```
function ForEach(AProc: TBucketProc; AInfo: Pointer = nil): Boolean; overload;
function ForEach(AEvent: TBucketEvent): Boolean; overload;
```

C++

```
__fastcall Boolean ForEach(TBucketProc AProc, void * AInfo = nil);
__fastcall Boolean ForEach(TBucketEvent AEvent);
```

Description

Call ForEach to execute the procedure specified by AProc for each item in the bucket list. ForEach iterates through all the items in the bucket list, passing in each item and its associated data to the specified callback.

AProc is the callback to execute.

AInfo has no predefined meaning. It is passed to the AInfo parameter of the callback.

ForEach returns true if it executes the callback for every item in the bucket list. It returns false if the callback set AContinue to false for some item, causing any subsequent items to be skipped.

31.1.4.3.11 TCustomBucketList.Remove Method

Removes a specified item from the list and returns its data.

Pascal

```
function Remove(AItem: Pointer): Pointer;
```

C++

```
__fastcall void * Remove(void * AItem);
```

Description

Call Remove to delete a specific item from the list.

AItem is the item to remove.

Remove returns the data associated with AItem. If AItem is not in the bucket list, Remove returns nil (Delphi) or NULL (C++).

See Also

Clear (see page 5665)

31.1.4.4 TCustomBucketList Properties

The properties of the TCustomBucketList class are listed here.

Protected Properties

	Name	Description
	BucketCount (see page 5668)	Indicates the number of buckets in the bucket list.
R	Buckets (see page 5669)	Lists the buckets in the bucket list

Public Properties

	Name	Description
	Data (see page 5669)	Represents the data associated with a specified item in the bucket list.

31.1.4.4.1 TCustomBucketList.BucketCount Property

Indicates the number of buckets in the bucket list.

Pascal

```
property BucketCount: Integer;
```

C++

```
__property int BucketCount;
```

Description

Use BucketCount to determine the number of buckets, or categories, that can hold items in the list. BucketCount determines the number of buckets that are listed by the Buckets (see page 5669) property.

See Also

Buckets (see page 5669)

31.1.4.4.2 TCustomBucketList.Buckets Property

Lists the buckets in the bucket list

Pascal

```
property Buckets: TBucketArray;
```

C++

```
__property TBucketArray Buckets;
```

Description

Use Buckets to access the buckets in the bucket list. Buckets is a dynamic array of TBucket (see page 5706) values, each of which can hold a set of items.

See Also

BucketCount (see page 5668)

BucketFor (see page 5665)

Find (see page 5666)

31.1.4.4.3 TCustomBucketList.Data Property

Represents the data associated with a specified item in the bucket list.

Pascal

```
property Data [AItem: Pointer]: Pointer;
```

C++

```
__property void * Data[void * AItem];
```

Description

Use Data to get or set the data associated with an item in the bucket list.

AItem points to an item currently in the bucket list. If AItem does not specify an item in one of the buckets of the bucket list, trying to read or set Data causes TCustomBucketList (see page 5661) to raise an EListError exception.

Note: In Delphi, Data is the default property of TCustomBucketList (see page 5661). This means that the property name can be omitted when using this property. For example, the following two lines of code are both acceptable and do the same thing:

```
BucketList1.Data[Name as Pointer] := Pointer(Form1.FindChildControl(Name));
```

```
BucketList1[Name as Pointer] := Pointer(Form1.FindChildControl(Name));
```

Note: In C++, Data can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

31.1.5 TIntegerBucketList Class

Class Hierarchy

Pascal

```
TIntegerBucketList = class(TBucketList);
```

C++

```
class TIntegerBucketList : public TBucketList;
```

File

Contnrs

Description

This is class Contnrs.TIntegerBucketList.

31.1.5.1 TIntegerBucketList Members

The following tables list the members exposed by TIntegerBucketList.

Protected Methods

	Name	Description
V	AddItem (see page 5664)	Inserts an item and its associated data into a specified bucket.
V	BucketFor (see page 5645)	Returns the index of the bucket in which a specified item belongs.
A	BucketFor (see page 5665)	Returns the index of the bucket in which a specified item belongs.
V	DeleteItem (see page 5666)	Deletes an item from a bucket in the bucket list.
V	FindItem (see page 5667)	Returns the location of an item in the bucket list.
	GetData (see page 5672)	This is GetData, a member of class TIntegerBucketList.
	SetData (see page 5672)	This is SetData, a member of class TIntegerBucketList.

Protected Properties

	Name	Description
	BucketCount (see page 5668)	Indicates the number of buckets in the bucket list.
R	Buckets (see page 5669)	Lists the buckets in the bucket list

Public Methods

	Name	Description
	Add (see page 5672)	This is Add, a member of class TIntegerBucketList.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5665)	Replaces all the items in this list with the items from another bucket list.

	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5665)	Empties the bucket list of all its items.
	Create (see page 5645)	Creates and initializes a TBucketList (see page 5643) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5663)	Destroys an instance of TCustomBucketList (see page 5661).
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Exists (see page 5666)	Indicates whether the bucket list contains a specified item.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 5666)	Returns the data associated with a specified item.
	ForEach (see page 5667)	This is the overview for the ForEach method overload.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Remove (see page 5672)	This is Remove, a member of class TIntegerBucketList.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Data (see page 5673)	Represents the data associated with a specified item in the bucket list.

31.1.5.2 TIntegerBucketList Methods

The methods of the TIntegerBucketList class are listed here.

Protected Methods

	Name	Description
	GetData (see page 5672)	This is GetData, a member of class TIntegerBucketList.
	SetData (see page 5672)	This is SetData, a member of class TIntegerBucketList.

Public Methods

	Name	Description
	Add (see page 5672)	This is Add, a member of class TIntegerBucketList.

	Remove (see page 5672)	This is Remove, a member of class TIntegerBucketList.

31.1.5.2.1 TIntegerBucketList.Add Method

Pascal

```
function Add(AItem: Integer; AData: Integer): Integer;
```

C++

```
__fastcall int Add(int AItem, int AData);
```

Description

This is Add, a member of class TIntegerBucketList.

31.1.5.2.2 TIntegerBucketList.GetData Method

Pascal

```
function GetData(AItem: Integer): Integer;
```

C++

```
__fastcall int GetData(int AItem);
```

Description

This is GetData, a member of class TIntegerBucketList.

31.1.5.2.3 TIntegerBucketList.Remove Method

Pascal

```
function Remove(AItem: Integer): Integer;
```

C++

```
__fastcall int Remove(int AItem);
```

Description

This is Remove, a member of class TIntegerBucketList.

31.1.5.2.4 TIntegerBucketList.SetData Method

Pascal

```
procedure SetData(AItem: Integer; const AData: Integer);
```

C++

```
__fastcall SetData(int AItem, const int AData);
```

Description

This is SetData, a member of class TIntegerBucketList.

31.1.5.3 TIntegerBucketList Properties

The properties of the TIntegerBucketList class are listed here.

Public Properties

	Name	Description
	Data (see page 5673)	Represents the data associated with a specified item in the bucket list.

31.1.5.3.1 TIntegerBucketList.Data Property

Represents the data associated with a specified item in the bucket list.

Pascal

```
property Data [AItem: Integer]: Integer;
```

C++

```
__property int Data[int AItem];
```

Description

Use Data to get or set the data associated with an item in the bucket list.

AItem points to an item currently in the bucket list. If AItem does not specify an item in one of the buckets of the bucket list, trying to read or set Data causes TCustomBucketList to raise an EListError exception.

Note: In Delphi, Data is the default property of TCustomBucketList. This means that the property name can be omitted when using this property. For example, the following two lines of code are both acceptable and do the same thing:

```
BucketList1.Data[Name as Pointer] := Pointer(Form1.FindChildControl(Name));
BucketList1[Name as Pointer] := Pointer(Form1.FindChildControl(Name));
```

Note: In C++, Data can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

31.1.6 TObjectBucketList Class

TObjectBucketList is a simple hash table that stores objects that are identified by other objects.

Class Hierarchy

Pascal

```
TObjectBucketList = class(TBucketList);
```

C++

```
class TObjectBucketList : public TBucketList;
```

File

Contnrs

Description

Use TObjectBucketList as a simple hash table to store objects that are indexed by other objects. TObjectBucketList includes methods to add, remove, and locate items in the list, as well as a method that executes a callback for every item in the list.

See Also

Working with Lists

31.1.6.1 TObjectBucketList Members

The following tables list the members exposed by TObjectBucketList.

Protected Methods

	Name	Description
V	AddItem (see page 5664)	Inserts an item and its associated data into a specified bucket.
V	BucketFor (see page 5645)	Returns the index of the bucket in which a specified item belongs.
A	BucketFor (see page 5665)	Returns the index of the bucket in which a specified item belongs.
V	DeleteItem (see page 5666)	Deletes an item from a bucket in the bucket list.
V	FindItem (see page 5667)	Returns the location of an item in the bucket list.
	GetData (see page 5676)	This is GetData, a member of class TObjectBucketList.
	SetData (see page 5676)	This is SetData, a member of class TObjectBucketList.

Protected Properties

	Name	Description
	BucketCount (see page 5668)	Indicates the number of buckets in the bucket list.
R	Buckets (see page 5669)	Lists the buckets in the bucket list

Public Methods

	Name	Description
	Add (see page 5675)	Inserts an item and its associated data into the object bucket list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5665)	Replaces all the items in this list with the items from another bucket list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5665)	Empties the bucket list of all its items.
	Create (see page 5645)	Creates and initializes a TBucketList (see page 5643) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5663)	Destroys an instance of TCustomBucketList (see page 5661).
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Exists (see page 5666)	Indicates whether the bucket list contains a specified item.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 5666)	Returns the data associated with a specified item.
	ForEach (see page 5667)	This is the overview for the ForEach method overload.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Remove (see page 5676)	Removes a specified item from the list and returns its data.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Data (see page 5677)	Represents the data associated with a specified item in the object bucket list.

31.1.6.2 TObjectBucketList Methods

The methods of the TObjectBucketList class are listed here.

Protected Methods

	Name	Description
	GetData (see page 5676)	This is GetData, a member of class TObjectBucketList.
	SetData (see page 5676)	This is SetData, a member of class TObjectBucketList.

Public Methods

	Name	Description
	Add (see page 5675)	Inserts an item and its associated data into the object bucket list.
	Remove (see page 5676)	Removes a specified item from the list and returns its data.

31.1.6.2.1 TObjectBucketList.Add Method

Inserts an item and its associated data into the object bucket list.

Pascal

```
function Add(AItem: TObject; AData: TObject): TObject;
```

C++

```
__fastcall TObject * Add(TObject * AItem, TObject * AData);
```

Description

Call Add to add an item and its associated data into the object bucket list. Add locates the bucket into which the specified item belongs. If the item is already in the bucket, Add raises an EListError exception. Otherwise, it adds the item to the correct bucket and returns AData.

See Also

EListError (see page 2701)

Data (see page 5677)

31.1.6.2.2 TObjectBucketList.GetData Method

Pascal

```
function GetData(AItem: TObject): TObject;
```

C++

```
__fastcall TObject * GetData(TObject * AItem);
```

Description

This is GetData, a member of class TObjectBucketList.

31.1.6.2.3 TObjectBucketList.Remove Method

Removes a specified item from the list and returns its data.

Pascal

```
function Remove(AItem: TObject): TObject;
```

C++

```
__fastcall TObject * Remove(TObject * AItem);
```

Description

Call Remove to delete a specific item from the list.

AItem is the item to remove.

Remove returns the data associated with AItem. If AItem is not in the object bucket list, Remove returns nil (Delphi) or NULL (C++).

See Also

Clear (see page 5665)

Add (see page 5675)

31.1.6.2.4 TObjectBucketList.SetData Method

Pascal

```
procedure SetData(AItem: TObject; const AData: TObject);
```

C++

```
__fastcall SetData(TObject * AItem, const TObject * AData);
```

Description

This is SetData, a member of class TObjectBucketList.

31.1.6.3 TObjectBucketList Properties

The properties of the TObjectBucketList class are listed here.

Public Properties

	Name	Description
	Data (see page 5677)	Represents the data associated with a specified item in the object bucket list.

31.1.6.3.1 TObjectBucketList.Data Property

Represents the data associated with a specified item in the object bucket list.

Pascal

```
property Data [AItem: TObject]: TObject;
```

C++

```
__property TObject * Data[TObject * AItem];
```

Description

Use Data to get or set the data object associated with an item in the bucket list.

AItem is the identifier of an item currently in the object bucket list. If AItem does not specify an item in one of the buckets of the bucket list, trying to read or set Data causes TObjectBucketList (see page 5673) to raise an EListError exception.

Note: In Delphi, Data is the default property of TObjectBucketList (see page 5673). This means that the property name can be omitted when using this property. Thus, for example, instead of

Note: ObjectBucketList1.Data[MyObject];

Note: you can write

Note: ObjectBucketList1[MyObject];

Find (see page 5666)

EListError (see page 2701)

operator_sb

31.1.7 TObjectList Class

TObjectList maintains a list of (owned) objects.

Class Hierarchy

Pascal

```
TObjectList = class(TList);
```

C++

```
class TObjectList : public TList;
```

File

Contnrs

Description

Use TObjectList to store and maintain a list of objects. TObjectList provides properties and methods to add, delete, rearrange, locate, access, and sort objects. If the OwnsObjects (see page 5686) property is set to true (the default), TObjectList controls the memory of its objects, freeing an object when its index is reassigned; when it is removed from the list with the Delete, Remove (see page 5684), or Clear method; or when the TObjectList instance is itself destroyed.

See Also

TList (see page 2868)

TComponentList (see page 5653)

TClassList (see page 5646)

TStack (see page 5701)

TObjectStack (see page 5690)

TObjectQueue (see page 5687)

TInterfaceList (see page 2855)

Working with Lists

31.1.7.1 TObjectList Members

The following tables list the members exposed by TObjectList.

Protected Methods

	Name	Description
	Get (see page 2878)	This is Get, a member of class TList.
	GetItem (see page 5682)	This is GetItem, a member of class TObjectList.
V	Grow (see page 2879)	This is Grow, a member of class TList.
V	Notify (see page 5684)	Responds when items are added, removed, or extracted from the list.
	Put (see page 2887)	This is Put, a member of class TList.
	SetCapacity (see page 2891)	This is SetCapacity, a member of class TList.
	SetCount (see page 2892)	This is SetCount, a member of class TList.
	SetItem (see page 5685)	This is SetItem, a member of class TObjectList.

Public Methods

	Name	Description
	Add (see page 5680)	Inserts an object at the end of the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2874)	Copies elements of one list to another.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 2874)	Deletes all items from the list.
	Create (see page 5679)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2874)	Removes the item at the position given by the Index parameter.

	Destroy (see page 2870)	Destroys an instance of TList (see page 2868).
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Error (see page 2875)	This is the overview for the Error method overload.
	Exchange (see page 2876)	Swaps the position of two items in the Items (see page 2898) array.
	Expand (see page 2877)	Increases the Capacity (see page 2895) of the list.
	Extract (see page 5681)	Removes a specified object from the list without freeing it.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindInstanceOf (see page 5682)	Finds the first instance of a specified class in the list.
	First (see page 5682)	Returns Items (see page 5685)[0].
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2878)	Returns a TList (see page 2868) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	IndexOf (see page 5683)	Returns the index of the first object in the list with a specified value.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 5683)	Adds an object to the list at a specified position.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Last (see page 5684)	Returns the object at the end of the Items (see page 5685) array.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 2884)	Changes the position of an item in the Items (see page 2898) array.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pack (see page 2885)	Deletes all nil (Delphi) or NULL (C++) items from the Items (see page 2898) array.
	Remove (see page 5684)	Removes a specified object from the list and (if OwnsObjects (see page 5686) is true) frees the object.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Sort (see page 2892)	Performs a QuickSort on the list based on the comparison function Compare.

Public Properties

	Name	Description
	Capacity (see page 2895)	Specifies the allocated size of the array of pointers maintained by the TList (see page 2868) object.
	Count (see page 2896)	Indicates the number of entries in the list that are in use.
	Items (see page 5685)	Lists the object references.
R	List (see page 2900)	Specifies the array of pointers that make up the Items (see page 2898) array.
	OwnsObjects (see page 5686)	Allows TObjectList (see page 5677) to free objects when they are deleted from the list or the list is destroyed.

31.1.7.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TObjectList.Create () (see page 5680)	Creates and initializes a TObjectList (see page 5677).

	TObjectList.Create (Boolean) (see page 5680)	Creates and initializes a TObjectList (see page 5677).

31.1.7.2.1 TObjectList.Create Constructor ()

Creates and initializes a TObjectList (see page 5677).

Pascal

```
constructor Create; overload;
constructor Create(AOwnsObjects: Boolean); overload;
```

C++

```
__fastcall TObjectList();
__fastcall TObjectList(Boolean AOwnsObjects);
```

Description

Create creates a TObjectList (see page 5677) instance. If no parameter is specified, or if the constructor is called with AOwnsObjects set to true, the new TObjectList (see page 5677) is initialized with OwnsObjects (see page 5686) set to true.

See Also

OwnsObjects (see page 5686)

31.1.7.3 TObjectList Methods

The methods of the TObjectList class are listed here.

Protected Methods

	Name	Description
	GetItem (see page 5682)	This is GetItem, a member of class TObjectList.
V	Notify (see page 5684)	Responds when items are added, removed, or extracted from the list.
	SetItem (see page 5685)	This is SetItem, a member of class TObjectList.

Public Methods

	Name	Description
	Add (see page 5680)	Inserts an object at the end of the list.
	Extract (see page 5681)	Removes a specified object from the list without freeing it.
	FindInstanceOf (see page 5682)	Finds the first instance of a specified class in the list.
	First (see page 5682)	Returns Items (see page 5685)[0].
	IndexOf (see page 5683)	Returns the index of the first object in the list with a specified value.
	Insert (see page 5683)	Adds an object to the list at a specified position.
	Last (see page 5684)	Returns the object at the end of the Items (see page 5685) array.
	Remove (see page 5684)	Removes a specified object from the list and (if OwnsObjects (see page 5686) is true) frees the object.

31.1.7.3.1 TObjectList.Add Method

Inserts an object at the end of the list.

Pascal

```
function Add(AObject: TObject): Integer;
```

C++

```
__fastcall int Add(TObject * AObject);
```

Description

Call Add to insert an object at the end of the list. Add places the object after the last item, even if the array contains nil (Delphi) or NULL (C++) references, and returns the index of the inserted object. (The first object in the list has an index of 0.)

Add increments Count and, if necessary, allocates memory by increasing the value of Capacity.

See Also

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 5683)

Items (see page 5685)

Remove (see page 5684)

Extract (see page 5681)

Clear (see page 2874)

Pack (see page 2885)

31.1.7.3.2 TObjectList.Extract Method

Removes a specified object from the list without freeing it.

Pascal

```
function Extract(Item: TObject): TObject;
```

C++

```
__fastcall TObject * Extract(TObject * Item);
```

Description

Call Extract to remove an object from the list without freeing the object itself. After an object is removed, all the objects that follow it are moved up in index position and Count is decremented.

See Also

Add (see page 5680)

Capacity (see page 2895)

Clear (see page 2874)

Count (see page 2896)

Insert (see page 5683)

Items (see page 5685)

Remove (see page 5684)

Delete (see page 2874)

OwnsObjects (see page 5686)

31.1.7.3.3 TObjectList.FindInstanceOf Method

Finds the first instance of a specified class in the list.

Pascal

```
function FindInstanceOf(AClass: TClass; AExact: Boolean = True; AStartAt: Integer = 0):
Integer;
```

C++

```
__fastcall int FindInstanceOf(TClass AClass, Boolean AExact = True, int AStartAt = 0);
```

Description

FindInstanceOf returns the index of the first instance of AClass appearing after AStartAt in the Items (see page 5685) array. If AExact is true, FindInstanceOf returns instances only of AClass itself, ignoring instances of descendant classes. If no instance of the specified class is found, FindInstanceOf returns –1.

See Also

IndexOf (see page 5683)

Items (see page 5685)

Count (see page 2896)

Sort (see page 2892)

31.1.7.3.4 TObjectList.First Method

Returns Items (see page 5685)[0].

Pascal

```
function First: TObject;
```

C++

```
__fastcall TObject * First();
```

Description

Call First to retrieve the first object reference in the Items (see page 5685) array.

See Also

Items (see page 5685)

Last (see page 5684)

31.1.7.3.5 TObjectList.GetItem Method

Pascal

```
function GetItem(Index: Integer): TObject;
```

C++

```
__fastcall TObject * GetItem(int Index);
```

Description

This is GetItem, a member of class TObjectList.

31.1.7.3.6 TObjectList.IndexOf Method

Returns the index of the first object in the list with a specified value.

Pascal

```
function IndexOf(AObject: TObject): Integer;
```

C++

```
__fastcall int IndexOf(TObject * AObject);
```

Description

Call IndexOf to get the index for a specified object in the list, where the first object has index 0, the second object has index 1, and so on. If an object is not in the list, IndexOf returns -1. If an object appears more than once, IndexOf returns the index of the first appearance.

See Also

Delete (see page 2874)

Items (see page 5685)

FindInstanceOf (see page 5682)

31.1.7.3.7 TObjectList.Insert Method

Adds an object to the list at a specified position.

Pascal

```
procedure Insert(Index: Integer; AObject: TObject);
```

C++

```
__fastcall Insert(int Index, TObject * AObject);
```

Description

Call Insert to add an object at a specified position in the list, shifting the item that previously occupied that position (and all subsequent items) up. Insert increments Count and, if necessary, allocates memory by increasing the value of Capacity.

The Index parameter is zero-based, so the first position in the list has an index of 0.

To replace a nil (Delphi) or NULL (C++) reference with a new object without growing the array, set the Items (see page 5685) property directly.

See Also

Add (see page 5680)

Capacity (see page 2895)

Count (see page 2896)

Delete (see page 2874)

Items (see page 5685)

Remove (see page 5684)

Pack (see page 2885)

Clear (see page 2874)

Extract (see page 5681)

31.1.7.3.8 TObjectList.Last Method

Returns the object at the end of the Items (see page 5685) array.

Pascal

```
function Last: TObject;
```

C++

```
__fastcall TObject * Last();
```

Description

Call Last to retrieve the last object in the Items (see page 5685) array.

See Also

Items (see page 5685)

First (see page 5682)

31.1.7.3.9 TObjectList.Notify Method

Responds when items are added, removed, or extracted from the list.

Pascal

```
procedure Notify(Ptr: Pointer; Action: TListNotification); override;
```

C++

```
virtual __fastcall Notify(void * Ptr, TListNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Ptr points to item affected by the change.

Action indicates the change.

As implemented in TList, Notify does nothing. Descendant classes can override Notify in order to implement an appropriate response to the change notification.

31.1.7.3.10 TObjectList.Remove Method

Removes a specified object from the list and (if OwnsObjects (see page 5686) is true) frees the object.

Pascal

```
function Remove(AObject: TObject): Integer;
```

C++

```
__fastcall int Remove(TObject * AObject);
```

Description

Call Remove to delete a specific object from the list when its index is unknown. The value returned is the index of the object in the Items (see page 5685) array before it was removed. If the specified object is not found on the list, Remove returns –1. If OwnsObjects (see page 5686) is true, Remove frees the object in addition to removing it from the list.

After an object is deleted, all the objects that follow it are moved up in index position and Count is decremented. If an object appears more than once on the list, Remove deletes only the first appearance. Hence, if OwnsObjects (see page 5686) is true,

removing an object that appears more than once results in empty object references later in the list.

To use an index position (rather than an object reference) to specify the object to be removed, call Delete.

To remove an object from the list without freeing it, call Extract (see page 5681).

See Also

Add (see page 5680)

Count (see page 2896)

Delete (see page 2874)

Insert (see page 5683)

Items (see page 5685)

OwnsObjects (see page 5686)

Extract (see page 5681)

Pack (see page 2885)

31.1.7.3.11 TObjectList.SetItem Method

Pascal

```
procedure SetItem(Index: Integer; AObject: TObject);
```

C++

```
__fastcall SetItem(int Index, TObject * AObject);
```

Description

This is SetItem, a member of class TObjectList.

31.1.7.4 TObjectList Properties

The properties of the TObjectList class are listed here.

Public Properties

	Name	Description
	Items (see page 5685)	Lists the object references.
	OwnsObjects (see page 5686)	Allows TObjectList (see page 5677) to free objects when they are deleted from the list or the list is destroyed.

31.1.7.4.1 TObjectList.Items Property

Lists the object references.

Pascal

```
property Items [Index: Integer]: TObject;
```

C++

```
__property TObject * Items[int Index];
```

Description

Use Items to access objects in the list. Items is a zero-based array: The first object is indexed as 0, the second object is indexed as 1, and so forth. You can read or change the value at a specific index, or use Items with the Count property to iterate through

the list.

If OwnsObjects (see page 5686) is true, reassigning an Items index frees the object that previously occupied that position in the list.

Items can contain nil (Delphi) or NULL (C++) references. To remove nil (Delphi) or NULL (C++) references and reduce the size of the array, call the Pack method.

Note: In Delphi, Items is the default property of TObjectList (see page 5677). This means you can omit the property name. Thus, the following two lines of code are both acceptable and do the same thing:

Note: ObjectList1.Items[i] := Form1.FindChildControl(ListBox1.Items[i]);

Note: ObjectList1[i] := Form1.FindChildControl(ListBox1.Items[i]);

See Also

OwnsObjects (see page 5686)

Add (see page 5680)

Insert (see page 5683)

Delete (see page 2874)

Remove (see page 5684)

List (see page 2900)

Extract (see page 5681)

Count (see page 2896)

Clear (see page 2874)

Pack (see page 2885)

operator_sb

31.1.7.4.2 TObjectList.OwnsObjects Property

Allows TObjectList (see page 5677) to free objects when they are deleted from the list or the list is destroyed.

Pascal

```
property OwnsObjects: Boolean;
```

C++

```
__property Boolean OwnsObjects;
```

Description

OwnsObjects allows TObjectList (see page 5677) to control the memory of its objects. If OwnsObjects is true (the default),

calling Delete or Remove (see page 5684) frees the deleted object in addition to removing it from the list.

calling Clear frees all the objects in the list in addition to emptying the list.

calling the destructor frees all the objects in the list in addition to destroying the TObjectList (see page 5677) itself.

assigning a new value to an index in Items (see page 5685) frees the object that previously occupied that position in the list.

Even if OwnsObjects is true, the Extract (see page 5681) method can be used to remove objects from the list without freeing them.

See Also

Items (see page 5685)

Delete (see page 2874)

Clear (see page 2874)

Destroy (see page 2870)

Remove (see page 5684)

Extract (see page 5681)

31.1.8 TObjectQueue Class

TObjectQueue maintains a first-in first-out list of objects.

Class Hierarchy

Pascal

```
TObjectQueue = class(TQueue);
```

C++

```
class TObjectQueue : public TQueue;
```

File

Contnrs

Description

Use a TObjectQueue to store and maintain a first-in first-out list of objects.

See Also

TStack (see page 5701)

TList (see page 2868)

TQueue (see page 5699)

TObjectStack (see page 5690)

TObjectList (see page 5677)

Working with Lists

31.1.8.1 TObjectQueue Members

The following tables list the members exposed by TObjectQueue.

Protected Methods

	Name	Description
	PeekItem (see page 5697)	Returns a pointer to the next item in the list.

V	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
A	PushItem (see page 5698)	Adds an item to the list.
V	PushItem (see page 5701)	Adds an item to the list.

Protected Properties

	Name	Description
R	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AtLeast (see page 5696)	Checks the size of the list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Count (see page 5696)	Returns the size of the list.
	Create (see page 5695)	Creates a TOrderedList (see page 5693) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5695)	Destroys the TOrderedList (see page 5693) instance.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Peek (see page 5689)	Returns a reference to the front of the queue.
	Pop (see page 5689)	Removes and returns the object at the front of the queue.
	Push (see page 5689)	Adds an object to the end of the queue.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

31.1.8.2 TObjectQueue Methods

The methods of the TObjectQueue class are listed here.

Public Methods

	Name	Description
	Peek (see page 5689)	Returns a reference to the front of the queue.
	Pop (see page 5689)	Removes and returns the object at the front of the queue.
	Push (see page 5689)	Adds an object to the end of the queue.

31.1.8.2.1 TObjectQueue.Peek Method

Returns a reference to the front of the queue.

Pascal

```
function Peek: TObject;
```

C++

```
__fastcall TObject * Peek();
```

Description

Call Peek to access the queue without removing an object. Peek returns a reference to the next object in the queue (that is, the earliest object added).

To remove an object from the queue, call Pop (see page 5689).

See Also

Pop (see page 5689)

Push (see page 5689)

31.1.8.2.2 TObjectQueue.Pop Method

Removes and returns the object at the front of the queue.

Pascal

```
function Pop: TObject;
```

C++

```
__fastcall TObject * Pop();
```

Description

Call Pop to retrieve an object from the queue. Pop removes the next object from the queue (that is, the earliest object added), then returns a reference to the deleted object.

To access the queue without removing an object, call Peek (see page 5689).

See Also

Push (see page 5689)

Peek (see page 5689)

31.1.8.2.3 TObjectQueue.Push Method

Adds an object to the end of the queue.

Pascal

```
function Push(AObject: TObject): TObject;
```

C++

```
__fastcall TObject * Push(TObject * AObject);
```

Description

Call Push to add an object to the queue.

AObject is the object to add to the queue.

Push returns a reference to the object that was just added (AObject).

See Also

Pop (see page 5689)

Peek (see page 5689)

31.1.9 TObjectStack Class

TObjectStack maintains a last-in first-out list of objects.

Class Hierarchy

Pascal

```
TObjectStack = class(TStack);
```

C++

```
class TObjectStack : public TStack;
```

File

Contnrs

Description

Use TObjectStack to store and maintain a last-in first-out list of objects.

See Also

TStack (see page 5701)

TList (see page 2868)

TQueue (see page 5699)

TObjectQueue (see page 5687)

TObjectList (see page 5677)

Working with Lists

31.1.9.1 TObjectStack Members

The following tables list the members exposed by TObjectStack.

Protected Methods

	Name	Description
V	PeekItem (see page 5697)	Returns a pointer to the next item in the list.
V	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
A	PushItem (see page 5698)	Adds an item to the list.
V	PushItem (see page 5703)	Adds an item to the list.

Protected Properties

	Name	Description
R	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AtLleast (see page 5696)	Checks the size of the list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Count (see page 5696)	Returns the size of the list.
	Create (see page 5695)	Creates a TOrderedList (see page 5693) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5695)	Destroys the TOrderedList (see page 5693) instance.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Peek (see page 5692)	Returns a reference to the top of the stack.
	Pop (see page 5692)	Removes and returns the object at the top of the stack.
	Push (see page 5693)	Adds an object to the top of the stack.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

31.1.9.2 TObjectStack Methods

The methods of the TObjectStack class are listed here.

Public Methods

	Name	Description
	Peek (see page 5692)	Returns a reference to the top of the stack.
	Pop (see page 5692)	Removes and returns the object at the top of the stack.
	Push (see page 5693)	Adds an object to the top of the stack.

31.1.9.2.1 TObjectStack.Peek Method

Returns a reference to the top of the stack.

Pascal

```
function Peek: TObject;
```

C++

```
__fastcall TObject * Peek();
```

Description

Call Peek to access the stack without removing an object. Peek returns a reference to the next object in the stack (that is, the last object added).

To remove an object from the stack, call Pop (see page 5692).

See Also

Push (see page 5693)

Pop (see page 5692)

31.1.9.2.2 TObjectStack.Pop Method

Removes and returns the object at the top of the stack.

Pascal

```
function Pop: TObject;
```

C++

```
__fastcall TObject * Pop();
```

Description

Call Pop to retrieve an object from the stack. Pop removes the next object from the stack (that is, the last object added), then returns a reference to the deleted object.

To access the stack without removing an object, call Peek (see page 5692).

See Also

Push (see page 5693)

Peek (see page 5692)

31.1.9.2.3 TObjectStack.Push Method

Adds an object to the top of the stack.

Pascal

```
function Push(AObject: TObject): TObject;
```

C++

```
__fastcall TObject * Push(TObject * AObject);
```

Description

Call Push to add an object to the stack.

AObject is the object to add to the beginning of the stack.

Push returns a reference to the object that was just added (AObject).

See Also

Pop (see page 5692)

Peek (see page 5692)

31.1.10 TOrderedList Class

TOrderedList maintains an array of pointers that must be accessed in serial order.

Class Hierarchy

Pascal

```
TOrderedList = class(TObject);
```

C++

```
class TOrderedList : public TObject;
```

File

Contnrs

Description

TOrderedList is an abstract class that represents a list. Descendant classes like TStack (see page 5701) and TQueue (see page 5699) override the protected PushItem (see page 5698) method to determine the order in which to access items.

See Also

TList (see page 2868)

TQueue (see page 5699)

TStack (see page 5701)

TObjectStack (see page 5690)

TObjectQueue (see page 5687)

31.1.10.1 TOrderedList Members

The following tables list the members exposed by TOrderedList.

Protected Methods

	Name	Description
V	PeekItem (see page 5697)	Returns a pointer to the next item in the list.
V	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
A	PushItem (see page 5698)	Adds an item to the list.

Protected Properties

	Name	Description
R	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AtLeast (see page 5696)	Checks the size of the list.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Count (see page 5696)	Returns the size of the list.
	Create (see page 5695)	Creates a TOrderedList (see page 5693) instance.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5695)	Destroys the TOrderedList (see page 5693) instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Peek (see page 5696)	Returns a pointer to the next item in the list.
	Pop (see page 5697)	Removes and returns the next item in the list.
	Push (see page 5698)	Adds an item to the list.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

31.1.10.2 TOrderedList.Create Constructor

Creates a TOrderedList (see page 5693) instance.

Pascal

```
constructor Create;
```

C++

```
__fastcall TOrderedList();
```

Description

Create generates a new list.

31.1.10.3 TOrderedList.Destroy Destructor

Destroys the TOrderedList (see page 5693) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOrderedList();
```

Description

Do not call Destroy directly. Instead, call Free. Free verifies that the TOrderedList (see page 5693) reference is not nil, and only then calls Destroy.

Destroy frees the memory used to store the TOrderedList (see page 5693) instance. It does not free the memory pointed to by the items in the list.

See Also

Free (see page 22300)

31.1.10.4 TOrderedList Methods

The methods of the TOrderedList class are listed here.

Protected Methods

	Name	Description
V	PeekItem (see page 5697)	Returns a pointer to the next item in the list.
V	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
A	PushItem (see page 5698)	Adds an item to the list.

Public Methods

	Name	Description
	AtLeast (see page 5696)	Checks the size of the list.
	Count (see page 5696)	Returns the size of the list.
	Peek (see page 5696)	Returns a pointer to the next item in the list.
	Pop (see page 5697)	Removes and returns the next item in the list.
	Push (see page 5698)	Adds an item to the list.

31.1.10.4.1 TOrderedList.AtLeast Method

Checks the size of the list.

Pascal

```
function AtLeast(ACount: Integer): Boolean;
```

C++

```
__fastcall Boolean AtLeast(int ACount);
```

Description

Call AtLeast to verify the size of the list. AtLeast returns true if the number of items in the list is greater than or equal to ACount.

See Also

Count (see page 5696)

31.1.10.4.2 TOrderedList.Count Method

Returns the size of the list.

Pascal

```
function Count: Integer;
```

C++

```
__fastcall int Count();
```

Description

Count returns the number of items in the list.

See Also

AtLeast (see page 5696)

31.1.10.4.3 TOrderedList.Peek Method

Returns a pointer to the next item in the list.

Pascal

```
function Peek: Pointer;
```

C++

```
__fastcall void * Peek();
```

Description

Call Peek to access the list without removing an item. Peek returns a pointer to the next item in the list.

Each TOrderedList (see page 5693) descendant implements Peek to return a specific item from the list. For example, TQueue (see page 5699) returns the item that was added first, while TStack (see page 5701) returns the item that was added last.

To remove an item from the list, call Pop (see page 5697).

See Also

Push (see page 5698)

Pop (see page 5697)

31.1.10.4.4 TOrderedList.PeekItem Method

Returns a pointer to the next item in the list.

Pascal

```
function PeekItem: Pointer; virtual;
```

C++

```
virtual __fastcall void * PeekItem();
```

Description

The protected PeekItem method provides the underlying implementation for the Peek (see page 5696) method. It returns the last item in the list specified by the List (see page 5699) property.

Override this method to return a different item in descendant classes that do not maintain the list in reverse output order.

See Also

Peek (see page 5696)

List (see page 5699)

31.1.10.4.5 TOrderedList.Pop Method

Removes and returns the next item in the list.

Pascal

```
function Pop: Pointer;
```

C++

```
__fastcall void * Pop();
```

Description

Call Pop to retrieve an item from the list. Pop removes the next item from the list, then returns a pointer to the deleted item.

Each TOrderedList (see page 5693) descendant implements Pop to remove and return a specific item from the list. For example, TQueue (see page 5699) returns the item that was added first, while TStack (see page 5701) returns the item that was added last.

To access the list without removing an item, call Peek (see page 5696).

See Also

Push (see page 5698)

Peek (see page 5696)

31.1.10.4.6 TOrderedList.PopItem Method

Removes and returns a pointer to the next item in the list.

Pascal

```
function PopItem: Pointer; virtual;
```

C++

```
virtual __fastcall void * PopItem();
```

Description

The protected PopItem method provides the underlying implementation for the Pop (see page 5697) method. It removes the last item from the list specified by the List (see page 5699) property and returns a pointer to the deleted item.

Override this method to remove and return a different item in descendant classes that do not maintain the list in reverse output order.

See Also

Pop (see page 5697)

List (see page 5699)

31.1.10.4.7 TOrderedList.Push Method

Adds an item to the list.

Pascal

```
function Push(AItem: Pointer): Pointer;
```

C++

```
__fastcall void * Push(void * AItem);
```

Description

Call Push to add an item to the list.

AItem is the item to add.

Push returns a reference to the item that was just added (AItem).

See Also

Pop (see page 5697)

Peek (see page 5696)

31.1.10.4.8 TOrderedList.PushItem Method

Adds an item to the list.

Pascal

```
procedure PushItem(AItem: Pointer); virtual; abstract;
```

C++

```
virtual __fastcall PushItem(void * AItem) = 0;
```

Description

The protected PushItem method provides the underlying implementation for the Push (see page 5698) method. In TOrderedList (see page 5693), PushItem has no implementation (it is abstract or, in C++ terminology, pure virtual).

Descendant classes override this method to add items to the list specified by the List (see page 5699) property. Each descendant class adds items so as to maintain the list in reverse output order. In TStack (see page 5701), items are added to the end of the list (so that the list is last-in first-out). In TQueue (see page 5699), items are added to the beginning (so that the list is first-in first-out).

See Also

Push (see page 5698)

Pop (see page 5697)

TStack (see page 5701)

TQueue (see page 5699)

List (see page 5699)

31.1.10.5 TOrderedList Properties

The properties of the TOrderedList class are listed here.

Protected Properties

	Name	Description
R	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

31.1.10.5.1 TOrderedList.List Property

Identifies the internal list used to store and manage the items in the ordered list.

Pascal

```
property List: TList;
```

C++

```
__property TList List;
```

Description

Applications can't use the protected List property. It is an internal TList object owned by TOrderedList (see page 5693), which stores and manages the items in the ordered list.

31.1.11 TQueue Class

TQueue maintains a first-in first-out array of pointers.

Class Hierarchy

Pascal

```
TQueue = class(TOrderedList);
```

C++

```
class TQueue : public TOrderedList;
```

File

Contnrs

Description

Use a TQueue object to store and maintain a first-in first-out list.

See Also

TList (see page 2868)

TStack (see page 5701)

TObjectQueue (see page 5687)

Working with Lists

31.1.11.1 TQueue Members

The following tables list the members exposed by TQueue.

Protected Methods

	Name	Description
	PeekItem (see page 5697)	Returns a pointer to the next item in the list.
	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
	PushItem (see page 5701)	Adds an item to the list.

Protected Properties

	Name	Description
	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AtLeast (see page 5696)	Checks the size of the list.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Count (see page 5696)	Returns the size of the list.
	Create (see page 5695)	Creates a TOrderedList (see page 5693) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5695)	Destroys the TOrderedList (see page 5693) instance.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Peek (see page 5696)	Returns a pointer to the next item in the list.
	Pop (see page 5697)	Removes and returns the next item in the list.
	Push (see page 5698)	Adds an item to the list.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

31.1.11.2 TQueue Methods

The methods of the TQueue class are listed here.

Protected Methods

	Name	Description
	PushItem (see page 5701)	Adds an item to the list.

31.1.11.2.1 TQueue.PushItem Method

Adds an item to the list.

Pascal

```
procedure PushItem(AItem: Pointer); override;
```

C++

```
virtual __fastcall PushItem(void * AItem);
```

Description

The protected PushItem method provides the underlying implementation for the Push method. In TOrderedList, PushItem has no implementation (it is abstract or, in C++ terminology, pure virtual).

Descendant classes override this method to add items to the list specified by the List property. Each descendant class adds items so as to maintain the list in reverse output order. In TStack, items are added to the end of the list (so that the list is last-in first-out). In TQueue, items are added to the beginning (so that the list is first-in first-out).

See Also

Push (see page 5698)

Pop (see page 5697)

TStack (see page 5701)

TQueue (see page 5699)

List (see page 5699)

31.1.12 TStack Class

TStack maintains a last-in first-out array of pointers.

Class Hierarchy

Pascal

```
TStack = class(TOrderedList);
```

C++

```
class TStack : public TOrderedList;
```

File

Contnrs

Description

Use a TStack object to store and maintain a last-in first-out list.

See Also

TList (see page 2868)

TQueue (see page 5699)

TObjectStack (see page 5690)

Working with Lists

31.1.12.1 TStack Members

The following tables list the members exposed by TStack.

Protected Methods

	Name	Description
	PeekItem (see page 5697)	Returns a pointer to the next item in the list.
	PopItem (see page 5697)	Removes and returns a pointer to the next item in the list.
	PushItem (see page 5703)	Adds an item to the list.

Protected Properties

	Name	Description
	List (see page 5699)	Identifies the internal list used to store and manage the items in the ordered list.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	AtLeast (see page 5696)	Checks the size of the list.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Count (see page 5696)	Returns the size of the list.
	Create (see page 5695)	Creates a TOrderedList (see page 5693) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5695)	Destroys the TOrderedList (see page 5693) instance.
	Destroy (see page 22287)	Disposes of an object instance.

	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Peek (see page 5696)	Returns a pointer to the next item in the list.
	Pop (see page 5697)	Removes and returns the next item in the list.
	Push (see page 5698)	Adds an item to the list.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

31.1.12.2 TStack Methods

The methods of the TStack class are listed here.

Protected Methods

	Name	Description
	PushItem (see page 5703)	Adds an item to the list.

31.1.12.2.1 TStack.PushItem Method

Adds an item to the list.

Pascal

```
procedure PushItem(AItem: Pointer); override;
```

C++

```
virtual __fastcall PushItem(void * AItem);
```

Description

The protected PushItem method provides the underlying implementation for the Push method. In TOrderedList, PushItem has no implementation (it is abstract or, in C++ terminology, pure virtual).

Descendant classes override this method to add items to the list specified by the List property. Each descendant class adds items so as to maintain the list in reverse output order. In TStack, items are added to the end of the list (so that the list is last-in first-out). In TQueue, items are added to the beginning (so that the list is first-in first-out).

See Also

Push (see page 5698)

Pop (see page 5697)

TStack (see page 5701)

TQueue (see page 5699)

List (see page 5699)

31.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	RaiseListError (see page 5705)	This is function Contnrs.RaiseListError.

31.2.1 Contnrs.RaiseListError Function

Pascal

```
procedure RaiseListError(const ATemplate: string; const AData: array of const);
```

C++

```
RaiseListError(const AnsiString ATemplate, const array of const AData);
```

File

Contnrs

Description

This is function Contnrs.RaiseListError.

31.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBucketListSizes (see page 5707)	TBucketListSizes indicates the number of distinct buckets in a TBucketList (see page 5643) object.

Records

	Name	Description
	TBucket (see page 5706)	TBucketArray (see page 5709) and TBucket represent a list of buckets that each store an array of items.
	TBucketItem (see page 5707)	TBucketItemArray (see page 5710) and TBucketItem represent the items in a TBucket (see page 5706) record (Delphi) or structure (C++).

31.3.1 Contnrs.TBucket Record

TBucketArray (see page 5709) and TBucket represent a list of buckets that each store an array of items.

Pascal

```
TBucket = record
  Count: Integer;
  Items: TBucketItemArray;
end;
```

C++

```
struct TBucket {
  int Count;
  TBucketItemArray Items;
};
```

File

Contnrs

Description

TBucketArray (see page 5709) is a dynamic array of TBucket vakyes. Each TBucket represents a dynamic array of items.

Count is the number of items in a bucket.

Items is the array of items that the bucket stores.

TBucketList (see page 5643) uses TBucketArray (see page 5709) to represent its collection of buckets, or categories, under which it stores items.

See Also

TBucketList

31.3.2 Contnrs.TBucketItem Record

TBucketItemArray (see page 5710) and TBucketItem represent the items in a TBucket (see page 5706) record (Delphi) or structure (C++).

Pascal

```
TBucketItem = record
  Data: Pointer;
  Item: Pointer;
end;
```

C++

```
struct TBucketItem {
  void * Data;
  void * Item;
};
```

File

Contnrs

Description

TBucketItemArray (see page 5710) is a dynamic array of TBucketItem values. Each TBucketItem stores an item and its associated data pointer.

Item points to the item in a bucket.

Data points to the data that is associated with Item.

See Also

TBucketArray

31.3.3 Contnrs.TBucketListSizes Enumeration

TBucketListSizes indicates the number of distinct buckets in a TBucketList (see page 5643) object.

Pascal

```
TBucketListSizes = (
  bl2,
  bl4,
  bl8,
  bl16,
  bl32,
  bl64,
  bl128,
  bl256
);
```

C++

```
enum TBucketListSizes {
  bl2,
  bl4,
  bl8,
  bl16,
  bl32,
```

```
    bl64,
    bl128,
    bl256
  };
```

File

Contnrs

Description

The following table lists the possible values:

Value	Number of buckets
bl2	2
bl4	4
bl8	8
bl16	16
bl32	32
bl64	64
bl128	128
bl256	256

31.4 Types

The following table lists types in this documentation.

Types

Name	Description
TBucketArray (see page 5709)	This is type Contnrs.TBucketArray.
TBucketEvent (see page 5709)	This is type Contnrs.TBucketEvent.
TBucketItemArray (see page 5710)	This is type Contnrs.TBucketItemArray.
TBucketProc (see page 5710)	This is type Contnrs.TBucketProc.

31.4.1 Contnrs.TBucketArray Type

Pascal

```
TBucketArray = array of TBucket;
```

C++

```
array of TBucket TBucketArray;
```

File

Contnrs

Description

This is type Contnrs.TBucketArray.

31.4.2 Contnrs.TBucketEvent Type

Pascal

```
TBucketEvent = procedure (AItem, AData: Pointer; out AContinue: Boolean) of object;
```

C++

```
(AItem, AData: Pointer; out AContinue: Boolean) ( TBucketEvent)();
```

File

Contnrs

Description

This is type Contnrs.TBucketEvent.

31.4.3 Contnrs.TBucketItemArray Type

Pascal

```
TBucketItemArray = array of TBucketItem;
```

C++

```
array of TBucketItem TBucketItemArray;
```

File

Contnrs

Description

This is type Contnrs.TBucketItemArray.

31.4.4 Contnrs.TBucketProc Type

Pascal

```
TBucketProc = procedure (AInfo, AItem, AData: Pointer; out AContinue: Boolean);
```

C++

```
(AInfo, AItem, AData: Pointer; out AContinue: Boolean) ( TBucketProc)();
```

File

Contnrs

Description

This is type Contnrs.TBucketProc.

32 Controls Namespace

This is namespace Controls.

Constants (see page 6323)	The following table lists constants in this documentation.

Classes

	Name	Description
	TBaseDragControlObject (see page 5719)	TBaseDragControlObject object provides support for drag-and-drop or drag-and-dock operations.
	TControl (see page 5724)	TControl is the base class for all components that are visible at runtime.
	TControlAction (see page 5877)	This is class Controls.TControlAction.
	TControlActionLink (see page 5892)	TControlActionLink links action objects to clients that descend from TControl (see page 5724).
	TControlCanvas (see page 5903)	TControlCanvas is a specialized canvas object associated with a control.
	TCustomControl (see page 5908)	Base class for controls that wrap Windows screen objects but perform their own rendering.
	TCustomControlAction (see page 5923)	This is class Controls.TCustomControlAction.
	TCustomListControl (see page 5928)	TCustomListControl is the base class for controls that display a list of items.
	TCustomMultiSelectListControl (see page 5944)	TCustomMultiSelectListControl is the base class for list controls that allow multiple items to be selected.
	TCustomPanningWindow (see page 5958)	This is an abstract base class that is used as an ancestor for users to implement a custom panning window.
	TCustomTransparentControl (see page 5970)	Base class for transparent controls.
	TDockTree (see page 5983)	TDockTree is the default docking manager for TWinControl (see page 6112).
	TDockZone (see page 5997)	This is class Controls.TDockZone.
	TDragControlObject (see page 6003)	TDragControlObject object provides for normal drag and drop operations.
	TDragControlObjectEx (see page 6007)	TDragControlObjectEx object provides for normal drag and drop operations.
	TDragDockObject (see page 6009)	Contains drag-and-dock information for a control.
	TDragDockObjectEx (see page 6018)	Contains drag-and-dock information for a control.

	TDragImageList (see page 6021)	TDragImageList represents a set of images that appear during drag operations.
	TDragObject (see page 6031)	TDragObject is a base class used for managing drag operations.
	TDragObjectEx (see page 6041)	TDragObjectEx is a base class used for managing drag operations.
	TGraphicControl (see page 6044)	TGraphicControl is the base class for all lightweight controls.
	THintWindow (see page 6055)	THintWindow implements the small pop-up window that appears over a control at runtime when the control has its ShowHint (see page 5840) property set to true.
	TImageList (see page 6078)	TImageList represents a collection of same-sized images, each of which can be referred to by its index.
	TMargins (see page 6087)	Contains margins for the control.
	TMouse (see page 6096)	TMouse surfaces information about the mouse and specifies how the application responds to mouse messages.
	TPadding (see page 6103)	Contains the padding for the control.
	TSizeConstraints (see page 6107)	Contains size constraints for a control.
	TWinControl (see page 6112)	TWinControl is the base class for all controls that are wrappers for Microsoft Windows screen objects.
	TWinControlActionLink (see page 6233)	TWinControlActionLink is an action link used by descendants of TWinControl (see page 6112).

Constants

Name	Description
AnchorAlign (see page 6325)	Defines the default sets of anchor types for all component alignment values.
CM_ACTIONEXECUTE (see page 6326)	This is constant Controls.CM_ACTIONEXECUTE.
CM_ACTIONUPDATE (see page 6327)	This is constant Controls.CM_ACTIONUPDATE.
CM_ACTIVATE (see page 6327)	This is constant Controls.CM_ACTIVATE.
CM_ALLCHILDRENFLIPPED (see page 6327)	This is constant Controls.CM_ALLCHILDRENFLIPPED.
CM_APPKEYDOWN (see page 6328)	This is constant Controls.CM_APPKEYDOWN.
CM_APPSYSCOMMAND (see page 6328)	This is constant Controls.CM_APPSYSCOMMAND.
CM_BASE (see page 6328)	This is constant Controls.CM_BASE.
CM_BIDIMODECHANGED (see page 6329)	This is constant Controls.CM_BIDIMODECHANGED.
CM_BORDERCHANGED (see page 6329)	This is constant Controls.CM_BORDERCHANGED.
CM_BUTTONPRESSED (see page 6329)	This is constant Controls.CM_BUTTONPRESSED.
CM_CANCELMODE (see page 6330)	This is constant Controls.CM_CANCELMODE.
CM_CHANGED (see page 6330)	This is constant Controls.CM_CHANGED.
CM_CHILDKEY (see page 6330)	This is constant Controls.CM_CHILDKEY.
CM_COLORCHANGED (see page 6331)	This is constant Controls.CM_COLORCHANGED.
CM_CONTROLCHANGE (see page 6331)	This is constant Controls.CM_CONTROLCHANGE.
CM_CONTROLLISTCHANGE (see page 6331)	This is constant Controls.CM_CONTROLLISTCHANGE.
CM_CONTROLLISTCHANGING (see page 6332)	This is constant Controls.CM_CONTROLLISTCHANGING.
CM_CREATEPOPUP (see page 6332)	This is constant Controls.CM_CREATEPOPUP.
CM_CTL3DCHANGED (see page 6332)	This is constant Controls.CM_CTL3DCHANGED.
CM_CTLCOLOREDITGLASS (see page 6333)	This is constant Controls.CM_CTLCOLOREDITGLASS.
CM_CURSORCHANGED (see page 6333)	This is constant Controls.CM_CURSORCHANGED.
CM_DEACTIVATE (see page 6333)	This is constant Controls.CM_DEACTIVATE.
CM_DESIGNHITTEST (see page 6334)	This is constant Controls.CM_DESIGNHITTEST.
CM_DESTROYHANDLE (see page 6334)	This is constant Controls.CM_DESTROYHANDLE.
CM_DIALOGCHAR (see page 6334)	This is constant Controls.CM_DIALOGCHAR.
CM_DIALOGHANDLE (see page 6335)	This is constant Controls.CM_DIALOGHANDLE.
CM_DIALOGKEY (see page 6335)	This is constant Controls.CM_DIALOGKEY.
CM_DOCKCLIENT (see page 6335)	This is constant Controls.CM_DOCKCLIENT.
CM_DOCKNOTIFICATION (see page 6336)	This is constant Controls.CM_DOCKNOTIFICATION.
CM_DOCWINDOWACTIVATE (see page 6336)	This is constant Controls.CM_DOCWINDOWACTIVATE.
CM_DRAG (see page 6336)	This is constant Controls.CM_DRAG.
CM_ENABLEDCHANGED (see page 6337)	This is constant Controls.CM_ENABLEDCHANGED.
CM_ENTER (see page 6337)	This is constant Controls.CM_ENTER.
CM_EXIT (see page 6337)	This is constant Controls.CM_EXIT.

CM_FLOAT (see page 6338)	This is constant Controls.CM_FLOAT.
CM_FOCUSCHANGED (see page 6338)	This is constant Controls.CM_FOCUSCHANGED.
CM_FONTCHANGE (see page 6338)	This is constant Controls.CM_FONTCHANGE.
CM_FONTCHANGED (see page 6339)	This is constant Controls.CM_FONTCHANGED.
CM_GETDATALINK (see page 6339)	This is constant Controls.CM_GETDATALINK.
CM_GOTFOCUS (see page 6339)	This is constant Controls.CM_GOTFOCUS.
CM_HINTSHOW (see page 6340)	This is constant Controls.CM_HINTSHOW.
CM_HINTSHOWPAUSE (see page 6340)	This is constant Controls.CM_HINTSHOWPAUSE.
CM_HITTEST (see page 6340)	This is constant Controls.CM_HITTEST.
CM_ICONCHANGED (see page 6341)	This is constant Controls.CM_ICONCHANGED.
CM_INVALIDATE (see page 6341)	This is constant Controls.CM_INVALIDATE.
CM_INVALIDATEDOCKHOST (see page 6341)	This is constant Controls.CM_INVALIDATEDOCKHOST.
CM_INVOKEHELP (see page 6342)	This is constant Controls.CM_INVOKEHELP.
CM_ISSHORTCUT (see page 6342)	This is constant Controls.CM_ISSHORTCUT.
CM_ISTOOLCONTROL (see page 6342)	This is constant Controls.CM_ISTOOLCONTROL.
CM_LOSTFOCUS (see page 6343)	This is constant Controls.CM_LOSTFOCUS.
CM_MENUCHANGED (see page 6343)	This is constant Controls.CM_MENUCHANGED.
CM_MOUSEACTIVATE (see page 6343)	This is constant Controls.CM_MOUSEACTIVATE.
CM_MOUSEENTER (see page 6344)	This is constant Controls.CM_MOUSEENTER.
CM_MOUSELEAVE (see page 6344)	This is constant Controls.CM_MOUSELEAVE.
CM_MOUSEWHEEL (see page 6344)	This is constant Controls.CM_MOUSEWHEEL.
CM_PARENTBIDIMODECHANGED (see page 6345)	This is constant Controls.CM_PARENTBIDIMODECHANGED.
CM_PARENTCOLORCHANGED (see page 6345)	This is constant Controls.CM_PARENTCOLORCHANGED.
CM_PARENTCTL3DCHANGED (see page 6345)	This is constant Controls.CM_PARENTCTL3DCHANGED.
CM_PARENTFONTCHANGED (see page 6346)	This is constant Controls.CM_PARENTFONTCHANGED.
CM_PARENTSHOWHINTCHANGED (see page 6346)	This is constant Controls.CM_PARENTSHOWHINTCHANGED.
CM_POPUPHWNDDESTROY (see page 6346)	This is constant Controls.CM_POPUPHWNDDESTROY.
CM_RECREATEWND (see page 6347)	This is constant Controls.CM_RECREATEWND.
CM_RELEASE (see page 6347)	This is constant Controls.CM_RELEASE.
CM_SETACTIVECONTROL (see page 6347)	This is constant Controls.CM_SETACTIVECONTROL.
CM_SHOWHINTCHANGED (see page 6348)	This is constant Controls.CM_SHOWHINTCHANGED.
CM_SHOWINGCHANGED (see page 6348)	This is constant Controls.CM_SHOWINGCHANGED.
CM_SYSCOLORCHANGE (see page 6348)	This is constant Controls.CM_SYSCOLORCHANGE.
CM_SYSFONTCHANGED (see page 6349)	This is constant Controls.CM_SYSFONTCHANGED.
CM_TABSTOPCHANGED (see page 6349)	This is constant Controls.CM_TABSTOPCHANGED.
CM_TEXTCHANGED (see page 6349)	This is constant Controls.CM_TEXTCHANGED.
CM_TIMECHANGE (see page 6350)	This is constant Controls.CM_TIMECHANGE.
CM_UIACTIVATE (see page 6350)	This is constant Controls.CM_UIACTIVATE.
CM_UIDEACTIVATE (see page 6350)	This is constant Controls.CM_UIDEACTIVATE.
CM_UNDOCKCLIENT (see page 6351)	This is constant Controls.CM_UNDOCKCLIENT.
CM_VISIBLECHANGED (see page 6351)	This is constant Controls.CM_VISIBLECHANGED.
CM_WANTSPECIALKEY (see page 6351)	This is constant Controls.CM_WANTSPECIALKEY.
CM_WINDOWHOOK (see page 6352)	This is constant Controls.CM_WINDOWHOOK.
CM_WININICHANGE (see page 6352)	This is constant Controls.CM_WININICHANGE.
CN_BASE (see page 6352)	This is constant Controls.CN_BASE.
CN_CHAR (see page 6353)	This is constant Controls.CN_CHAR.
CN_CHARTOITEM (see page 6353)	This is constant Controls.CN_CHARTOITEM.
CN_COMMAND (see page 6353)	This is constant Controls.CN_COMMAND.
CN_COMPAREITEM (see page 6354)	This is constant Controls.CN_COMPAREITEM.
CN_CTLCOLORBTN (see page 6354)	This is constant Controls.CN_CTLCOLORBTN.
CN_CTLCOLORDLG (see page 6354)	This is constant Controls.CN_CTLCOLORDLG.
CN_CTLCOLOREDIT (see page 6355)	This is constant Controls.CN_CTLCOLOREDIT.
CN_CTLCOLORLISTBOX (see page 6355)	This is constant Controls.CN_CTLCOLORLISTBOX.
CN_CTLCOLORMSGBOX (see page 6355)	This is constant Controls.CN_CTLCOLORMSGBOX.

CN_CTLCOLORSCROLLBAR (see page 6356)	This is constant Controls.CN_CTLCOLORSCROLLBAR.
CN_CTLCOLORSTATIC (see page 6356)	This is constant Controls.CN_CTLCOLORSTATIC.
CN_DELETEITEM (see page 6356)	This is constant Controls.CN_DELETEITEM.
CN_DRAWITEM (see page 6357)	This is constant Controls.CN_DRAWITEM.
CN_HSCROLL (see page 6357)	This is constant Controls.CN_HSCROLL.
CN_KEYDOWN (see page 6357)	This is constant Controls.CN_KEYDOWN.
CN_KEYUP (see page 6358)	This is constant Controls.CN_KEYUP.
CN_MEASUREITEM (see page 6358)	This is constant Controls.CN_MEASUREITEM.
CN_NOTIFY (see page 6358)	This is constant Controls.CN_NOTIFY.
CN_PARENTNOTIFY (see page 6359)	This is constant Controls.CN_PARENTNOTIFY.
CN_SYSCHAR (see page 6359)	This is constant Controls.CN_SYSCHAR.
CN_SYSKEYDOWN (see page 6359)	This is constant Controls.CN_SYSKEYDOWN.
CN_VKEYTOITEM (see page 6360)	This is constant Controls.CN_VKEYTOITEM.
CN_VSCROLL (see page 6360)	This is constant Controls.CN_VSCROLL.
crAppStart (see page 6360)	Identifies the default cursor.
crArrow (see page 6361)	Identifies an arrow cursor.
crCross (see page 6361)	Identifies an cross cursor.
crDefault (see page 6362)	Identifies the default cursor.
crDrag (see page 6362)	Identifies a drag cursor.
crHandPoint (see page 6363)	Identifies a pointing hand cursor.
crHelp (see page 6363)	Identifies a help cursor.
crHourGlass (see page 6364)	Identifies an hour glass cursor.
crHSplit (see page 6364)	Identifies a horizontal split cursor.
crIBeam (see page 6365)	Identifies a text insert cursor.
crMultiDrag (see page 6365)	Identifies a multiple item drag cursor.
crNo (see page 6366)	Identifies a not allowed cursor.
crNoDrop (see page 6366)	Identifies a not allowed to drop cursor.
crNone (see page 6367)	Identifies an invisible cursor.
crSize (see page 6367)	Identifies an obsolete cursor.
crSizeAll (see page 6368)	Identifies a size in all directions cursor.
crSizeNESW (see page 6368)	Identifies a North-East to South-West sizing cursor.
crSizeNS (see page 6369)	Identifies a vertical sizing cursor.
crSizeNWSE (see page 6369)	Identifies a North-West to South-East sizing cursor.
crSizeWE (see page 6370)	Identifies a horizontal sizing cursor.
crSQLWait (see page 6370)	Identifies an SQL wait hour glass cursor.
crUpArrow (see page 6371)	Identifies an upwards pointing arrow cursor.
crVSplit (see page 6371)	Identifies a vertical split cursor.
CTL3D_ALL (see page 6372)	This is constant Controls.CTL3D_ALL.
mrAbort (see page 6372)	Indicates that Abort was selected in a modal dialog.
mrAll (see page 6372)	This is constant Controls.mrAll.
mrCancel (see page 6373)	Indicates that Cancel was selected in a modal dialog.
mrIgnore (see page 6373)	Indicates that Ignore was selected in a modal dialog.
mrNo (see page 6374)	Indicates that No was selected in a modal dialog.
mrNone (see page 6374)	The default modal dialog return value.
mrNoToAll (see page 6375)	Indicates that 'No To All' was selected in a modal dialog.
mrOk (see page 6375)	This is constant Controls.mrOk.
mrRetry (see page 6375)	Indicates that Retry was selected in a modal dialog.
mrYes (see page 6376)	Indicates that Yes was selected in a modal dialog.
mrYesToAll (see page 6376)	Indicates that 'Yes To All' was selected in a modal dialog.
NullDockSite (see page 6377)	This is constant Controls.NullDockSite.

Functions

	Name	Description
	CancelDrag (see page 6247)	Cancels a drag-and-drop or drag-and-dock operation that is in progress.

	ChangeBiDiModeAlignment (see page 6247)	This is function Controls.ChangeBiDiModeAlignment.
	CursorToIdent (see page 6247)	Returns the name of the predefined constant that corresponds to a cursor.
	CursorToString (see page 6248)	Returns the AnsiString representation of a cursor.
	DragDone (see page 6249)	This is function Controls.DragDone.
	FindControl (see page 6249)	Returns the windowed control (Windows) or widget (cross-platform) whose window is identified by the specifiedhandle or which appears at a specified position.
	FindDragTarget (see page 6249)	Returns the control at a specified screen coordinate.
	FindVCLWindow (see page 6250)	Returns the windowed control, if any, at the specified location.
	GetCaptureControl (see page 6251)	Returns the control, if any, that currently receives all mouse messages.
	GetCursorValues (see page 6251)	Passes the name of every predefined cursor constant to a callback.
	GetLongHint (see page 6252)	Returns the second part of a two-part hint string.
	GetShortHint (see page 6253)	Returns the first part of a two-part hint string.
	IdentToCursor (see page 6254)	Translates a predefined cursor constant into a cursor.
	Imm32GetCompositionString (see page 6254)	This is function Controls.Imm32GetCompositionString.
	Imm32GetContext (see page 6255)	This is function Controls.Imm32GetContext.
	Imm32GetConversionStatus (see page 6255)	This is function Controls.Imm32GetConversionStatus.
	Imm32IsIME (see page 6255)	This is function Controls.Imm32IsIME.
	Imm32NotifyIME (see page 6256)	This is function Controls.Imm32NotifyIME.
	Imm32ReleaseContext (see page 6256)	This is function Controls.Imm32ReleaseContext.
	Imm32SetCompositionFont (see page 6256)	This is function Controls.Imm32SetCompositionFont.
	Imm32SetCompositionWindow (see page 6257)	This is function Controls.Imm32SetCompositionWindow.
	Imm32SetConversionStatus (see page 6257)	This is function Controls.Imm32SetConversionStatus.
	Imm32SetOpenStatus (see page 6257)	This is function Controls.Imm32SetOpenStatus.
	InitWndProc (see page 6258)	This is function Controls.InitWndProc.
	IsAbortResult (see page 6258)	Checks the return value from a modal form dialog and indicates whether the user selected Abort or Cancel.
	IsAnAllResult (see page 6259)	Checks the return value from a modal form dialog and indicates whether the user selected All, Yes to All, or No to All.
	IsDragObject (see page 6259)	Indicates whether a specified object is a TDragObject (see page 6031) descendant.
	IsNegativeResult (see page 6260)	Checks the return value from a modal form dialog and indicates whether the user selected No or No to All.
	IsPositiveResult (see page 6260)	Checks the return value from a modal form dialog and indicates whether the user selected Ok, Yes, Yes to All, or All.
	IsVCLControl (see page 6261)	IsVCLControl returns true if a control is a VCL control.
	MoveWindowOrg (see page 6262)	Changes the location of the point (0,0) within a device context.
	PerformEraseBackground (see page 6262)	This is function Controls.PerformEraseBackground.
	SendAppMessage (see page 6262)	Sends a Windows message to the application.
	SetCaptureControl (see page 6263)	Causes the specified control to receive all mouse messages.
	SetImeMode (see page 6264)	This is function Controls.SetImeMode.
	SetImeName (see page 6264)	This is function Controls.SetImeName.
	StringToCursor (see page 6264)	Returns a TCursor (see page 6305) value given its string representation.
	StripAllFromResult (see page 6265)	Converts a TModalResult (see page 6312) value from a constant that refers to "all" to the corresponding simple constant.
	Win32NLSEnableIME (see page 6266)	This is function Controls.Win32NLSEnableIME.

Interfaces

	Name	Description
	IDockManager (see page 6238)	IDockManager is the interface for docking managers.

Structs, Records, Enums

	Name	Description
	TAlign (see page 6268)	TAlign specifies the alignment of a control within its parent.
	TAlignInfo (see page 6269)	This is record Controls.TAlignInfo.
	TAnchorKind (see page 6269)	TAnchorKind and TAnchors (see page 6294) specify how a control is anchored to its parent.

	TBevelCut (see page 6270)	TBevelCut specifies a bevel's cut.
	TBevelEdge (see page 6270)	TBevelEdge and TBevelEdges (see page 6295) specify which edges of a window are beveled.
	TBevelKind (see page 6271)	TBevelKind specifies the kind of bevel that appears on a control.
	TCMCancelMode (see page 6272)	This is record Controls.TCMCancelMode.
	TCMChanged (see page 6272)	This is record Controls.TCMChanged.
	TCMChildKey (see page 6273)	This is record Controls.TCMChildKey.
	TCMControlChange (see page 6273)	This is record Controls.TCMControlChange.
	TCMControlListChange (see page 6274)	This is record Controls.TCMControlListChange.
	TCMControlListChanging (see page 6274)	This is record Controls.TCMControlListChanging.
	TCMCreatePopup (see page 6275)	This is record Controls.TCMCreatePopup.
	TCMDockClient (see page 6275)	This is record Controls.TCMDockClient.
	TCMDockNotification (see page 6276)	This is record Controls.TCMDockNotification.
	TCMDrag (see page 6276)	This is record Controls.TCMDrag.
	TCMFloat (see page 6277)	This is record Controls.TCMFloat.
	TCMFocusChanged (see page 6277)	This is record Controls.TCMFocusChanged.
	TCMMouseActivate (see page 6278)	This is record Controls.TCMMouseActivate.
	TCMMouseWheel (see page 6278)	This is record Controls.TCMMouseWheel.
	TCMPopupHWndDestroy (see page 6279)	This is record Controls.TCMPopupHWndDestroy.
	TCMUnDockClient (see page 6279)	This is record Controls.TCMUnDockClient.
	TControlListItem (see page 6280)	This is record Controls.TControlListItem.
	TCreateParams (see page 6280)	TCreateParams is the window-creation parameter record used to specify the type of window to create for a windowed control.
	TDockNotifyRec (see page 6281)	TDockNotifyRec represents the information from a Windows docking notification message, and PDockNotifyRec (see page 6291) is a pointer to a TDockNotifyRec value.
	TDockOrientation (see page 6282)	TDockOrientation specifies the orientation of controls in a docking zone.
	TDragKind (see page 6282)	TDragKind indicates the type of operation that occurs when the user drags a control.
	TDragMessage (see page 6283)	This is record Controls.TDragMessage.
	TDragMode (see page 6283)	TDragMode indicates how a control initiates drag operations.
	TDragRec (see page 6284)	This is record Controls.TDragRec.
	TDragState (see page 6284)	TDragState is used to specify how the mouse is moving in relation to a control.
	TImeMode (see page 6285)	TImeMode represents the current mode of an Input Method Editor (IME).
	TMouseActivate (see page 6287)	TMouseActivate defines values for the OnMouseActivate event.
	TMouseActivateRec (see page 6288)	This is record Controls.TMouseActivateRec.
	TMouseButton (see page 6288)	TMouseButton identifies a mouse button in a mouse-event handler.
	TPopupFormInfo (see page 6289)	This is record Controls.TPopupFormInfo.

Types

Name	Description
PControlListItem (see page 6291)	This is type Controls.PControlListItem.
PDockNotifyRec (see page 6291)	This is type Controls.PDockNotifyRec.
PDragRec (see page 6292)	This is type Controls.PDragRec.
PMouseActivateRec (see page 6292)	This is type Controls.PMouseActivateRec.
PPopupFormInfo (see page 6292)	This is type Controls.PPopupFormInfo.
TAlignInsertBeforeEvent (see page 6293)	TAlignInsertBeforeEvent is the function type for an OnAlignInsertBefore event.
TAlignPositionEvent (see page 6293)	TAlignPositionEvent is the function type for an OnAlignPosition event.
TAlignSet (see page 6294)	TAlignSet specifies the alignment of a child control within its parent.
TAnchors (see page 6294)	TBorderWidth (see page 6296) defines the distance, in pixels, between the outer and inner bevels of a control.
TAnimateWindowProc (see page 6295)	This is type Controls.TAnimateWindowProc.
TBevelEdges (see page 6295)	TBevelEdge (see page 6270) and TBevelEdges specify which edges of a window are beveled.
TBevelWidth (see page 6296)	This is type Controls.TBevelWidth.
TBorderWidth (see page 6296)	This is type Controls.TBorderWidth.
TCanResizeEvent (see page 6296)	TCanResizeEvent is the type of the OnCanResize event handler.

TCaption (see page 6297)	TCaption is the type of the Caption property.
TCMActivate (see page 6297)	This is type Controls.TCMActivate.
TCMDeactivate (see page 6297)	This is type Controls.TCMDeactivate.
TCMDesignHitTest (see page 6298)	This is type Controls.TCMDesignHitTest.
TCMDialogChar (see page 6298)	This is type Controls.TCMDialogChar.
TCMDialogKey (see page 6298)	This is type Controls.TCMDialogKey.
TCMEnter (see page 6299)	This is type Controls.TCMEnter.
TCMExit (see page 6299)	This is type Controls.TCMExit.
TCMGotFocus (see page 6299)	This is type Controls.TCMGotFocus.
TCMHitTest (see page 6300)	This is type Controls.TCMHitTest.
TCMLostFocus (see page 6300)	This is type Controls.TCMLostFocus.
TCMWantSpecialKey (see page 6300)	This is type Controls.TCMWantSpecialKey.
TConstrainedResizeEvent (see page 6301)	This is type Controls.TConstrainedResizeEvent.
TConstraintSize (see page 6301)	This is type Controls.TConstraintSize.
TContextPopupEvent (see page 6301)	This is type Controls.TContextPopupEvent.
TControlActionLinkClass (see page 6302)	TControlActionLinkClass defines the metaclass for TControlActionLink (see page 5892).
TControlClass (see page 6302)	TControlClass defines the metaclass for TControl (see page 5724).
TControlState (see page 6302)	TControlState describes the current state of a control.
TControlStyle (see page 6303)	The TControlStyle type describes the current style of the control.
TCursor (see page 6305)	TCursor identifies the cursor type.
TDate (see page 6306)	TDate is used to represent a date.
TDockDropEvent (see page 6307)	TDockDropEvent is the type of the OnDockDrop event handler.
TDockOverEvent (see page 6307)	TDockOverEvent is the type of the OnDockOver event handler.
TDockTreeClass (see page 6308)	TDockTreeClass defines the metaclass for TDockTree (see page 5983).
TDragDropEvent (see page 6308)	This is type Controls.TDragDropEvent.
TDragObjectClass (see page 6308)	TDragObjectClass defines the metaclass for TDragObject (see page 6031).
TDragOverEvent (see page 6309)	This is type Controls.TDragOverEvent.
TEndDragEvent (see page 6309)	This is type Controls.TEndDragEvent.
TForEachZoneProc (see page 6309)	This is type Controls.TForEachZoneProc.
TGetSiteInfoEvent (see page 6310)	TGetSiteInfoEvent is the type of the OnGetSiteInfo event handler.
THintWindowClass (see page 6310)	THintWindowClass defines the metaclass for THintWindow (see page 6055).
TImeName (see page 6311)	TImeName is the type that represents the name of an Input Method Editor.
TKeyEvent (see page 6311)	This is type Controls.TKeyEvent.
TKeyPressEvent (see page 6311)	This is type Controls.TKeyPressEvent.
TMarginSize (see page 6312)	This is type Controls.TMarginSize.
TModalResult (see page 6312)	TModalResult represents the return value from a modal dialog.
TMouseActivateEvent (see page 6313)	This is type Controls.TMouseActivateEvent.
TMouseEvent (see page 6313)	This is type Controls.TMouseEvent.
TMouseMoveEvent (see page 6314)	This is type Controls.TMouseMoveEvent.
TMouseWheelEvent (see page 6314)	This is type Controls.TMouseWheelEvent.
TMouseWheelUpDownEvent (see page 6314)	This is type Controls.TMouseWheelUpDownEvent.
TPanningWindowClass (see page 6315)	TPanningWindowClass defines the metaclass for TPanningWindow.
TScalingFlags (see page 6315)	TScalingFlags describes the way controls are scaled.
TStartDockEvent (see page 6316)	TStartDockEvent is the type of the OnStartDock event handler.
TStartDragEvent (see page 6316)	This is type Controls.TStartDragEvent.
TTabOrder (see page 6317)	TTabOrder defines the tab order of a control.
TTime (see page 6317)	TTime is used to represent a time.
TUnDockEvent (see page 6317)	TUnDockEvent is the type of the OnUnDock event handler.
TWinControlActionLinkClass (see page 6318)	TWinControlActionLinkClass defines the metaclass for TWinControlActionLink (see page 6233).
TWinControlClass (see page 6318)	TWinControlClass defines the metaclass for TWinControl (see page 6112).
TWndMethod (see page 6319)	TWndMethod is the type for Windows message procedures.

Variables

Name	Description
AnimateWindowProc (see page 6320)	This is variable Controls.AnimateWindowProc.
CreationControl (see page 6320)	This is variable Controls.CreationControl.
DefaultDockTreeClass (see page 6321)	Provides the default implementation class for the DockManager property of container controls.
IsVCLControlHook (see page 6321)	This is variable Controls.IsVCLControlHook.
Mouse (see page 6321)	Contains information about the system's mouse.
NewStyleControls (see page 6322)	Determines whether controls are drawn using the Windows 3.x "look".

32.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TBaseDragControlObject (see page 5719)	TBaseDragControlObject object provides support for drag-and-drop or drag-and-dock operations.
	TControl (see page 5724)	TControl is the base class for all components that are visible at runtime.
	TControlAction (see page 5877)	This is class Controls.TControlAction.
	TControlActionLink (see page 5892)	TControlActionLink links action objects to clients that descend from TControl (see page 5724).
	TControlCanvas (see page 5903)	TControlCanvas is a specialized canvas object associated with a control.
	TCustomControl (see page 5908)	Base class for controls that wrap Windows screen objects but perform their own rendering.
	TCustomControlAction (see page 5923)	This is class Controls.TCustomControlAction.
	TCustomListControl (see page 5928)	TCustomListControl is the base class for controls that display a list of items.
	TCustomMultiSelectListControl (see page 5944)	TCustomMultiSelectListControl is the base class for list controls that allow multiple items to be selected.
	TCustomPanningWindow (see page 5958)	This is an abstract base class that is used as an ancestor for users to implement a custom panning window.
	TCustomTransparentControl (see page 5970)	Base class for transparent controls.
	TDockTree (see page 5983)	TDockTree is the default docking manager for TWinControl (see page 6112).
	TDockZone (see page 5997)	This is class Controls.TDockZone.
	TDragControlObject (see page 6003)	TDragControlObject object provides for normal drag and drop operations.
	TDragControlObjectEx (see page 6007)	TDragControlObjectEx object provides for normal drag and drop operations.
	TDragDockObject (see page 6009)	Contains drag-and-dock information for a control.
	TDragDockObjectEx (see page 6018)	Contains drag-and-dock information for a control.
	TDragImageList (see page 6021)	TDragImageList represents a set of images that appear during drag operations.
	TDragObject (see page 6031)	TDragObject is a base class used for managing drag operations.
	TDragObjectEx (see page 6041)	TDragObjectEx is a base class used for managing drag operations.
	TGraphicControl (see page 6044)	TGraphicControl is the base class for all lightweight controls.
	THintWindow (see page 6055)	THintWindow implements the small pop-up window that appears over a control at runtime when the control has its ShowHint (see page 5840) property set to true.
	TImageList (see page 6078)	TImageList represents a collection of same-sized images, each of which can be referred to by its index.
	TMargins (see page 6087)	Contains margins for the control.
	TMouse (see page 6096)	TMouse surfaces information about the mouse and specifies how the application responds to mouse messages.
	TPadding (see page 6103)	Contains the padding for the control.
	TSizeConstraints (see page 6107)	Contains size constraints for a control.
	TWinControl (see page 6112)	TWinControl is the base class for all controls that are wrappers for Microsoft Windows screen objects.
	TWinControlActionLink (see page 6233)	TWinControlActionLink is an action link used by descendants of TWinControl (see page 6112).

32.1.1 TBaseDragControlObject Class

TBaseDragControlObject object provides support for drag-and-drop or drag-and-dock operations.

Class Hierarchy

System::TObject → Controls.TDragObject → Controls.TBaseDragControlObject

Pascal

```
TBaseDragControlObject = class(TDragObject);
```

C++

```
class TBaseDragControlObject : public TDragObject;
```

File

Controls

Description

Do not create instances of TBaseDragControlObject. TBaseDragControlObject, like its immediate ancestor TDragObject (see page 6031), handles operations common to both drag-and-drop and drag-and-dock behavior. TBaseDragControlObject adds support for associating a control with the drag object.

TBaseDragControlObject has two descendants: TDragControlObject (see page 6003), which is specialized for drag-and-drop operations, and TDragDockObject (see page 6009), which is specialized for drag-and-dock operations.

See Also

TDragDockObject (see page 6009)

32.1.1.1 TBaseDragControlObject Members

The following tables list the members exposed by TBaseDragControlObject.

Protected Methods

	Name	Description
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	Finished (see page 5723)	Finished ends a drag and drop operation.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5722)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5721)	Creates an instance of the TBaseDragControlObject (see page 5719) and stores a reference to the control that is being dragged.

V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetName (see page 6036)	Returns a string that identifies the drag operation.
V	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	Control (see page 5724)	Indicates the control that is being dragged.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.1.2 TBaseDragControlObject.Create Constructor

Creates an instance of the TBaseDragControlObject (see page 5719) and stores a reference to the control that is being dragged.

Pascal

```
constructor Create(AControl: TControl); virtual;
```

C++

```
virtual __fastcall TBaseDragControlObject(TControl * AControl);
```

Description

Call Create to instantiate a specialized descendant of TBaseDragControlObject (see page 5719) from the OnStartDrag event

handler of a control that can be dragged. Pass the control that is about to be dragged as the AControl parameter. This control becomes the value of the Control (see page 5724) property.

See Also

Control (see page 5724)

OnStartDrag (see page 5871)

OnStartDock (see page 5871)

32.1.1.3 TBaseDragControlObject Methods

The methods of the TBaseDragControlObject class are listed here.

Protected Methods

	Name	Description
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	Finished (see page 5723)	Finished ends a drag and drop operation.

Public Methods

	Name	Description
	Assign (see page 5722)	Copies the properties of another drag control object.

32.1.1.3.1 TBaseDragControlObject.Assign Method

Copies the properties of another drag control object.

Pascal

```
procedure Assign(Source: TDragObject); override;
```

C++

```
virtual __fastcall Assign(TDragObject Source);
```

Description

Call Assign to copy the properties of another drag object. Assign changes the DragTarget (see page 6039), DragHandle (see page 6039), DragPos (see page 6039), DragTargetPos (see page 6040), MouseDeltaX (see page 6040) and MouseDeltaY (see page 6041) properties to match a drag object supplied as the Source parameter. If Source is a descendant of TBaseDragControlObject (see page 5719) (normally the case), assign copies the Control (see page 5724) property as well.

See Also

Control (see page 5724)

DragTarget (see page 6039)

DragHandle (see page 6039)

DragPos (see page 6039)

DragTargetPos (see page 6040)

MouseDeltaX (see page 6040)

MouseDeltaY (see page 6041)

Assign (see page 2930)

32.1.1.3.2 TBaseDragControlObject.EndDrag Method

Generates an OnEndDrag event for the control that is being dragged.

Pascal

```
procedure EndDrag(Target: TObject; X: Integer; Y: Integer); virtual;
```

C++

```
virtual __fastcall EndDrag(TObject * Target, int X, int Y);
```

Description

EndDrag is called automatically when the user drops the control or cancels the drag operation. It calls the DoEndDrag method of the control specified by the Control (see page 5724) property. By default, this method generates an OnEndDrag event for that control.

The Target parameter indicates the object that accepted the control. If the drag operation was canceled or the control was dragged to a floating position (in a drag-and-dock operation), Target is nil (Delphi) or NULL (C++). The X and Y parameters indicate where the control is dropped.

See Also

Control (see page 5724)

OnEndDrag (see page 5860)

DoEndDrag (see page 5751)

32.1.1.3.3 TBaseDragControlObject.Finished Method

Finished ends a drag and drop operation.

Pascal

```
procedure Finished(Target: TObject; X: Integer; Y: Integer; Accepted: Boolean); override;
```

C++

```
virtual __fastcall Finished(TObject * Target, int X, int Y, Boolean Accepted);
```

Description

Finished is called automatically when the user drops the control or cancels the drag operation. Accepted indicates whether the Target control at X, Y position accepts the drag and drop or drag and dock operation. If a target does not accept the dragged object, its DragCanceled method is called before the EndDrag (see page 5723) method generates an OnEndDrag event.

See Also

DragCanceled (see page 5754)

EndDrag (see page 5723)

32.1.1.4 TBaseDragControlObject Properties

The properties of the TBaseDragControlObject class are listed here.

Public Properties

	Name	Description
	Control (see page 5724)	Indicates the control that is being dragged.

32.1.1.4.1 TBaseDragControlObject.Control Property

Indicates the control that is being dragged.

Pascal

```
property Control: TControl;
```

C++

```
__property TControl * Control;
```

Description

Use Control to gain access to the object that is being dragged. Depending on the operation, its properties can affect the appearance of the drag cursor and whether a drag target accepts the control.

See Also

Create (see page 5721)

32.1.2 TControl Class

TControl is the base class for all components that are visible at runtime.

Class Hierarchy

Pascal

```
TControl = class(TComponent);
```

C++

```
class TControl : public TComponent;
```

File

Controls

Description

Controls (see page 5711) are visual components, meaning the user can see them and possibly interact with them at runtime. All controls have properties, methods, and events that describe aspects of their appearance, such as the position of the control, the cursor or hint associated with the control, methods to paint or move the control, and events that respond to user actions.

TControl has many protected properties and methods that are used or published by its descendants.

VCL Overview

32.1.2.1 TControl Members

The following tables list the members exposed by TControl.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.

	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.

	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.

	Create (see page 5731)	Creates an instance of TControl (see page 5724).
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.

	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.

R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.2.2 TControl.Create Constructor

Creates an instance of TControl (see page 5724).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TControl(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TControl (see page 5724). However, you should never attempt to instantiate a TControl (see page 5724). This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants.

Create calls the parent constructor and initializes the control.

When overriding Create, always call the inherited Create method first, then proceed with the control's initialization. Remember to specify the override directive when overriding the Create method.

Note: If a control's constructor allocates resources or memory, also override the destructor to free those resources.

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

See Also

Destroy (see page 5732)

Create (see page 2766)

32.1.2.3 TControl.Destroy Destructor

Destroys an instance of TControl (see page 5724).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TControl();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the control is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Frees the TFont object in its Font (see page 5823) property.

Calls its inherited destructor.

Override Destroy to free any memory or resources allocated in the Create (see page 5731) method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

Create (see page 5731)

Free (see page 22300)

Owner (see page 2807)

32.1.2.4 TControl Fields

The fields of the TControl class are listed here.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

32.1.2.4.1 TControl.FAnchorMove Field

Pascal

```
FAnchorMove: Boolean;
```

C++

```
Boolean FAnchorMove;
```

Description

This is FAnchorMove, a member of class TControl.

32.1.2.4.2 TControl.FAnchorOrigin Field

Pascal

```
FAnchorOrigin: TPoint;
```

C++

```
TPoint FAnchorOrigin;
```

Description

This is FAnchorOrigin, a member of class TControl.

32.1.2.4.3 TControl.FAnchorRules Field

Pascal

```
FAnchorRules: TPoint;
```

C++

```
TPoint FAnchorRules;
```

Description

This is FAnchorRules, a member of class TControl.

32.1.2.4.4 TControl.FExplicitHeight Field

Pascal

```
FExplicitHeight: Integer;
```

C++

```
int FExplicitHeight;
```

Description

This is FExplicitHeight, a member of class TControl.

32.1.2.4.5 TControl.FExplicitLeft Field

Pascal

```
FExplicitLeft: Integer;
```

C++

```
int FExplicitLeft;
```

Description

This is FExplicitLeft, a member of class TControl.

32.1.2.4.6 TControl.FExplicitTop Field

Pascal

```
FExplicitTop: Integer;
```

C++

```
int FExplicitTop;
```

Description

This is FExplicitTop, a member of class TControl.

32.1.2.4.7 TControl.FExplicitWidth Field

Pascal

```
FExplicitWidth: Integer;
```

C++

```
int FExplicitWidth;
```

Description

This is FExplicitWidth, a member of class TControl.

32.1.2.4.8 TControl.FOriginalParentSize Field

Pascal

```
FOriginalParentSize: TPoint;
```

C++

```
TPoint FOriginalParentSize;
```

Description

This is FOriginalParentSize, a member of class TControl.

32.1.2.5 TControl Methods

The methods of the TControl class are listed here.

Protected Methods

	Name	Description
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.

	DoDock (see page 5750)	Docking event dispatcher.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.

	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.

Public Methods

	Name	Description
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	Dock (see page 5749)	Used internally to dock the control.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
V	Invalidate (see page 5770)	Completely repaint control.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	Refresh (see page 5779)	Repaints the control on the screen.
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

32.1.2.5.1 TControl.ActionChange Method

Responds when the action associated with the control changes.

Pascal

```
procedure ActionChange(Sender: TObject; CheckDefaults: Boolean); dynamic;
```

C++

```
__fastcall ActionChange(TObject * Sender, Boolean CheckDefaults);
```

Description

ActionChange is called automatically when the action object specified by the Action (see page 5797) property, or any of its properties, changes. By default, the control's action link's OnChange event handler calls ActionChange.

ActionChange updates the control properties that correspond to properties of the associated action. These properties include the Caption (see page 5806), Enabled (see page 5821), Hint (see page 5827), and Visible (see page 5847) properties and the OnClick (see page 5851) event handler.

The Sender parameter is the action object that changed. The CheckDefaults parameter indicates whether the control's properties should all be updated or only those that have not been explicitly changed from their default values. When CheckDefaults is true, only those properties and event handlers that have not been changed from the default values are updated.

See Also

Action (see page 5797)

OnChange (see page 2725)

32.1.2.5.2 TControl.AdjustSize Method

Sets the size of the control as determined by the AutoSize (see page 5803) property.

Pascal

```
procedure AdjustSize; dynamic;
```

C++

```
__fastcall AdjustSize();
```

Description

If the AutoSize (see page 5803) property is true, AdjustSize is called automatically when the control needs to automatically resize itself to its contents. As implemented in TControl (see page 5724), AdjustSize calls SetBounds (see page 5783) with the values of its Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties. This call can result in a change of size if these values are altered in the control's OnCanResize (see page 5851) or OnConstrainedResize (see page 5853) event handlers, or if the control's OnResize (see page 5870) event handler makes any final adjustments.

Descendant classes override AdjustSize to change the size of the control to adjust to its contents.

Other controls can call AdjustSize after changing the control's contents. Do not call AdjustSize in application code.

See Also

AutoSize (see page 5803)

SetBounds (see page 5783)

OnCanResize (see page 5851)

OnConstrainedResize (see page 5853)

OnResize (see page 5870)

32.1.2.5.3 TControl.AssignTo Method

Overrides the inherited AssignTo function to enable assignments to TAction objects.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Do not call the protected AssignTo method in application code. The Assign method of a persistent object calls AssignTo if it is passed the control as a Source and the persistent object does not know how to copy the properties of the control. The Dest parameter is the persistent object that should have its properties copied from the control.

As implemented in TControl (see page 5724), AssignTo checks whether the Dest parameter is a TCustomAction object, and if so, assigns values to its Enabled (see page 5821), Hint (see page 5827), Caption (see page 5806), and Visible (see page 5847) properties and its OnExecute event. This allows arbitrary controls to assign these to an associated action object.

See Also

Assign (see page 2930)

TcustomAction

ActionChange (see page 5737)

32.1.2.5.4 TControl.BeginAutoDrag Method

Begin Automatic Drag.

Pascal

```
procedure BeginAutoDrag; dynamic;
```

C++

```
__fastcall BeginAutoDrag();
```

Description

BeginAutoDrag is called automatically when a user drags a control whose DragMode (see page 5819) is dmAutomatic. Do not call BeginAutoDrag in application code.

As implemented in TControl (see page 5724), BeginAutoDrag calls BeginDrag (see page 5740), passing in the global Mouse (see page 6321) variable's DragImmediate and DragThreshold properties.

See Also

DragKind (see page 5819)

DragMode (see page 5819)

EndDrag (see page 5757)

Mouse (see page 6321)

DragImmediate (see page 6100)

DragThreshold (see page 6101)

Mouse (see page 6321)

32.1.2.5.5 TControl.BeginDrag Method

Starts the dragging of a control.

Pascal

```
procedure BeginDrag(Immediate: Boolean; Threshold: Integer = -1);
```

C++

```
__fastcall BeginDrag(Boolean Immediate, int Threshold = -1);
```

Description

Call BeginDrag to start a drag operation. BeginDrag is called in application code only when the value of the control's DragMode (see page 5819) is dmManual. If DragMode (see page 5819) is dmAutomatic, BeginDrag is called automatically.

If the Immediate parameter is true, the mouse pointer changes to the value of the DragCursor (see page 5818) property and dragging begins immediately. If Immediate is false, the mouse pointer doesn't change to the value of the DragCursor (see page 5818) property and dragging doesn't begin until the user moves the mouse pointer the number of pixels specified by the Threshold parameter. If the caller passes a Threshold value less than 0 (such as the default value for this parameter), BeginDrag uses the DragThreshold property of the global Mouse (see page 6321) variable.

Setting Immediate to false allows the control to accept mouse clicks without beginning a drag-and-drop or drag-and-dock operation.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

EndDrag (see page 5757)

DragThreshold (see page 6101)

Mouse (see page 6321)

DragKind (see page 5819)

32.1.2.5.6 TControl.BringToFront Method

Puts the control in front of all other controls in its parent control.

Pascal

```
procedure BringToFront;
```

C++

```
__fastcall BringToFront();
```

Description

Call BringToFront to ensure that a form is visible or to reorder overlapping controls within a form.

Note that controls that wrap Windows screen objects (control classes descended from TWinControl (see page 6112)) always "stack" above lightweight controls (control classes descended from TGraphicControl (see page 6044)). BringToFront can force a lightweight control, such as a Shape, to stack above other lightweight controls, but wrapped controls, such as an Edit, will still stack above the Shape.

Without BringToFront, controls are stacked in their order they were placed on the form.

C++ Examples:

```
/*
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must include Unit2.h in this
module.
*/
#include "Unit2.h"

void __fastcall TForm1::ShowPaletteButtonClick(TObject *Sender)
{
  if (!Form2->Visible)
  {
    Form2->Visible = true;
    Form2->BringToFront();
  }
}
```

Delphi Examples:

```
{
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must add Unit2 in the uses clause
of your unit.
}
procedure TForm1.ShowPaletteButtonClick(Sender: TObject);
begin
if Form2.Visible = False then Form2.Visible := True;
Form2.BringToFront;
end;
```

See Also

SendToBack (see page 5782)

32.1.2.5.7 TControl.CalcCursorPos Method

Pascal

```
function CalcCursorPos: TPoint;
```

C++

```
__fastcall TPoint CalcCursorPos();
```

Description

This is CalcCursorPos, a member of class TControl.

32.1.2.5.8 TControl.CanAutoSize Method

Indicates whether the control can resize itself automatically to accommodate its contents.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize (see page 5803) property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize (see page 5803) property before the resize sequence that begins with the

OnCanResize (see page 5851) and OnConstrainedResize (see page 5853) events and ends with the OnResize (see page 5870) event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width (see page 5849) and Height (see page 5825), CanAutoSize returns true, and the resize sequence is aborted.

As implemented in TControl (see page 5724), CanAutoSize always returns true without changing NewWidth or NewHeight. Override CanAutoSize to implement the AutoSize (see page 5803) property for a particular control class's contents.

See Also

AutoSize (see page 5803)

OnResize (see page 5870)

OnCanResize (see page 5851)

OnConstrainedResize (see page 5853)

Width (see page 5849)

Height (see page 5825)

32.1.2.5.9 TControl.CanResize Method

OnCanResize (see page 5851) event dispatcher.

Pascal

```
function CanResize(var NewWidth: Integer; var NewHeight: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CanResize(int NewWidth, int NewHeight);
```

Description

CanResize is called automatically when an attempt is made to resize the control, after any autosizing has occurred. The NewWidth and NewHeight arguments specify the attempted new values for the control's height and width. CanResize optionally adjusts the values of NewWidth and NewHeight, and returns true if the control can be resized to the returned values. CanResize returns false if the control cannot be resized.

CanResize generates an OnCanResize (see page 5851) event. An OnCanResize (see page 5851) event handler may change the values of NewHeight and NewWidth.

See Also

OnCanResize (see page 5851)

AutoSize (see page 5803)

32.1.2.5.10 TControl.Changed Method

Sends a CM_CHANGED (see page 6330) message to the control.

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

Call Changed after changing the properties of the control in a way that affects the properties of a parent object. Changed sends a CM_CHANGED (see page 6330) message back to the control. If the control is a windowed control, this message is bubbled up to the parent so that it can make any necessary adjustments.

See Also

Parent (see page 5832)

32.1.2.5.11 TControl.ChangeScale Method

Rescaling event dispatcher.

Pascal

```
procedure ChangeScale(M: Integer; D: Integer); dynamic;
```

C++

```
__fastcall ChangeScale(int M, int D);
```

Description

ChangeScale is called automatically when some event requires that the control resize itself. Most often, this event is call to the ScaleBy method of the control itself or the control's parent. This allows the control to adjust its own special properties, such as font sizes and display regions.

ChangeScale parameters have the same meaning as for ScaleBy.

Note: Because control sizes and coordinates are integers, scaling can result in round-off error. Repeated calls to ChangeScale can make the control gradually shrink away or creep off the form. Consider destroying and reloading the form after several rescalings.

See Also

Height (see page 5825)

Left (see page 5830)

Top (see page 5844)

Width (see page 5849)

ScaleBy (see page 6175)

32.1.2.5.12 TControl.Click Method

Respond to user click.

Pascal

```
procedure Click; dynamic;
```

C++

```
__fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user

mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl (see page 5724), Click queries whether the OnClick (see page 5851) event handler exists and is different from the OnExecute handler for the control's Action (see page 5797). If this is true, the OnClick (see page 5851) event handler is called. If this is false, and the Action (see page 5797) OnExecute event handler exists, the Action (see page 5797)'s Execute method is called. Override Click to provide additional behavior.

See Also

Action (see page 5797)

OnExecute (see page 2716)

Execute (see page 2712)

DblClick (see page 5747)

OnClick (see page 5851)

32.1.2.5.13 TControl.ClientToParent Method

Translates client coordinates to parent coordinates.

Pascal

```
function ClientToParent(const Point: TPoint; AParent: TWinControl = nil): TPoint;
```

C++

```
__fastcall TPoint ClientToParent(const TPoint Point, TWinControl * AParent = nil);
```

Description

ClientToParent translates Point from the current control's coordinate system to AParent's coordinate system. AParent must be a control that can be found by iterating up the chain of Parent (see page 5832) properties. If AParent is nil (Delphi) or NULL (C++), the control's immediate parent is used.

An EInvalidOperation exception is thrown if AParent is not an ancestor control or the Parent (see page 5832) property is nil (Delphi) or NULL (C++).

See Also

ParentToClient (see page 5776)

ClientToScreen (see page 5744)

32.1.2.5.14 TControl.ClientToScreen Method

Translates a given point from client area coordinates to global screen coordinates.

Pascal

```
function ClientToScreen(const Point: TPoint): TPoint;
```

C++

```
__fastcall TPoint ClientToScreen(const TPoint Point);
```

Description

Use ClientToScreen to convert a point whose coordinates are expressed locally to the control to the corresponding point in screen coordinates. In client area coordinates (0, 0) corresponds to the upper left corner of the control's client area. In screen coordinates (0, 0) corresponds to the upper left corner of the screen.

Use ScreenToClient (see page 5781) along with ClientToScreen to convert from one control's coordinate system to another

control's coordinate system. For example,

```
P := TargetControl.ScreenToClient(SourceControl.ClientToScreen(P));
P = TargetControl->ScreenToClient(SourceControl->ClientToScreen(P));
```

converts P from coordinates in SourceControl to coordinates in TargetControl.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
```

```
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

See Also

ScreenToClient (see page 5781)

32.1.2.5.15 TControl.ConstrainedResize Method

Notify control of resize with constraints.

Pascal

```
procedure ConstrainedResize(var MinWidth: Integer; var MinHeight: Integer; var MaxWidth:
Integer; var MaxHeight: Integer); virtual;
```

C++

```
virtual __fastcall ConstrainedResize(int MinWidth, int MinHeight, int MaxWidth, int MaxHeight);
```

Description

ConstrainedResize is called automatically when a control is resized and has nonzero Constraints (see page 5812). This allows the control to modify the constraints before they are applied.

As implemented in TControl (see page 5724), ConstrainedResize simply calls the OnConstrainedResize (see page 5853) event handler.

See Also

OnConstrainedResize (see page 5853)

CanResize (see page 5742)

Constraints (see page 5812)

32.1.2.5.16 TControl.DblClick Method

OnDblClick (see page 5854) event dispatcher.

Pascal

```
procedure DblClick; dynamic;
```

C++

```
__fastcall DblClick();
```

Description

DblClick calls any event handler attached to the OnDblClick (see page 5854) event. Override DblClick to provide other responses in addition to the inherited event-handler call when the user double-clicks the control.

The DblClick method is triggered by left mouse-button double-click message (WM_LBUTTONDBLCLK) from Windows.

See Also

Click (see page 5743)

OnDblClick (see page 5854)

32.1.2.5.17 TControl.DefaultDockImage Method

Handles the painting and erasing of a dock image.

Pascal

```
procedure DefaultDockImage(DragDockObject: TDragDockObject; Erase: Boolean); dynamic;
```

C++

```
__fastcall DefaultDockImage(TDragDockObject DragDockObject, Boolean Erase);
```

Description

The DrawDragDockImage (see page 5755) and EraseDragDockImage (see page 5757) methods call DefaultDockImage to paint or erase the drag image of a control while the user drags it in a drag-and-dock operation.

DragDockObject contains the drag-and-dock information for the control.

Erase specifies whether to draw or erase the image.

See Also

DrawDragDockImage (see page 5755)

EraseDragDockImage (see page 5757)

OnStartDock (see page 5871)

32.1.2.5.18 TControl.DefaultHandler Method

Provides message handling for all messages that do not have specific handlers.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to extend the default handling of messages. DefaultHandler is the final opportunity for component writers to handle messages to controls. The method referenced by WindowProc (see page 5872) provides the first opportunity. Individual message methods such as Click (see page 5743) provide additional opportunities.

DefaultHandler handles the messages Windows sends to manage the control's text: WM_GETTEXT, WM_SETTEXT, and WM_GETTEXTLENGTH.

See Also

DefaultHandler

WndProc (see page 5791)

WindowProc (see page 5872)

TMessage

32.1.2.5.19 TControl.DefineProperties Method

Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties is called automatically by the streaming system that loads and saves VCL components. It allows persistent objects to read and write properties that are not published. Published properties are loaded and stored automatically.

DefineProperties uses the methods of the filer passed as the Filer parameter to assign methods that can load and save the IsControl (see page 5829) property.

Override DefineProperties to persist unpublished properties. Call the DefineBinaryProperty or DefineProperty method of the Filer parameter to assign methods that load or save property values.

Note: When overriding this method, call the parent class's DefineProperties method first.

See Also

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

DefineProperties (see page 2771)

IsControl (see page 5829)

32.1.2.5.20 TControl.DesignWndProc Method

Pascal

```
function DesignWndProc(var Message: TMessage): Boolean; dynamic;
```

C++

```
__fastcall Boolean DesignWndProc(TMessage Message);
```

Description

This is DesignWndProc, a member of class TControl.

32.1.2.5.21 TControl.Dock Method

Used internally to dock the control.

Pascal

```
procedure Dock(NewDockSite: TWinControl; ARect: TRect); dynamic;
```

C++

```
__fastcall Dock(TWinControl * NewDockSite, TRect ARect);
```

Description

Do not call Dock in applications. It is called automatically to implement many of the details of docking the control to a dock site.

To dock the control programmatically, use ManualDock (see page 5771) instead.

The NewDockSite parameter specifies the docking site to which the control is being docked. The ARect parameter indicates the new dimensions of the control when it is docked to NewDockSite.

See Also

ManualDock (see page 5771)

32.1.2.5.22 TControl.DockTrackNoTarget Method

Handles dragging of the control over an invalid docking target.

Pascal

```
procedure DockTrackNoTarget(Source: TDragDockObject; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall DockTrackNoTarget(TDragDockObject Source, int X, int Y);
```

Description

DockTrackNoTarget is called automatically when the control is dragged over an invalid docking target. It updates the docking rectangle of the TDragDockObject (see page 6009) specified by Source to reflect the current mouse coordinates, as given by X and Y.

See Also

DockRect (see page 6015)

PositionDockRect (see page 5777)

32.1.2.5.23 TControl.DoContextPopup Method

OnContextPopup (see page 5854) event dispatcher.

Pascal

```
procedure DoContextPopup(MousePos: TPoint; var Handled: Boolean); dynamic;
```

C++

```
__fastcall DoContextPopup(TPoint MousePos, Boolean Handled);
```

Description

OnContextPopup (see page 5854) calls any event handler attached to the OnContextPopup (see page 5854) event. When creating a component that descends from TControl (see page 5724), override OnContextPopup (see page 5854) to provide other responses in addition to the inherited event-handler call when the user invokes the control's context menu.

MousePos indicates the position where the user right-clicked the control. If the user invoked the context menu using the keyboard, MousePos is (-1,-1).

Handled returns a Boolean value indicating whether the control should continue with its default response to the user action.

See Also

OnContextPopup (see page 5854)

32.1.2.5.24 TControl.DoDock Method

Docking event dispatcher.

Pascal

```
procedure DoDock(NewDockSite: TWinControl; var ARect: TRect); dynamic;
```

C++

```
__fastcall DoDock(TWinControl * NewDockSite, TRect ARect);
```

Description

DoDock is called automatically as part of the docking process. It updates the control's dimensions and causes it to repaint.

NewDockSite is the control's new dock site. This value can be nil (Delphi) or NULL (C++) or NullDockSite (see page 6377) (a constant that indicates no dock site).

ARect specifies the control's new dimensions once it is docked to NewDockSite.

See Also

ManualDock (see page 5771)

ManualFloat (see page 5772)

32.1.2.5.25 TControl.DoEndDock Method

OnEndDock (see page 5859) event dispatcher.

Pascal

```
procedure DoEndDock(Target: TObject; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall DoEndDock(TObject * Target, int X, int Y);
```

Description

OnEndDock (see page 5859) calls any event handler attached to the OnEndDock (see page 5859) event. When creating a component that descends from TControl (see page 5724), override OnEndDock (see page 5859) to provide other responses in addition to the inherited event-handler call when the user finishes a drag-and-dock operation.

See Also

DoStartDock (see page 5753)

OnEndDock (see page 5859)

32.1.2.5.26 TControl.DoEndDrag Method

OnEndDrag (see page 5860) event dispatcher.

Pascal

```
procedure DoEndDrag(Target: TObject; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall DoEndDrag(TObject * Target, int X, int Y);
```

Description

DoEndDrag calls any event handler attached to the OnEndDrag (see page 5860) event. When creating a component that descends from TControl (see page 5724), override DoEndDrag to provide other responses in addition to the inherited event-handler call when the user drops an object or cancels a drag-and-drop operation.

See Also

DoStartDrag (see page 5753)

OnEndDrag (see page 5860)

32.1.2.5.27 TControl.DoMouseWheel Method

Processes mouse wheel motion.

Pascal

```
function DoMouseWheel(Shift: TShiftState; WheelDelta: Integer; MousePos: TPoint): Boolean;
dynamic;
```

C++

```
__fastcall Boolean DoMouseWheel(TShiftState Shift, int WheelDelta, TPoint MousePos);
```

Description

DoMouseWheel is called automatically when the user rotates the mouse wheel.

The Shift parameter indicates the current state of the Shift, Alt, and Ctrl keys.

The WheelDelta parameter indicates the distance the wheel was rotated. WheelDelta is positive if the mouse was rotated upward, negative if the mouse was rotated downward.

The MousePos parameter indicates the current position of the mouse pointer.

DoMouseWheel returns true if an event handler was found and indicated that it handled the event.

As implemented in TControl (see page 5724), DoMouseWheel first attempts to call the OnMouseWheel (see page 5869) event handler. If this routine exists and succesfully handles the event, DoMouseWheel returns true. Otherwise, DoMouseWheel repeatedly calls DoMouseWheelDown (see page 5752) or DoMouseWheelUp (see page 5752), depending on the direction

the user turned the mouse wheel. These routines, in turn, call the OnMouseWheelUp (see page 5870) or OnMouseWheelDown (see page 5869) event handlers.

Before the first call to DoMouseWheelDown (see page 5752) or DoMouseWheelUp (see page 5752), DoMouseWheel adds WheelDelta to the WheelAccumulator (see page 5849) property. After each call, DoMouseWheel adjusts WheelAccumulator (see page 5849) towards zero; each adjustment is by an internal constant that defines the minimum meaningful wheel motion. When the absolute value of of WheelAccumulator (see page 5849) drops below the value of this constant, DoMouseWheel exits, returning the value returned by the final call to DoMouseWheelDown (see page 5752) or DoMouseWheelUp (see page 5752).

See Also

OnMouseWheel (see page 5869)

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

MouseWheelHandler (see page 5774)

WheelAccumulator (see page 5849)

32.1.2.5.28 TControl.DoMouseWheelDown Method

OnMouseWheelDown (see page 5869) event dispatcher.

Pascal

```
function DoMouseWheelDown(Shift: TShiftState; MousePos: TPoint): Boolean; dynamic;
```

C++

```
__fastcall Boolean DoMouseWheelDown(TShiftState Shift, TPoint MousePos);
```

Description

The DoMouseWheel (see page 5751) method calls DoMouseWheelDown to generate an OnMouseWheelDown (see page 5869) event.

The Shift parameter indicates the state of the Shift, Alt, and Ctrl keys.

The MousePos parameter indicates the position of the mouse pointer.

DoMouseWheelDown returns true if an event handler indicates that it handled the message, and false otherwise.

Override DoMouseWheelDown to perform class-specific tasks in addition to calling the event handler when the mouse wheel is rotated downward.

See Also

OnMouseWheelDown (see page 5869)

DoMouseWheel (see page 5751)

32.1.2.5.29 TControl.DoMouseWheelUp Method

OnMouseWheelUp (see page 5870) event dispatcher.

Pascal

```
function DoMouseWheelUp(Shift: TShiftState; MousePos: TPoint): Boolean; dynamic;
```

C++

```
__fastcall Boolean DoMouseWheelUp(TShiftState Shift, TPoint MousePos);
```

Description

The DoMouseWheel (see page 5751) method calls DoMouseWheelUp to generate an OnMouseWheelUp (see page 5870) event.

The Shift parameter indicates the state of the Shift, Alt, and Ctrl keys.

The MousePos parameter indicates the position of the mouse pointer.

DoMouseWheelUp returns true if an event handler indicates that it handled the message, and false otherwise.

Override DoMouseWheelUp to perform class-specific tasks in addition to calling the event handler when the mouse wheel is rotated upward.

See Also

OnMouseWheelUp (see page 5870)

DoMouseWheel (see page 5751)

32.1.2.5.30 TControl.DoStartDock Method

OnStartDock (see page 5871) event dispatcher.

Pascal

```
procedure DoStartDock(var DragObject: TDragObject); dynamic;
```

C++

```
__fastcall DoStartDock(TDragObject DragObject);
```

Description

DoStartDock calls any event handler attached to the OnStartDock (see page 5871) event. When creating a component that descends from TControl (see page 5724), override DoStartDock to provide other responses in addition to the inherited event-handler call when the user starts a drag-and-dock operation.

See Also

DoEndDock (see page 5750)

OnStartDock (see page 5871)

32.1.2.5.31 TControl.DoStartDrag Method

OnStartDrag (see page 5871) event dispatcher.

Pascal

```
procedure DoStartDrag(var DragObject: TDragObject); dynamic;
```

C++

```
__fastcall DoStartDrag(TDragObject DragObject);
```

Description

DoStartDrag calls any event handler attached to the OnStartDrag (see page 5871) event. When creating a component that descends from TControl (see page 5724), override DoStartDrag to provide other responses in addition to the inherited event-handler call when the user starts a drag-and-drop operation.

See Also

DoEndDrag (see page 5751)

OnStartDrag (see page 5871)

32.1.2.5.32 TControl.DragCanceled Method

Provides the interface for a method that responds to the cancellation of a drag.

Pascal

```
procedure DragCanceled; dynamic;
```

C++

```
__fastcall DragCanceled();
```

Description

DragCanceled is called automatically when a drag operation is canceled. As implemented in TControl (see page 5724), DragCanceled does nothing. When creating a component that descends from TControl (see page 5724), override DragCanceled to provide code that executes when a drag-and-drop or drag-and-dock operation is canceled.

See Also

OnEndDrag (see page 5860)

OnEndDock (see page 5859)

32.1.2.5.33 TControl.DragDrop Method

OnDragDrop (see page 5855) event dispatcher.

Pascal

```
procedure DragDrop(Source: TObject; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall DragDrop(TObject * Source, int X, int Y);
```

Description

When creating a component that descends from TControl (see page 5724), override DragDrop to add additional code that executes before the OnDragDrop (see page 5855) event handler is called.

The Source parameter is the object that was dropped onto the control. The X and Y parameters are the mouse coordinates where the object was dropped.

See Also

DragCanceled (see page 5754)

OnDragDrop (see page 5855)

32.1.2.5.34 TControl.Dragging Method

Indicates whether a control is being dragged.

Pascal

```
function Dragging: Boolean;
```

C++

```
__fastcall Boolean Dragging();
```

Description

Use Dragging to determine the drag state of the control. If Dragging returns true, the control is being dragged. If Dragging is false, the control is not being dragged.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

OnDragDrop (see page 5855)

OnDockOver (see page 6216)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

32.1.2.5.35 TControl.DragOver Method

OnDragOver (see page 5857) event dispatcher.

Pascal

```
procedure DragOver(Source: TObject; X: Integer; Y: Integer; State: TDragState; var Accept:
Boolean); dynamic;
```

C++

```
__fastcall DragOver(TObject * Source, int X, int Y, TDragState State, Boolean Accept);
```

Description

Override DragOver to add additional code that executes before the OnDragOver (see page 5857) event handler is called.

DragOver sets the Accept parameter to true to indicate that the user can drop the dragged object on the control. It sets Accept to false to indicate that the user cannot drop the dragged object on the control.

The Source parameter is the object being dragged. The State parameter indicates how the dragged object is moving in relation to the control. X and Y indicate the current position of the mouse.

See Also

DragDrop (see page 5754)

OnDragOver (see page 5857)

32.1.2.5.36 TControl.DrawDragDockImage Method

Draws the dock image for the control.

Pascal

```
procedure DrawDragDockImage(DragDockObject: TDragDockObject); dynamic;
```

C++

```
__fastcall DrawDragDockImage(TDragDockObject DragDockObject);
```

Description

DrawDragDockImage is called automatically to draw the control (or, more typically, the drag rectangle) when the control is manipulated in drag-and-dock operations.

DrawDragDockImage calls DefaultDockImage (see page 5747) to render the image.

See Also

DefaultDockImage (see page 5747)

EraseDragDockImage (see page 5757)

32.1.2.5.37 TControl.DrawTextBiDiModeFlags Method

Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.

Pascal

```
function DrawTextBiDiModeFlags(Flags: Longint): Longint;
```

C++

```
__fastcall Longint DrawTextBiDiModeFlags(Longint Flags);
```

Description

Call DrawTextBiDiModeFlags to obtain a value for the TextFlags property of a canvas when drawing the control's text or caption. The return value can also be used with the Windows API DrawText function.

Flags are the current text flags, unaltered by any bi-directional mode considerations.

DrawTextBiDiModeFlags adds or removes the DT_RIGHT or DT_RTLREADING flags based on the values returned from the UseRightToLeftAlignment (see page 5790) and UseRightToLeftReading (see page 5790) methods.

See Also

TextFlags (see page 14495)

DrawTextBiDiModeFlagsReadingOnly (see page 5756)

BiDiMode (see page 5803)

Text (see page 5842)

Caption (see page 5806)

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

32.1.2.5.38 TControl.DrawTextBiDiModeFlagsReadingOnly Method

Returns the text flag to add that indicates whether the control's text should read from right to left.

Pascal

```
function DrawTextBiDiModeFlagsReadingOnly: Longint;
```

C++

```
__fastcall Longint DrawTextBiDiModeFlagsReadingOnly();
```

Description

Call DrawTextBiDiModeFlagsReadingOnly to determine whether the DT_RTLREADING flag should be added when calling the Windows API DrawText or when assigning the TextFlags property of a canvas.

DrawTextBiDiModeFlagsReadingOnly returns the DT_RTLREADING flag or 0, depending on the value returned from the UseRightToLeftReading (see page 5790) method.

To obtain the text flags that indicate the bi-directional alignment as well as text direction for the control, use DrawTextBiDiModeFlags (see page 5756) instead.

See Also

TextFlags (see page 14495)

DrawTextBiDiModeFlags (see page 5756)

BiDiMode (see page 5803)

Text (see page 5842)

Caption (see page 5806)

UseRightToLeftReading (see page 5790)

32.1.2.5.39 TControl.EndDrag Method

Stops a control from being dragged any further.

Pascal

```
procedure EndDrag(Drop: Boolean);
```

C++

```
__fastcall EndDrag(Boolean Drop);
```

Description

Use EndDrag to stop a dragging operation that began with a call to the BeginDrag (see page 5740) method.

If the Drop parameter is true, the control being dragged is dropped or docked. If the Drop parameter is false, the control is not dropped or docked and dragging is canceled.

See Also

BeginDrag (see page 5740)

OnEndDrag (see page 5860)

OnEndDock (see page 5859)

DragKind (see page 5819)

32.1.2.5.40 TControl.EraseDragDockImage Method

Erases the dock image for the control.

Pascal

```
procedure EraseDragDockImage(DragDockObject: TDragDockObject); dynamic;
```

C++

```
__fastcall EraseDragDockImage(TDragDockObject DragDockObject);
```

Description

DrawDragDockImage (see page 5755) is called automatically to erase the control (or, more typically, the drag rectangle) when the control is manipulated in drag-and-dock operations.

See Also

DefaultDockImage (see page 5747)

EraseDragDockImage

32.1.2.5.41 TControl.GetAction Method

Pascal

```
function GetAction: TBasicAction; virtual;
```

C++

```
virtual __fastcall TBasicAction GetAction();
```

Description

This is GetAction, a member of class TControl.

32.1.2.5.42 TControl.GetActionLinkClass Method

Returns the appropriate action link class that is associated with the control class.

Pascal

```
function GetActionLinkClass: TControlActionLinkClass; dynamic;
```

C++

```
__fastcall TControlActionLinkClass GetActionLinkClass();
```

Description

GetActionLinkClass returns the appropriate class type for the action link used with a control. This class is used internally to create an action link object for the control when it has an associated action. The action link links the action to the control client. Each Action (see page 5797) link class is designed to link specific properties and event handlers of the action to its client, based on the types of properties the client supports.

As implemented in TControl (see page 5724), GetActionLinkClass returns the TControlActionLink (see page 5892) class type, which associates the ShowHint (see page 5840), Caption (see page 5806), Enabled (see page 5821) and Visible (see page 5847) properties and the OnClick (see page 5851) event handler. Descendants of TControl (see page 5724) override this method to specify a descendant of TControlActionLink (see page 5892) that handles their configuration of properties and events.

See Also

TControlActionLink (see page 5892)

ActionLink (see page 5798)

Action (see page 5797)

32.1.2.5.43 TControl.GetClientOrigin Method

Returns the screen coordinates of the top-left corner of the control's client area.

Pascal

```
function GetClientOrigin: TPoint; virtual;
```

C++

```
virtual __fastcall TPoint GetClientOrigin();
```

Description

Override GetClientOrigin to change how the ClientOrigin (see page 5809) is calculated.

The GetClientOrigin method is the protected method for reading the ClientOrigin (see page 5809) property. GetClientOrigin

calculates the ClientOrigin (see page 5809) by adding the control's Left (see page 5830) and Top (see page 5844) values to the ClientOrigin (see page 5809) coordinates of its parent.

See Also

ClientOrigin (see page 5809)

GetClientRect (see page 5759)

Left (see page 5830)

Top (see page 5844)

32.1.2.5.44 TControl.GetClientRect Method

Returns a rectangle defining the client area of the control.

Pascal

```
function GetClientRect: TRect; virtual;
```

C++

```
virtual __fastcall TRect GetClientRect();
```

Description

Override GetClientRect to change how the client area is calculated.

The GetClientRect method is the protected method for reading the ClientRect (see page 5810) property. GetClientRect returns a rectangle with the rectangle's Top (see page 5844) and Left (see page 5830) fields set to zero, and its Bottom and Right fields set to the control's ClientHeight (see page 5808) and ClientWidth (see page 5811), respectively.

See Also

BoundsRect (see page 5803)

ClientHeight (see page 5808)

ClientWidth (see page 5811)

GetClientOrigin (see page 5758)

32.1.2.5.45 TControl.GetControlsAlignment Method

Indicates how text is aligned within the control.

Pascal

```
function GetControlsAlignment: TAlignment; dynamic;
```

C++

```
__fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the alignment of the control. For controls that do not have an Alignment property, GetControlsAlignment returns taLeftJustify.

Note: GetControlsAlignment returns the alignment of text before it is altered by the BiDiMode (see page 5803) property. To check if the alignment should be reversed to reflect the BiDiMode (see page 5803) property, call UseRightToLeftAlignment (see page 5790).

See Also

BiDiMode (see page 5803)

Text (see page 5842)

Caption (see page 5806)

UseRightToLeftAlignment (see page 5790)

32.1.2.5.46 TControl.GetDeviceContext Method

Returns a device context for the control.

Pascal

```
function GetDeviceContext(var WindowHandle: HWnd): HDC; virtual;
```

C++

```
virtual __fastcall HDC GetDeviceContext(HWnd WindowHandle);
```

Description

Call GetDeviceContext to obtain a device context and window handle. Override GetDeviceContext to change how the device context is obtained.

The window handle used by the control is returned in the WindowHandle parameter. GetDeviceContext returns the device context of this, the parent control's window.

C++ Examples:

```
/*
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
*/
class TMyControl : public TColorListBox
{
__published:    // IDE-managed Components
    void __fastcall SaveAsBmp(TFileName fileName);
private:    // User declarations
public:     // User declarations
    __fastcall TMyControl(TComponent* Owner);
};

TForm1 *Form1;
TMyControl *MyControl1;

__fastcall TForm1::TForm1(TComponent* Owner)
    : TForm(Owner)
{
}
__fastcall TMyControl::TMyControl(TComponent* Owner)
    : TColorListBox(Owner)
{
}

typedef struct {
  TLogPalette lpal;
  TPaletteEntry dummy[256];
} LogPal;

void __fastcall TMyControl::SaveAsBmp(TFileName fileName)
```

```
{
  TCanvas *tempCanvas = new TCanvas;
  try
  {
    HWND notUsed;
    tempCanvas->Handle = GetDeviceContext(notUsed);
    TImage *image2save = new TImage(Form1);
    try
    {
      image2save->Height = Height;
      image2save->Width = Width;
      TRect destRect = Rect(0,0,Width,Height);
      TRect sourceRect = destRect;
      image2save->Canvas->CopyRect(destRect, tempCanvas, sourceRect);
      LogPal SysPal;
      SysPal.lpal.palVersion = 0x300;
      SysPal.lpal.palNumEntries = 256;
      GetSystemPaletteEntries(tempCanvas->Handle,0,256,SysPal.lpal.palPalEntry);
      image2save->Picture->Bitmap->Palette = CreatePalette((const tagLOGPALETTE
*)&SysPal.lpal);
      image2save->Picture->SaveToFile(fileName);
    }
    __finally
    {
     delete image2save;
    }
  }
  __finally
  {
    delete tempCanvas;
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MyControl1->SaveAsBmp("../foo.bmp");
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyControl1 = new TMyControl(Form1);
  MyControl1->Parent = Form1;
  MyControl1->Visible  = true;
}
```

Delphi Examples:

```
{
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
}
type
  TMyControl = class(TColorListBox)
    procedure SaveAsBmp(fileName: TFileName);
  end;
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;
```

```
var
  Form1: TForm1;
  MyControl1: TMyControl;
implementation

{$R *.dfm}

type
  LogPal = record
  lpal : TLogPalette;
  dummy:Array[0..255] of TPaletteEntry;
  end;

procedure TMyControl.SaveAsBmp(fileName: TFileName);
var
  Source: TComponent;
  SysPal : LogPal;
  tempCanvas: TCanvas;
  sourceRect, destRect: TRect;
  image2save: TImage;
  notUsed: HWND;
begin
  tempCanvas := TCanvas.Create;
  try
    tempCanvas.Handle := GetDeviceContext(notUsed);
    image2save:=TImage.create(self);
    try
      with image2save do
      begin
        Height := Self.Height;
        Width :=  Self.Width;
        destRect := Rect(0,0,Width,Height);
        sourceRect := destRect;
        Canvas.CopyRect(destRect,tempCanvas,sourceRect);
        SysPal.lPal.palVersion:=$300;
        SysPal.lPal.palNumEntries:=256;
        GetSystemPaletteEntries(
          tempCanvas.Handle,0,256,SysPal.lpal.palPalEntry);
        Picture.Bitmap.Palette:= CreatePalette(Syspal.lpal);
      end;
      image2save.Picture.SaveToFile(fileName);
    finally
     image2save.Free;
    end;
  finally
    tempCanvas.Free;
  end;
end;
procedure TForm1.Button1Click(Sender: TObject);
begin
  MyControl1.SaveAsBmp('foo.bmp');
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  MyControl1:= TMyControl.Create(Form1);
  MyControl1.Parent:= Form1;
  MyControl1.visible := true;
end;
```

See Also

Parent (see page 5832)

WindowHandle (see page 6212)

Handle (see page 14489)

32.1.2.5.47 TControl.GetDockEdge Method

Returns the edge on which another control should be docked when it is dragged over the control.

Pascal

```
function GetDockEdge(MousePos: TPoint): TAlign; dynamic;
```

C++

```
__fastcall TAlign GetDockEdge(TPoint MousePos);
```

Description

Use GetDockEdge to get the edge on which another control should be docked when it is dragged over the control.

MousePos is the position of the mouse.

GetDockEdge is called automatically during drag-and-dock operations involving the control.

See Also

OnEndDock (see page 5859)

OnDockDrop (see page 6214)

ManualDock (see page 5771)

32.1.2.5.48 TControl.GetDragImages Method

Returns the control's image list containing the image to be displayed while dragging.

Pascal

```
function GetDragImages: TDragImageList; virtual;
```

C++

```
virtual __fastcall TDragImageList GetDragImages();
```

Description

Override GetDragImages to provide a custom image list for the control. As implemented in TControl (see page 5724), GetDragImages returns nil (Delphi) or NULL (C++).

See Also

DragCursor (see page 5818)

OnStartDrag (see page 5871)

32.1.2.5.49 TControl.GetEnabled Method

Returns the value of the Enabled (see page 5821) property.

Pascal

```
function GetEnabled: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetEnabled();
```

Description

GetEnabled is the read implementation of the Enabled (see page 5821) property.

Override GetEnabled and SetEnabled (see page 5785) to change the implementation of the Enabled (see page 5821) property. For example, A descendant of TControl (see page 5724) might change the way the Enabled (see page 5821) property interacts with an associated action.

See Also

Enabled (see page 5821)

SetEnabled (see page 5785)

32.1.2.5.50 TControl.GetFloating Method

Returns the value of the Floating (see page 5823) property.

Pascal

```
function GetFloating: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetFloating();
```

Description

GetFloating is the implementation of the read-only Floating (see page 5823) property. GetFloating returns true if the HostDockSite (see page 5829) property is either nil (Delphi) or NULL (C++) or of type FloatingDockSiteClass (see page 5823).

Override this method to change the way a control determines if it is floating.

See Also

Floating (see page 5823)

FloatingDockSiteClass (see page 5823)

HostDockSite (see page 5829)

32.1.2.5.51 TControl.GetFloatingDockSiteClass Method

Returns the class used for the control when it is floating.

Pascal

```
function GetFloatingDockSiteClass: TWinControlClass; virtual;
```

C++

```
virtual __fastcall TWinControlClass GetFloatingDockSiteClass();
```

Description

GetFloatingDockSiteClass is the read implementation of the FloatingDockSiteClass (see page 5823) property. Override this method to change the implementation of FloatingDockSiteClass (see page 5823).

See Also

FloatingDockSiteClass (see page 5823)

32.1.2.5.52 TControl.GetPalette Method

Returns the handle to a palette for use by the control.

Pascal

```
function GetPalette: HPALETTE; dynamic;
```

C++

```
__fastcall HPALETTE GetPalette();
```

Description

As implemented in TControl (see page 5724), GetPalette returns a null handle, indicating that the control does not have a palette. Override GetPalette to implement derived objects that use a palette. Create (see page 5731) a palette handle for the control by a call to the Windows API function CreatePalette. GetPalette should return the palette handle for the control.

Specifying the palette for a control tells the application that the control's palette needs to be realized and designates the palette to use for realization.

GetPalette is called only if the run-time video mode requires color palette support, for example, in 256-color mode.

See Also

PaletteChanged (see page 5775)

32.1.2.5.53 TControl.GetParentComponent Method

Returns the parent of the control.

Pascal

```
function GetParentComponent: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetParentComponent();
```

Description

GetParentComponent is called by the streaming system that loads and saves VCL components. The component returned by GetParentComponent is responsible for loading and saving the control when it is streamed in or out. As implemented in TControl (see page 5724), GetParentComponent returns the value of the Parent (see page 5832) property.

See Also

Parent (see page 5832)

GetParentComponent

SetParentComponent (see page 5787)

HasParent (see page 5768)

32.1.2.5.54 TControl.GetPopupMenu Method

Returns the pop-up menu associated with the control.

Pascal

```
function GetPopupMenu: TPopupMenu; dynamic;
```

C++

```
__fastcall TPopupMenu GetPopupMenu();
```

Description

Call GetPopupMenu to find the popup menu associated with the control. Override GetPopupMenu to change which popup menu is associated with the control or to specify different popup menus depending on the state of the control.

GetPopupMenu returns the value of the Popup property.

See Also

PopupMenu (see page 5835)

32.1.2.5.55 TControl.GetTextBuf Method

Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.

Pascal

```
function GetTextBuf(Buffer: PChar; BufSize: Integer): Integer;
```

C++

```
__fastcall int GetTextBuf(const char * Buffer, int BufSize);
```

Description

Call GetTextBuf to retrieve the text of a control into a fixed size buffer. The text copied is the value of the Text (see page 5842) property. GetTextBuf returns the number of characters that were actually copied, which is either the length of the Text (see page 5842) property, or BufSize - 1, whichever is smaller.

To find out how many characters the buffer needs to hold the entire text, call the GetTextLen (see page 5767) method before allocating a buffer for GetTextBuf.

Note: GetTextBuf is available for compatibility with 16-bit code. Where backward compatibility is not an issue, use the Text (see page 5842) property.

Note: To obtain the control's text as an AnsiString, use the Text (see page 5842) property instead.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                        //Add room for null character
  char *Buffer = new char[Size];  //Creates Buffer dynamic variable
  Edit1->GetTextBuf(Buffer,Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
  delete [] Buffer;
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
```

```
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

GetTextLen (see page 5767)

Text (see page 5842)

32.1.2.5.56 TControl.GetTextLen Method

Returns the length of the control's text.

Pascal

```
function GetTextLen: Integer;
```

C++

```
__fastcall int GetTextLen();
```

Description

Call GetTextLen to find the length of the control's text. This is the size needed for a text buffer to be used by the GetTextBuf (see page 5766) method.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
```

```
  Size++;                        //Add room for null character
  char *Buffer = new char[Size];  //Creates Buffer dynamic variable
  Edit1->GetTextBuf(Buffer,Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
  delete [] Buffer;
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

GetTextBuf (see page 5766)

Text (see page 5842)

32.1.2.5.57 TControl.HasParent Method

Indicates whether the control has a parent.

Pascal

```
function HasParent: Boolean; override;
```

C++

```
virtual __fastcall Boolean HasParent();
```

Description

HasParent indicates whether the Parent (see page 5832) property has been assigned a value. This method is used by the streaming system to determine whether the control has a parent that is responsible for writing it to a stream. As implemented in TControl (see page 5724), HasParent returns true if the Parent (see page 5832) property is not nil (Delphi) or NULL (C++),

and false otherwise.

See Also

GetParentComponent (see page 5765)

SetParentComponent (see page 5787)

Parent (see page 5832)

32.1.2.5.58 TControl.Hide Method

Makes the control invisible.

Pascal

```
procedure Hide;
```

C++

```
__fastcall Hide();
```

Description

Call Hide to hide a control. Hide sets the Visible (see page 5847) property of the control to false.

Although a control that is hidden is not visible, its properties and methods are still available.

See Also

Show (see page 5788)

Visible (see page 5847)

32.1.2.5.59 TControl.InitiateAction Method

Calls the action link's Update (see page 5789) method if the control is associated with an action link.

Pascal

```
procedure InitiateAction; virtual;
```

C++

```
virtual __fastcall InitiateAction();
```

Description

When the application is idle, the library makes a series of calls to allow controls to update their associated actions so that they reflect the current properties of the controls. The first of these is to the InitiateAction method of the each form, followed by the InitiateAction methods of its visible menus and controls.

InitiateAction calls the action's update method indirectly (through its action link), which leads to a number of events, any of which may update the action and stop the update process:

1.First, the action list that contains the action receives an OnUpdate event.

2.If the action list does not handle the OnUpdate event, then the Application object receives an OnActionUpdate event.

3.If the OnActionUpdate event handler does not update the action, the action itself receives an OnUpdate event.

4.If that does not update the action, the active control's UpdateAction method is called.

5. Finally, if the action is still not updated, the active form's UpdateAction method is called.

See Also

OnActionUpdate (see page 13726)

Action (see page 5797)

ActionLink (see page 5798)

UpdateAction

OnUpdate (see page 327)

OnUpdate (see page 2718)

Update (see page 2714)

32.1.2.5.60 TControl.Invalidate Method

Completely repaint control.

Pascal

```
procedure Invalidate; virtual;
```

C++

```
virtual __fastcall Invalidate();
```

Description

Use Invalidate when the entire control needs to be repainted. When more than one region within the control needs repainting, Invalidate will cause the entire window to be repainted in a single pass, avoiding flicker caused by redundant repaints. There is no performance penalty for calling Invalidate multiple times before the control is actually repainted.

See Also

Refresh (see page 5779)

Repaint (see page 5779)

Update (see page 5789)

32.1.2.5.61 TControl.IsRightToLeft Method

Indicates whether the control should be reversed right to left.

Pascal

```
function IsRightToLeft: Boolean;
```

C++

```
__fastcall Boolean IsRightToLeft();
```

Description

Use IsRightToLeft to determine whether the control should be reversed in any way because it is running on a system with a Middle Eastern locale. IsRightToLeft is intended for component writers to ease the process of implementing the BiDiMode (see page 5803) property.

IsRightToLeft returns true if the application is running on a Middle East-enabled version of Windows and the BiDiMode (see page 5803) property indicates that the control should make any adjustments.

See Also

BiDiMode (see page 5803)

UseRightToLeftReading (see page 5790)

UseRightToLeftAlignment (see page 5790)

UseRightToLeftScrollBar (see page 5791)

32.1.2.5.62 TControl.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action (see page 5797). To change the properties the control copies from its action, override the ActionChange (see page 5737) method.

See Also

Loaded (see page 2782)

Action (see page 5797)

ActionChange (see page 5737)

32.1.2.5.63 TControl.ManualDock Method

Docks the control.

Pascal

```
function ManualDock(NewDockSite: TWinControl; DropControl: TControl = nil; ControlSide: TAlign
= alNone): Boolean;
```

C++

```
__fastcall Boolean ManualDock(TWinControl * NewDockSite, TControl * DropControl = nil, TAlign
ControlSide = alNone);
```

Description

Use ManualDock to dock the control programmatically. ManualDock undocks the control from its current dock site, then docks the control to its new dock site.

NewDockSite is the control's new dock site.

DropControl is the control in the new dock site, if any, on which to drop the control. For example, when docking to a page control, DropControl would be a tab sheet.

ControlSide specifies on which side of DropControl or NewDockSite (if DropControl is nil (Delphi) or NULL (C++)) the control should be docked. This value can be obtained by calling the dock site's GetDockEdge (see page 5763) method.

See Also

ManualFloat (see page 5772)

GetDockEdge (see page 5763)

32.1.2.5.64 TControl.ManualFloat Method

Undocks the control.

Pascal

```
function ManualFloat(ScreenPos: TRect): Boolean;
```

C++

```
__fastcall Boolean ManualFloat(TRect ScreenPos);
```

Description

Use ManualFloat to undock the control programmatically.

ScreenPos is the rectangle in which the control is displayed when it starts floating.

C++ Examples:

```
{
This example shows how to undock a dockable object.  This example
is part of the Docking Demo.
}

void __fastcall TTabDockHost::FormClose(TObject *Sender, TCloseAction &Action)
{
  TRect ARect;
  TPoint point;
  if (PageControl1->DockClientCount == 1)
  {
    point =  PageControl1->DockClients[0]->ClientToScreen(Point(0, 0));
    ARect.left = point.x;
    ARect.top = point.y;
    point = PageControl1->DockClients[0]->ClientToScreen(
      Point(PageControl1->DockClients[0]->UndockWidth,
PageControl1->DockClients[0]->UndockHeight));
    ARect.right = point.x;
    ARect.bottom = point.y;
    PageControl1->DockClients[0]->ManualFloat(ARect);
    Action = caFree;
  }
  else
    Action = caHide;
}
```

Delphi Examples:

```
procedure TTabDockHost.FormClose(Sender: TObject;
  var Action: TCloseAction);
var
  ARect: TRect;
begin
  if PageControl1.DockClientCount = 1 then
  begin
    with PageControl1.DockClients[0] do
    begin
      ARect.TopLeft := ClientToScreen(Point(0, 0));
      ARect.BottomRight := ClientToScreen(Point(UndockWidth, UndockHeight));
      ManualFloat(ARect);
    end;
    Action := caFree;
  end else
    Action := caHide;
end;
```

See Also

ManualDock (see page 5771)

Floating (see page 5823)

32.1.2.5.65 TControl.MouseActivate Method

Pascal

```
function MouseActivate(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer;
HitTest: Integer): TMouseActivate; dynamic;
```

C++

```
__fastcall TMouseActivate MouseActivate(TMouseButton Button, TShiftState Shift, int X, int Y,
int HitTest);
```

Description

This is MouseActivate, a member of class TControl.

32.1.2.5.66 TControl.MouseDown Method

OnMouseDown (see page 5862) event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown (see page 5862) event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

See Also

MouseMove (see page 5773)

MouseUp (see page 5774)

OnMouseDown (see page 5862)

32.1.2.5.67 TControl.MouseMove Method

Respond to mouse moving over control area..

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseMove method to provide other responses in addition to calling the OnMouseMove (see page 5865) event handler when the user moves the mouse.

A control calls MouseMove in response to any of the Windows mouse-move messages (WM_MOUSEMOVE), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively.

As the mouse cursor moves across a control, this method is called repeatedly. Each time it is called, it is with the new coordinates that reflect the continuous path of the mouse cursor across the screen real estate covered by the control's visual representation.

See Also

MouseDown (see page 5773)

MouseUp (see page 5774)

OnMouseMove (see page 5865)

32.1.2.5.68 TControl.MouseUp Method

OnMouseUp (see page 5867) event dispatcher.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown (see page 5773) method to provide other responses in addition to calling the OnMouseDown (see page 5862) event handler when the user releases a previously pressed mouse button while the cursor's hotspot is over the control.

A control calls MouseUp in response to any of the Windows mouse-up messages (WM_LBUTTONUP, WM_MBUTTONUP, WM_RBUTTONUP), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was released: left, right, or middle

See Also

MouseDown (see page 5773)

MouseMove (see page 5773)

OnMouseUp (see page 5867)

32.1.2.5.69 TControl.MouseWheelHandler Method

Dispatches messages received from a mouse wheel.

Pascal

```
procedure MouseWheelHandler(var Message: TMessage); dynamic;
```

C++

```
__fastcall MouseWheelHandler(TMessage Message);
```

Description

The WndProc (see page 5791) method calls MouseWheelHandler when it receives a mouse wheel message. MouseWheelHandler checks whether the windowed control is embedded in a form, and if so, calls the form's MouseWheelHandler method. This allows the form to respond to mouse wheel messages before they are handled by individual controls. If the windowed control is not in a form, MouseWheelHandler passes the mouse wheel message to the Perform (see page 5776) method, which generates an OnMouseWheel (see page 5869) event, followed (if necessary) by an OnMouseWheelUp (see page 5870) or OnMouseWheelDown (see page 5869) event.

See Also

MouseWheelHandler (see page 13881)

OnMouseWheel (see page 5869)

Perform (see page 5776)

WndProc (see page 6187)

OnMouseWheelUp (see page 5870)

OnMouseWheelDown (see page 5869)

32.1.2.5.70 TControl.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl (see page 5724) to update its PopupMenu (see page 5835) property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

32.1.2.5.71 TControl.PaletteChanged Method

Responds to changes in the system's palette by realizing the control's palette.

Pascal

```
function PaletteChanged(Foreground: Boolean): Boolean; dynamic;
```

C++

```
__fastcall Boolean PaletteChanged(Boolean Foreground);
```

Description

Override PaletteChanged to change how the control responds to Windows notifications that the system palette is changing. TControl (see page 5724) responds to these notifications by trying to realize the control's palette, if any, into the current device context. If the change in the system palette causes the actual value of the control's palette to change, PaletteChanged invalidates the control so that it can repaint with the new palette.

Windows paints the active window with a foreground palette, while other windows are forced to use background palettes. Background palettes are approximate matches to the colors specified by the control's logical palette, given the limitations imposed by implementing the foreground palette. Windows only allows a single foreground palette.

PaletteChanged allows the control to obtain a new realization of its palette when the system palette changes. When Foreground is true, the form has been activated and the control is specifying the new foreground palette. When Foreground is false, another application or form has changed the foreground palette, and controls that are sensitive to the available palette should realize new background palettes to best match their logical palettes.

If the control does not have a logical palette to be realized into the current device context, GetPalette (see page 5765) returns a handle of 0, and PaletteChanged returns false, indicating that no palette was realized. If GetPalette (see page 5765) returns the handle to a logical palette, PaletteChanged realizes this palette into the current device context, and returns true.

Note: PaletteChanged is called only when the runtime video mode requires palette support, such as for 256 color mode, but not 16 million color mode.

See Also

GetDeviceContext (see page 5760)

GetPalette (see page 5765)

32.1.2.5.72 TControl.ParentToClient Method

Translate parent coordinates to client coordinates.

Pascal

```
function ParentToClient(const Point: TPoint; AParent: TWinControl = nil): TPoint;
```

C++

```
__fastcall TPoint ParentToClient(const TPoint Point, TWinControl * AParent = nil);
```

Description

ParentToClient translates Point from the AParent's coordinate system to the current control's coordinate system. AParent must be a control that can be found by iterating up the chain of Parent (see page 5832) properties. If AParent is nil (Delphi) or NULL (C++), the control's immediate parent is used.

An EInvalidOperation exception is thrown if AParent is not an ancestor control or the Parent (see page 5832) property is nil (Delphi) or NULL (C++).

See Also

ClientToParent (see page 5744)

32.1.2.5.73 TControl.Perform Method

Responds as if the control received a specified Windows message.

Pascal

```
function Perform(Msg: Cardinal; WParam: Longint; LParam: Longint): Longint;
```

C++

```
__fastcall Longint Perform(unsigned Msg, Longint WParam, Longint LParam);
```

Description

Call Perform to bypass the Windows message queue and send a message directly to the control's window procedure.

Perform fills a message record (of type TMessage) with the message ID passed in the Msg parameter, the message parameters passed in WParam and LParam, and a result field of zero. Perform then passes the message record to the WindowProc (see page 5872) method for processing.

C++ Examples:

```
/*
The following example demonstrates the use of the Perform method
to send a windows message. The EM_SCROLLCARET message scrolls the
caret in the rich edit into view. The caret position is set to the
contents of the mask edit prior to calling Perform.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    RichEdit1->SelStart = StrToInt(MaskEdit1->Text);
    Edit1->Text = IntToStr(RichEdit1->SelStart);
    RichEdit1->Perform(EM_SCROLLCARET, 0, 0);
    RichEdit1->SetFocus();
}
```

Delphi Examples:

```
{
The following example demonstrates the use of the Perform method
to send a windows message. The EM_SCROLLCARET message scrolls the
caret in the rich edit into view. The caret position is set to the
contents of the mask edit prior to calling Perform.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
with RichEdit1 do
  Begin
    SelStart := StrToInt(MaskEdit1.Text);
    Edit1.Text := InttoStr(SelStart);
    RichEdit1.Perform(EM_SCROLLCARET, 0, 0);
    RichEdit1.SetFocus;
  end;
end;
```

See Also

WindowProc (see page 5872)

TMessage

32.1.2.5.74 TControl.PositionDockRect Method

Positions the docking rectangle according to the current drag-and-dock state.

Pascal

```
procedure PositionDockRect(DragDockObject: TDragDockObject); dynamic;
```

C++

```
__fastcall PositionDockRect(TDragDockObject DragDockObject);
```

Description

Use PositionDockRect to adjust the docking rectangle of the drag-and-dock object specified by DragDockObject. DragDockObject's DockRect property is updated to reflect the current drag-and-dock state. This updating process makes use of the UndockWidth (see page 5846), UndockHeight (see page 5845), LRDockWidth (see page 5831), or TBDockHeight (see page 5842) property, as appropriate.

See Also

AdjustDockRect (see page 6012)

UndockWidth (see page 5846)

UndockHeight (see page 5845)

LRDockWidth (see page 5831)

TBDockHeight (see page 5842)

DockRect (see page 6015)

PositionDockRect (see page 6242)

32.1.2.5.75 TControl.ReadState Method

Prepares the control for having its properties assigned values read from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

ReadState is part of a sequence of calls used by the streaming system that loads and saves component state. It reads the values of all the control's published properties, stored data, and owned components from the reader object passed in Reader.

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Remember to include a call to the inherited class's method when overriding ReadState.

As implemented in TControl (see page 5724), ReadState assigns the Reader parameter's Parent (see page 5832) property to the control's own Parent (see page 5832) property before calling the inherited ReadState method of TComponent. Finally, ReadState synchronizes the Font (see page 5823), Color (see page 5812), and ShowHint (see page 5840) properties with the parent control, as indicated by the ParentFont (see page 5834), ParentColor (see page 5834), and ParentShowHint (see page 5835) properties, respectively.

See Also

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

ReadState

TReader (see page 2933)

32.1.2.5.76 TControl.Refresh Method

Repaints the control on the screen.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh method to repaint the control immediately. Refresh calls the Repaint (see page 5779) method. Use the Refresh and Repaint (see page 5779) methods interchangeably.

See Also

Invalidate (see page 5770)

Parent (see page 5832)

Repaint (see page 5779)

Update (see page 5789)

32.1.2.5.77 TControl.Repaint Method

Forces the control to repaint its image on the screen.

Pascal

```
procedure Repaint; virtual;
```

C++

```
virtual __fastcall Repaint();
```

Description

Call Repaint to force the control to repaint its image immediately. If the ControlStyle (see page 5814) property includes csOpaque, the control paints itself directly. Otherwise, the Repaint method calls the Invalidate (see page 5770) method and then the Update (see page 5789) method so that any visible portions of controls beneath the control will be repainted as well.

See Also

ControlStyle (see page 5814)

GetDeviceContext (see page 5760)

Invalidate (see page 5770)

Parent (see page 5832)

Update (see page 5789)

32.1.2.5.78 TControl.ReplaceDockedControl Method

Docks the control in the place where another control is already docked.

Pascal

```
function ReplaceDockedControl(Control: TControl; NewDockSite: TWinControl; DropControl:
TControl; ControlSide: TAlign): Boolean;
```

C++

```
__fastcall Boolean ReplaceDockedControl(TControl * Control, TWinControl * NewDockSite,
TControl * DropControl, TAlign ControlSide);
```

Description

Call ReplaceDockedControl to replace a control that is already docked while moving that control to another dock site.

Control is the control whose place this control is taking.

NewDockSite is the new dock site for the control that is replaced.

DropControl is a control in the new dock site on which to drop the control that is replaced. For example, if NewDockSite were a page control, DropControl would be a tab sheet.

ControlSide specifies on which side of DropControl or NewDockSite (if DropControl is nil (Delphi) or NULL (C++)) the replaced control should be docked. This value can be obtained by calling the dock site's GetDockEdge (see page 5763) method.

ReplaceDockedControl does the same thing as calling the ManualDock (see page 5771) method of the control specified by the Control parameter (using the values of NewDockSite, DropControl, and ControlSide) in addition to calling ManualDock (see page 5771) for the control whose method this is, docking it in the current position of the Control parameter. However, calling ReplaceDockedControl is more efficient, and prevents unnecessary flicker.

See Also

ManualDock (see page 5771)

32.1.2.5.79 TControl.RequestAlign Method

Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.

Pascal

```
procedure RequestAlign; virtual;
```

C++

```
virtual __fastcall RequestAlign();
```

Description

Controls (see page 5711) call RequestAlign internally when changes are made to the size or position of the control, so that they remain properly aligned within the parent control. Do not call RequestAlign in application code.

See Also

Align (see page 5798)

Parent (see page 5832)

32.1.2.5.80 TControl.Resize Method

Respond to control resize.

Pascal

```
procedure Resize; dynamic;
```

C++

```
__fastcall Resize();
```

Description

Resize is called automatically immediately after the control's dimensions change. As implemented in TControl (see page 5724), Resize calls the control's OnResize (see page 5870) event handler if it is assigned.

See Also

OnResize (see page 5870)

32.1.2.5.81 TControl.ScaleConstraints Method

Pascal

```
procedure ScaleConstraints(M: Integer; D: Integer);
```

C++

```
__fastcall ScaleConstraints(int M, int D);
```

Description

This is ScaleConstraints, a member of class TControl.

32.1.2.5.82 TControl.ScreenToClient Method

Converts the screen coordinates of a specified point on the screen to client coordinates.

Pascal

```
function ScreenToClient(const Point: TPoint): TPoint;
```

C++

```
__fastcall TPoint ScreenToClient(const TPoint Point);
```

Description

Use ScreenToClient to convert a point in screen coordinates to local, or client area, coordinates. In client area coordinates (0, 0) corresponds to the upper left corner of the control's client area. In screen coordinates (0, 0) corresponds to the upper left corner of the screen.

Use ScreenToClient along with ClientToScreen (see page 5744) to convert from one control's coordinate system to another control's coordinate system. For example,

```
P := TargetControl.ScreenToClient(SourceControl.ClientToScreen(P));
P = TargetControl->ScreenToClient(SourceControl->ClientToScreen(P));
```

converts P from coordinates in SourceControl to coordinates in TargetControl.

See Also

ClientToScreen (see page 5744)

32.1.2.5.83 TControl.SendCancelMode Method

Cancels the modal state of the control.

Pascal

```
procedure SendCancelMode(Sender: TControl);
```

C++

```
__fastcall SendCancelMode(TControl * Sender);
```

Description

Call SendCancelMode to cancel the modal state of the control. Various controls implemented in the VCL support a model state where the user must respond to the control before interacting with any other object on the form. An example is the dropped-down state of a combo box when the drop-down list is showing. For these controls, specific user actions send a Windows message to the control to end the model state, such as a mouse click that closes up the dropped-down list.

SendCancelMode allows an application to end the modal state of the control in the absence of a user action, or when implementing a new user interface response.

See Also

Perform (see page 5776)

DroppedDown

32.1.2.5.84 TControl.SendDockNotification Method

Sends a Windows message to the control's host dock site.

Pascal

```
procedure SendDockNotification(Msg: Cardinal; WParam: Integer; LParam: Integer);
```

C++

```
__fastcall SendDockNotification(unsigned Msg, int WParam, int LParam);
```

Description

Use SendDockNotification to send a Windows message to the control's host dock site.

SendDockNotification is called automatically when the control's text or visibility changes.

See Also

WindowProc (see page 5872)

TMessage

WndProc (see page 6187)

32.1.2.5.85 TControl.SendToBack Method

Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.

Pascal

```
procedure SendToBack;
```

C++

```
__fastcall SendToBack();
```

Description

Use SendToBack to change the order of overlapping controls or forms.

The order in which controls stack on top of each other (also called the Z order) depends on the order the controls are placed on the form. For example, if you put a label and an image on a form so that one is on top of the other, the one that was placed first

on the form becomes the one on the bottom. Because both the label and the image are non-windowed controls, they "stack" as you would expect them to. Call the SendToBack method for the top object to move it below the other object.

The stacking order of two windowed controls is the same as the stacking of two non-windowed controls. For example, if you put a memo on a form, then put a check box on top of it, the check box remains on top. Calling SendToBack for the check box makes the memo appear on top.

The stacking order of windowed and non-windowed controls cannot be mingled. For example, if you put a memo, a windowed control, on a form, and then put a label, a non-windowed control, on top of it, the label disappears behind the memo. Windowed controls always stack on top of non-windowed controls. In this example, calling the SendToBack method of the memo does nothing, the label remains behind the memo.

If the control has the input focus when the SendToBack method executes, it loses the input focus.

See Also

BringToFront (see page 5740)

32.1.2.5.86 TControl.SetAutoSize Method

Pascal

```
procedure SetAutoSize(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

This is SetAutoSize, a member of class TControl.

32.1.2.5.87 TControl.SetBiDiMode Method

Sets the control's bi-directional mode.

Pascal

```
procedure SetBiDiMode(Value: TBiDiMode); virtual;
```

C++

```
virtual __fastcall SetBiDiMode(TBiDiMode Value);
```

Description

SetBiDiMode is the write implementation of the control's BiDiMode (see page 5803) property. Override this method to change the implementation of BiDiMode (see page 5803).

See Also

BiDiMode (see page 5803)

32.1.2.5.88 TControl.SetBounds Method

Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer); virtual;
```

C++

```
virtual __fastcall SetBounds(int ALeft, int ATop, int AWidth, int AHeight);
```

Description

Use SetBounds to change all of the component's boundary properties at one time. The same effect can be achieved by setting the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties separately, but SetBounds changes all four properties at once ensuring that the control will not repaint between changes.

Specify the values for the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties as the value of the ALeft, ATop, AWidth, and AHeight parameters, respectively.

Calling SetBounds does not necessarily result in the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties changing to the specified values. Before the properties are changed, the AutoSize (see page 5803) or Constraints (see page 5812) property may limit the changes, and an OnCanResize (see page 5851) (or OnConstrainedResize (see page 5853)) event handler may change the new values. After the control's Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties are changed, SetBounds generates an OnResize (see page 5870) event.

Note: Component writers can change the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties while bypassing all resize events and constraint or autosize logic by using the UpdateBoundsRect (see page 5789) method instead.

See Also

Height (see page 5825)

Left (see page 5830)

Top (see page 5844)

Width (see page 5849)

BoundsRect (see page 5803)

AutoSize (see page 5803)

Constraints (see page 5812)

OnCanResize (see page 5851)

OnConstrainedResize (see page 5853)

OnResize (see page 5870)

UpdateBoundsRect (see page 5789)

32.1.2.5.89 TControl.SetDesignVisible Method

Makes a control visible at design time.

Pascal

```
procedure SetDesignVisible(Value: Boolean); dynamic;
```

C++

```
__fastcall SetDesignVisible(Boolean Value);
```

Description

SetDesignVisible is used internally by Delphi during form design.

See Also

TComponentState

32.1.2.5.90 TControl.SetDragMode Method

Sets the drag mode for the control.

Pascal

```
procedure SetDragMode(Value: TDragMode); virtual;
```

C++

```
virtual __fastcall SetDragMode(TDragMode Value);
```

Description

SetDragMode is the protected write implementation for the DragMode (see page 5819) property. Override SetDragMode to execute additional code when the value of the DragMode (see page 5819) property changes.

See Also

DragMode (see page 5819)

32.1.2.5.91 TControl.SetEnabled Method

Sets the value of the Enabled (see page 5821) property.

Pascal

```
procedure SetEnabled(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetEnabled(Boolean Value);
```

Description

SetEnabled is the protected write implementation of the Enabled (see page 5821) property. After changing the internal representation of the Enabled (see page 5821) property, SetEnabled sends a Windows message back to the control so that it can respond to the change. When TControl (see page 5724) receives this message, it invalidates the control so that its appearance reflects the change (for example, so that it appears grayed). Some descendants respond to this message in other ways (for example, windowed controls ensure that a disabled control does not have focus).

Override GetEnabled (see page 5763) and SetEnabled to change the implementation of the Enabled (see page 5821) property. For example, A descendant of TControl (see page 5724) might change the way the Enabled (see page 5821) property interacts with an associated action. When overriding SetEnabled, be sure to call the inherited method.

See Also

GetEnabled (see page 5763)

Enabled (see page 5821)

Invalidate (see page 5770)

32.1.2.5.92 TControl.SetName Method

Sets the name of the control.

Pascal

```
procedure SetName(const Value: TComponentName); override;
```

C++

```
virtual __fastcall SetName(const TComponentName Value);
```

Description

SetName is the protected write implementation of the Name property. TControl (see page 5724) updates the Text (see page 5842) or Caption (see page 5806) property, if appropriate, after changing the value of Name.

Override SetName to execute additional code when the value of the Name property changes.

See Also

Name

Caption (see page 5806)

Text (see page 5842)

32.1.2.5.93 TControl.SetParent Method

Sets the parent of the control.

Pascal

```
procedure SetParent(AParent: TWinControl); virtual;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent (see page 5832) property. Override SetParent to execute additional code when the value of the Parent (see page 5832) property changes.

The AParent parameter specifies the new parent of the control.

If the control already has a parent, SetParent removes the control from that parent's list of controls by calling the parent's RemoveControl method. If AParent is not nil (Delphi) or NULL (C++), SetParent calls its InsertControl method to add the control to its list of controls.

The TControl (see page 5724) destructor calls SetParent(nil (Delphi) or NULL (C++)) to remove the control from its parent's control list before destroying the component.

See Also

Destroy (see page 5732)

InsertControl (see page 6160)

Parent (see page 5832)

RemoveControl (see page 6172)

32.1.2.5.94 TControl.SetParentBiDiMode Method

Specifies whether the control uses its parent's BiDiMode (see page 5803).

Pascal

```
procedure SetParentBiDiMode(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetParentBiDiMode(Boolean Value);
```

Description

SetParentBiDiMode is the protected write implementation of the ParentBiDiMode (see page 5833) property.

See Also

ParentBiDiMode (see page 5833)

32.1.2.5.95 TControl.SetParentComponent Method

Sets the parent for the control.

Pascal

```
procedure SetParentComponent(Value: TComponent); override;
```

C++

```
virtual __fastcall SetParentComponent(TComponent * Value);
```

Description

Do not call the SetParentComponent method. It is used by the streaming system that loads and saves VCL components. SetParentComponent makes the component specified by the Value parameter the parent of the control.

SetParentComponent calls the SetParent (see page 5786) method only if the component specified as the parent is a windowed control.

See Also

HasParent (see page 5768)

SetParent (see page 5786)

GetParentComponent (see page 5765)

SetParentComponent

32.1.2.5.96 TControl.SetTextBuf Method

Sets the text of the control.

Pascal

```
procedure SetTextBuf(Buffer: PChar);
```

C++

```
__fastcall SetTextBuf(const char * Buffer);
```

Description

Call the SetTextBuf method to set the text of the control to the text in the specified buffer.

The text is set to the text in the buffer pointed to by the Buffer parameter. Buffer must point to a null-terminated string. The SetTextBuf method sends the WM_SETTEXT and CM_TEXTCHANGED (see page 6349) messages. If done in the tight execution of a function, this could result in the change not being seen until messages from the Windows message queue being processed after the function finishes executing. To interrupt a function's execution and process messages, use the ProcessMessages method of the Application object.

Note: The SetTextBuf method is provided for backwards compatibility only. To set the text of a control now, assign a string

value to the Text (see page 5842) property.

See Also

Text (see page 5842)

application

ProcessMessages (see page 13691)

32.1.2.5.97 TControl.SetZOrder Method

Repositions the control in its parent's control list, thereby changing position onscreen.

Pascal

```
procedure SetZOrder(TopMost: Boolean); dynamic;
```

C++

```
__fastcall SetZOrder(Boolean TopMost);
```

Description

Call SetZOrder to change the z-order of the control. To make the control the topmost control, specify the TopMost value as true. To make the control the bottommost, set TopMost to false.

After changing the order, SetZOrder invalidates the control to ensure repainting to reflect the new order.

The stacking order of windowed and non-windowed controls cannot be mingled. For example, if you put a memo, a windowed control, on a form, and then put a label, a non-windowed control, on top of it, the label disappears behind the memo. Windowed controls always stack on top of non-windowed controls. In this example, calling the SetZOrder method of the label or the memo has no effect, the label always remains behind the memo.

See Also

BringToFront (see page 5740)

Invalidate (see page 5770)

SendToBack (see page 5782)

32.1.2.5.98 TControl.Show Method

Makes a control visible.

Pascal

```
procedure Show;
```

C++

```
__fastcall Show();
```

Description

Use the Show method to make visible a control that was previously hidden.

The Show method sets the control's Visible (see page 5847) property to true and ensures that the parent control is also visible.

See Also

Hide (see page 5769)

Visible (see page 5847)

32.1.2.5.99 TControl.Update Method

Processes any pending paint messages immediately.

Pascal

```
procedure Update; virtual;
```

C++

```
virtual __fastcall Update();
```

Description

Call Update to force the control to be repainted before any more, possibly time-consuming, processing takes place. Use Update to provide immediate feedback to the user that cannot wait for the Windows paint message to arrive.

Update does not invalidate the control, but simply forces a repaint of any regions that have already been invalidated. Call Repaint (see page 5779) instead to invalidate the control as well.

See Also

Invalidate (see page 5770)

Refresh (see page 5779)

Repaint (see page 5779)

32.1.2.5.100 TControl.UpdateBoundsRect Method

Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.

Pascal

```
procedure UpdateBoundsRect(const R: TRect);
```

C++

```
__fastcall UpdateBoundsRect(const TRect R);
```

Description

UpdateBoundsRect is used internally by controls to stay synchronized with changes made by the underlying Windows screen object. UpdateBoundsRect updates the properties to match those passed in the rectangle as the R parameter.

See Also

BoundsRect (see page 5803)

SetBounds (see page 5783)

32.1.2.5.101 TControl.UpdateExplicitBounds Method

Pascal

```
procedure UpdateExplicitBounds;
```

C++

```
__fastcall UpdateExplicitBounds();
```

Description

This is UpdateExplicitBounds, a member of class TControl.

32.1.2.5.102 TControl.UseRightToLeftAlignment Method

Specifies whether the control's alignment should be reversed right-to-left.

Pascal

```
function UseRightToLeftAlignment: Boolean; dynamic;
```

C++

```
__fastcall Boolean UseRightToLeftAlignment();
```

Description

Controls (see page 5711) call UseRightToLeftAlignment when implementing the BiDiMode (see page 5803) property. UseRightToLeftAlignment indicates whether the control's alignment should be reversed right-to-left. This information can be used when painting the control or when responding to mouse events.

UseRightToLeftAlignment returns true if the application is running on a system with a Middle Eastern locale and the BiDiMode (see page 5803) property is bdRightToLeft. Otherwise, it returns false. Descendants override UseRightToLeftAlignment if alignment in Middle Eastern locales depends on other factors.

See Also

BiDiMode (see page 5803)

GetControlsAlignment (see page 5759)

Text (see page 5842)

Caption (see page 5806)

32.1.2.5.103 TControl.UseRightToLeftReading Method

Specifies whether the control is using a right-to-left reading order.

Pascal

```
function UseRightToLeftReading: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftReading();
```

Description

Controls (see page 5711) call UseRightToLeftReading when implementing the BiDiMode (see page 5803) property. UseRightToLeftReading indicates whether the control's text should read from right to left. This information can be used to determine which style flags to set for the control when it is created and which flags to set for drawing text.

UseRightToLeftReading returns true if the application is running on a system with a Middle Eastern locale and the BiDiMode (see page 5803) property is not bdLeftToRight. UseRightToLeftReading returns falseotherwise.

See Also

BiDiMode (see page 5803)

Text (see page 5842)

Caption (see page 5806)

DrawTextBiDiModeFlags (see page 5756)

DrawTextBiDiModeFlagsReadingOnly (see page 5756)

32.1.2.5.104 TControl.UseRightToLeftScrollBar Method

Specifies whether the vertical scroll bar appears on the left side of the control.

Pascal

```
function UseRightToLeftScrollBar: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftScrollBar();
```

Description

Controls (see page 5711) call UseRightToLeftScrollBar when implementing the BiDiMode (see page 5803) property. UseRightToLeftScrollBar returns true when the vertical scroll bar appears on the left side of the control, and false when it appears on the right.

UseRightToLeftScrollBar returns true if the application is running on a system with a Middle Eastern locale and the BiDiMode (see page 5803) property is bdRightToLeft or bdRightToLeftNoAlign.

See Also

BiDiMode (see page 5803)

32.1.2.5.105 TControl.VisibleChanging Method

Provides the interface for a method that responds to changes in the control's visibility.

Pascal

```
procedure VisibleChanging; dynamic;
```

C++

```
__fastcall VisibleChanging();
```

Description

VisibleChanging is called before the value of a control's Visible (see page 5847) property changes. As implemented in TControl (see page 5724), it does nothing. Override VisibleChanging to respond to changes in the control's visibility. For example, if a control should not change its visibility, override VisibleChanging to raise an exception when an attempt is made to alter the control's visibility.

See Also

Visible (see page 5847)

32.1.2.5.106 TControl.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc (see page 5872) property is initialized to WndProc.

WndProc implements the mouse behavior specified by the ControlStyle (see page 5814) and DragMode (see page 5819) properties, and updates the ControlState (see page 5813) property. It passes any unhandled messages on to the Dispatch method.

When overriding WndProc to provide specialized responses to messages, be sure to call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/
class TMyListBoxDescendant : public TListBox
{
__published:    // IDE-managed Components

32.1.2.6 TControl Properties

The properties of the TControl class are listed here.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowText (see page 5850)	Contains the text string of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Constraints (see page 5812)	Specifies the size constraints for the control.

	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Parent (see page 5832)	Indicates the parent of the control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	Visible (see page 5847)	Determines whether the component appears onscreen.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.2.6.1 TControl.Action Property

Designates the action associated with the control.

Pascal

```
property Action: TBasicAction;
```

C++

```
__property TBasicAction Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick (see page 5851) event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

32.1.2.6.2 TControl.ActionLink Property

Contains the action link object associated with the control.

Pascal

```
property ActionLink: TControlActionLink;
```

C++

```
__property TControlActionLink ActionLink;
```

Description

ActionLink handles the association between the control and the action specified by the Action (see page 5797) property. The action link determines which properties and events of the action object determine the values of corresponding properties and events of the control.

Most applications do not use the ActionLink property. Component writers can change this property in TControl (see page 5724) descendants to be a custom descendant of TControl (see page 5724) ActionLink that handles a desired configuration of properties and events.

See Also

TBasicAction (see page 2707)

Action (see page 5797)

32.1.2.6.3 TControl.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors (see page 5802) property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
```

```

32.1.2.6.4 TControl.AlignWithMargins Property

Indicates whether a control should be constrained by margins.

Pascal

```
property AlignWithMargins: Boolean;
```

C++

```
__property Boolean AlignWithMargins;
```

Description

If AlignWithMargins is true, use the Margins (see page 5831) property of the control to govern the spacing relative to other controls that are aligned with this one. The controls are not allowed to be any closer than the spacing specified in Margins (see page 5831). This spacing is maintained as controls are moved when the parent control resizes.

AlignWithMargins is **true** if the style **csAlignWithMargins**, a TControlStyle (see page 6303) type, is in the control's ControlStyle (see page 5814) property and false otherwise.

TMargins (see page 6087)

ControlStyle (see page 5814)

Margins (see page 5831)

TControlStyle

32.1.2.6.5 TControl.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align (see page 5798) property instead. Unlike Anchors, Align (see page 5798) allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

32.1.2.6.6 TControl.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

32.1.2.6.7 TControl.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

32.1.2.6.8 TControl.BoundsRect Property

Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.

Pascal

```
property BoundsRect: TRect;
```

C++

```
__property TRect BoundsRect;
```

Description

Use BoundsRect as a quick way to obtain the pixel locations of all corners of the control all at once.

For example, the statement

```
R := Control.BoundsRect;
R = Control->BoundsRect;
```

corresponds to

```
R.Left := Control.Left;
R.Top := Control.Top;
R.Right := Control.Left + Control.Width;
R.Bottom := Control.Top + Control.Height;
R.Left = Control->Left;
R.Top = Control->Top;
R.Right = Control->Left + Control->Width;
R.Bottom = Control->Top + Control->Height;
```

The origin of the pixel coordinate system is in the top left corner of the parent window.

Note: A point is considered within the control's bounds rectangle if it lies on the left or top side but not if it lies on the right or bottom side. That is, to be inside the bounds rectangle, the x-coordinate must be greater than or equal to BoundsRect.Left (see page 5830) and less than BoundsRect.Right, and the y-coordinate must be greater than or equal to BoundsRect.Top (see page 5844) and less than BoundsRect.Bottom.

C++ Examples:

```
/*
This code resizes the active control to twice as wide and
half as high:
*/
void __fastcall TForm1::ButtonTSClick(TObject *Sender)
{
  TRect MyRect;
  if (myActiveControl == NULL) exit;
  MyRect = myActiveControl->BoundsRect;
  MyRect.Right = MyRect.Left + (MyRect.Right - MyRect.Left) / 2;
  MyRect.Bottom = MyRect.Top + 2 * (MyRect.Bottom - MyRect.Top);
  myActiveControl->BoundsRect = MyRect;
}
void __fastcall TForm1::ButtonSFClick(TObject *Sender)
{
  TRect MyRect;
  if (myActiveControl == NULL) exit;
  MyRect = myActiveControl->BoundsRect;
  MyRect.Right = MyRect.Left + 2 * (MyRect.Right - MyRect.Left);
  MyRect.Bottom = MyRect.Top + (MyRect.Bottom - MyRect.Top) / 2;
  myActiveControl->BoundsRect = MyRect;
}
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TComponent *Temp;
  TListItem *ListItem;
  ListView1->ViewStyle = vsList;
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Components: ";
```

```
  for (int I = ComponentCount - 1; I >= 0; I--)
  {
    Temp = Components[I];
    ListItem = ListView1->Items->Add();
    ListItem->Caption = Temp->Name;
  }
}
void __fastcall TForm1::ListView1SelectItem(TObject *Sender, TListItem *Item,
      bool Selected)
{
  TComponent *comp = FindComponent(Item->Caption);
  if (dynamic_cast<TWinControl *>(comp) != NULL)
    myActiveControl = (TWinControl *)comp;
}
```

Delphi Examples:

```
{
This code resizes the active control to twice as wide and
half as high:
}
procedure TForm1.ButtonSFClick(Sender: TObject);
var
  MyRect: TRect;
begin
  if (myActiveControl = nil) then exit;
  MyRect := myActiveControl.BoundsRect;
  MyRect.Right := MyRect.Left + (MyRect.Right - MyRect.Left) * 2;
  MyRect.Bottom := MyRect.Top + (MyRect.Bottom - MyRect.Top) div 2;
  myActiveControl.BoundsRect := MyRect;
end;

procedure TForm1.ButtonTSClick(Sender: TObject);
var
  MyRect: TRect;
begin
  if (myActiveControl = nil) then exit;
  MyRect := myActiveControl.BoundsRect;
  MyRect.Right := MyRect.Left + (MyRect.Right - MyRect.Left) div 2;
  MyRect.Bottom := MyRect.Top + (MyRect.Bottom - MyRect.Top) * 2;
  myActiveControl.BoundsRect := MyRect;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
  Temp: TComponent;
  ListItem: TListItem;
begin
  ListView1.ViewStyle := vsList;
  ListItem := ListView1.Items.Add;
  ListItem.Caption := 'Components: ';
  for I := ComponentCount - 1 downto 0 do
  begin
    Temp := Components[I];
    begin
      ListItem := ListView1.Items.Add;
      ListItem.Caption := Temp.Name;
    end;
  end;
end;

procedure TForm1.ListView1SelectItem(Sender: TObject; Item: TListItem;
  Selected: Boolean);
var comp: TComponent;
begin
  comp := FindComponent(Item.Caption);
```

```
  if comp is TWinControl then
    myActiveControl := TWinControl(comp);
end;
```

Height (see page 5825)

Left (see page 5830)

Top (see page 5844)

Width (see page 5849)

32.1.2.6.9 TControl.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls (see page 5711) that display text use either the Caption property or the Text (see page 5842) property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text (see page 5842) is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
```

```
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
```

```
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

32.1.2.6.10 TControl.ClientHeight Property

Specifies the height of the control's client area in pixels.

Pascal

```
property ClientHeight: Integer;
```

C++

```
__property int ClientHeight;
```

Description

Use ClientHeight to read or change the height of the control's client area.

For TControl (see page 5724), ClientHeight is the same as Height (see page 5825). Derived classes may implement a ClientHeight property that differs from Height (see page 5825). For example, the ClientHeight of a form is the value of the Height (see page 5825) property minus the height of the title bar, resize border, and scroll bars.

C++ Examples:

```
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

See Also

ClientOrigin (see page 5809)

ClientRect (see page 5810)

ClientWidth (see page 5811)

Height (see page 5825)

32.1.2.6.11 TControl.ClientOrigin Property

Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.

Pascal

```
property ClientOrigin: TPoint;
```

C++

```
__property TPoint ClientOrigin;
```

Description

Read ClientOrigin to locate the top-left corner of the control's client area. ClientOrigin returns X and Y coordinates as a TPoint type, where X specifies the horizontal coordinate of the point and Y specifies the vertical coordinate.

The screen coordinates of a control that is descended from TControl (see page 5724) and not TWinControl (see page 6112) are the screen coordinates of the control's parent added to its Left (see page 5830) and Top (see page 5844) properties. If the control doesn't have a parent, an EInvalidOperation exception is raised when ClientOrigin is read.

See Also

ClientHeight (see page 5808)

ClientRect (see page 5810)

ClientWidth (see page 5811)

EInvalidOperation (see page 2700)

32.1.2.6.12 TControl.ClientRect Property

Specifies the size (in pixels) of a control's client area.

Pascal

```
property ClientRect: TRect;
```

C++

```
__property TRect ClientRect;
```

Description

Read ClientRect to find the size of the client area of a control. ClientRect returns a rectangle with its Top (see page 5844) and Left (see page 5830) fields set to zero, and its Bottom and Right fields set to the control's Height (see page 5825) and Width (see page 5849), respectively. ClientRect is equivalent to Rect(0, 0, ClientWidth (see page 5811), ClientHeight (see page 5808)).

A point is considered within the control's client rectangle if it lies on the left or top side but not if it lies on the right or bottom side. That is, to be inside the client rectangle, the x-coordinate must be greater than or equal to ClientRect.Left (see page 5830) and less than ClientRect.Right, and the y-coordinate must be greater than or equal to ClientRect.Top (see page 5844) and less than ClientRect.Bottom.

Note: ClientRect is the size of the physical client area of the control, not its logical client area. If the control supports scrolling, the ClientRect is not the entire scrolling range, but only the region that is available at any given time.

C++ Examples:

```
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TToolBar *myToolBar;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TToolBar")
  {
    myToolBar = (TToolBar *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
```

```
    myToolBar->Canvas->MoveTo(myToolBar->ClientRect.Left, myToolBar->ClientRect.Top);
    myToolBar->Canvas->LineTo(myToolBar->ClientRect.Right, myToolBar->ClientRect.Bottom);
    myToolBar = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TToolBar) then
  begin
    myToolBar:= (ListBox1.Items.Objects[Index] as TToolBar);
    with myToolBar.ClientRect do
    begin // make sure we are using the TControls canvas and not the from's!
      myToolBar.Canvas.MoveTo(Left, Top);
      myToolBar.Canvas.LineTo(Right, Bottom);
    end;
  myToolBar:= nil;
  end;
```

See Also

BoundsRect (see page 5803)

ClientHeight (see page 5808)

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

Top (see page 5844)

Width (see page 5849)

Rect (see page 23299)

32.1.2.6.13 TControl.ClientWidth Property

Specifies the horizontal size of the control's client area in pixels.

Pascal

```
property ClientWidth: Integer;
```

C++

```
__property int ClientWidth;
```

Description

Use ClientWidth to read or change the width of the control's client area. ClientWidth is equivalent to ClientRect.Right.

For TControl (see page 5724), ClientWidth is the same as Width (see page 5849). Derived classes may implement a ClientWidth property that differs from Width (see page 5849). For example, the ClientWidth of a form is the value of the Width (see page 5849) property minus the width of the resize border and scroll bars.

See Also

ClientHeight (see page 5808)

ClientOrigin (see page 5809)

ClientRect (see page 5810)

Width (see page 5849)

32.1.2.6.14 TControl.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor (see page 5834) property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor (see page 5834) property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

32.1.2.6.15 TControl.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight (see page 5808) when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight (see page 5808) is represented by x: `Constraints.MinHeight := x + Height (see page 5825) - ClientHeight (see page 5808)`.

Warning: Do not set up constraints that conflict with the value of the Align (see page 5798) or Anchors (see page 5802) property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

32.1.2.6.16 TControl.ControlState Property

Indicates the current state of a control at runtime.

Pascal

```
property ControlState: TControlState;
```

C++

```
__property TControlState ControlState;
```

Description

Read ControlState to find out various conditions that affect the control such as whether it has been clicked or needs alignment. ControlState reflects transient conditions of an instance of the control, as opposed to attributes of the control class as a whole. ControlState consists of a set of flags drawn from the following values:

Flag	Meaning
csLButtonDown	The left mouse button was clicked and not yet released. This is set for all mouse-down events.
csClicked	The same as csLButtonDown, but only set if ControlStyle (see page 5814) contains csClickEvents, meaning that mouse-down events are interpreted as clicks.
csPalette	The system palette has changed and the control or one of its descendants has not finished adjusting by realizing its palette.
csReadingState	The control is reading its state from a stream.

csAlignmentNeeded	The control needs to realign itself when alignment is re-enabled.
csFocusing	The application is processing messages intended to give the control focus. This does not guarantee the control will receive focus, but prevents recursive calls.
csCreating	The control and/or its owner and subcontrols are being created. This flag clears when all have finished creating.
csPaintCopy	The control is being replicated, meaning a copy of the control is being painted. The ControlStyle (see page 5814) flag csReplicatable must be set for this state to occur.
csCustomPaint	The control is processing custom paint messages.
csDestroyingHandle	The control's window is being destroyed.
csDocking	The control is being docked.

The flags in ControlState are specific to controls, and augment the state flags in the ComponentState property.

ControlState is primarily used by component writers in the implementation of components derived from TControl (see page 5724).

See Also

ControlStyle (see page 5814)

ComponentState (see page 2804)

32.1.2.6.17 TControl.ControlStyle Property

Determines style characteristics of the control.

Pascal

```
property ControlStyle: TControlStyle;
```

C++

```
__property TControlStyle ControlStyle;
```

Description

Use ControlStyle to determine various attributes of the control, such as whether the control can capture the mouse or has a fixed size. The ControlStyle property contains a set of style flags indicating these attributes. The following table lists the flags and their meanings:

Flag	Meaning
csAcceptsControls	The control becomes the parent of any controls dropped on it at design time.
csCaptureMouse	The control captures mouse events when it is clicked.
csDesignInteractive	The control maps right mouse-button clicks at design time into left mouse-button clicks to manipulate the control.
csClickEvents	The control can receive and respond to mouse clicks. Some controls may not inherit this attribute, for example, TButton.
csFramed	The control has a 3D frame.
csSetCaption	The control's Caption (see page 5806) should match the Name property if it has not been explicitly set to something else.
csOpaque	The control completely fills its client rectangle.
csDoubleClicks	The control can receive and respond to double-click messages. Otherwise, map double-clicks into clicks.
csFixedWidth	The width of the control does not vary or scale.

csFixedHeight	The height of the control does not vary or scale.
csNoDesignVisible	The control is not visible at design time.
csReplicatable	The control can be copied using the PaintTo method to draw its image to an arbitrary canvas.
csNoStdEvents	Standard events such as mouse, key, and click events are ignored. This flag allows an application to run faster when there is no need respond to these events.
csDisplayDragImage	If some control that has an associated drag image list is dragged across a control with this setting, then the image list is used to enhance the drag cursor while the cursor is over it. Otherwise, the drag cursor is used on its own.
csReflector	The control responds to Windows dialog messages, focus messages, or size change messages. Use this setting if the control can be used as an ActiveX control, so that it receives notification of these events.
csActionClient	The control is linked to an action object. This flag is set when the Action (see page 5797) property is set, and cleared if the Action (see page 5797) property is cleared.
csMenuEvents	The control responds to system menu commands.

ControlStyle describes all controls instantiated from a given class. ControlStyle should not be modified at run time, except in the constructor. The ControlState (see page 5813) property records transient conditions.

The TControl (see page 5724) constructor initializes ControlStyle to the set of csCaptureMouse, csClickEvents, csSetCaption, and csDoubleClicks.

ControlStyle is primarily used by component writers when implementing components derived from TControl (see page 5724).

ControlState (see page 5813)

Create (see page 5731)

32.1.2.6.18 TControl.Cursor Property

Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.

Pascal

```
property Cursor: TCursor;
```

C++

```
__property TCursor Cursor;
```

Description

Change the value of Cursor to provide feedback to the user when the mouse pointer enters the control. The value of Cursor is the index of the cursor in the list of cursors maintained by the global variable, Screen. In addition to the built-in cursors provided by TScreen, applications can add custom cursors to the list.

C++ Examples:

```
/*
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
*/
Graphics::TBitmap *bmpMask, *bmpColor;
TIconInfo *iconInfo;

const crMyCursor = 5;
```

```
  void __fastcall TForm1::Button2Click(TObject *Sender)
{
  bmpMask = new Graphics::TBitmap();
  bmpColor = new Graphics::TBitmap();
  iconInfo = new TIconInfo();

  bmpMask->LoadFromFile("../SquareMask.bmp");
  bmpColor->LoadFromFile("../Square.bmp");

  iconInfo->fIcon = false;
  iconInfo->xHotspot = 15;
  iconInfo->yHotspot = 15;
  iconInfo->hbmMask = bmpMask->Handle;
  iconInfo->hbmColor = bmpColor->Handle;

  Screen->Cursors[crMyCursor] = CreateIconIndirect(iconInfo);

  Screen->Cursor = crMyCursor;

  delete bmpMask;
  delete bmpColor;
  delete iconInfo;
}
```

Delphi Examples:

```
{
This example uses a splitter and two image controls to
create a "slide show" effect.  The example displays an image
(the current "slide"), which can be hidden behind a screen
that looks like a venetian blind. When the blind is pulled
down to completely cover the current slide, the slide changes
to a different image.  When the blind is raised, the new
image appears.
To prepare this example, follow these steps:
1. Place an image control on the form.
Set the picture property to a bitmap of a venetian blind,
Set the Stretch property to True.
Set the Align property to alTop.
2. Add a splitter control to the form.
Set the Align property to alTop.
Set the Cursor property to crVSplit.
Set the OnMoved event handler to the code that appears below.
Set the MinSize property to 1.
3. Add a second image control to the form.
Set the Align property to alClient.
Set the Stretch property to True.
4. Select the form and add the OnCreate and OnDestroy event
   handlers that appear below.
5. Add the global variables below to the unit.
}
var
  CurImage: Integer;
  BMPs: Array[1..5] of TBitmap;

procedure TForm1.Splitter1Moved(Sender: TObject);
begin
  { check if the blind is closed }
  if Image2.Height <= 1 then
  begin
    { the blind is closed, change the current slide }
    CurImage := CurImage + 1;
    if CurImage = 6 then
       CurImage := 1;
    Image2.Picture.Bitmap := BMPs[CurImage];
  end;
```

```
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  { Initialize the array of slides.
    These must be freed in the OnDestroy event handler. }
  BMPs[1] := TBitmap.Create;
  BMPs[1].LoadFromFile('Factory.bmp');
  BMPs[2] := TBitmap.Create;
  BMPs[2].LoadFromFile('Rhododendron.bmp');
  BMPs[3] := TBitmap.Create;
  BMPs[3].LoadFromFile('littleB_64.bmp');
  BMPs[4] := TBitmap.Create;
  BMPs[4].LoadFromFile('Soap bubbles.bmp');
  BMPs[5] := TBitmap.Create;
  BMPs[5].LoadFromFile('Gone Fishing.bmp');
  CurImage := 1;
  Image2.Picture.Bitmap := BMPs[1];
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  { clean up }
  for I := 1 to 5 do
    BMPs[I].Free;
end;
{
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
}
var
  bmpMask : TBitmap;
  bmpColor : TBitmap;
  iconInfo : TIconInfo;
const
  crMyCursor = 5;

procedure TForm1.Button2Click(Sender: TObject);
begin
  bmpMask := TBitmap.Create;
  bmpColor := TBitmap.Create;

  bmpMask.LoadFromFile('SquareMask.bmp');
  bmpColor.LoadFromFile('Square.bmp');

  with iconInfo do
  begin
    fIcon := false;
    xHotspot := 15;
    yHotspot := 15;
    hbmMask := bmpMask.Handle;
    hbmColor := bmpColor.Handle;
  end;

  Screen.Cursors[crMyCursor] := CreateIconIndirect(iconInfo);

  Screen.Cursor := crMyCursor;

  bmpMask.Free;
  bmpColor.Free;
end;
```

```
procedure TForm1.FormDestroy(Sender: TObject);
begin
  DestroyIcon(Screen.Cursors[crMyCursor]);
end;
```

32.1.2.6.19 TControl.DesktopFont Property

Specifies whether the control uses the Windows icon font when writing text.

Pascal

```
property DesktopFont: Boolean;
```

C++

```
__property Boolean DesktopFont;
```

Description

Set DesktopFont to true to specify that the control should use the Windows icon font for its Font (see page 5823) property. The Windows icon font is the value of the IconFont property of the global Screen variable.

When DesktopFont is true, the control's Font (see page 5823) property updates every time the Windows icon font changes. This font can be changed by setting the IconFont property of the global Screen variable, or by the actions of other programs. Setting the Font (see page 5823) property from the IconFont property of the Screen object does not allow controls to dynamically respond in this manner when the Windows icon font changes.

See Also

Font (see page 5823)

IconFont (see page 14226)

32.1.2.6.20 TControl.DockOrientation Property

Specifies how the control is docked relative to other controls docked in the same parent.

Pascal

```
property DockOrientation: TDockOrientation;
```

C++

```
__property TDockOrientation DockOrientation;
```

Description

Use DockOrientation to determine the position of the control relative to other controls docked to the same parent. Docking zones can be arranged from left to right or from top to bottom.

32.1.2.6.21 TControl.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor (see page 5815) property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

32.1.2.6.22 TControl.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

32.1.2.6.23 TControl.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

32.1.2.6.24 TControl.Enabled Property

Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

32.1.2.6.25 TControl.ExplicitHeight Property

Specifies the explicit vertical size of the control in pixels.

Pascal

```
property ExplicitHeight: Integer;
```

C++

```
__property int ExplicitHeight;
```

Description

ExplicitHeight is a read only property used internally by Delphi. Use Height (see page 5825) in applications, thereby allowing read and write access.

See Also

Height (see page 5825)

32.1.2.6.26 TControl.ExplicitLeft Property

Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.

Pascal

```
property ExplicitLeft: Integer;
```

C++

```
__property int ExplicitLeft;
```

Description

ExplicitLeft is a read only property used internally by Delphi. Use Left (see page 5830) in applications, thereby allowing read and write access.

See Also

Left (see page 5830)

32.1.2.6.27 TControl.ExplicitTop Property

Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.

Pascal

```
property ExplicitTop: Integer;
```

C++

```
__property int ExplicitTop;
```

Description

ExplicitTop is a read only property used internally by Delphi. Use Top (see page 5844) in applications, thereby allowing read and write access.

See Also

Top (see page 5844)

32.1.2.6.28 TControl.ExplicitWidth Property

Specifies the explicit horizontal size of the control in pixels.

Pascal

```
property ExplicitWidth: Integer;
```

C++

```
__property int ExplicitWidth;
```

Description

ExplicitWidth is a read only property used internally by Delphi. Use Width (see page 5849) in applications, thereby allowing read and write access.

See Also

Width (see page 5849)

32.1.2.6.29 TControl.Floating Property

Indicates whether the control is floating.

Pascal

```
property Floating: Boolean;
```

C++

```
__property Boolean Floating;
```

Description

Read Floating to determine whether a dockable control appears in a floating window, rather than docked to a parent control.

Note: Use Floating rather than the Parent (see page 5832) property to determine whether a control is free-floating. Floating controls may have a non-nil (Delphi) or NULL (C++) parent if the FloatingDockSiteClass (see page 5823) property specifies a floating window type.

See Also

DragKind (see page 5819)

FloatingDockSiteClass (see page 5823)

Parent (see page 5832)

HostDockSite (see page 5829)

32.1.2.6.30 TControl.FloatingDockSiteClass Property

Specifies the class of the temporary control that hosts the control when it is floating.

Pascal

```
property FloatingDockSiteClass: TWinControlClass;
```

C++

```
__property TWinControlClass FloatingDockSiteClass;
```

Description

Use FloatingDockSiteClass to specify the class that houses the control when it is floating. This class must be a descendant of TWinControl (see page 6112). By default, it is TCustomDockForm. When the control is undocked, a temporary control of this type is created and the control is docked to that control. When the control is docked to another control, the temporary floating dock site is freed.

If the control can float as a stand-alone window, FloatingDockSiteClass is nil (Delphi) or NULL (C++).

See Also

Floating (see page 5823)

Parent (see page 5832)

HostDockSite (see page 5829)

TCustomDockForm (see page 13829)

32.1.2.6.31 TControl.Font Property

Controls (see page 5711) the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color (see page 5812), Height (see page 5825), Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

32.1.2.6.32 TControl.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
```

```
        HideSelection := False;
    end;
end;
```

Width (see page 5849)

Using TDBListBox and TDBComboBox

32.1.2.6.33 TControl.HelpContext Property

Numeric ID for control's context-sensitive help topic

Pascal

```
property HelpContext: THelpContext;
```

C++

```
__property THelpContext HelpContext;
```

Description

HelpContext supports help systems that use numeric topic IDs. For help systems that use topic keywords, see HelpKeyword (see page 5826).

To enable context-sensitive help for a control, set HelpType (see page 5827) to htContext and set HelpContext to a numeric topic ID. A topic ID of 0 (default) means that no help topic is provided for the control.

See Also

HelpType (see page 5827)

HelpKeyword (see page 5826)

InvokeHelp

32.1.2.6.34 TControl.HelpKeyword Property

Keyword for control's context-sensitive help topic

Pascal

```
property HelpKeyword: String;
```

C++

```
__property AnsiString HelpKeyword;
```

Description

HelpKeyword supports help systems that use topic keywords. For help systems that use numeric topic IDs, see HelpContext (see page 5826).

To enable context-sensitive help for a control, set HelpType (see page 5827) to htKeyword and set HelpKeyword to a keyword string. No keyword (zero-length string; default) means that no help topic is provided for the control.

See Also

HelpType (see page 5827)

HelpContext (see page 5826)

InvokeHelp

32.1.2.6.35 TControl.HelpType Property

Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.

Pascal

```
property HelpType: THelpType;
```

C++

```
__property THelpType HelpType;
```

Description

Set HelpType to specify whether the control identifies its context-sensitive help topic by ID or keyword. When HelpType is htContext, the HelpContext (see page 5826) property identifies the control's help topic. When HelpType is htKeyword, the HelpKeyword (see page 5826) property identifies the control's help topic.

32.1.2.6.36 TControl.Hint Property

Contains the text string that can appear when the user moves the mouse over the control.

Pascal

```
property Hint: string;
```

C++

```
__property AnsiString Hint;
```

Description

Use the Hint property to provide a string of help text either as a Help Hint, or as help text on a particular location such as a status bar.

A Help Hint is a box containing help text that appears for a control when the user moves the mouse pointer over the control and pauses momentarily. To set up Help Hints:

Specify the Hint property of each control for which a Help Hint should appear.

Set the ShowHint (see page 5840) property of each appropriate control to true, or set the ParentShowHint (see page 5835) property of all controls to true and set the ShowHint (see page 5840) property of the form to true.

At runtime, set the value of the application's ShowHint (see page 5840) property to true.

To show the Hint on a status bar or other location, use the OnHint event handler of the application. The application's OnHint event occurs when the mouse pointer moves over the control.

Specify a hint to be used for both a Help Hint box and by an OnHint handler by specifying two values separated by a | character (the vertical bar "or" symbol). For example,

```
Edit1.Hint := 'Name|Enter Name in the edit box';
Edit1->Hint = "Name|Enter Name in the edit box";
```

The "Name" part appears in the Help Hint box and the "Enter full name in the edit box" part can be extracted using the GetLongHint (see page 6252) function for use in an OnHint event handler.

If Hint contains only one value, the entire string is used as a Help Hint and returned by the GetLongHint (see page 6252) function. If a control has no Hint value specified, but its parent control does, the control uses the Hint value of the parent control (as long as the control's ShowHint (see page 5840) property is true).

Note: If the application's ShowHint (see page 5840) property is false, the Help Hint does not appear, but the OnHint event handler is still called.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

ShowHint (see page 13721)

Hint (see page 312)

32.1.2.6.37 TControl.HostDockSite Property

Specifies the control in which the control is docked.

Pascal

```
property HostDockSite: TWinControl;
```

C++

```
__property TWinControl * HostDockSite;
```

Description

Read HostDockSite to access the windowed control to which the control is docked. If the control is floating, HostDockSite is a temporary control of type FloatingDockSiteClass (see page 5823) or (if there is no floating dock site class) nil (Delphi) or NULL (C++).

Most applications should use the ManualDock (see page 5771) method rather than setting HostDockSite. Setting HostDockSite automatically undocks the control from its previous host (if any) and docks it to the specified control, but does not adjust the control's position and alignment and bypasses the standard docking events.

For dock clients, the value of HostDockSite is the same as the value of Parent (see page 5832). For controls that are not docking clients, HostDockSite is nil (Delphi) or NULL (C++) while Parent (see page 5832) specifies the containing control.

See Also

DockClients (see page 6201)

ManualDock (see page 5771)

FloatingDockSiteClass (see page 5823)

Parent (see page 5832)

32.1.2.6.38 TControl.IsControl Property

Determines whether a form stores its form-specific properties to a stream.

Pascal

```
property IsControl: Boolean;
```

C++

```
__property Boolean IsControl;
```

Description

Use IsControl to use a form as a complex control, rather than as a desktop form. IsControl affects the way the form gets saved. When IsControl is true, form-specific properties do not get saved with the form. When IsControl is false, the form-specific properties get saved along with the other properties.

IsControl permits you to use the forms designer to create complex controls by creating those controls as forms, placing and naming their contained controls, and attaching code to events. After saving the form, edit the form as text, and in the text version set IsControl to true. The next time the form is loaded and saved, only those form properties appropriate to use as a control are stored, not the properties specific to TForm. Next, edit the form file as text, changing the type of the component from TForm to the desired control type, such as TPanel.

See Also

TForm (see page 13992)

32.1.2.6.39 TControl.Left Property

Specifies the horizontal coordinate of the left edge of a component relative to its parent.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

Use the Left property to determine where the left side of the control begins or to reposition the left side of the control.

If the control is contained in another control, the Left and Top (see page 5844) properties are relative to the parent control. If the control is contained directly by the form, the property values are relative to the form. For forms, the value of the Left property is relative to the screen in pixels.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

See Also

Top (see page 5844)

32.1.2.6.40 TControl.LRDockWidth Property

Specifies the width of the control when it is docked horizontally.

Pascal

```
property LRDockWidth: Integer;
```

C++

```
__property int LRDockWidth;
```

Description

Read LRDockWidth to get the width of the control from the last time it was docked horizontally. Set LRDockWidth to indicate the width the control should have the next time it is docked horizontally.

LRDockWidth allows a control to "remember" its docked size even when its width changes because it is undocked or docked with a vertical orientation.

See Also

Width (see page 5849)

DockOrientation (see page 5818)

TBDockHeight (see page 5842)

UndockWidth (see page 5846)

32.1.2.6.41 TControl.Margins Property

Specifies the margins for the control.

Pascal

```
property Margins: TMargins;
```

C++

```
__property TMargins Margins;
```

Description

Use the Margins property to set the margins for the control.

32.1.2.6.42 TControl.MouseCapture Property

Indicates whether the control has "captured" mouse events.

Pascal

```
property MouseCapture: Boolean;
```

C++

```
__property Boolean MouseCapture;
```

Description

Use MouseCapture to determine whether a control has captured the mouse. When a control captures the mouse, all subsequent mouse events go to that control until the user releases the mouse button.

A control captures the mouse when the user drags an item from it. In addition, if the control has the csCaptureMouse flag set in its ControlStyle (see page 5814) property, it captures the mouse when the user presses the left mouse button over it, until the

user releases the mouse button.

See Also

ControlStyle (see page 5814)

GetCaptureControl (see page 6251)

SetCaptureControl (see page 6263)

OnMouseDown (see page 5862)

32.1.2.6.43 TControl.Parent Property

Indicates the parent of the control.

Pascal

```
property Parent: TWinControl;
```

C++

```
__property TWinControl * Parent;
```

Description

Use the Parent property to get or set the parent of this control. The parent of a control is the control that contains the control. For example, if an application includes three radio buttons in a group box, the group box is the parent of the three radio buttons, and the radio buttons are the child controls of the group box.

To serve as a parent, a control must be an instance of a descendant of TWinControl (see page 6112).

When creating a new control at runtime, assign a Parent property value for the new control. Usually, this is a form, panel, group box, or some control that is designed to contain another. Changing the parent of a control moves the control onscreen so that it is displayed within the new parent. When the parent control moves, the child moves with the parent.

Some controls (such as ActiveX controls) are contained in native windows rather than in a parent VCL control. For these controls, the value of Parent is nil (Delphi) or NULL (C++) and the ParentWindow property specifies the window.

Note: The Parent property declared in TControl (see page 5724) is similar to the Owner property declared in TComponent, in that the Parent of a control frees the control just as the Owner of a component frees that Component. However, the Parent of a control is always a windowed control that visually contains the control, and is responsible for writing the control to a stream when the form is saved. The Owner of a component is the component that was passed as a parameter in the constructor and, if assigned, initiates the process of saving all objects (including the control and its parent) when the form is saved.

C++ Examples:

```
/*
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (Button1->Parent != GroupBox1) // second click?
  {
    RemoveControl(Button1);
    GroupBox1->InsertControl(Button1);
  }
}

/*
Note that it was necessary to remove the button from the Controls
```

```
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
*/

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Button2->Parent = GroupBox1;
}
```

Delphi Examples:

```
{
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (Button1.Parent <> GroupBox1) then // second click?
  begin
    RemoveControl(Button1);
    GroupBox1.InsertControl(Button1);
  end;
end;

{
Note that it was necessary to remove the button from the Controls
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
}

procedure TForm1.Button2Click(Sender: TObject);
begin
  Button2.Parent := GroupBox1;
end;
```

Owner (see page 2807)

Controls (see page 6197)

HostDockSite (see page 5829)

ParentWindow (see page 6210)

32.1.2.6.44 TControl.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode (see page 5803).

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode (see page 5803). When ParentBiDiMode is true, the control's BiDiMode (see page 5803) property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode (see page 5803) property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode (see page 5803) property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

32.1.2.6.45 TControl.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color (see page 5812) property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color (see page 5812) property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

32.1.2.6.46 TControl.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font (see page 5823) property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font (see page 5823) property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

32.1.2.6.47 TControl.ParentShowHint Property

Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint (see page 5840) property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint (see page 5840) property.

To provide Help Hints for only selected controls on a form, set the ShowHint (see page 5840) property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint (see page 5840) property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

32.1.2.6.48 TControl.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup (see page 5854) event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
```

```
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
```

```
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
```

```
the menu item OnClick event.
}

type
  TForm1 = class(TForm)

32.1.2.6.49 TControl.ScalingFlags Property

Reflects which attributes of the control have been scaled.

Pascal

```
property ScalingFlags: TScalingFlags;
```

C++

```
__property TScalingFlags ScalingFlags;
```

Description

ScalingFlags is an internal set of flags used primarily in scaling inherited forms and their controls. Applications should not use this property without a serious need.

These are the flags and their meanings:

Flag	Meaning
sfLeft	Left (see page 5830) side of control not yet scaled.
sfTop	Top (see page 5844) of control not yet scaled.
sfWidth	Width (see page 5849) of control not yet scaled.
sfHeight	Height (see page 5825) of control not yet scaled.
sfFont	Font (see page 5823) of control not yet scaled.
sfDesignSize	Design-time dimensions of control not yet scaled.

See Also

ChangeScale (see page 5743)

32.1.2.6.50 TControl.ShowHint Property

Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint (see page 5827) is the value of the Hint (see page 5827) property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint (see page 5827) appears for the control.

To enable Help Hint (see page 5827) for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint (see page 5835) property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint (see page 5835) property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint (see page 5827).

Changing the ShowHint value automatically sets the ParentShowHint (see page 5835) property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
```

```
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }
```

32.1.2.6.51 TControl.TBDockHeight Property

Specifies the height of the control when it is docked vertically.

Pascal

```
property TBDockHeight: Integer;
```

C++

```
__property int TBDockHeight;
```

Description

Read TBDockHeight to get the height of the control from the last time it was docked vertically. Set TBDockHeight to indicate the height the control should have the next time it is docked vertically.

TBDockHeight allows a control to "remember" its docked size even when its height changes because it is undocked or docked with a horizontal orientation.

See Also

Height (see page 5825)

DockOrientation (see page 5818)

LRDockWidth (see page 5831)

UndockHeight (see page 5845)

32.1.2.6.52 TControl.Text Property

Contains a text string associated with the control.

Pascal

```
property Text: TCaption;
```

C++

```
__property TCaption Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls (see page 5711) that display text use either the Caption (see page 5806) property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption (see page 5806) is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                        //Add room for null character
  char *Buffer = new char[Size];  //Creates Buffer dynamic variable
  Edit1->GetTextBuf(Buffer,Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
  delete [] Buffer;
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

Caption (see page 5806)

Lines (see page 21380)

32.1.2.6.53 TControl.Top Property

Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

Use Top to locate the top of the control or reposition the control to a different Y coordinate. The Top property, like the Left (see page 5830) property, is the position of the control relative to its container. Thus, if a control is contained in a TPanel, the Left (see page 5830) and Top properties are relative to the panel. If the control is contained directly by the form, it is relative to the form. For forms, the value of the Top property is relative to the screen in pixels.

C++ Examples:

```
/*
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
*/
void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  int I;
  TControl *ChildControl;

  for (I = 0; I < GroupBox1->ControlCount; I++)
  {
    ChildControl = GroupBox1->Controls[I];
    if (Button == btNext)
      ChildControl->Top = ChildControl->Top + 15;
    else
      ChildControl->Top = ChildControl->Top - 15;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorarray[5] = {clYellow, clGreen, clBlue, clLime, clFuchsia};
  GroupBox1->Brush->Color = clRed;
  for (int i = 0; i < GroupBox1->ControlCount; i++)
    ((TWinControl *)GroupBox1->Controls[i])->Brush->Color = colorarray[i];
}
```

Delphi Examples:

```
{
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
}
procedure TForm1.FormCreate(Sender: TObject);
var
```

```
    I: Integer;
  const
    colorarray : Array[0..4] of TColor = (clYellow, clGreen, clBlue, clLime, clFuchsia);
  begin
     GroupBox1.Brush.Color := clRed;
    for I:= 0 to GroupBox1.ControlCount -1 do
    begin
      TWinControl(GroupBox1.Controls[I]).Brush.Color := colorarray[I];
    end;
  end;

  procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
  var
    I: Integer;
    ChildControl: TControl;
  begin
    for I:= 0 to GroupBox1.ControlCount -1 do
    begin
      ChildControl := GroupBox1.Controls[I];
      if Button = btNext then
        ChildControl.Top := ChildControl.Top + 15
      else
        ChildControl.Top := ChildControl.Top - 15;
    end;
  end;
```

See Also

Left (see page 5830)

32.1.2.6.54 TControl.UndockHeight Property

Specifies the height of the control when it is floating.

Pascal

```
property UndockHeight: Integer;
```

C++

```
__property int UndockHeight;
```

Description

Read UndockHeight to get the height of the control from the last time it was floating. Set UndockHeight to indicate the height the control should have the next time it is undocked.

UndockHeight allows a control to "remember" its floating size even when its height changes because it is docked.

C++ Examples:

```
{
This example shows how to undock a dockable object.  This example
is part of the Docking Demo.
}

void __fastcall TTabDockHost::FormClose(TObject *Sender, TCloseAction &Action)
{
  TRect ARect;
  TPoint point;
  if (PageControl1->DockClientCount == 1)
  {
    point =  PageControl1->DockClients[0]->ClientToScreen(Point(0, 0));
    ARect.left = point.x;
    ARect.top = point.y;
    point = PageControl1->DockClients[0]->ClientToScreen(
      Point(PageControl1->DockClients[0]->UndockWidth,
```

```
PageControl1->DockClients[0]->UndockHeight));
    ARect.right = point.x;
    ARect.bottom = point.y;
    PageControl1->DockClients[0]->ManualFloat(ARect);
    Action = caFree;
  }
  else
    Action = caHide;
}
```

Delphi Examples:

```
procedure TTabDockHost.FormClose(Sender: TObject;
  var Action: TCloseAction);
var
  ARect: TRect;
begin
  if PageControl1.DockClientCount = 1 then
  begin
    with PageControl1.DockClients[0] do
    begin
      ARect.TopLeft := ClientToScreen(Point(0, 0));
      ARect.BottomRight := ClientToScreen(Point(UndockWidth, UndockHeight));
      ManualFloat(ARect);
    end;
    Action := caFree;
  end else
    Action := caHide;
end;
```

See Also

Height (see page 5825)

Floating (see page 5823)

TBDockHeight (see page 5842)

UndockWidth (see page 5846)

32.1.2.6.55 TControl.UndockWidth Property

Specifies the width of the control when it is floating.

Pascal

```
property UndockWidth: Integer;
```

C++

```
__property int UndockWidth;
```

Description

Read UndockWidth to get the width of the control from the last time it was floating. Set UndockWidth to indicate the width the control should have the next time it is undocked.

UndockWidth allows a control to "remember" its floating size even when its width changes because it is docked.

C++ Examples:

```
{
This example shows how to undock a dockable object.  This example
is part of the Docking Demo.
}

void __fastcall TTabDockHost::FormClose(TObject *Sender, TCloseAction &Action)
{
```

```
  TRect ARect;
  TPoint point;
  if (PageControl1->DockClientCount == 1)
  {
    point =  PageControl1->DockClients[0]->ClientToScreen(Point(0, 0));
    ARect.left = point.x;
    ARect.top = point.y;
    point = PageControl1->DockClients[0]->ClientToScreen(
      Point(PageControl1->DockClients[0]->UndockWidth,
PageControl1->DockClients[0]->UndockHeight));
    ARect.right = point.x;
    ARect.bottom = point.y;
    PageControl1->DockClients[0]->ManualFloat(ARect);
    Action = caFree;
  }
  else
    Action = caHide;
}
```

Delphi Examples:

```
procedure TTabDockHost.FormClose(Sender: TObject;
  var Action: TCloseAction);
var
  ARect: TRect;
begin
  if PageControl1.DockClientCount = 1 then
  begin
    with PageControl1.DockClients[0] do
    begin
      ARect.TopLeft := ClientToScreen(Point(0, 0));
      ARect.BottomRight := ClientToScreen(Point(UndockWidth, UndockHeight));
      ManualFloat(ARect);
    end;
    Action := caFree;
  end else
    Action := caHide;
end;
```

32.1.2.6.56 TControl.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show (see page 5788) method sets the control's Visible property to true. Calling the Hide (see page 5769)

method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
```

```
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

32.1.2.6.57 TControl.WheelAccumulator Property

Accumulates mouse wheel rotations.

Pascal

```
property WheelAccumulator: Integer;
```

C++

```
__property int WheelAccumulator;
```

Description

WheelAccumulator contains a value indicating the progress of event handlers in response to mouse wheel motion. See DoMouseWheel (see page 5751) for more information.

See Also

DoMouseWheel (see page 5751)

32.1.2.6.58 TControl.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

See Also

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

32.1.2.6.59 TControl.WindowText Property

Contains the text string of the control.

Pascal

```
property WindowText: PChar;
```

C++

```
__property const char * WindowText;
```

Description

Use WindowText to determine the text associated with the control. When setting WindowText, the control frees the memory associated with the previous value of WindowText before assigning a new value. Any memory associated with WindowText is freed when the control is destroyed. By default, WindowText is the same string as the Text (see page 5842) property. Descendants of TControl (see page 5724) can override the Text (see page 5842) property to implement a different value.

For an edit box, the WindowText is the content of the control. For a combo box, the text string is the content of the edit box part of the combo box. For a button, the string is the button name. For all other controls, the string is the window title.

32.1.2.7 TControl Events

The events of the TControl class are listed here.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.

	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

32.1.2.7.1 TControl.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize (see page 5853) event.

See Also

OnConstrainedResize (see page 5853)

SetBounds (see page 5783)

OnResize (see page 5870)

32.1.2.7.2 TControl.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.

- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption (see page 5806) property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click (see page 5743) method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

32.1.2.7.3 TControl.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize: TConstrainedResizeEvent;
```

C++

```
__property TConstrainedResizeEvent OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints (see page 5812) object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize (see page 5741) method or an OnCanResize (see page 5851) event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize (see page 5870) event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize (see page 5851) handler.

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

Constraints (see page 5812)

OnResize (see page 5870)

CanAutoSize (see page 5741)

32.1.2.7.4 TControl.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu (see page 5835) property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent (see page 5832) controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

32.1.2.7.5 TControl.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

32.1.2.7.6 TControl.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
```

```
    end;
  end;
end;
```

32.1.2.7.7 TControl.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor (see page 5818) property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
```

```
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

32.1.2.7.8 TControl.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

32.1.2.7.9 TControl.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

32.1.2.7.10 TControl.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate (see page 5773) is a protected virtual function in TControl (see page 5724). MouseActivate (see page 5773) can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate (see page 5773) as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate (see page 5773), the behavior is the same as if a control set TMouseActivate (see page 6287) to maActivate. At any point, a control can set the value of TMouseActivate (see page 6287) and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate (see page 6287) is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate (see page 5773), based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl (see page 5724) level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl (see page 5724) descendants also have OnMouseDown (see page 5862), OnMouseMove (see page 5865), and OnMouseUp (see page 5867) events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseUp (see page 5867)

MouseCapture (see page 5831)

32.1.2.7.11 TControl.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}
```

```
// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

32.1.2.7.12 TControl.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

32.1.2.7.13 TControl.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

32.1.2.7.14 TControl.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown (see page 5862) event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

32.1.2.7.15 TControl.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
```

```
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
```

```
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

Responding to a Mouse-up Action

32.1.2.7.16 TControl.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp (see page 5870) or OnMouseWheelDown (see page 5869) event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

32.1.2.7.17 TControl.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel (see page 5869) event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

32.1.2.7.18 TControl.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel (see page 5869) event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

32.1.2.7.19 TControl.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize (see page 5851) or OnConstrainedResize (see page 5853).

Note: Some controls call this event handler when the control is first created.

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
```

```
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

AutoSize (see page 5803)

OnConstrainedResize (see page 5853)

32.1.2.7.20 TControl.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx (see page 6018) object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx (see page 6018) as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject (see page 6009), your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject (see page 6009) object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

32.1.2.7.21 TControl.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind (see page 5819) is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx (see page 6007) instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx (see page 6007) instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject (see page 6003) instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject (see page 6003) object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag (see page 5860) events for drag operations within the control.

See Also

OnEndDrag (see page 5860)

TDragControlObjectEx (see page 6007)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDragDrop (see page 5855)

32.1.2.7.22 TControl.WindowProc Event

Points to the window procedure that responds to messages sent to the control.

Pascal

```
property WindowProc: TWndMethod;
```

C++

```
__property TWndMethod WindowProc;
```

Description

Use the WindowProc property to temporarily replace or subclass the window procedure of the control. Component writers that are customizing the window procedure for a descendant class should override the WndProc (see page 5791) method instead.

Before assigning a new value to WindowProc, store the original value. WindowProc is initially set to the WndProc (see page 5791) method, so if the value has not been changed since then, the original value need not be stored. Within the procedure that is used as the new value for WindowProc, pass any unhandled messages to the original procedure that was the value of WindowProc. After completing any specialized message handling, restore the value of WindowProc to the original procedure.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/
class TMyListBoxDescendant : public TListBox
{
```

```

32.1.3 TControlAction Class

Class Hierarchy

Pascal

```
TControlAction = class(TCustomControlAction);
```

C++

```
class TControlAction : public TCustomControlAction;
```

File

Controls

Description

This is class Controls.TControlAction.

32.1.3.1 TControlAction Members

The following tables list the members exposed by TControlAction.

Protected Events

	Name	Description
	OnChange (see page 2716)	Occurs when one of the action's properties changes.

Protected Fields

	Name	Description
	FClients (see page 2711)	This is FClients, a member of class TBasicAction.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FImage (see page 302)	This is FImage, a member of class TCustomAction.
	FMask (see page 303)	This is FMask, a member of class TCustomAction.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 303)	Copies the properties of this action to a destination object.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Change (see page 2712)	Generates an OnChange (see page 2716) event.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.

	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleShortCut (see page 306)	Executes the action when the user types on of its short cuts.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2713)	Responds when components are created or destroyed.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 294)	This is ReadState, a member of class TContainedAction.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetHelpContext (see page 306)	This is SetHelpContext, a member of class TCustomAction.
	SetHelpKeyword (see page 306)	This is SetHelpKeyword, a member of class TCustomAction.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 307)	Sets the value of the Name property.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetOnExecute (see page 2714)	Assigns an OnExecute (see page 2716) event handler.
	SetParentComponent (see page 294)	This is SetParentComponent, a member of class TContainedAction.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	SavedEnabledState (see page 313)	Saves the value of the Enabled (see page 310) property when the action is suspended.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 301)	Instantiates and initializes a TCustomAction (see page 297) object.
V	Create (see page 2710)	Instantiates and initializes a TBasicAction (see page 2707) object.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 292)	Destroys the instance of the contained action.
V	Destroy (see page 302)	Frees an instance of TCustomAction (see page 297).
V	Destroy (see page 2711)	Disposes of an instance of a TBasicAction (see page 2707) object.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoHint (see page 303)	Generates an OnHint (see page 315) event.
V	Execute (see page 293)	Responds when the client control "fires".
V	Execute (see page 304)	Responds when a client control "fires".
	Execute (see page 2712)	Generates an OnExecute (see page 2716) event.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
V	ExecuteTarget (see page 2712)	Introduces an interface for invoking an action on a target client component or control.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetParentComponent (see page 293)	Returns the action list or action manager that contains the action.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	HandlesTarget (see page 2713)	Introduces an interface for verifying that the type, and state, of a target component or control are appropriate for the action.
V	HasParent (see page 294)	Indicates whether the action is contained in an action list or action manager.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RegisterChanges (see page 2713)	Associates the action with an action link.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UnRegisterChanges (see page 2714)	Breaks the association between the action and the action link.
V	Update (see page 295)	Indicates whether the action updates itself.
V	Update (see page 2714)	Provides an opportunity to execute centralized code when an application is idle.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
V	UpdateTarget (see page 2715)	Introduces an interface for a method of notifying a client when the action updates itself.

Public Properties

	Name	Description
	ActionComponent (see page 2715)	Indicates the client component that caused this action to execute.
	ActionList (see page 295)	Indicates the action list or action manager that contains the action.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DisableIfNoHandler (see page 310)	Indicates whether client components should be disabled if no handler is found.
	Index (see page 296)	Specifies the index of the action in its action list or action manager.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnExecute (see page 5888)	Occurs when the client event that is linked to it fires.
	OnHint (see page 5890)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 5890)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	AutoCheck (see page 5881)	Controls whether the Checked property toggles when the action executes.
	Caption (see page 5882)	Represents the caption of client controls and menu items.
	Category (see page 296)	Specifies the category under which the action appears in its action list or action manager.
	Checked (see page 5882)	Indicates whether client controls and menu items appear checked.
	DropdownMenu (see page 5883)	This is DropdownMenu, a member of class TControlAction.

	Enabled (see page 5884)	Indicates whether client controls and menu items are enabled.
	EnableDropdown (see page 5884)	This is EnableDropdown, a member of class TControlAction.
	GroupIndex (see page 5884)	Indicates whether the action acts like a radio button with other actions in the same action list.
	HelpContext (see page 5885)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 5885)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 5886)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 5886)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 5886)	Indicates the ImageIndex property for client controls and menu items.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PopupMenu (see page 5887)	This is PopupMenu, a member of class TControlAction.
	SecondaryShortCuts (see page 5887)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 5887)	Specifies the ShortCut property for client menu items.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 5888)	Specifies the Visible property for client controls and menu items.

32.1.3.2 TControlAction Properties

The properties of the TControlAction class are listed here.

Published Properties

	Name	Description
	AutoCheck (see page 5881)	Controls whether the Checked property toggles when the action executes.
	Caption (see page 5882)	Represents the caption of client controls and menu items.
	Checked (see page 5882)	Indicates whether client controls and menu items appear checked.
	DropdownMenu (see page 5883)	This is DropdownMenu, a member of class TControlAction.
	Enabled (see page 5884)	Indicates whether client controls and menu items are enabled.
	EnableDropdown (see page 5884)	This is EnableDropdown, a member of class TControlAction.
	GroupIndex (see page 5884)	Indicates whether the action acts like a radio button with other actions in the same action list.
	HelpContext (see page 5885)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 5885)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 5886)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 5886)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 5886)	Indicates the ImageIndex property for client controls and menu items.
	PopupMenu (see page 5887)	This is PopupMenu, a member of class TControlAction.
	SecondaryShortCuts (see page 5887)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 5887)	Specifies the ShortCut property for client menu items.
	Visible (see page 5888)	Specifies the Visible property for client controls and menu items.

32.1.3.2.1 TControlAction.AutoCheck Property

Controls whether the Checked property toggles when the action executes.

Pascal

```
property AutoCheck: Boolean;
```

C++

```
__property Boolean AutoCheck;
```

Description

AutoCheck causes the checked property to toggle when the action executes. This allows the action's Checked property to remain in sync with the client's Checked property (or equivalent). If the client is a menu item (where the Checked property does

not necessarily toggle), AutoCheck is propagated to the AutoCheck property of the menu item.

See Also

Checked (see page 308)

Execute (see page 304)

AutoCheck (see page 16134)

32.1.3.2.2 TControlAction.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption (see page 5806)

Caption (see page 16136)

32.1.3.2.3 TControlAction.Checked Property

Indicates whether client controls and menu items appear checked.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Checked specifies the checked state for the action. The value of Checked is propagated to client controls and menu items.

Note: If the action has a GroupIndex value greater than 0, then setting Checked to true causes all other actions in the group to have their Checked property set to false.

Note: Use the AutoCheck property to ensure that the action's Checked property stays synchronized with client's Checked properties.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
```

```
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (pa->Checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     pa->Checked = ToolBar1->Visible;
   }
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

GroupIndex (see page 311)

AutoCheck (see page 308)

32.1.3.2.4 TControlAction.DropdownMenu Property

Pascal

```
property DropdownMenu: TPopupMenu;
```

C++

```
__property TPopupMenu DropdownMenu;
```

Description

This is DropdownMenu, a member of class TControlAction.

32.1.3.2.5 TControlAction.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled (see page 5821)

Enabled (see page 16145)

32.1.3.2.6 TControlAction.EnableDropdown Property

Pascal

```
property EnableDropdown: Boolean;
```

C++

```
__property Boolean EnableDropdown;
```

Description

This is EnableDropdown, a member of class TControlAction.

32.1.3.2.7 TControlAction.GroupIndex Property

Indicates whether the action acts like a radio button with other actions in the same action list.

Pascal

```
property GroupIndex: Integer;
```

C++

```
__property int GroupIndex;
```

Description

GroupIndex is used to define groups of actions that act like radio buttons. When GroupIndex is greater than 0, it identifies the group to which the action belongs. When the Checked property of any action in that group is set to true, the Checked property of all other actions in the group is set to false. That is, only one action in the group can be checked at a time.

Note: All actions in a group must be listed by the same action list or action manager.

See Also

Checked (see page 308)

GroupIndex (see page 2360)

32.1.3.2.8 TControlAction.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext: THelpContext;
```

C++

```
__property THelpContext HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType (see page 312)

HelpKeyword (see page 311)

32.1.3.2.9 TControlAction.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword: string;
```

C++

```
__property AnsiString HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword (see page 5826)

HelpContext (see page 311)

HelpType (see page 312)

HelpKey

32.1.3.2.10 TControlAction.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType: THelpType;
```

C++

```
__property THelpType HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType (see page 5827)

HelpType

HelpContext (see page 311)

HelpKeyword (see page 311)

32.1.3.2.11 TControlAction.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint: string;
```

C++

```
__property AnsiString Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint (see page 5827)

Hint (see page 16148)

32.1.3.2.12 TControlAction.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an

image that is associated with controls and menu items that use this action.

See Also

ImageIndex (see page 5135)

ImageIndex (see page 16148)

Images (see page 325)

32.1.3.2.13 TControlAction.PopupMenu Property

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

This is PopupMenu, a member of class TControlAction.

32.1.3.2.14 TControlAction.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts: TShortCutList;
```

C++

```
__property TShortCutList SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut (see page 314)

Execute (see page 304)

32.1.3.2.15 TControlAction.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut: TShortCut;
```

C++

```
__property TShortCut ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 16152)

SecondaryShortCuts (see page 314)

32.1.3.2.16 TControlAction.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 16153)

Visible (see page 5847)

32.1.3.3 TControlAction Events

The events of the TControlAction class are listed here.

Published Events

	Name	Description
	OnExecute (see page 5888)	Occurs when the client event that is linked to it fires.
	OnHint (see page 5890)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 5890)	Occurs when the application is idle or when the action list updates.

32.1.3.3.1 TControlAction.OnExecute Event

Occurs when the client event that is linked to it fires.

Pascal

```
property OnExecute: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExecute;
```

Description

Write an OnExecute event handler when you want to respond when the user triggers the client object's default event (typically an OnClick event). For most target clients, OnExecute is triggered on a Click method, and is associated with the OnClick event.

OnExecute also occurs when the user types the shortcut (or one of the secondary shortcuts) associated with the action or its client.

Warning: If you assign an OnExecute event handler to a predefined action, the default behavior of that action will not occur.

C++ Examples:

```
/*
This example requires a TApplicationEvents, a TActionList
and a TListBox in the form.  Select the TApplicationEvents,
double click on the OnActionExecute event and add the
following code to the handler.  Create an TAction named
MyAction in a TActionList.  The TActionList must have no
OnExecute event handler, and the TAction has an OnExecute
event handler called MyActionExecute.  Then set an object's
(such as a button) Action to MyAction.  The Handled
parameter of the event handler returns false by default. If
the handler handles the event, it should change Handled to
true, thereby preventing further attempts to handle the
action.
*/
void __fastcall TAppEventForm::ApplicationEventsActionExecute(
      TBasicAction *Action, bool &Handled)
{
    lbOther->Items->Add("Event OnActionExecute");
}

void __fastcall TAppEventForm::ActionExecute(TObject *Sender)
{
    ShowMessage("Action executed");
}
/*
When a client component or control is clicked, the OnExecute
event occurs for it’s associated action. For example, the
following code illustrates the OnExecute event handler for
an action that toggles the visibility of a toolbar when the
action is executed. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TActionList must have no OnExecute event handler, and the
TAction has an OnExecute event handler called Action1Execute.
Then set an object's (such as a button or menu item) Action
to Action1.  Set the TToolbar color to something that will
make it obvious when it is visible.  Also remember to uncheck
Project|Options|Applications|Enable runtime themes.
*/
void __fastcall TMainForm::Action1Execute(TObject *Sender)
{
  // Toggle Toolbar1's visibility
  ToolBar1->Visible = !ToolBar1->Visible;
  if (ToolBar1->Visible)
    lbOther->Items->Add("Event Action1Execute: toolbar visible");
  else
    lbOther->Items->Add("Event Action1Execute: toolbar not visible");
}
```

Delphi Examples:

```
{
This example requires a TApplicationEvents, a TActionList
and a TListBox in the form.  Select the TApplicationEvents,
double click on the OnActionExecute event and add the
following code to the handler.  Create an TAction named
MyAction in a TActionList.  The TActionList must have no
OnExecute event handler, and the TAction has an OnExecute
event handler called MyActionExecute.  Then set an object's
(such as a button) Action to MyAction.  The Handled
parameter of the event handler returns false by default. If
the handler handles the event, it should change Handled to
true, thereby preventing further attempts to handle the
action.
}
```

```
procedure TMainForm.ApplicationEventsActionExecute(Action: TBasicAction;
  var Handled: Boolean);
begin
  lbOther.Items.Add('Event OnActionExecute');
end;

procedure TMainForm.MyActionExecute(Sender: TObject);
begin
  ShowMessage('Action executed');
end;
{
When a client component or control is clicked, the OnExecute
event occurs for it's associated action. For example, the
following code illustrates the OnExecute event handler for
an action that toggles the visibility of a toolbar when the
action is executed. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TActionList must have no OnExecute event handler, and the
TAction has an OnExecute event handler called Action1Execute.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Execute(Sender: TObject);
begin
    { Toggle Toolbar1's visibility }
    ToolBar1.Visible := not ToolBar1.Visible;
  if ToolBar1.Visible then
    lbOther.Items.Add('Event Action1Execute: toolbar visible')
  else
    lbOther.Items.Add('Event Action1Execute: toolbar not visible')
end;
```

OnClick (see page 5851)

ShortCut (see page 314)

32.1.3.3.2 TControlAction.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint: THintEvent;
```

C++

```
__property THintEvent OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

32.1.3.3.3 TControlAction.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (pa->Checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     pa->Checked = ToolBar1->Visible;
   }
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction (see page 2790)

32.1.4 TControlActionLink Class

TControlActionLink links action objects to clients that descend from TControl (see page 5724).

Class Hierarchy

Pascal

```
TControlActionLink = class(TActionLink);
```

C++

```
class TControlActionLink : public TActionLink;
```

File

Controls

Description

TControlActionLink is designed to link actions to generic control clients. It overrides methods to determine whether the action and client are linked, and to ensure that action events are appropriate for properties and events of control clients.

TControlActionLink overrides methods to support linking the following properties and events with control client properties or events, most of which have the same name:

Caption

Enabled

Hint

Visible

OnExecute

Use TControlActionLink as a base class when creating an action link class that targets a more specific client type. Descendant classes of TControlActionLink already support certain branches of the VCL, such as TWinControlActionLink (see page 6233), which supports TWinControl (see page 6112) client types.

TWinControlActionLink (see page 6233)

TControl (see page 5724)

TBasicAction (see page 2707)

TControl (see page 5724)

32.1.4.1 TControlActionLink Members

The following tables list the members exposed by TControlActionLink.

Protected Fields

	Name	Description
	FAction (see page 2722)	This is FAction, a member of class TBasicActionLink.
	FClient (see page 5894)	This is FClient, a member of class TControlActionLink.

Protected Methods

	Name	Description
	AssignClient (see page 5895)	Assigns a client control that is linked to the associated action.
	Change (see page 2723)	This is Change, a member of class TBasicActionLink.
	DoShowHint (see page 5896)	Indicates whether the hint is shown, and modified.
	IsCaptionLinked (see page 5896)	Indicates whether the caption for the action and the client are linked.
	IsCheckedLinked (see page 269)	Indicates whether the Checked properties for the action and client are linked.
	IsDropdownMenuLinked (see page 5896)	This is IsDropdownMenuLinked, a member of class TControlActionLink.
	IsEnabledLinked (see page 5897)	Indicates whether the enabled state for the action and the client are linked.
	IsEnableDropdownLinked (see page 5897)	This is IsEnableDropdownLinked, a member of class TControlActionLink.
	IsGroupIndexLinked (see page 270)	Indicates whether the GroupIndex property for the action controls client behavior.
	IsHelpContextLinked (see page 270)	Indicates whether the HelpContext properties for the action and client controls are linked.
	IsHelpLinked (see page 5897)	Indicates whether the help properties for the action and the client are linked.
	IsHintLinked (see page 5898)	Indicates whether the Hint property for the action and the client are linked.
	IsImageIndexLinked (see page 272)	Indicates whether the image index for the action and the client are linked.
	IsOnExecuteLinked (see page 5898)	Indicates whether the OnExecute event handler for the action and the client are linked.
	IsPopupMenuLinked (see page 5898)	This is IsPopupMenuLinked, a member of class TControlActionLink.
	IsShortCutLinked (see page 272)	Indicates whether the ShortCut properties for the action and client are linked.
	IsVisibleLinked (see page 5899)	Indicates whether the visible state for the action and the client are linked.
	SetAction (see page 2724)	This is SetAction, a member of class TBasicActionLink.
	SetAutoCheck (see page 274)	Introduces an interface for setting the AutoCheck property of a client.
	SetCaption (see page 5899)	Sets the caption of a control if the client is linked to the action for this event.
	SetChecked (see page 274)	Introduces an interface for setting the checked state of a client.
	SetDropdownMenu (see page 5899)	This is SetDropdownMenu, a member of class TControlActionLink.
	SetEnabled (see page 5900)	Sets the enabled state of a control if the client is linked to the action for this event.
	SetEnableDropdown (see page 5900)	This is SetEnableDropdown, a member of class TControlActionLink.
	SetGroupIndex (see page 275)	Introduces an interface for setting the GroupIndex property of a client.
	SetHelpContext (see page 5900)	Sets the HelpContext of a control if the client is linked to the action help properties.
	SetHelpKeyword (see page 5901)	Sets the HelpKeyword of a control if the client is linked to the action help properties.
	SetHelpType (see page 5901)	Sets the HelpType of a control if the client is linked to the action help properties.
	SetHint (see page 5901)	Sets the hint of a control if the client is linked to the action for this event.
	SetImageIndex (see page 278)	Introduces an interface for setting the image index for a client.
	SetOnExecute (see page 5902)	Sets the execution event handler for a control if the client is linked to the action for this event.
	SetPopupMenu (see page 5902)	This is SetPopupMenu, a member of class TControlActionLink.
	SetShortCut (see page 279)	Introduces an interface for setting the shortcut for a client.
	SetVisible (see page 5902)	Sets the visible state of a control if the client is linked to the action for this event.

Public Events

	Name	Description
	OnChange (see page 2725)	Occurs when an OnChange event is triggered on the action.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2721)	Instantiates and initializes a TBasicActionLink (see page 2720) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2722)	Destroys an instance of an action link object.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Execute (see page 2723)	Invokes the action's Execute method.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Update (see page 2724)	Invokes the action's Update method.

Public Properties

	Name	Description
	Action (see page 2725)	Indicates which action the link connects to its client.

32.1.4.2 TControlActionLink Fields

The fields of the TControlActionLink class are listed here.

Protected Fields

	Name	Description
	FClient (see page 5894)	This is FClient, a member of class TControlActionLink.

32.1.4.2.1 TControlActionLink.FClient Field

Pascal

```
FClient: TControl;
```

C++

```
TControl * FClient;
```

Description

This is FClient, a member of class TControlActionLink.

32.1.4.3 TControlActionLink Methods

The methods of the TControlActionLink class are listed here.

Protected Methods

	Name	Description
	AssignClient (see page 5895)	Assigns a client control that is linked to the associated action.
	DoShowHint (see page 5896)	Indicates whether the hint is shown, and modified.
	IsCaptionLinked (see page 5896)	Indicates whether the caption for the action and the client are linked.
	IsDropdownMenuLinked (see page 5896)	This is IsDropdownMenuLinked, a member of class TControlActionLink.
	IsEnabledLinked (see page 5897)	Indicates whether the enabled state for the action and the client are linked.
	IsEnableDropdownLinked (see page 5897)	This is IsEnableDropdownLinked, a member of class TControlActionLink.
	IsHelpLinked (see page 5897)	Indicates whether the help properties for the action and the client are linked.
	IsHintLinked (see page 5898)	Indicates whether the Hint property for the action and the client are linked.
	IsOnExecuteLinked (see page 5898)	Indicates whether the OnExecute event handler for the action and the client are linked.
	IsPopupMenuLinked (see page 5898)	This is IsPopupMenuLinked, a member of class TControlActionLink.
	IsVisibleLinked (see page 5899)	Indicates whether the visible state for the action and the client are linked.
	SetCaption (see page 5899)	Sets the caption of a control if the client is linked to the action for this event.
	SetDropdownMenu (see page 5899)	This is SetDropdownMenu, a member of class TControlActionLink.
	SetEnabled (see page 5900)	Sets the enabled state of a control if the client is linked to the action for this event.
	SetEnableDropdown (see page 5900)	This is SetEnableDropdown, a member of class TControlActionLink.
	SetHelpContext (see page 5900)	Sets the HelpContext of a control if the client is linked to the action help properties.
	SetHelpKeyword (see page 5901)	Sets the HelpKeyword of a control if the client is linked to the action help properties.
	SetHelpType (see page 5901)	Sets the HelpType of a control if the client is linked to the action help properties.
	SetHint (see page 5901)	Sets the hint of a control if the client is linked to the action for this event.
	SetOnExecute (see page 5902)	Sets the execution event handler for a control if the client is linked to the action for this event.
	SetPopupMenu (see page 5902)	This is SetPopupMenu, a member of class TControlActionLink.
	SetVisible (see page 5902)	Sets the visible state of a control if the client is linked to the action for this event.

32.1.4.3.1 TControlActionLink.AssignClient Method

Assigns a client control that is linked to the associated action.

Pascal

```
procedure AssignClient(AClient: TObject); override;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

TControlActionLink (see page 5892) overrides AssignClient to ensure that the client for the action descends from TControl (see page 5724). Descendants of TControlActionLink (see page 5892) can further limit the type of client associated with the link.

See Also

Action (see page 5797)

32.1.4.3.2 TControlActionLink.DoShowHint Method

Indicates whether the hint is shown, and modified.

Pascal

```
function DoShowHint(var HintStr: string): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoShowHint(AnsiString HintStr);
```

Description

DoShowHint determines whether a hint is shown when the mouse moves across a control. DoShowHint also provides an opportunity to modify the hint, and/or append a shortcut to the end of the hint string. If either the application, the control, or the action veto showing the hint, then the hint is not shown. DoShowHint returns true by default. You can override this function to return false if the hint is not shown or modified, or if the shortcut is not appended.

See Also

ShowHint (see page 5840)

DoHint (see page 303)

32.1.4.3.3 TControlActionLink.IsCaptionLinked Method

Indicates whether the caption for the action and the client are linked.

Pascal

```
function IsCaptionLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCaptionLinked();
```

Description

IsCaptionLinked indicates whether the Caption property is linked to the appropriate client property. IsCaptionLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Caption (see page 308)

Caption (see page 5806)

SetCaption (see page 5899)

32.1.4.3.4 TControlActionLink.IsDropdownMenuLinked Method

Pascal

```
function IsDropdownMenuLinked: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsDropdownMenuLinked();
```

Description

This is IsDropdownMenuLinked, a member of class TControlActionLink.

32.1.4.3.5 TControlActionLink.IsEnabledLinked Method

Indicates whether the enabled state for the action and the client are linked.

Pascal

```
function IsEnabledLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsEnabledLinked();
```

Description

IsEnabledLinked indicates whether the Enabled property is linked to the appropriate client property. IsEnabledLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Enabled (see page 310)

Enabled (see page 5821)

SetEnabled (see page 5900)

32.1.4.3.6 TControlActionLink.IsEnableDropdownLinked Method

Pascal

```
function IsEnableDropdownLinked: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsEnableDropdownLinked();
```

Description

This is IsEnableDropdownLinked, a member of class TControlActionLink.

32.1.4.3.7 TControlActionLink.IsHelpLinked Method

Indicates whether the help properties for the action and the client are linked.

Pascal

```
function IsHelpLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsHelpLinked();
```

Description

IsHelpLinked indicates whether the HelpContext, HelpKeyword, and HelpType properties are linked to the appropriate client properties. IsHelpLinked returns true if the client requests that the action control all of these properties, false otherwise.

See Also

HelpKeyword (see page 311)

HelpContext (see page 311)

HelpType (see page 312)

HelpKeyword (see page 5826)

HelpContext (see page 5826)

HelpType (see page 5827)

SetHelpContext (see page 5900)

SetHelpKeyword (see page 5901)

SetHelpType (see page 5901)

32.1.4.3.8 TControlActionLink.IsHintLinked Method

Indicates whether the Hint property for the action and the client are linked.

Pascal

```
function IsHintLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsHintLinked();
```

Description

IsHintLinked indicates whether the Hint property is linked to the appropriate client property. IsHintLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Hint (see page 312)

Hint (see page 5827)

SetHint (see page 5901)

32.1.4.3.9 TControlActionLink.IsOnExecuteLinked Method

Indicates whether the OnExecute event handler for the action and the client are linked.

Pascal

```
function IsOnExecuteLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsOnExecuteLinked();
```

Description

IsOnExecuteLinked indicates whether the OnExecute event handler is linked to the appropriate client event. IsOnExecuteLinked returns true if the client requests that the action control this event, false otherwise.

See Also

OnExecute (see page 2716)

OnClick (see page 5851)

SetOnExecute (see page 5902)

32.1.4.3.10 TControlActionLink.IsPopupMenuLinked Method

Pascal

```
function IsPopupMenuLinked: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsPopupMenuLinked();
```

Description

This is IsPopupMenuLinked, a member of class TControlActionLink.

32.1.4.3.11 TControlActionLink.IsVisibleLinked Method

Indicates whether the visible state for the action and the client are linked.

Pascal

```
function IsVisibleLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsVisibleLinked();
```

Description

IsVisibleLinked indicates whether the Visible property is linked to the appropriate client property. IsVisibleLinked returns true if the client requests that the action control this property, false otherwise.

See Also

Visible (see page 314)

Visible (see page 5847)

SetVisible (see page 5902)

32.1.4.3.12 TControlActionLink.SetCaption Method

Sets the caption of a control if the client is linked to the action for this event.

Pascal

```
procedure SetCaption(const Value: string); override;
```

C++

```
virtual __fastcall SetCaption(const AnsiString Value);
```

Description

SetCaption sets the caption of a control, and is called only if the client is linked for this event. Value specifies the string to which the caption should be set.

See Also

Caption (see page 308)

Caption (see page 5806)

IsCaptionLinked (see page 5896)

32.1.4.3.13 TControlActionLink.SetDropdownMenu Method

Pascal

```
procedure SetDropdownMenu(Value: TPopupMenu); virtual;
```

C++

```
virtual __fastcall SetDropdownMenu(TPopupMenu Value);
```

Description

This is SetDropdownMenu, a member of class TControlActionLink.

32.1.4.3.14 TControlActionLink.SetEnabled Method

Sets the enabled state of a control if the client is linked to the action for this event.

Pascal

```
procedure SetEnabled(Value: Boolean); override;
```

C++

```
virtual __fastcall SetEnabled(Boolean Value);
```

Description

SetEnabled sets the enabled state of a control, and is called only if the client is linked for this event. Value specifies whether the enabled state should be set.

See Also

Enabled (see page 310)

Enabled (see page 5821)

IsEnabledLinked (see page 5897)

32.1.4.3.15 TControlActionLink.SetEnableDropdown Method

Pascal

```
procedure SetEnableDropdown(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetEnableDropdown(Boolean Value);
```

Description

This is SetEnableDropdown, a member of class TControlActionLink.

32.1.4.3.16 TControlActionLink.SetHelpContext Method

Sets the HelpContext of a control if the client is linked to the action help properties.

Pascal

```
procedure SetHelpContext(Value: THelpContext); override;
```

C++

```
virtual __fastcall SetHelpContext(THelpContext Value);
```

Description

SetHelpContext sets the HelpContext property of a control, and is called only if the client is linked for help properties. Value specifies the help context ID to which the HelpContext property should be set.

See Also

HelpContext (see page 311)

HelpContext (see page 5826)

IsHelpLinked (see page 5897)

32.1.4.3.17 TControlActionLink.SetHelpKeyword Method

Sets the HelpKeyword of a control if the client is linked to the action help properties.

Pascal

```
procedure SetHelpKeyword(const Value: string); override;
```

C++

```
virtual __fastcall SetHelpKeyword(const AnsiString Value);
```

Description

SetHelpKeyword sets the HelpKeyword property of a control, and is called only if the client is linked for help properties. Value specifies the keyword to which the HelpKeyword property should be set.

See Also

HelpKeyword (see page 311)

HelpKeyword (see page 5826)

IsHelpLinked (see page 5897)

32.1.4.3.18 TControlActionLink.SetHelpType Method

Sets the HelpType of a control if the client is linked to the action help properties.

Pascal

```
procedure SetHelpType(Value: THelpType); override;
```

C++

```
virtual __fastcall SetHelpType(THelpType Value);
```

Description

SetHelpType sets the HelpType property of a control, and is called only if the client is linked for help properties. Value indicates the value to which the HelpType property should be set.

See Also

HelpType (see page 312)

HelpType (see page 5827)

IsHelpLinked (see page 5897)

32.1.4.3.19 TControlActionLink.SetHint Method

Sets the hint of a control if the client is linked to the action for this event.

Pascal

```
procedure SetHint(const Value: string); override;
```

C++

```
virtual __fastcall SetHint(const AnsiString Value);
```

Description

SetHint sets the hint of a control, and is called only if the client is linked for this event. Value specifies the string to which the hint should be set.

See Also

Hint (see page 312)

Hint (see page 5827)

IsHintLinked (see page 5898)

DoShowHint (see page 5896)

32.1.4.3.20 TControlActionLink.SetOnExecute Method

Sets the execution event handler for a control if the client is linked to the action for this event.

Pascal

```
procedure SetOnExecute(Value: TNotifyEvent); override;
```

C++

```
virtual __fastcall SetOnExecute(TNotifyEvent Value);
```

Description

SetOnExecute sets the appropriate execution event handler of a control, and is called only if the client is linked for this event. Value specifies the procedure that should be used for this event.

See Also

OnExecute (see page 2716)

OnClick (see page 5851)

IsOnExecuteLinked (see page 5898)

32.1.4.3.21 TControlActionLink.SetPopupMenu Method

Pascal

```
procedure SetPopupMenu(Value: TPopupMenu); virtual;
```

C++

```
virtual __fastcall SetPopupMenu(TPopupMenu Value);
```

Description

This is SetPopupMenu, a member of class TControlActionLink.

32.1.4.3.22 TControlActionLink.SetVisible Method

Sets the visible state of a control if the client is linked to the action for this event.

Pascal

```
procedure SetVisible(Value: Boolean); override;
```

C++

```
virtual __fastcall SetVisible(Boolean Value);
```

Description

SetVisible sets the visible state of a control, and is called only if the client is linked for this event. Value specifies whether the visible state should be set.

See Also

Visible (see page 314)

Visible (see page 5847)

IsVisibleLinked (see page 5899)

32.1.5 TControlCanvas Class

TControlCanvas is a specialized canvas object associated with a control.

Class Hierarchy

Pascal

```
TControlCanvas = class(TCanvas);
```

C++

```
class TControlCanvas : public TCanvas;
```

File

Controls

Description

TControlCanvas provides a graphics context for controls that render their own images.

Not all controls need a canvas. Many controls rely on rely on underlying Windows screen objects to provide rendering logic.

TControlCanvas is descended from TCanvas, which provides many properties, events, and methods to aid in the creation of rich images. TControlCanvas adds properties and methods to interact with a control object, and to manage the device context associated with the control.

See Also

TCustomControl (see page 5908)

TGraphicControl (see page 6044)

32.1.5.1 TControlCanvas Members

The following tables list the members exposed by TControlCanvas.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14450)	This is Changed, a member of class TCanvas.
	Changing (see page 14450)	This is Changing, a member of class TCanvas.
	CreateHandle (see page 5906)	This is CreateHandle, a member of class TControlCanvas.

	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	RequiredState (see page 14470)	This is RequiredState, a member of class TCanvas.

Public Events

	Name	Description
	OnChange (see page 14496)	Occurs when the image has just changed.
	OnChanging (see page 14496)	Occurs just before a change is made to the image.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Arc (see page 14448)	Draws an arc on the image along the perimeter of the ellipse bounded by the specified rectangle.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BrushCopy (see page 14449)	Copies a portion of a bitmap onto a rectangle on the canvas, replacing one of the colors of the bitmap with the brush of the canvas.
	Chord (see page 14451)	Draws a closed figure represented by the intersection of a line and an ellipse.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyRect (see page 14452)	Copies part of an image from another canvas into the canvas.
	Create (see page 14443)	Creates an instance of TCanvas (see page 14441).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 5906)	Destroys an instance of TControlCanvas (see page 5903).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Draw (see page 14454)	Renders the graphic specified by the Graphic parameter on the canvas at the location given by the coordinates (X, Y).
	DrawFocusRect (see page 14455)	Draws a rectangle in the style used to indicate that the object inside the rectangle has focus.
	Ellipse (see page 14457)	This is the overview for the Ellipse method overload.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FillRect (see page 14458)	Fills the specified rectangle on the canvas using the current brush.
	FloodFill (see page 14459)	Fills an area of the canvas using the current brush.
	FrameRect (see page 14460)	Draws a rectangle using the Brush (see page 14484) of the canvas to draw the border.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeHandle (see page 5906)	Releases the handle to a device context (HDC) used by the control canvas object.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14461)	Indicates whether the TCanvas (see page 14441) object has acquired a handle to a device context.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LineTo (see page 14462)	Draws a line on the canvas from PenPos (see page 14494) to the point specified by X and Y, and sets the pen position to (X, Y).
	Lock (see page 14463)	Prevents other threads from drawing on the canvas.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveTo (see page 14463)	Changes the current drawing position to the point (X,Y).
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pie (see page 14464)	Draws a pie-shaped the section of the ellipse bounded by the rectangle (X1, Y1) and (X2, Y2) on the canvas.
	PolyBezier (see page 14464)	Draws a set of Bezier curves.
	PolyBezierTo (see page 14465)	Draws a set of Bezier curves and updates the value of PenPos (see page 14494).
	Polygon (see page 14466)	Draws a series of lines on the canvas connecting the points passed in and closing the shape by drawing a line from the last point to the first point.
	Polyline (see page 14467)	Draws a series of lines on the canvas with the current pen, connecting each of the points passed to it in Points.
	Rectangle (see page 14468)	This is the overview for the Rectangle method overload.
	Refresh (see page 14470)	Deselects the Pen (see page 14492), Brush (see page 14484), and Font (see page 14488) from the device context.
	RoundRect (see page 14471)	Draws a rectangle with rounded corners on the canvas.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	StretchDraw (see page 14472)	Draws the graphic specified by the Graphic parameter in the rectangle specified by the Rect parameter.
	TextExtent (see page 14474)	Returns the width and height, in pixels, of a string rendered in the current font.
	TextHeight (see page 14474)	Returns the height, in pixels, of a string rendered in the current font.
	TextOut (see page 14475)	Writes a string on the canvas, starting at the point (X,Y), and then updates the PenPos (see page 14494) to the end of the string.
	TextRect (see page 14480)	This is the overview for the TextRect method overload.
	TextWidth (see page 14481)	Returns the width, in pixels, of a string rendered in the current font.
	TryLock (see page 14483)	Locks the canvas if it is currently unlocked.
	Unlock (see page 14483)	Decreases the LockCount (see page 14492) property, allowing other threads to execute when LockCount (see page 14492) reaches 0.
	UpdateTextFlags (see page 5907)	This is UpdateTextFlags, a member of class TControlCanvas.

Public Properties

	Name	Description
R	CanvasOrientation (see page 14485)	Determines the orientation of the canvas as left-to-right or right-to-left.
R	ClipRect (see page 14486)	Read-only property that specifies the boundaries of the clipping rectangle.
	Control (see page 5907)	Specifies the control associated with the control canvas object.
	Handle (see page 14489)	Specifies the handle for this canvas.
R	LockCount (see page 14492)	Indicates the number of times the canvas has been locked to prevent interference from other threads.
	PenPos (see page 14494)	Specifies the current drawing position of the Pen (see page 14492).
	Pixels (see page 14494)	Specifies the color of the pixels within the current ClipRect (see page 14486).
	TextFlags (see page 14495)	Specifies how text is written to the canvas.

Published Properties

	Name	Description
	Brush (see page 14484)	Determines the color and pattern for filling graphical shapes and backgrounds.
	CopyMode (see page 14487)	Specifies how a graphical image is copied onto the canvas.
	Font (see page 14488)	Specifies the font to use when writing text on the image.
	Pen (see page 14492)	Specifies the kind of pen the canvas uses for drawing lines and outlining shapes.

32.1.5.2 TControlCanvas.Destroy Destructor

Destroys an instance of TControlCanvas (see page 5903).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TControlCanvas();
```

Description

Do not call Destroy directly in an application. The controls that use a TControlCanvas (see page 5903) object destroy it by calling Free from their own destructors. Free verifies that the TControlCanvas (see page 5903) object is not nil and only then calls Destroy.

Destroy releases the handle to a device context (HDC) the control canvas uses before freeing the memory associated with the object.

See Also

Free (see page 22300)

FreeHandle (see page 5906)

Handle (see page 14489)

32.1.5.3 TControlCanvas Methods

The methods of the TControlCanvas class are listed here.

Protected Methods

	Name	Description
	CreateHandle (see page 5906)	This is CreateHandle, a member of class TControlCanvas.

Public Methods

	Name	Description
	FreeHandle (see page 5906)	Releases the handle to a device context (HDC) used by the control canvas object.
	UpdateTextFlags (see page 5907)	This is UpdateTextFlags, a member of class TControlCanvas.

32.1.5.3.1 TControlCanvas.CreateHandle Method

Pascal

```
procedure CreateHandle; override;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

This is CreateHandle, a member of class TControlCanvas.

32.1.5.3.2 TControlCanvas.FreeHandle Method

Releases the handle to a device context (HDC) used by the control canvas object.

Pascal

```
procedure FreeHandle;
```

C++

```
__fastcall FreeHandle();
```

Description

Call FreeHandle to free the HDC used by the control canvas. FreeHandle sets the Handle property to NULL. After calling FreeHandle, an HDC will be reacquired if any of the drawing methods are called.

Note: Setting the Handle property to NULL does not free the HDC. Set the Handle property to NULL rather than call FreeHandle if the HDC is release by the application.

See Also

Handle (see page 14489)

32.1.5.3.3 TControlCanvas.UpdateTextFlags Method

Pascal

```
procedure UpdateTextFlags;
```

C++

```
__fastcall UpdateTextFlags();
```

Description

This is UpdateTextFlags, a member of class TControlCanvas.

32.1.5.4 TControlCanvas Properties

The properties of the TControlCanvas class are listed here.

Public Properties

	Name	Description
	Control (see page 5907)	Specifies the control associated with the control canvas object.

32.1.5.4.1 TControlCanvas.Control Property

Specifies the control associated with the control canvas object.

Pascal

```
property Control: TControl;
```

C++

```
__property TControl * Control;
```

Description

Read Control to gain access to the control associated with the control canvas object. Descendants of TWinControl (see page 6112) that use a control canvas set the Control property to form the association. The control canvas object uses the Control property to get information from its associated control.

32.1.6 TCustomControl Class

Base class for controls that wrap Windows screen objects but perform their own rendering.

Class Hierarchy

Pascal

```
TCustomControl = class(TWinControl);
```

C++

```
class TCustomControl : public TWinControl;
```

File

Controls

Description

In most descendants of TWinControl (see page 6112), the job of drawing the control's surface belongs to the underlying Windows screen object. If a control has visible features that cannot be rendered by a Windows screen object, it requires access to a canvas object so it can do its own drawing.

TCustomControl is one of two base classes for controls that draw their own surfaces. Because TCustomControl is descended from TWinControl (see page 6112), instances of its descendants can receive the focus and serve as containers.

Classes (see page 2685) of controls that perform their own screen rendering and do not need the features of TWinControl (see page 6112) should be descendants of TGraphicControl (see page 6044) instead of TCustomControl. TGraphicControl (see page 6044) objects can render themselves with less overhead, because they do not have underlying Windows screen objects.

TCustomControl objects have a Paint (see page 5920) method, which is called whenever the control needs to render its image. Custom controls paint themselves using the Canvas (see page 5921) property.

See Also

TCanvas (see page 14441)

TGraphicControl (see page 6044)

TWinControl (see page 6112)

32.1.6.1 TCustomControl Members

The following tables list the members exposed by TCustomControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.

	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.

	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.

	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.

	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.

	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.

	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 5918)	Creates an instance of TCustomControl (see page 5908).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.

	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.

V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.

R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.6.2 TCustomControl.Create Constructor

Creates an instance of TCustomControl (see page 5908).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomControl(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TCustomControl (see page 5908). However, you should never attempt to instantiate a TCustomControl (see page 5908). This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants. Controls (see page 5711) placed on forms at design time are created automatically.

After calling the inherited constructor, Create initializes the control, including the following property settings:

Initializes a TCanvas object for its Canvas (see page 5921) property.

When overriding Create, always call the inherited Create method first, then proceed with the control's initialization. Remember to specify the override directive when overriding the Create method.

Note: If a component's constructor allocates resources or memory, also override the destructor to free those resources.

See Also

Create (see page 6123)

Destroy (see page 5919)

Canvas (see page 5921)

Owner (see page 2807)

32.1.6.3 TCustomControl.Destroy Destructor

Destroys an instance of TCustomControl (see page 5908).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomControl();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the control is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Destroys the TCanvas object in its Canvas (see page 5921) property.

Override Destroy to free any memory or resources allocated in the Create (see page 5918) method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

Create (see page 5918)

32.1.6.4 TCustomControl Methods

The methods of the TCustomControl class are listed here.

Protected Methods

	Name	Description
	Paint (see page 5920)	Renders the image of a custom control.
	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.

32.1.6.4.1 TCustomControl.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; virtual;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl (see page 5908) does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow (see page 5920) method, after that method has supplied the Canvas (see page 5921) with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

See Also

Canvas (see page 5921)

PaintWindow (see page 5920)

GetDeviceContext (see page 6155)

ClipRect (see page 14486)

32.1.6.4.2 TCustomControl.PaintWindow Method

Renders the image of the control on a specified device context.

Pascal

```
procedure PaintWindow(DC: HDC); override;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

PaintWindow is called automatically when a custom control receives a WM_PAINT message. PaintWindow assigns the device context specified by the DC parameter to the custom control's canvas, calls the Paint (see page 5920) method, and finally removes the device context. Override PaintWindow to provide additional responses to the WM_PAINT message. To draw the

image of the control, override the Paint (see page 5920) method instead.

Canvas (see page 5921)

Paint (see page 5920)

GetDeviceContext (see page 6155)

32.1.6.5 TCustomControl Properties

The properties of the TCustomControl class are listed here.

Protected Properties

	Name	Description
	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.

32.1.6.5.1 TCustomControl.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl (see page 5908).

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
```

```
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = (TStringGrid *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
```

```
if (ListBox1.Items.Objects[Index] is TStringGrid) then
begin
  myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
  with myStringGrid.ClientRect do
  begin // make sure we are using the TControl's canvas and not the form's!
    myStringGrid.Canvas.MoveTo(Left, Top);
    myStringGrid.Canvas.LineTo(Right, Bottom);
  end;
myStringGrid:= nil;
end;
```

32.1.7 TCustomControlAction Class

Class Hierarchy

Pascal

```
TCustomControlAction = class(TCustomAction);
```

C++

```
class TCustomControlAction : public TCustomAction;
```

File

Controls

Description

This is class Controls.TCustomControlAction.

32.1.7.1 TCustomControlAction Members

The following tables list the members exposed by TCustomControlAction.

Protected Events

	Name	Description
	OnChange (see page 2716)	Occurs when one of the action's properties changes.

Protected Fields

	Name	Description
	FClients (see page 2711)	This is FClients, a member of class TBasicAction.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FImage (see page 302)	This is FImage, a member of class TCustomAction.
	FMask (see page 303)	This is FMask, a member of class TCustomAction.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.

	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 303)	Copies the properties of this action to a destination object.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Change (see page 2712)	Generates an OnChange (see page 2716) event.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	HandleShortCut (see page 306)	Executes the action when the user types on of its short cuts.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2713)	Responds when components are created or destroyed.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 294)	This is ReadState, a member of class TContainedAction.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetHelpContext (see page 306)	This is SetHelpContext, a member of class TCustomAction.
V	SetHelpKeyword (see page 306)	This is SetHelpKeyword, a member of class TCustomAction.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 307)	Sets the value of the Name property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetOnExecute (see page 2714)	Assigns an OnExecute (see page 2716) event handler.
V	SetParentComponent (see page 294)	This is SetParentComponent, a member of class TContainedAction.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	SavedEnabledState (see page 313)	Saves the value of the Enabled (see page 310) property when the action is suspended.

Public Events

	Name	Description
	OnExecute (see page 2716)	Occurs when the client event that is linked to it fires.
	OnHint (see page 315)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 2718)	Occurs when the application is idle or when the action list updates.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 301)	Instantiates and initializes a TCustomAction (see page 297) object.
V	Create (see page 2710)	Instantiates and initializes a TBasicAction (see page 2707) object.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 292)	Destroys the instance of the contained action.
V	Destroy (see page 302)	Frees an instance of TCustomAction (see page 297).
V	Destroy (see page 2711)	Disposes of an instance of a TBasicAction (see page 2707) object.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoHint (see page 303)	Generates an OnHint (see page 315) event.
V	Execute (see page 293)	Responds when the client control "fires".
V	Execute (see page 304)	Responds when a client control "fires".
	Execute (see page 2712)	Generates an OnExecute (see page 2716) event.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
V	ExecuteTarget (see page 2712)	Introduces an interface for invoking an action on a target client component or control.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.

	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetParentComponent (see page 293)	Returns the action list or action manager that contains the action.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	HandlesTarget (see page 2713)	Introduces an interface for verifying that the type, and state, of a target component or control are appropriate for the action.
V	HasParent (see page 294)	Indicates whether the action is contained in an action list or action manager.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RegisterChanges (see page 2713)	Associates the action with an action link.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UnRegisterChanges (see page 2714)	Breaks the association between the action and the action link.
V	Update (see page 295)	Indicates whether the action updates itself.
V	Update (see page 2714)	Provides an opportunity to execute centralized code when an application is idle.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
V	UpdateTarget (see page 2715)	Introduces an interface for a method of notifying a client when the action updates itself.

Public Properties

	Name	Description
	ActionComponent (see page 2715)	Indicates the client component that caused this action to execute.
	ActionList (see page 295)	Indicates the action list or action manager that contains the action.
	AutoCheck (see page 308)	Controls (see page 5711) whether the Checked (see page 308) property toggles when the action executes.
	Caption (see page 308)	Represents the caption of client controls and menu items.
	Checked (see page 308)	Indicates whether client controls and menu items appear checked.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.

R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DisableIfNoHandler (see page 310)	Indicates whether client components should be disabled if no handler is found.
	DropdownMenu (see page 5927)	This is DropdownMenu, a member of class TCustomControlAction.
	Enabled (see page 310)	Indicates whether client controls and menu items are enabled.
	EnableDropdown (see page 5928)	This is EnableDropdown, a member of class TCustomControlAction.
	GroupIndex (see page 311)	Indicates whether the action acts like a radio button with other actions in the same action list.
	HelpContext (see page 311)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 311)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 312)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 312)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 313)	Indicates the ImageIndex property for client controls and menu items.
	Index (see page 296)	Specifies the index of the action in its action list or action manager.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	PopupMenu (see page 5928)	This is PopupMenu, a member of class TCustomControlAction.
	SecondaryShortCuts (see page 314)	Specifies the short cuts (in addition to ShortCut (see page 314)) for triggering clients.
	ShortCut (see page 314)	Specifies the ShortCut property for client menu items.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 314)	Specifies the Visible property for client controls and menu items.

Published Properties

	Name	Description
	Category (see page 296)	Specifies the category under which the action appears in its action list or action manager.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

32.1.7.2 TCustomControlAction Properties

The properties of the TCustomControlAction class are listed here.

Public Properties

	Name	Description
	DropdownMenu (see page 5927)	This is DropdownMenu, a member of class TCustomControlAction.
	EnableDropdown (see page 5928)	This is EnableDropdown, a member of class TCustomControlAction.
	PopupMenu (see page 5928)	This is PopupMenu, a member of class TCustomControlAction.

32.1.7.2.1 TCustomControlAction.DropdownMenu Property

Pascal

```
property DropdownMenu: TPopupMenu;
```

C++

```
__property TPopupMenu DropdownMenu;
```

Description

This is DropdownMenu, a member of class TCustomControlAction.

32.1.7.2.2 TCustomControlAction.EnableDropdown Property

Pascal

```
property EnableDropdown: Boolean;
```

C++

```
__property Boolean EnableDropdown;
```

Description

This is EnableDropdown, a member of class TCustomControlAction.

32.1.7.2.3 TCustomControlAction.PopupMenu Property

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

This is PopupMenu, a member of class TCustomControlAction.

32.1.8 TCustomListControl Class

TCustomListControl is the base class for controls that display a list of items.

Class Hierarchy

Pascal

```
TCustomListControl = class(TWinControl);
```

C++

```
class TCustomListControl : public TWinControl;
```

File

Controls

Description

TCustomListControl is the common base class for controls that represent a list of items. Its descendants include combo boxes, list boxes, and list views. TCustomListControl introduces a common set of properties and methods for working with the items in the list. This includes the ability to

Add items to the list.

Delete items from the list.

Select items in the list.

Copy items to another TCustomListControl descendant.

Rearrange the order of items.

TCustomListControl cannot be instantiated directly.

See Also

TComboBox (see page 21064)

TComboBoxEx (see page 3463)

TColorBox (see page 12182)

TListBox (see page 21598)

TListView (see page 4285)

32.1.8.1 TCustomListControl Members

The following tables list the members exposed by TCustomListControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.

	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.

	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.

	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.

	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.

	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.

	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
A	AddItem (see page 5940)	Adds an item to the list control.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 5940)	Deletes all of the items from the list control.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.

	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.

	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MoveSelection (see page 5942)	Moves all selected items to another list control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.

	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.8.2 TCustomListControl Methods

The methods of the TCustomListControl class are listed here.

Protected Methods

	Name	Description
A	GetCount (see page 5942)	Returns the number of items in the list.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.

Public Methods

	Name	Description
A	AddItem (see page 5940)	Adds an item to the list control.
A	Clear (see page 5940)	Deletes all of the items from the list control.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	MoveSelection (see page 5942)	Moves all selected items to another list control.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.

32.1.8.2.1 TCustomListControl.AddItem Method

Adds an item to the list control.

Pascal

```
procedure AddItem(Item: String; AObject: TObject); virtual; abstract;
```

C++

```
virtual __fastcall AddItem(AnsiString Item, TObject * AObject) = 0;
```

Description

AddItem adds an item to the end of the list, possibly associating it with a specified object.

Item is the text that is the item's value. This is the string that appears for the item in the list control.

AObject is an object that you can associated with the item. Note that the list control does not take ownership of this object. That is, if you delete the item, the corresponding object is not freed.

32.1.8.2.2 TCustomListControl.Clear Method

Deletes all of the items from the list control.

Pascal

```
procedure Clear; virtual; abstract;
```

C++

```
virtual __fastcall Clear() = 0;
```

Description

Clear empties the list control so that it contains no items.

See Also

DeleteSelected (see page 5941)

32.1.8.2.3 TCustomListControl.ClearSelection Method

Removes the selection, leaving all items unselected.

Pascal

```
procedure ClearSelection; virtual; abstract;
```

C++

```
virtual __fastcall ClearSelection() = 0;
```

Description

Call ClearSelection to deselect any selected items in the list control. ClearSelection removes the selection, but leaves the items in the list.

See Also

Clear (see page 5940)

CopySelection (see page 5941)

DeleteSelected (see page 5941)

MoveSelection (see page 5942)

SelectAll (see page 5943)

ItemIndex (see page 5944)

32.1.8.2.4 TCustomListControl.CopySelection Method

Copies the selected item or items to another TCustomListControl (see page 5928) descendant.

Pascal

```
procedure CopySelection(Destination: TCustomListControl); virtual; abstract;
```

C++

```
virtual __fastcall CopySelection(TCustomListControl Destination) = 0;
```

Description

CopySelection adds all selected items to another TCustomListControl (see page 5928) descendant.

Destination is the list control that receives the items.

See Also

ClearSelection (see page 5940)

DeleteSelected (see page 5941)

MoveSelection (see page 5942)

SelectAll (see page 5943)

ItemIndex (see page 5944)

AddItem (see page 5940)

32.1.8.2.5 TCustomListControl.DeleteSelected Method

Deletes all the selected items.

Pascal

```
procedure DeleteSelected; virtual; abstract;
```

C++

```
virtual __fastcall DeleteSelected() = 0;
```

Description

Call DeleteSelected to remove all selected items from the list control. DeleteSelected deletes only the item or items that are selected.

See Also

Clear (see page 5940)

CopySelection (see page 5941)

ClearSelection (see page 5940)

MoveSelection (see page 5942)

SelectAll (see page 5943)

ItemIndex (see page 5944)

32.1.8.2.6 TCustomListControl.GetCount Method

Returns the number of items in the list.

Pascal

```
function GetCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetCount() = 0;
```

Description

Call GetCount to determine the number of items in the list control.

32.1.8.2.7 TCustomListControl.GetItemIndex Method

Returns the value of the ItemIndex (see page 5944) property.

Pascal

```
function GetItemIndex: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemIndex() = 0;
```

Description

Override GetItemIndex to provide the read implementation for the ItemIndex (see page 5944) property. GetItemIndex returns the index of the selected item, where the first item in the list has index 0, the second item has index 1, and so on. If no item is selected, GetItemIndex returns -1. If the list control supports multiple selected items, GetItemIndex returns the index of the selected item that has focus.

See Also

ItemIndex (see page 5944)

SetItemIndex (see page 5943)

32.1.8.2.8 TCustomListControl.MoveSelection Method

Moves all selected items to another list control.

Pascal

```
procedure MoveSelection(Destination: TCustomListControl); virtual;
```

C++

```
virtual __fastcall MoveSelection(TCustomListControl Destination);
```

Description

Call MoveSelection to copy all selected items to another list control and then delete them from this list control.

See Also

Clear (see page 5940)

CopySelection (see page 5941)

ClearSelection (see page 5940)

DeleteSelected (see page 5941)

SelectAll (see page 5943)

ItemIndex (see page 5944)

32.1.8.2.9 TCustomListControl.SelectAll Method

Selects all items or all text in the selected item.

Pascal

```
procedure SelectAll; virtual; abstract;
```

C++

```
virtual __fastcall SelectAll() = 0;
```

Description

SelectAll performs different tasks, depending on the custom list control descendant. In list controls that allow multiple items to be selected, SelectAll selects all items in the list. In list controls that allow only one item to be selected, SelectAll selects the entire text of the current item.

See Also

Clear (see page 5940)

CopySelection (see page 5941)

ClearSelection (see page 5940)

DeleteSelected (see page 5941)

MoveSelection (see page 5942)

ItemIndex (see page 5944)

32.1.8.2.10 TCustomListControl.SetItemIndex Method

Sets the value of the ItemIndex (see page 5944) property.

Pascal

```
procedure SetItemIndex(const Value: Integer); virtual; abstract; overload;
```

C++

```
virtual __fastcall SetItemIndex(const int Value) = 0;
```

Description

Override SetItemIndex to provide the write implementation for the ItemIndex (see page 5944) property.

Value represents the index of the item to select, where the first item in the list has index 0, the second item has index 1, and so on. If Value is –1, SetItemIndex deselects all items (the same as the ClearSelection (see page 5940) method).

See Also

ItemIndex (see page 5944)

GetItemIndex (see page 5942)

ClearSelection (see page 5940)

32.1.8.3 TCustomListControl Properties

The properties of the TCustomListControl class are listed here.

Public Properties

	Name	Description
	ItemIndex (see page 5944)	Specifies the index of the selected item.

32.1.8.3.1 TCustomListControl.ItemIndex Property

Specifies the index of the selected item.

Pascal

```
property ItemIndex: Integer;
```

C++

```
__property int ItemIndex;
```

Description

Read ItemIndex to determine which item is selected. The first item in the list has index 0, the second item has index 1, and so on. If no item is selected, the value of ItemIndex is -1. If the list control supports multiple selected items, ItemIndex is the index of the selected item that has focus.

Set ItemIndex programmatically to select an item by passing in the index value.

Note: To implement the ItemIndex property in a TCustomListControl (see page 5928) descendant, override the protected GetItemIndex (see page 5942) and SetItemIndex (see page 5943) methods.

See Also

GetItemIndex (see page 5942)

SetItemIndex (see page 5943)

32.1.9 TCustomMultiSelectListControl Class

TCustomMultiSelectListControl is the base class for list controls that allow multiple items to be selected.

Class Hierarchy

Pascal

```
TCustomMultiSelectListControl = class(TCustomListControl);
```

C++

```
class TCustomMultiSelectListControl : public TCustomListControl;
```

File

Controls

Description

TCustomMultiSelectListControl is the common base class for controls that represent a list of items where the user can select one or more of those items. Its descendants include list boxes and list views. TCustomMultiSelectListControl implements a common set of properties and methods for working with the items in the list. This includes the ability to

Specify whether the control allows one or multiple items to be selected.

Determine the number of selected items.

Add items to the list.

Delete items from the list.

Select items in the list.

Copy items to another list control.

Rearrange the order of items.

TCustomMultiSelectListControl is an abstract class and cannot be directly instantiated.

See Also

TListBox (see page 21598)

TListView (see page 4285)

32.1.9.1 TCustomMultiSelectListControl Members

The following tables list the members exposed by TCustomMultiSelectListControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FMultiSelect (see page 5956)	This is FMultiSelect, a member of class TCustomMultiSelectListControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.

	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.

	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
A	GetSelCount (see page 5956)	Returns the value of the SelCount (see page 5957) property.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.

V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.

	SetMultiSelect (see page 5956)	Sets the value of the MultiSelect (see page 5957) property.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.

	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
A	AddItem (see page 5940)	Adds an item to the list control.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 5940)	Deletes all of the items from the list control.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.

V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.

	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MoveSelection (see page 5942)	Moves all selected items to another list control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.

	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.

R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	MultiSelect (see page 5957)	Specifies whether the user can select more than one item.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	SelCount (see page 5957)	Indicates the number of selected items.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.9.2 TCustomMultiSelectListControl Fields

The fields of the TCustomMultiSelectListControl class are listed here.

Protected Fields

	Name	Description
	FMultiSelect (see page 5956)	This is FMultiSelect, a member of class TCustomMultiSelectListControl.

32.1.9.2.1 TCustomMultiSelectListControl.FMultiSelect Field

Pascal

```
FMultiSelect: Boolean;
```

C++

```
Boolean FMultiSelect;
```

Description

This is FMultiSelect, a member of class TCustomMultiSelectListControl.

32.1.9.3 TCustomMultiSelectListControl Methods

The methods of the TCustomMultiSelectListControl class are listed here.

Protected Methods

	Name	Description
	GetSelCount (see page 5956)	Returns the value of the SelCount (see page 5957) property.
	SetMultiSelect (see page 5956)	Sets the value of the MultiSelect (see page 5957) property.

32.1.9.3.1 TCustomMultiSelectListControl.GetSelCount Method

Returns the value of the SelCount (see page 5957) property.

Pascal

```
function GetSelCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetSelCount() = 0;
```

Description

Override GetSelCount to provide the read implementation for the SelCount (see page 5957) property. GetSelCount returns the number of items that are currently selected.

See Also

SelCount (see page 5957)

32.1.9.3.2 TCustomMultiSelectListControl.SetMultiSelect Method

Sets the value of the MultiSelect (see page 5957) property.

Pascal

```
procedure SetMultiSelect(Value: Boolean); virtual; abstract;
```

C++

```
virtual __fastcall SetMultiSelect(Boolean Value) = 0;
```

Description

Override SetMultiSelect to provide the write implementation for the MultiSelect (see page 5957) property.

Value is true if the control should allow the user to select more than one item at a time, false if the control should support at most one selected item.

See Also

MultiSelect (see page 5957)

32.1.9.4 TCustomMultiSelectListControl Properties

The properties of the TCustomMultiSelectListControl class are listed here.

Public Properties

	Name	Description
	MultiSelect (see page 5957)	Specifies whether the user can select more than one item.
R	SelCount (see page 5957)	Indicates the number of selected items.

32.1.9.4.1 TCustomMultiSelectListControl.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect: Boolean;
```

C++

```
__property Boolean MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount (see page 5957) property indicates the number of selected items. When MultiSelect is false, the user can only select one item, which is indicated by the ItemIndex (see page 5944) property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl (see page 5944) descendant, override the protected SetMultiSelect (see page 5956) method.

See Also

SelCount (see page 5957)

ItemIndex (see page 5944)

32.1.9.4.2 TCustomMultiSelectListControl.SelCount Property

Indicates the number of selected items.

Pascal

```
property SelCount: Integer;
```

C++

```
__property int SelCount;
```

Description

Read SelCount to determine the number of items that are currently selected. If the value of the MultiSelect (see page 5957)

property is false, SelCount is always -1. If MultiSelect (see page 5957) is true, the value of SelCount can be greater than 1 as well.

Note: To implement the SelCount property in a TCustomMultiSelectListControl (see page 5944) descendant, override the protected GetSelCount (see page 5956) method.

See Also

MultiSelect (see page 5957)

ItemIndex (see page 5944)

32.1.10 TCustomPanningWindow Class

This is an abstract base class that is used as an ancestor for users to implement a custom panning window.

Class Hierarchy

Pascal

```
TCustomPanningWindow = class(TCustomControl);
```

C++

```
class TCustomPanningWindow : public TCustomControl;
```

File

Controls

Description

To create a custom panning window, create a sub-class of this class and over-ride the method for the part of the implementation that you want to customize.

See Also

TCustomPanningWindow

GetIsPanning

StartPanning

StopPanning

32.1.10.1 TCustomPanningWindow Members

The following tables list the members exposed by TCustomPanningWindow.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.

	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.

	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.

	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.

	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.

	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.

	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 5918)	Creates an instance of TCustomControl (see page 5908).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
A	GetIsPanning (see page 5969)	Returns whether or not the mouse is actively panning.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.

	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
A	StartPanning (see page 5969)	Tells the panning window to start the panning operation.
A	StopPanning (see page 5969)	Tells the panning window to stop the panning operation.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.

R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.

	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.10.2 TCustomPanningWindow Methods

The methods of the TCustomPanningWindow class are listed here.

Public Methods

	Name	Description
	GetIsPanning (see page 5969)	Returns whether or not the mouse is actively panning.
	StartPanning (see page 5969)	Tells the panning window to start the panning operation.
	StopPanning (see page 5969)	Tells the panning window to stop the panning operation.

32.1.10.2.1 TCustomPanningWindow.GetIsPanning Method

Returns whether or not the mouse is actively panning.

Pascal

```
function GetIsPanning: Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean GetIsPanning() = 0;
```

Description

This method brings back a boolean value. True means that the mouse is actively panning; False indicates that no panning is occurring.

32.1.10.2.2 TCustomPanningWindow.StartPanning Method

Tells the panning window to start the panning operation.

Pascal

```
function StartPanning(AHandle: THandle; AControl: TControl): Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean StartPanning(THandle AHandle, TControl * AControl) = 0;
```

Description

Include this method in your code where you want the panning window to start the panning operation.

32.1.10.2.3 TCustomPanningWindow.StopPanning Method

Tells the panning window to stop the panning operation.

Pascal

```
procedure StopPanning; virtual; abstract;
```

C++

```
virtual __fastcall StopPanning() = 0;
```

Description

Add this method to your code where you want the panning window to stop the panning operation.

32.1.11 TCustomTransparentControl Class

Base class for transparent controls.

Class Hierarchy

Pascal

```
TCustomTransparentControl = class(TCustomControl);
```

C++

```
class TCustomTransparentControl : public TCustomControl;
```

File

Controls

Description

Use TCustomTransparentControl as the base class for drawing transparent controls.

32.1.11.1 TCustomTransparentControl Members

The following tables list the members exposed by TCustomTransparentControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.

	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 5981)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateControlsUnderneath (see page 5982)	This is InvalidateControlsUnderneath, a member of class TCustomTransparentControl.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.

	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.

	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WMNCHitTest (see page 5982)	This is WMNCHitTest, a member of class TCustomTransparentControl.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.

R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.

	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 5980)	Creates an instance of TCustomControl.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.

	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5982)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.

	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.

	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	InterceptMouse (see page 5983)	Specifies whether the control is transparent to the mouse.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.11.2 TCustomTransparentControl.Create Constructor

Creates an instance of TCustomControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomTransparentControl(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TCustomControl. However, you should never attempt to instantiate a TCustomControl. This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants. Controls placed on forms at design time are created automatically.

After calling the inherited constructor, Create initializes the control, including the following property settings:

Initializes a TCanvas object for its Canvas property.

When overriding Create, always call the inherited Create method first, then proceed with the control's initialization. Remember to specify the override directive when overriding the Create method.

Note: If a component's constructor allocates resources or memory, also override the destructor to free those resources.

See Also

Create (see page 6123)

Destroy (see page 5919)

Canvas (see page 5921)

Owner (see page 2807)

32.1.11.3 TCustomTransparentControl Methods

The methods of the TCustomTransparentControl class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 5981)	Initializes a window-creation parameter data structure.
	InvalidateControlsUnderneath (see page 5982)	This is InvalidateControlsUnderneath, a member of class TCustomTransparentControl.
	WMNCHitTest (see page 5982)	This is WMNCHitTest, a member of class TCustomTransparentControl.

Public Methods

	Name	Description
	Invalidate (see page 5982)	Schedules a control repaint.

32.1.11.3.1 TCustomTransparentControl.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

32.1.11.3.2 TCustomTransparentControl.Invalidate Method

Schedules a control repaint.

Pascal

```
procedure Invalidate; override;
```

C++

```
virtual __fastcall Invalidate();
```

Description

Invalidate informs a control that its entire surface needs to be repainted. Calling Invalidate can prevent flicker caused by a series of partial repaints. There is no performance penalty for calling Invalidate multiple times before the control is actually repainted.

The actual repaint does not occur until the control is updated. To force an immediate repaint, call Repaint instead.

See Also

Repaint (see page 6174)

Update (see page 6183)

32.1.11.3.3 TCustomTransparentControl.InvalidateControlsUnderneath Method

Pascal

```
procedure InvalidateControlsUnderneath;
```

C++

```
__fastcall InvalidateControlsUnderneath();
```

Description

This is InvalidateControlsUnderneath, a member of class TCustomTransparentControl.

32.1.11.3.4 TCustomTransparentControl.WMNCHitTest Method

Pascal

```
procedure WMNCHitTest(var Message: TWMNCHitTest); message WM_NCHITTEST;
```

C++

```
__fastcall WMNCHitTest(TWMNCHitTest Message);
```

Description

This is WMNCHitTest, a member of class TCustomTransparentControl.

32.1.11.4 TCustomTransparentControl Properties

The properties of the TCustomTransparentControl class are listed here.

Public Properties

	Name	Description
	InterceptMouse (see page 5983)	Specifies whether the control is transparent to the mouse.

32.1.11.4.1 TCustomTransparentControl.InterceptMouse Property

Specifies whether the control is transparent to the mouse.

Pascal

```
property InterceptMouse: Boolean;
```

C++

```
__property Boolean InterceptMouse;
```

Description

If set to True, the transparent control captures mouse clicks. If set to False, the transparent control ignores mouse clicks. By default, this property is set to False.

32.1.12 TDockTree Class

TDockTree is the default docking manager for TWinControl (see page 6112).

Class Hierarchy

Pascal

```
TDockTree = class(TInterfacedObject, IDockManager);
```

C++

```
class TDockTree : public TInterfacedObject, public IDockManager;
```

File

Controls

Description

TDockTree handles the tasks of inserting and removing controls when they are docked to or undocked from a windowed control, including details such as positioning controls and any painting that is associated with docking operations. TDockTree implements the type of docking zones that appear in the IDE, with splitters that let users resize the docking zones, and grab regions where users must click to start an undock operation.

If an application does not explicitly assign a value to a windowed control's DockManager property, then the windowed control uses TDockTree to handle docking operations (if the UseDockManager property is true).

TDockTree implements the IDockManager (see page 6238) interface.

See Also

DefaultDockTreeClass (see page 6321)

TWinControl (see page 6112)

TWinControl (see page 6112)

IDockManager (see page 6238)

32.1.12.1 TDockTree Members

The following tables list the members exposed by TDockTree.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
V	AdjustDockRect (see page 5987)	Adjusts the boundaries of the docking zone where a specified control is docked.
V	AdjustFrameRect (see page 5988)	This is AdjustFrameRect, a member of class TDockTree.
	BeginUpdate (see page 5988)	Responds when the docked controls are about to change.
	EndUpdate (see page 5988)	Responds when the docked controls have finished changing.
	FindControlAtPos (see page 5989)	This is FindControlAtPos, a member of class TDockTree.
	GetControlBounds (see page 5989)	Returns the dimensions allotted to a control that is already docked.
V	HitTest (see page 5990)	Indicates which docked control is at a specified mouse position.
V	InsertControl (see page 5990)	Handles the docking of a control into the associated DockSite (see page 5996).
V	LoadFromStream (see page 5991)	Creates docking zones for a set of docked controls read from a stream.
V	MouseDown (see page 5991)	This is MouseDown, a member of class TDockTree.
V	MouseMove (see page 5991)	This is MouseMove, a member of class TDockTree.
V	MouseUp (see page 5992)	This is MouseUp, a member of class TDockTree.
V	PaintDockFrame (see page 5992)	Paints the elements of a docking zone that surround a docked control.
V	PositionDockRect (see page 5993)	Computes the dimensions of a new docking zone.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.
V	ReferenceFromOrient (see page 5993)	This is ReferenceFromOrient, a member of class TDockTree.
V	RemoveControl (see page 5993)	Handles the undocking of a control from the associated DockSite (see page 5996).
V	ResetBounds (see page 5994)	Recomputes the layout of docked controls.
V	SaveToStream (see page 5994)	Saves a list of the set of docked controls and their positions to a stream.
	SetReplacingControl (see page 5995)	Prepares the dock tree for replacing one docked control with another.
V	ShowHint (see page 5995)	This is ShowHint, a member of class TDockTree.
	UpdateAll (see page 5995)	Makes any internal adjustments to reflect the current state of the docked controls.
V	WndProc (see page 5996)	This is WndProc, a member of class TDockTree.
V	ZoneCaptionHitTest (see page 5996)	This is ZoneCaptionHitTest, a member of class TDockTree.

Protected Properties

	Name	Description
	DockSite (see page 5996)	Specifies the windowed control that uses this dock tree to manage docking operations.
	RelativeSizes (see page 5997)	This is RelativeSizes, a member of class TDockTree.

R	TopZone (see page 5997)	This is TopZone, a member of class TDockTree.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 5985)	Creates and initializes a TDockTree (see page 5983) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 5986)	Frees the memory associated with the TDockTree (see page 5983) object.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	PaintSite (see page 5992)	Paints the elements that surround all docked controls.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

32.1.12.2 TDockTree.Create Constructor

Creates and initializes a TDockTree (see page 5983) object.

Pascal

```
constructor Create(DockSite: TWinControl); virtual;
```

C++

```
virtual __fastcall TDockTree(TWinControl * DockSite);
```

Description

Createinstantiates a new TDockTree (see page 5983) object to manage docking operations for the control specified by the DockSite (see page 5996) parameter. Typically, applications do not create TDockTree (see page 5983) objects. Instead, the windowed control that is the value of the DockSite (see page 5996) parameter creates the dock tree when an application sets its UseDockManager property to true.

DockSite (see page 5996) is the windowed control that uses the dock tree to manage the docking of child controls. It becomes the value of the DockSite (see page 5996) property.

Createinitializes the new dock tree to reflect any controls currently docked in DockSite (see page 5996). It then replaces the WindowProc property of DockSite (see page 5996) with a method that handles all docking-related messages, passing any other messages on to DockSite (see page 5996)'s previous window procedure.

See Also

UseDockManager (see page 6212)

DockManager (see page 6202)

DefaultDockTreeClass (see page 6321)

DockSite (see page 5996)

WindowProc (see page 5872)

32.1.12.3 TDockTree.Destroy Destructor

Frees the memory associated with the TDockTree (see page 5983) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDockTree();
```

Description

Do not explicitly destroy TDockTree (see page 5983) objects. As interfaced objects, dock trees are destroyed automatically when the reference count of their IDockManager (see page 6238) interface drops to zero.

Destroy detaches the dock tree from the windowed control specified by the DockSite (see page 5996) property, restoring its WindowProc property to the value it had when it called the TDockTree (see page 5983) constructor.

See Also

RefCount (see page 22281)

Create (see page 5985)

DockSite (see page 5996)

WindowProc (see page 5872)

32.1.12.4 TDockTree Methods

The methods of the TDockTree class are listed here.

Protected Methods

	Name	Description
	AdjustDockRect (see page 5987)	Adjusts the boundaries of the docking zone where a specified control is docked.
	AdjustFrameRect (see page 5988)	This is AdjustFrameRect, a member of class TDockTree.
	BeginUpdate (see page 5988)	Responds when the docked controls are about to change.
	EndUpdate (see page 5988)	Responds when the docked controls have finished changing.
	FindControlAtPos (see page 5989)	This is FindControlAtPos, a member of class TDockTree.
	GetControlBounds (see page 5989)	Returns the dimensions allotted to a control that is already docked.
	HitTest (see page 5990)	Indicates which docked control is at a specified mouse position.
	InsertControl (see page 5990)	Handles the docking of a control into the associated DockSite (see page 5996).
	LoadFromStream (see page 5991)	Creates docking zones for a set of docked controls read from a stream.
	MouseDown (see page 5991)	This is MouseDown, a member of class TDockTree.
	MouseMove (see page 5991)	This is MouseMove, a member of class TDockTree.
	MouseUp (see page 5992)	This is MouseUp, a member of class TDockTree.
	PaintDockFrame (see page 5992)	Paints the elements of a docking zone that surround a docked control.
	PositionDockRect (see page 5993)	Computes the dimensions of a new docking zone.
	ReferenceFromOrient (see page 5993)	This is ReferenceFromOrient, a member of class TDockTree.
	RemoveControl (see page 5993)	Handles the undocking of a control from the associated DockSite (see page 5996).
	ResetBounds (see page 5994)	Recomputes the layout of docked controls.
	SaveToStream (see page 5994)	Saves a list of the set of docked controls and their positions to a stream.
	SetReplacingControl (see page 5995)	Prepares the dock tree for replacing one docked control with another.
	ShowHint (see page 5995)	This is ShowHint, a member of class TDockTree.
	UpdateAll (see page 5995)	Makes any internal adjustments to reflect the current state of the docked controls.
	WndProc (see page 5996)	This is WndProc, a member of class TDockTree.
	ZoneCaptionHitTest (see page 5996)	This is ZoneCaptionHitTest, a member of class TDockTree.

Public Methods

	Name	Description
	PaintSite (see page 5992)	Paints the elements that surround all docked controls.

32.1.12.4.1 TDockTree.AdjustDockRect Method

Adjusts the boundaries of the docking zone where a specified control is docked.

Pascal

```
procedure AdjustDockRect(Control: TControl; var ARect: TRect); virtual;
```

C++

```
virtual __fastcall AdjustDockRect(TControl * Control, TRect ARect);
```

Description

Applications can't call the protected AdjustDockRect method. It is called automatically to make any final adjustments to the rectangle where a client control is docked.

Control is the control that is docked.

On entry, ARect indicates the boundaries of Control when it is docked to the windowed control specified by the DockSite (see page 5996) property. AdjustDockRect changes this to make any final adjustments to the space in which Control is docked.

In TDockTree (see page 5983), AdjustDockRect expands the ARect parameter to make room for the "grab region" around a docked control. (The grab region is indicated by a double bevel, and is where the user can click with the mouse to start an undocking operation.) AdjustDockRect checks the Align property of the dock site to determine whether the grab region should appear on the side or the top of the docked control.

See Also

Align (see page 5798)

DockSite (see page 5996)

32.1.12.4.2 TDockTree.AdjustFrameRect Method

Pascal

```
procedure AdjustFrameRect(Control: TControl; var ARect: TRect); virtual;
```

C++

```
virtual __fastcall AdjustFrameRect(TControl * Control, TRect ARect);
```

Description

This is AdjustFrameRect, a member of class TDockTree.

32.1.12.4.3 TDockTree.BeginUpdate Method

Responds when the docked controls are about to change.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

BeginUpdate implements the BeginUpdate method of the IDockManager (see page 6238) interface. This method is called before controls are docked or undocked. For example, TDockTree (see page 5983) calls BeginUpdate internally from the LoadFromStream (see page 5991) method, before docking the controls it reads from a stream.

Once all docking or undocking is complete, the EndUpdate (see page 5988) method is called so that the dock tree can make any final adjustments. Every call to BeginUpdate should be paired with a call to EndUpdate (see page 5988). BeginUpdate/EndUpdate (see page 5988) pairs can be nested.

See Also

EndUpdate (see page 5988)

LoadFromStream (see page 5991)

32.1.12.4.4 TDockTree.EndUpdate Method

Responds when the docked controls have finished changing.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

EndUpdate implements the EndUpdate method of the IDockManager (see page 6238) interface. This method is called after controls are docked or undocked. For example, TDockTree (see page 5983) calls EndUpdate internally from the LoadFromStream (see page 5991) method, after docking the controls it reads from a stream.

EndUpdate checks that every previous call to the BeginUpdate (see page 5988) method has been matched with an EndUpdate call. If so, it calls the UpdateAll (see page 5995) method to perform any final adjustments to the docked controls, now that they are all in place.

Each call to EndUpdate should be paired by a call to BeginUpdate (see page 5988), which is made before docking or undocking controls. BeginUpdate (see page 5988)/EndUpdate pairs can be nested.

See Also

BeginUpdate (see page 5988)

LoadFromStream (see page 5991)

UpdateAll (see page 5995)

32.1.12.4.5 TDockTree.FindControlAtPos Method

Pascal

```
function FindControlAtPos(const Pos: TPoint): TControl;
```

C++

```
__fastcall TControl * FindControlAtPos(const TPoint Pos);
```

Description

This is FindControlAtPos, a member of class TDockTree.

32.1.12.4.6 TDockTree.GetControlBounds Method

Returns the dimensions allotted to a control that is already docked.

Pascal

```
procedure GetControlBounds(Control: TControl; out CtlBounds: TRect);
```

C++

```
__fastcall GetControlBounds(TControl * Control, TRect CtlBounds);
```

Description

GetControlBounds returns the dimensions of the zone in which a control is currently docked.

Control is the currently docked control.

CtlBounds returns the dimensions of the zone in which control is docked. If Control does not specify an object that is currently docked in the associated dock site, CtlBounds returns (0,0,0,0).

See Also

PositionDockRect (see page 5993)

ResetBounds (see page 5994)

32.1.12.4.7 TDockTree.HitTest Method

Indicates which docked control is at a specified mouse position.

Pascal

```
function HitTest(const MousePos: TPoint; out HTFlag: Integer): TControl; virtual;
```

C++

```
virtual __fastcall TControl * HitTest(const TPoint MousePos, int HTFlag);
```

Description

Applications can't call this protected method. TDockTree (see page 5983) uses HitTest internally to determine how to respond to mouse clicks.

MousePos indicates the position of the mouse pointer.

HTFlag indicates where the mouse pointer is relative to the docked control that is the return value. It is one of the following values:

Value	Meaning
HTNOWHERE	The mouse pointer is not anywhere in the docking region.
HTCLIENT	The mouse pointer is over the client area of the docked control.
HTBORDER	The mouse pointer is over the splitter that allows docking zones to be resized.
HTCAPTION	The mouse pointer is over the grab region where users can start to drag a docked control out of its docked position.
HTCLOSE	The mouse pointer is over the portion of the grab region that contains the "close" button for closing the docked control window.

HitTest returns the docked client that is under the mouse.

See Also

GetControlBounds (see page 5989)

32.1.12.4.8 TDockTree.InsertControl Method

Handles the docking of a control into the associated DockSite (see page 5996).

Pascal

```
procedure InsertControl(Control: TControl; InsertAt: TAlign; DropCtl: TControl); virtual;
```

C++

```
virtual __fastcall InsertControl(TControl * Control, TAlign InsertAt, TControl * DropCtl);
```

Description

InsertControl is called immediately after the windowed control that uses the dock tree adds a new control to its list of docked controls.

Control is the newly docked control.

InsertAt indicates where Control was docked within the windowed control.

DropCtl is the windowed control in which Control was docked. It should be the same as the value of the DockSite (see page 5996) property.

InsertControl sets up the docking zone for the control (including a splitter for resizing the zone and a grab region so that the control can be undocked. It then invalidates the windowed control in which Control was docked so that it can repaint itself to display the new docking region and docked object.

See Also

DockSite (see page 5996)

Invalidate (see page 6161)

RemoveControl (see page 5993)

32.1.12.4.9 TDockTree.LoadFromStream Method

Creates docking zones for a set of docked controls read from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); virtual;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream);
```

Description

LoadFromStream updates the dock tree to reflect the set of docked controls it reads from a stream. The stream must reflect the same format as is written by the SaveToStream (see page 5994) method.

Stream is the stream object to use for reading the docked controls.

See Also

SaveToStream (see page 5994)

32.1.12.4.10 TDockTree.MouseDown Method

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer; var
Handled: Boolean); virtual;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y, Boolean
Handled);
```

Description

This is MouseDown, a member of class TDockTree.

32.1.12.4.11 TDockTree.MouseMove Method

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer; var Handled: Boolean); virtual;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y, Boolean Handled);
```

Description

This is MouseMove, a member of class TDockTree.

32.1.12.4.12 TDockTree.MouseUp Method

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer; var
Handled: Boolean); virtual;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y, Boolean
Handled);
```

Description

This is MouseUp, a member of class TDockTree.

32.1.12.4.13 TDockTree.PaintDockFrame Method

Paints the elements of a docking zone that surround a docked control.

Pascal

```
procedure PaintDockFrame(Canvas: TCanvas; Control: TControl; const ARect: TRect); virtual;
```

C++

```
virtual __fastcall PaintDockFrame(TCanvas Canvas, TControl * Control, const TRect ARect);
```

Description

Application's can't call the protected PaintDockFrame method. It is used by the PaintSite (see page 5992) method to render the grab lines and close buttons that make up the grab region of a docking zone.

Canvas is the drawing surface on which to paint.

Control is the control that is docked in the zone being rendered.

ARect indicates the boundaries of the entire docking zone.

Note: Descendants classes can override this method to change the way a dock tree paints docking zones. The descendant class should only paint in the portions of ARect that are not occupied by Control.

See Also

PaintSite (see page 5992)

32.1.12.4.14 TDockTree.PaintSite Method

Paints the elements that surround all docked controls.

Pascal

```
procedure PaintSite(DC: HDC); virtual;
```

C++

```
virtual __fastcall PaintSite(HDC DC);
```

Description

Windowed controls that use a docking manager call PaintSite when they need to paint their docked child controls.

DC is the handle to the device context to use when rendering those elements of the docking zones other than the docked controls themselves.

PaintSite iterates through the docked controls, and for each one, calls the PaintDockFrame (see page 5992) method to

perform the actual painting.

See Also

PaintDockFrame (see page 5992)

PaintControls (see page 6166)

UseDockManager (see page 6212)

32.1.12.4.15 TDockTree.PositionDockRect Method

Computes the dimensions of a new docking zone.

Pascal

```
procedure PositionDockRect(Client: TControl; DropCtl: TControl; DropAlign: TAlign; var
DockRect: TRect); virtual;
```

C++

```
virtual __fastcall PositionDockRect(TControl * Client, TControl * DropCtl, TAlign DropAlign,
TRect DockRect);
```

Description

The control that is being docked calls PositionDockRect from its own PositionDockRect method when it is being docked to a windowed control that uses a dock manager. It allows the dock tree to indicate where a specified control would appear if the user released the mouse.

Client is the control that is being dragged to a docking position.

DropCtl is the windowed control into which Client will be docked. It should be the same as the value of DockSite (see page 5996).

DropAlign indicates where Control is to be docked within the windowed control.

DockRect returns the boundaries of the docking zone where Control can be docked.

See Also

PositionDockRect (see page 5777)

UseDockManager (see page 6212)

DockSite (see page 5996)

32.1.12.4.16 TDockTree.ReferenceFromOrient Method

Pascal

```
function ReferenceFromOrient(const Orient: TDockOrientation): Integer; virtual;
```

C++

```
virtual __fastcall int ReferenceFromOrient(const TDockOrientation Orient);
```

Description

This is ReferenceFromOrient, a member of class TDockTree.

32.1.12.4.17 TDockTree.RemoveControl Method

Handles the undocking of a control from the associated DockSite (see page 5996).

Pascal

```
procedure RemoveControl(Control: TControl); virtual;
```

C++

```
virtual __fastcall RemoveControl(TControl * Control);
```

Description

The windowed control that uses the dock tree calls RemoveControl when one of its docked controls is undocked.

Control is the control that was just undocked.

RemoveControl adjusts the dock tree's internal structures to indicate that the control is no longer docked, changes the control's DockOrientation property to doNoOrient, and calls DockSite (see page 5996)'s Invalidate method so that the region will be repainted.

See Also

InsertControl (see page 5990)

DockSite (see page 5996)

DockOrientation (see page 5818)

Invalidate (see page 6161)

32.1.12.4.18 TDockTree.ResetBounds Method

Recomputes the layout of docked controls.

Pascal

```
procedure ResetBounds(Force: Boolean); virtual;
```

C++

```
virtual __fastcall ResetBounds(Boolean Force);
```

Description

ResetBounds updates the layout of the docked controls and their surrounding docking zones, based on the current dimensions of DockSite (see page 5996). It is used to update the dock tree to reflect current conditions (for example, when DockSite (see page 5996) is resized).

Force indicates whether ResetBounds should recompute the layout if the dimensions of DockSite (see page 5996) have not changed. When Force is false, ResetBounds only updates the layout of docked controls if the dimensions of DockSite (see page 5996) have changed. When Force is true, ResetBounds updates the layout of docked controls even if the dimensions of DockSite (see page 5996) have not changed.

See Also

DockSite (see page 5996)

UpdateAll (see page 5995)

32.1.12.4.19 TDockTree.SaveToStream Method

Saves a list of the set of docked controls and their positions to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); virtual;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream);
```

Description

SaveToStream writes enough information to a stream that the dock tree can reconstruct the docking zone structure when it reads that information back at a later time.

Stream is the stream object to use for writing the information.

Note: To reconstruct the docking structure at a later time, use the LoadFromStream (see page 5991) method.

See Also

LoadFromStream (see page 5991)

32.1.12.4.20 TDockTree.SetReplacingControl Method

Prepares the dock tree for replacing one docked control with another.

Pascal

```
procedure SetReplacingControl(Control: TControl);
```

C++

```
__fastcall SetReplacingControl(TControl * Control);
```

Description

SetReplacingControl is called from a control's ReplaceDockedControl method. It informs the dock tree that the next control that is removed will be immediately replaced by a different control. It allows the dock tree to optimize the work of the RemoveControl (see page 5993) and InsertControl (see page 5990) methods.

See Also

ReplaceDockedControl (see page 5779)

InsertControl (see page 5990)

RemoveControl (see page 5993)

32.1.12.4.21 TDockTree.ShowHint Method

Pascal

```
procedure ShowHint(CursorPos: TPoint; var CursorRect: TRect; var HintStr: string); virtual;
```

C++

```
virtual __fastcall ShowHint(TPoint CursorPos, TRect CursorRect, AnsiString HintStr);
```

Description

This is ShowHint, a member of class TDockTree.

32.1.12.4.22 TDockTree.UpdateAll Method

Makes any internal adjustments to reflect the current state of the docked controls.

Pascal

```
procedure UpdateAll;
```

C++

```
__fastcall UpdateAll();
```

Description

Applications can't call the protected UpdateAll method. It is called by the EndUpdate (see page 5988) method when a series of updates to the dock tree have been completed.

UpdateAll adjusts the internal structures of the dock tree to reflect the current layout of all docked controls.

See Also

ResetBounds (see page 5994)

EndUpdate (see page 5988)

32.1.12.4.23 TDockTree.WndProc Method

Pascal

```
procedure WndProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

This is WndProc, a member of class TDockTree.

32.1.12.4.24 TDockTree.ZoneCaptionHitTest Method

Pascal

```
function ZoneCaptionHitTest(const Zone: TDockZone; const MousePos: TPoint; var HTFlag:
Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ZoneCaptionHitTest(const TDockZone Zone, const TPoint MousePos, int
HTFlag);
```

Description

This is ZoneCaptionHitTest, a member of class TDockTree.

32.1.12.5 TDockTree Properties

The properties of the TDockTree class are listed here.

Protected Properties

	Name	Description
	DockSite (see page 5996)	Specifies the windowed control that uses this dock tree to manage docking operations.
	RelativeSizes (see page 5997)	This is RelativeSizes, a member of class TDockTree.
R	TopZone (see page 5997)	This is TopZone, a member of class TDockTree.

32.1.12.5.1 TDockTree.DockSite Property

Specifies the windowed control that uses this dock tree to manage docking operations.

Pascal

```
property DockSite: TWinControl;
```

C++

```
__property TWinControl * DockSite;
```

Description

Applications can't use the protected DockSite property. TDockTree (see page 5983) uses this property internally when it needs to interact with the windowed control for which it manages docking operations.

DockSite is set in the TDockTree (see page 5983) constructor.

See Also

UseDockManager (see page 6212)

Create (see page 5985)

32.1.12.5.2 TDockTree.RelativeSizes Property

Pascal

```
property RelativeSizes: Boolean;
```

C++

```
__property Boolean RelativeSizes;
```

Description

This is RelativeSizes, a member of class TDockTree.

32.1.12.5.3 TDockTree.TopZone Property

Pascal

```
property TopZone: TDockZone;
```

C++

```
__property TDockZone TopZone;
```

Description

This is TopZone, a member of class TDockTree.

32.1.13 TDockZone Class

Class Hierarchy

Pascal

```
TDockZone = class;
```

C++

```
class TDockZone;
```

File

Controls

Description

This is class Controls.TDockZone.

32.1.13.1 TDockZone Members

The following tables list the members exposed by TDockZone.

Public Methods

	Name	Description
	Create (see page 5998)	This is Create, a member of class TDockZone.
	ExpandZoneLimit (see page 5999)	This is ExpandZoneLimit, a member of class TDockZone.
	FirstVisibleChild (see page 5999)	This is FirstVisibleChild, a member of class TDockZone.
	NextVisible (see page 5999)	This is NextVisible, a member of class TDockZone.
	PrevVisible (see page 5999)	This is PrevVisible, a member of class TDockZone.
	ResetChildren (see page 6000)	This is ResetChildren, a member of class TDockZone.
	ResetZoneLimits (see page 6000)	This is ResetZoneLimits, a member of class TDockZone.
	Update (see page 6000)	This is Update, a member of class TDockZone.

Public Properties

	Name	Description
R	ChildControl (see page 6001)	This is ChildControl, a member of class TDockZone.
R	ChildCount (see page 6001)	This is ChildCount, a member of class TDockZone.
R	Height (see page 6001)	This is Height, a member of class TDockZone.
R	Left (see page 6001)	This is Left, a member of class TDockZone.
R	LimitBegin (see page 6002)	This is LimitBegin, a member of class TDockZone.
R	LimitSize (see page 6002)	This is LimitSize, a member of class TDockZone.
R	Top (see page 6002)	This is Top, a member of class TDockZone.
R	Visible (see page 6002)	This is Visible, a member of class TDockZone.
R	VisibleChildCount (see page 6002)	This is VisibleChildCount, a member of class TDockZone.
R	Width (see page 6003)	This is Width, a member of class TDockZone.
	ZoneLimit (see page 6003)	This is ZoneLimit, a member of class TDockZone.

32.1.13.2 TDockZone.Create Constructor

Pascal

```
constructor Create(Tree: TDockTree);
```

C++

```
__fastcall TDockZone(TDockTree Tree);
```

Description

This is Create, a member of class TDockZone.

32.1.13.3 TDockZone Methods

The methods of the TDockZone class are listed here.

Public Methods

	Name	Description
	ExpandZoneLimit (see page 5999)	This is ExpandZoneLimit, a member of class TDockZone.
	FirstVisibleChild (see page 5999)	This is FirstVisibleChild, a member of class TDockZone.
	NextVisible (see page 5999)	This is NextVisible, a member of class TDockZone.
	PrevVisible (see page 5999)	This is PrevVisible, a member of class TDockZone.
	ResetChildren (see page 6000)	This is ResetChildren, a member of class TDockZone.
	ResetZoneLimits (see page 6000)	This is ResetZoneLimits, a member of class TDockZone.
	Update (see page 6000)	This is Update, a member of class TDockZone.

32.1.13.3.1 TDockZone.ExpandZoneLimit Method

Pascal

```
procedure ExpandZoneLimit(NewLimit: Integer);
```

C++

```
__fastcall ExpandZoneLimit(int NewLimit);
```

Description

This is ExpandZoneLimit, a member of class TDockZone.

32.1.13.3.2 TDockZone.FirstVisibleChild Method

Pascal

```
function FirstVisibleChild: TDockZone;
```

C++

```
__fastcall TDockZone FirstVisibleChild();
```

Description

This is FirstVisibleChild, a member of class TDockZone.

32.1.13.3.3 TDockZone.NextVisible Method

Pascal

```
function NextVisible: TDockZone;
```

C++

```
__fastcall TDockZone NextVisible();
```

Description

This is NextVisible, a member of class TDockZone.

32.1.13.3.4 TDockZone.PrevVisible Method

Pascal

```
function PrevVisible: TDockZone;
```

C++

```
__fastcall TDockZone PrevVisible();
```

Description

This is PrevVisible, a member of class TDockZone.

32.1.13.3.5 TDockZone.ResetChildren Method

Pascal

```
procedure ResetChildren;
```

C++

```
__fastcall ResetChildren();
```

Description

This is ResetChildren, a member of class TDockZone.

32.1.13.3.6 TDockZone.ResetZoneLimits Method

Pascal

```
procedure ResetZoneLimits;
```

C++

```
__fastcall ResetZoneLimits();
```

Description

This is ResetZoneLimits, a member of class TDockZone.

32.1.13.3.7 TDockZone.Update Method

Pascal

```
procedure Update;
```

C++

```
__fastcall Update();
```

Description

This is Update, a member of class TDockZone.

32.1.13.4 TDockZone Properties

The properties of the TDockZone class are listed here.

Public Properties

	Name	Description
R	ChildControl (see page 6001)	This is ChildControl, a member of class TDockZone.
R	ChildCount (see page 6001)	This is ChildCount, a member of class TDockZone.
R	Height (see page 6001)	This is Height, a member of class TDockZone.
R	Left (see page 6001)	This is Left, a member of class TDockZone.
R	LimitBegin (see page 6002)	This is LimitBegin, a member of class TDockZone.
R	LimitSize (see page 6002)	This is LimitSize, a member of class TDockZone.
R	Top (see page 6002)	This is Top, a member of class TDockZone.
R	Visible (see page 6002)	This is Visible, a member of class TDockZone.

R	VisibleChildCount (see page 6002)	This is VisibleChildCount, a member of class TDockZone.
R	Width (see page 6003)	This is Width, a member of class TDockZone.
	ZoneLimit (see page 6003)	This is ZoneLimit, a member of class TDockZone.

32.1.13.4.1 TDockZone.ChildControl Property

Pascal

```
property ChildControl: TControl;
```

C++

```
__property TControl * ChildControl;
```

Description

This is ChildControl, a member of class TDockZone.

32.1.13.4.2 TDockZone.ChildCount Property

Pascal

```
property ChildCount: Integer;
```

C++

```
__property int ChildCount;
```

Description

This is ChildCount, a member of class TDockZone.

32.1.13.4.3 TDockZone.Height Property

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

This is Height, a member of class TDockZone.

32.1.13.4.4 TDockZone.Left Property

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

This is Left, a member of class TDockZone.

32.1.13.4.5 TDockZone.LimitBegin Property

Pascal

```
property LimitBegin: Integer;
```

C++

```
__property int LimitBegin;
```

Description

This is LimitBegin, a member of class TDockZone.

32.1.13.4.6 TDockZone.LimitSize Property

Pascal

```
property LimitSize: Integer;
```

C++

```
__property int LimitSize;
```

Description

This is LimitSize, a member of class TDockZone.

32.1.13.4.7 TDockZone.Top Property

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

This is Top, a member of class TDockZone.

32.1.13.4.8 TDockZone.Visible Property

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

This is Visible, a member of class TDockZone.

32.1.13.4.9 TDockZone.VisibleChildCount Property

Pascal

```
property VisibleChildCount: Integer;
```

C++

```
__property int VisibleChildCount;
```

Description

This is VisibleChildCount, a member of class TDockZone.

32.1.13.4.10 TDockZone.Width Property

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

This is Width, a member of class TDockZone.

32.1.13.4.11 TDockZone.ZoneLimit Property

Pascal

```
property ZoneLimit: Integer;
```

C++

```
__property int ZoneLimit;
```

Description

This is ZoneLimit, a member of class TDockZone.

32.1.14 TDragControlObject Class

TDragControlObject object provides for normal drag and drop operations.

Class Hierarchy

Pascal

```
TDragControlObject = class(TBaseDragControlObject);
```

C++

```
class TDragControlObject : public TBaseDragControlObject;
```

File

Controls

Description

TDragControlObject object performs normal drag and drop operations. When TDragControlObject is used, the OnDragOver and OnDragDrop events receive the control being dragged as the Sender, instead of the drag object itself.

Note: TDragControlObject is not automatically freed at the end of a drag operation. For a drag object that is automatically freed, use TDragControlObjectEx (see page 6007) instead.

See Also

TDragDockObject (see page 6009)

TControl (see page 5724)

TControl (see page 5724)

TDragControlObjectEx (see page 6007)

32.1.14.1 TDragControlObject Members

The following tables list the members exposed by TDragControlObject.

Protected Methods

	Name	Description
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	Finished (see page 5723)	Finished ends a drag and drop operation.
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6005)	Returns the correct drag cursor to display at the X, Y position for the drag and drop operation.
	GetDragImages (see page 6006)	Returns the control's image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5722)	Copies the properties of another drag control object.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5721)	Creates an instance of the TBaseDragControlObject (see page 5719) and stores a reference to the control that is being dragged.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetName (see page 6036)	Returns a string that identifies the drag operation.
	HideDragImage (see page 6006)	Hides the image used in the drag cursor.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ShowDragImage (see page 6006)	Shows the image used in the drag cursor.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	Control (see page 5724)	Indicates the control that is being dragged.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.14.2 TDragControlObject Methods

The methods of the TDragControlObject class are listed here.

Protected Methods

	Name	Description
V	GetDragCursor (see page 6005)	Returns the correct drag cursor to display at the X, Y position for the drag and drop operation.
V	GetDragImages (see page 6006)	Returns the control's image list containing the image to be displayed while dragging.

Public Methods

	Name	Description
V	HideDragImage (see page 6006)	Hides the image used in the drag cursor.
V	ShowDragImage (see page 6006)	Shows the image used in the drag cursor.

32.1.14.2.1 TDragControlObject.GetDragCursor Method

Returns the correct drag cursor to display at the X, Y position for the drag and drop operation.

Pascal

```
function GetDragCursor(Accepted: Boolean; X: Integer; Y: Integer): TCursor; override;
```

C++

```
virtual __fastcall TCursor GetDragCursor(Boolean Accepted, int X, int Y);
```

Description

If the control at the X, Y position accepts the drag (in an OnDragOver event handler), the drag object sets the drag cursor to the

control's DragCursor property; otherwise, it displays the crNoDrop (see page 6366) cursor.

See Also

DragCursor (see page 5818)

OnDragOver (see page 5857)

32.1.14.2.2 TDragControlObject.GetDragImages Method

Returns the control's image list containing the image to be displayed while dragging.

Pascal

```
function GetDragImages: TDragImageList; override;
```

C++

```
virtual __fastcall TDragImageList GetDragImages();
```

Description

GetDragImages calls the associated control's GetDragImages method. The image list normally contains only one image, which the control creates and maintains. For many controls in the VCL, GetDragImages returns nil (Delphi) or NULL (C++).

See Also

Control (see page 5724)

GetDragImages (see page 5763)

32.1.14.2.3 TDragControlObject.HideDragImage Method

Hides the image used in the drag cursor.

Pascal

```
procedure HideDragImage; override;
```

C++

```
virtual __fastcall HideDragImage();
```

Description

If the control being dragged contains an image list containing an image for dragging, it will be hidden. This allows control over when a drag image is displayed.

See Also

ShowDragImage (see page 6006)

GetDragImages (see page 6006)

32.1.14.2.4 TDragControlObject.ShowDragImage Method

Shows the image used in the drag cursor.

Pascal

```
procedure ShowDragImage; override;
```

C++

```
virtual __fastcall ShowDragImage();
```

Description

If the control being dragged contains an image list containing an image for dragging, it will be shown. This allows control over when a drag image is shown.

See Also

HideDragImage (see page 6006)

GetDragImages (see page 6006)

32.1.15 TDragControlObjectEx Class

TDragControlObjectEx object provides for normal drag and drop operations.

Class Hierarchy

Pascal

```
TDragControlObjectEx = class(TDragControlObject);
```

C++

```
class TDragControlObjectEx : public TDragControlObject;
```

File

Controls

Description

TDragControlObjectEx object performs normal drag and drop operations. When TDragControlObjectEx is used, the OnDragOver and OnDragDrop events receive the control being dragged as the Sender, instead of the drag object itself.

Note: Unlike its immediate ancestor (TDragControlObject (see page 6003)), TDragControlObjectEx is automatically freed at the end of a drag operation.

See Also

TDragDockObject (see page 6009)

TControl (see page 5724)

TControl (see page 5724)

32.1.15.1 TDragControlObjectEx Members

The following tables list the members exposed by TDragControlObjectEx.

Protected Methods

	Name	Description
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	Finished (see page 5723)	Finished ends a drag and drop operation.
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6005)	Returns the correct drag cursor to display at the X, Y position for the drag and drop operation.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.

	GetDragImages (see page 6006)	Returns the control's image list containing the image to be displayed while dragging.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5722)	Copies the properties of another drag control object.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6009)	Allows the application to detect that the drag object needs to be freed.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 5721)	Creates an instance of the TBaseDragControlObject (see page 5719) and stores a reference to the control that is being dragged.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetName (see page 6036)	Returns a string that identifies the drag operation.
	HideDragImage (see page 6006)	Hides the image used in the drag cursor.
	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ShowDragImage (see page 6006)	Shows the image used in the drag cursor.
	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.

	Control (see page 5724)	Indicates the control that is being dragged.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.15.2 TDragControlObjectEx Methods

The methods of the TDragControlObjectEx class are listed here.

Public Methods

	Name	Description
V	BeforeDestruction (see page 6009)	Allows the application to detect that the drag object needs to be freed.

32.1.15.2.1 TDragControlObjectEx.BeforeDestruction Method

Allows the application to detect that the drag object needs to be freed.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

Do not call BeforeDestruction. This method is called automatically before any TDragControlObjectEx (see page 6007) destructors are called. It suppresses the inherited method, which prevents the drag object from being freed at the end of a drag operation.

32.1.16 TDragDockObject Class

Contains drag-and-dock information for a control.

Class Hierarchy

Pascal

```
TDragDockObject = class(TBaseDragControlObject);
```

C++

```
class TDragDockObject : public TBaseDragControlObject;
```

File

Controls

Description

TDragDockObject is used in several events and methods that use drag-and-dock information, including the OnDockDrop and OnDockOver events of TWinControl (see page 6112).

Note: TDragDockObject is not automatically freed at the end of a drag-and-dock operation. To work with a drag object that is freed at the end of the drag-and-dock operation, use TDragDockObjectEx (see page 6018) instead.

See Also

TWinControl (see page 6112)

TWinControl (see page 6112)

TDragDockObjectEx (see page 6018)

32.1.16.1 TDragDockObject Members

The following tables list the members exposed by TDragDockObject.

Protected Methods

	Name	Description
	AdjustDockRect (see page 6012)	This is AdjustDockRect, a member of class TDragDockObject.
	DrawDragDockImage (see page 6013)	Called when the dock image for a control is drawn.
	EndDrag (see page 6013)	Called when a control is released from dragging.
	EraseDragDockImage (see page 6013)	Called when the dock image for a control is erased.
	Finished (see page 5723)	Finished ends a drag and drop operation.
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6014)	Returns the cursor used during dragging.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	GetEraseWhenMoving (see page 6014)	This is GetEraseWhenMoving, a member of class TDragDockObject.
	GetFrameWidth (see page 6014)	Returns the value of the FrameWidth (see page 6018) property.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 6012)	Enables assignments of TDragDockObject (see page 6009) objects.
	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6011)	Creates and initializes an instance of TDragDockObject (see page 6009).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 6012)	Destroys an instance of TDragDockObject (see page 6009).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetName (see page 6036)	Returns a string that identifies the drag operation.
V	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Brush (see page 6015)	Specifies the brush used to draw the dock image.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	Control (see page 5724)	Indicates the control that is being dragged.
	DockRect (see page 6015)	Specifies the rectangle on which the control is docked if released.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	DropAlign (see page 6017)	Specifies how the control will be aligned when docked.
R	DropOnControl (see page 6017)	Specifies the control on which the dragged control will be docked if released.
R	Dropped (see page 6040)	Drag ended with drop.
	EraseDockRect (see page 6017)	This is EraseDockRect, a member of class TDragDockObject.
R	EraseWhenMoving (see page 6018)	This is EraseWhenMoving, a member of class TDragDockObject.
	Floating (see page 6018)	Specifies whether the control is floating.
R	FrameWidth (see page 6018)	Specifies the border width, in pixels, of the frame drawn around the drag image.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.16.2 TDragDockObject.Create Constructor

Creates and initializes an instance of TDragDockObject (see page 6009).

Pascal

```
constructor Create(AControl: TControl); override;
```

C++

```
virtual __fastcall TDragDockObject(TControl * AControl);
```

Description

Create calls the inherited constructor and allocates memory for the Brush (see page 6015) property.

32.1.16.3 TDragDockObject.Destroy Destructor

Destroys an instance of TDragDockObject (see page 6009).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDragDockObject();
```

Description

Do not call Destroy directly. Instead, call Free.

Destroy frees the memory associated with the Brush (see page 6015) property and then calls the inherited destructor.

32.1.16.4 TDragDockObject Methods

The methods of the TDragDockObject class are listed here.

Protected Methods

	Name	Description
	AdjustDockRect (see page 6012)	This is AdjustDockRect, a member of class TDragDockObject.
	DrawDragDockImage (see page 6013)	Called when the dock image for a control is drawn.
	EndDrag (see page 6013)	Called when a control is released from dragging.
	EraseDragDockImage (see page 6013)	Called when the dock image for a control is erased.
	GetDragCursor (see page 6014)	Returns the cursor used during dragging.
	GetEraseWhenMoving (see page 6014)	This is GetEraseWhenMoving, a member of class TDragDockObject.
	GetFrameWidth (see page 6014)	Returns the value of the FrameWidth (see page 6018) property.

Public Methods

	Name	Description
	Assign (see page 6012)	Enables assignments of TDragDockObject (see page 6009) objects.

32.1.16.4.1 TDragDockObject.AdjustDockRect Method

Pascal

```
procedure AdjustDockRect(ARect: TRect); virtual;
```

C++

```
virtual __fastcall AdjustDockRect(TRect ARect);
```

Description

This is AdjustDockRect, a member of class TDragDockObject.

32.1.16.4.2 TDragDockObject.Assign Method

Enables assignments of TDragDockObject (see page 6009) objects.

Pascal

```
procedure Assign(Source: TDragObject); override;
```

C++

```
virtual __fastcall Assign(TDragObject Source);
```

Description

Assign calls the inherited Assign method and then handles the assignment of TDragDockObject (see page 6009) objects.

32.1.16.4.3 TDragDockObject.DrawDragDockImage Method

Called when the dock image for a control is drawn.

Pascal

```
procedure DrawDragDockImage; virtual;
```

C++

```
virtual __fastcall DrawDragDockImage();
```

Description

Override DrawDragDockImage in a derived class to change the way the dock image is drawn.

32.1.16.4.4 TDragDockObject.EndDrag Method

Called when a control is released from dragging.

Pascal

```
procedure EndDrag(Target: TObject; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall EndDrag(TObject * Target, int X, int Y);
```

Description

Override EndDrag in a derived class to perform actions when a control is released from dragging.

As implemented in TDragDockObject (see page 6009), EndDrag calls the dragged control's DoEndDock method.

Target is the object in which the control is docked. If the control is not docked, Target is nil (Delphi) or NULL (C++).

X and Y are the coordinates of the control.

See Also

DoEndDock (see page 5750)

32.1.16.4.5 TDragDockObject.EraseDragDockImage Method

Called when the dock image for a control is erased.

Pascal

```
procedure EraseDragDockImage; virtual;
```

C++

```
virtual __fastcall EraseDragDockImage();
```

Description

Override EraseDragDockImage in a derived class to perform actions when the dock image for a control is erased.

As implemented in TDragDockObject (see page 6009), EndDrag (see page 6013) calls the dragged control's EraseDragDockImage method.

32.1.16.4.6 TDragDockObject.GetDragCursor Method

Returns the cursor used during dragging.

Pascal

```
function GetDragCursor(Accepted: Boolean; X: Integer; Y: Integer): TCursor; override;
```

C++

```
virtual __fastcall TCursor GetDragCursor(Boolean Accepted, int X, int Y);
```

Description

Override GetDragCursor to specify the cursor used during dragging.

By default, GetDragCursor returns crDefault (see page 6362).

See Also

Cursor (see page 5815)

32.1.16.4.7 TDragDockObject.GetEraseWhenMoving Method

Pascal

```
function GetEraseWhenMoving: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetEraseWhenMoving();
```

Description

This is GetEraseWhenMoving, a member of class TDragDockObject.

32.1.16.4.8 TDragDockObject.GetFrameWidth Method

Returns the value of the FrameWidth (see page 6018) property.

Pascal

```
function GetFrameWidth: Integer; virtual;
```

C++

```
virtual __fastcall int GetFrameWidth();
```

Description

Override GetFrameWidth to change the width of the frame that is drawn around the drag image. As implemented in TDragDockObject (see page 6009), GetFrameWidth returns 4.

See Also

FrameWidth (see page 6018)

32.1.16.5 TDragDockObject Properties

The properties of the TDragDockObject class are listed here.

Public Properties

	Name	Description
	Brush (see page 6015)	Specifies the brush used to draw the dock image.
	DockRect (see page 6015)	Specifies the rectangle on which the control is docked if released.
R	DropAlign (see page 6017)	Specifies how the control will be aligned when docked.
R	DropOnControl (see page 6017)	Specifies the control on which the dragged control will be docked if released.
	EraseDockRect (see page 6017)	This is EraseDockRect, a member of class TDragDockObject.
R	EraseWhenMoving (see page 6018)	This is EraseWhenMoving, a member of class TDragDockObject.
	Floating (see page 6018)	Specifies whether the control is floating.
R	FrameWidth (see page 6018)	Specifies the border width, in pixels, of the frame drawn around the drag image.

32.1.16.5.1 TDragDockObject.Brush Property

Specifies the brush used to draw the dock image.

Pascal

```
property Brush: TBrush;
```

C++

```
__property TBrush Brush;
```

Description

Use Brush to specify the brush used to draw the dock image.

32.1.16.5.2 TDragDockObject.DockRect Property

Specifies the rectangle on which the control is docked if released.

Pascal

```
property DockRect: TRect;
```

C++

```
__property TRect DockRect;
```

Description

Use DockRect to determine the rectangle on which the control is docked if released.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
```

```
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
```

```
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

32.1.16.5.3 TDragDockObject.DropAlign Property

Specifies how the control will be aligned when docked.

Pascal

```
property DropAlign: TAlign;
```

C++

```
__property TAlign DropAlign;
```

Description

Use DropAlign to determine how the control will be aligned when docked.

32.1.16.5.4 TDragDockObject.DropOnControl Property

Specifies the control on which the dragged control will be docked if released.

Pascal

```
property DropOnControl: TControl;
```

C++

```
__property TControl * DropOnControl;
```

Description

Use DropOnControl to determine the control on which the dragged control would be dropped if released.

32.1.16.5.5 TDragDockObject.EraseDockRect Property

Pascal

```
property EraseDockRect: TRect;
```

C++

```
__property TRect EraseDockRect;
```

Description

This is EraseDockRect, a member of class TDragDockObject.

32.1.16.5.6 TDragDockObject.EraseWhenMoving Property

Pascal

```
property EraseWhenMoving: Boolean;
```

C++

```
__property Boolean EraseWhenMoving;
```

Description

This is EraseWhenMoving, a member of class TDragDockObject.

32.1.16.5.7 TDragDockObject.Floating Property

Specifies whether the control is floating.

Pascal

```
property Floating: Boolean;
```

C++

```
__property Boolean Floating;
```

Description

Use Floating to determine whether the control is floating.

32.1.16.5.8 TDragDockObject.FrameWidth Property

Specifies the border width, in pixels, of the frame drawn around the drag image.

Pascal

```
property FrameWidth: Integer;
```

C++

```
__property int FrameWidth;
```

Description

Read FrameWidth to determine the size of the frame drawn around the drag image. As implemented in TDragDockObject (see page 6009), this value is always 4 pixels.

See Also

DrawDragDockImage (see page 6013)

32.1.17 TDragDockObjectEx Class

Contains drag-and-dock information for a control.

Class Hierarchy

System::TObject → Controls.TDragObject → Controls.TBaseDragControlObject → Controls.TDragDockObject → Controls.TDragDockObjectEx

Pascal

```
TDragDockObjectEx = class(TDragDockObject);
```

C++

```
class TDragDockObjectEx : public TDragDockObject;
```

File

Controls

Description

TDragDockObjectEx is used in several events and methods that use drag-and-dock information, including the OnDockDrop and OnDockOver events of TWinControl (see page 6112). Unlike its immediate ancestor, TDragDockObject (see page 6009), TDragDockObjectEx is automatically freed at the end of a drag-and-dock operation.

See Also

TWinControl (see page 6112)

TWinControl (see page 6112)

TControl (see page 5724)

32.1.17.1 TDragDockObjectEx Members

The following tables list the members exposed by TDragDockObjectEx.

Protected Methods

	Name	Description
	AdjustDockRect (see page 6012)	This is AdjustDockRect, a member of class TDragDockObject.
	DrawDragDockImage (see page 6013)	Called when the dock image for a control is drawn.
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	EndDrag (see page 6013)	Called when a control is released from dragging.
	EraseDragDockImage (see page 6013)	Called when the dock image for a control is erased.
	Finished (see page 5723)	Finished ends a drag and drop operation.
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6014)	Returns the cursor used during dragging.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	GetEraseWhenMoving (see page 6014)	This is GetEraseWhenMoving, a member of class TDragDockObject.
	GetFrameWidth (see page 6014)	Returns the value of the FrameWidth (see page 6018) property.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5722)	Copies the properties of another drag control object.
	Assign (see page 6012)	Enables assignments of TDragDockObject (see page 6009) objects.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6021)	Allows the application to detect that the drag object needs to be freed.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 5721)	Creates an instance of the TBaseDragControlObject (see page 5719) and stores a reference to the control that is being dragged.
V	Create (see page 6011)	Creates and initializes an instance of TDragDockObject (see page 6009).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6012)	Destroys an instance of TDragDockObject (see page 6009).
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetName (see page 6036)	Returns a string that identifies the drag operation.
V	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Brush (see page 6015)	Specifies the brush used to draw the dock image.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	Control (see page 5724)	Indicates the control that is being dragged.
	DockRect (see page 6015)	Specifies the rectangle on which the control is docked if released.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	DropAlign (see page 6017)	Specifies how the control will be aligned when docked.
R	DropOnControl (see page 6017)	Specifies the control on which the dragged control will be docked if released.
R	Dropped (see page 6040)	Drag ended with drop.
	EraseDockRect (see page 6017)	This is EraseDockRect, a member of class TDragDockObject.
R	EraseWhenMoving (see page 6018)	This is EraseWhenMoving, a member of class TDragDockObject.
	Floating (see page 6018)	Specifies whether the control is floating.

R	FrameWidth (see page 6018)	Specifies the border width, in pixels, of the frame drawn around the drag image.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.17.2 TDragDockObjectEx Methods

The methods of the TDragDockObjectEx class are listed here.

Public Methods

	Name	Description
V	BeforeDestruction (see page 6021)	Allows the application to detect that the drag object needs to be freed.

32.1.17.2.1 TDragDockObjectEx.BeforeDestruction Method

Allows the application to detect that the drag object needs to be freed.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

Do not call BeforeDestruction. This method is called automatically before any TDragDockObjectEx (see page 6018) destructors are called. It suppresses the inherited method, which prevents the drag object from being freed at the end of a drag operation.

32.1.18 TDragImageList Class

TDragImageList represents a set of images that appear during drag operations.

Class Hierarchy

Pascal

```
TDragImageList = class(TCustomImageList);
```

C++

```
class TDragImageList : public TCustomImageList;
```

File

Controls

Description

TDragImageList is used to hold images that are displayed during drag and drop or drag and dock operations. It is created by the

control that is dragged, which returns the drag image list in its GetDragImages method. During a drag operation, a TDragControlObject (see page 6003) instance uses the drag image list to display or hide the images in the list.

See Also

GetDragImages

32.1.18.1 TDragImageList Members

The following tables list the members exposed by TDragImageList.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 15370)	Copies the image list's properties to another image list.
	Change (see page 15371)	Generates an OnChange (see page 15393) event.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 15371)	Allows bitmap data to be saved and loaded.
V	DoDraw (see page 15372)	Draws the specified image onto the provided Canvas in the indicated style.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetImages (see page 15378)	Returns a specified image and its mask as bitmaps.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleNeeded (see page 15381)	This is HandleNeeded, a member of class TCustomImageList.
V	Initialize (see page 6028)	Sets numerous image list properties to their default values and creates instances of objects used internal to the image list.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadData (see page 15383)	This is ReadData, a member of class TCustomImageList.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.

	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteData (see page 15386)	This is WriteData, a member of class TCustomImageList.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Events

	Name	Description
	OnChange (see page 15393)	Occurs when the image list changes.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	Add (see page 15368)	Adds an Image and its Mask (see page 15797) to the image list object.
	AddIcon (see page 15368)	Adds an icon to the image list object.
	AddImage (see page 15368)	Adds single image from another image list.
	AddImages (see page 15369)	Adds all images from another image list.
	AddMasked (see page 15369)	Adds an image to the image list along with a color which is used to generate the transparent mask.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 15370)	Copies the information from one image list to another.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 6026)	Starts the dragging of an image list.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 15371)	Clears all images from the image list.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 15365)	Creates an empty image list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateSize (see page 15366)	Creates an empty image list of a specified size.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 15372)	Deletes a particular image from the image list.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 15366)	Destroys the image list and releases the memory allocated to it.
V	Destroy (see page 22287)	Disposes of an object instance.

	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DragLock (see page 6026)	Associates the drag image with the given Window handle and draws it at the position given by the parameters XPos and YPos while the window is in drag mode.
	DragMove (see page 6027)	Moves the drag image set by SetDragImage (see page 6029) to a new position specified by X and Y within its currently associated window while the window is in drag mode.
	DragUnlock (see page 6027)	Removes the association between the drag image and a window.
	Draw (see page 15373)	This is the overview for the Draw method overload.
	DrawOverlay (see page 15374)	This is the overview for the DrawOverlay method overload.
	EndDrag (see page 6028)	Ends the drag operation.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FileLoad (see page 15375)	Loads a resourced image into the image list.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetBitmap (see page 15376)	Retrieves a specified image as a bitmap.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetHotSpot (see page 6028)	Returns the hot spot location associated with the current drag image.
	GetIcon (see page 15377)	This is the overview for the GetIcon method overload.
	GetImageBitmap (see page 15378)	Returns a handle to a bitmap containing all of the images in the image list.
	GetInstRes (see page 15378)	This is the overview for the GetInstRes method overload.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetMaskBitmap (see page 15379)	Returns a handle to a bitmap containing all masks for images in the image list.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetResource (see page 15380)	Loads the specified bitmap, cursor, or icon resource into the image list.
	HandleAllocated (see page 15380)	Indicates whether a window handle exists for the image list.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HideDragImage (see page 6028)	Hides the current drag image if it was previously shown.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 15381)	Inserts a bitmap and its mask into the image list following a specified image.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertIcon (see page 15382)	Inserts an icon at a specified position in the image list.
	InsertMasked (see page 15382)	Inserts a bitmap at a specified position, creating the mask from a specified transparent color.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 15382)	Moves a specified image to another position.

V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Overlay (see page 15383)	Identifies an image in the list as an image that can be used as an overlay mask.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RegisterChanges (see page 15383)	Registers an object to be notified when changes occur in the image list.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Replace (see page 15384)	Replaces an image in the image list with a new image and mask.
	ReplaceIcon (see page 15384)	Replaces an image in the image list with an icon.
	ReplaceMasked (see page 15384)	Replaces an image in the image list with a new image and automatically-generated mask.
	ResInstLoad (see page 15385)	Loads a resource into the image list.
	ResourceLoad (see page 15385)	Loads a resource into the image list.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetDragImage (see page 6029)	Sets an image within the image list to be shown during a drag and drop operation.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	ShowDragImage (see page 6029)	Shows the current drag image if it was previously hidden.
	UnRegisterChanges (see page 15386)	Removes an object from the list of objects to be notified when the image list changes.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
	AllocBy (see page 15387)	Sets the number of images by which the image list grows when it needs to make room for new images.
	BkColor (see page 15387)	Determines which background color to use when drawing an image.
	BlendColor (see page 15387)	Determines which foreground color to use when drawing an image.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Count (see page 15388)	Indicates the number of images in the image list.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DragCursor (see page 6030)	Specifies the current drag cursor that is associated with the image list.
R	Dragging (see page 6030)	Indicates whether an image in the image list is being dragged.
	DragHotspot (see page 6030)	This is DragHotspot, a member of class TDragImageList.
	DrawingStyle (see page 15390)	Specifies the style to be used when the image list is drawing an image.
	Handle (see page 15390)	Designates the handle for the image list.
	Height (see page 15391)	Specifies the height of images within the image list.
	ImageType (see page 15391)	Determines whether the image list uses the associated mask when drawing.
	Masked (see page 15392)	Specifies whether the image list includes masks that can be combined with the images.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ShareImages (see page 15392)	Specifies whether the image list destroys its handle when the image list is destroyed.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Width (see page 15392)	Specifies the width of all images within the image list.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

32.1.18.2 TDragImageList Methods

The methods of the TDragImageList class are listed here.

Protected Methods

	Name	Description
	Initialize (see page 6028)	Sets numerous image list properties to their default values and creates instances of objects used internal to the image list.

Public Methods

	Name	Description
	BeginDrag (see page 6026)	Starts the dragging of an image list.
	DragLock (see page 6026)	Associates the drag image with the given Window handle and draws it at the position given by the parameters XPos and YPos while the window is in drag mode.
	DragMove (see page 6027)	Moves the drag image set by SetDragImage (see page 6029) to a new position specified by X and Y within its currently associated window while the window is in drag mode.
	DragUnlock (see page 6027)	Removes the association between the drag image and a window.
	EndDrag (see page 6028)	Ends the drag operation.
	GetHotSpot (see page 6028)	Returns the hot spot location associated with the current drag image.
	HideDragImage (see page 6028)	Hides the current drag image if it was previously shown.
	SetDragImage (see page 6029)	Sets an image within the image list to be shown during a drag and drop operation.
	ShowDragImage (see page 6029)	Shows the current drag image if it was previously hidden.

32.1.18.2.1 TDragImageList.BeginDrag Method

Starts the dragging of an image list.

Pascal

```
function BeginDrag(Window: HWND; X: Integer; Y: Integer): Boolean;
```

C++

```
__fastcall Boolean BeginDrag(HWND Window, int X, int Y);
```

Description

Use BeginDrag to start dragging the image set by SetDragImage (see page 6029). The image starts at the position specified by X and Y, which are the coordinates of the drag image relative to the window whose handle is specified by the Window parameter. BeginDrag returns true if it was successful in starting the drag of the image.

See Also

EndDrag (see page 6028)

Dragging (see page 6030)

32.1.18.2.2 TDragImageList.DragLock Method

Associates the drag image with the given Window handle and draws it at the position given by the parameters XPos and YPos while the window is in drag mode.

Pascal

```
function DragLock(Window: HWND; XPos: Integer; YPos: Integer): Boolean;
```

C++

```
__fastcall Boolean DragLock(HWND Window, int XPos, int YPos);
```

Description

Call DragLock to use an image in the image list as a drag image when a particular window is dragged. DragLock returns true if successful.

See Also

DragUnlock (see page 6027)

Dragging (see page 6030)

DragMove (see page 6027)

32.1.18.2.3 TDragImageList.DragMove Method

Moves the drag image set by SetDragImage (see page 6029) to a new position specified by X and Y within its currently associated window while the window is in drag mode.

Pascal

```
function DragMove(X: Integer; Y: Integer): Boolean;
```

C++

```
__fastcall Boolean DragMove(int X, int Y);
```

Description

Use the DragMove method to move the image that is being dragged during a drag-and-drop operation. DragMove returns true if successful.

See Also

SetDragImage (see page 6029)

DragLock (see page 6026)

32.1.18.2.4 TDragImageList.DragUnlock Method

Removes the association between the drag image and a window.

Pascal

```
procedure DragUnlock;
```

C++

```
__fastcall DragUnlock();
```

Description

Call DragUnlock when an image is no longer needed as a drag image for a particular window. DragUnlock removes the association started by the DragLock (see page 6026) method.

See Also

DragLock (see page 6026)

32.1.18.2.5 TDragImageList.EndDrag Method

Ends the drag operation.

Pascal

```
function EndDrag: Boolean;
```

C++

```
__fastcall Boolean EndDrag();
```

Description

Use EndDrag after BeginDrag (see page 6026) has been called to end the drag operation. EndDrag returns true if successful.

See Also

BeginDrag (see page 6026)

32.1.18.2.6 TDragImageList.GetHotSpot Method

Returns the hot spot location associated with the current drag image.

Pascal

```
function GetHotSpot: TPoint; override;
```

C++

```
virtual __fastcall TPoint GetHotSpot();
```

Description

Use the GetHotSpot method to obtain the position of the hot spot of the current drag image. The hot spot represents the current mouse position.

32.1.18.2.7 TDragImageList.HideDragImage Method

Hides the current drag image if it was previously shown.

Pascal

```
procedure HideDragImage;
```

C++

```
__fastcall HideDragImage();
```

Description

Most applications do not need to use HideDragImage to hide the current drag image. The drag control object calls this method when it is needed.

See Also

ShowDragImage (see page 6029)

32.1.18.2.8 TDragImageList.Initialize Method

Sets numerous image list properties to their default values and creates instances of objects used internal to the image list.

Pascal

```
procedure Initialize; override;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize is called from the constructors of the image list.

See Also

Create

32.1.18.2.9 TDragImageList.SetDragImage Method

Sets an image within the image list to be shown during a drag and drop operation.

Pascal

```
function SetDragImage(Index: Integer; HotSpotX: Integer; HotSpotY: Integer): Boolean;
```

C++

```
__fastcall Boolean SetDragImage(int Index, int HotSpotX, int HotSpotY);
```

Description

Use the SetDragImage method to set the image specified by Index within the image list to be shown when the image list is being used for drag and drop. The hot spot of the image is specified by HotSpotX and HotSpotY.

See Also

ShowDragImage (see page 6029)

GetHotSpot (see page 6028)

32.1.18.2.10 TDragImageList.ShowDragImage Method

Shows the current drag image if it was previously hidden.

Pascal

```
procedure ShowDragImage;
```

C++

```
__fastcall ShowDragImage();
```

Description

Most applications do not need to use ShowDragImage to display the current drag image. The drag control object calls this method when it is needed.

See Also

HideDragImage (see page 6028)

32.1.18.3 TDragImageList Properties

The properties of the TDragImageList class are listed here.

Public Properties

	Name	Description
	DragCursor (see page 6030)	Specifies the current drag cursor that is associated with the image list.

R	Dragging (see page 6030)	Indicates whether an image in the image list is being dragged.
	DragHotspot (see page 6030)	This is DragHotspot, a member of class TDragImageList.

32.1.18.3.1 TDragImageList.DragCursor Property

Specifies the current drag cursor that is associated with the image list.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use DragCursor to determine which cursor should be displayed when an image in the image list is dragged. When an image is dragged, a new drag image is created by combining the given image (typically a mouse cursor image) with the current drag cursor.

See Also

Cursor (see page 5815)

DragCursor (see page 5818)

32.1.18.3.2 TDragImageList.Dragging Property

Indicates whether an image in the image list is being dragged.

Pascal

```
property Dragging: Boolean;
```

C++

```
__property Boolean Dragging;
```

Description

When Dragging returns true, an image in the image list is being dragged. When Dragging returns false, no image is being dragged.

See Also

BeginDrag (see page 6026)

32.1.18.3.3 TDragImageList.DragHotspot Property

Pascal

```
property DragHotspot: TPoint;
```

C++

```
__property TPoint DragHotspot;
```

Description

This is DragHotspot, a member of class TDragImageList.

32.1.19 TDragObject Class

TDragObject is a base class used for managing drag operations.

Class Hierarchy

Pascal

```
TDragObject = class(TObject);
```

C++

```
class TDragObject : public TObject;
```

File

Controls

Description

Use TDragObject as a base class when creating a custom drag object to manage drag-and-drop operations or drag-and-dock operations. If the drag operation is associated with a single control that is dragged, derive the custom drag object from TBaseDragControlObject (see page 5719) instead. Create the custom drag object in the OnStartDrag event of the dragged control. Use the public IsDragObject (see page 6259) function within a target's OnDragOver event when accepting a drag drop.

Note: TDragObject is not automatically freed at the end of a drag operation. To work with a drag object that is freed at the end of the drag operation, use TDragObjectEx (see page 6041) instead.

In Applications that do not need to override the virtual methods of TDragObject, a drag object is created automatically to manage drag operations.

TDragObject allows more flexible drag operation handling. Normally, the Source parameter of the OnDragOver and OnDragDrop events is the control that starts the drag operation. If multiple controls of differing kinds need to start a drag of the same kind of data (for example, a file name, text, or a dollar amount), the source would need support for each kind of control. A drag object allows the target to handle drag sources as a single class of object, because each source control creates the same kind of drag object in their OnStartDrag events. The OnDragOver and OnDragDrop event handlers can tell if the source is a drag object, as opposed to the control, by calling IsDragObject (see page 6259).

Drag objects can be dragged between multiple .DLLs as well as inside the main .EXE. This is useful if you are not using packages but still want drag operations to function from forms implemented in .EXEs to forms implemented in .DLLs.

See Also

TDragControlObject (see page 6003)

TControl (see page 5724)

IsDragObject (see page 6259)

TDragObjectEx (see page 6041)

Customizing Drag and Drop with a Drag Object

32.1.19.1 TDragObject Members

The following tables list the members exposed by TDragObject.

Protected Methods

	Name	Description
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetName (see page 6036)	Returns a string that identifies the drag operation.
	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.19.2 TDragObject Methods

The methods of the TDragObject class are listed here.

Protected Methods

	Name	Description
V	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
V	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
V	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
V	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
V	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
V	Assign (see page 6034)	Copies the properties of another drag control object.
V	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
V	GetName (see page 6036)	Returns a string that identifies the drag operation.
V	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
V	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

32.1.19.2.1 TDragObject.AfterConstruction Method

Responds after the last constructor has executed.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

The System::TObject::AfterConstruction method implemented in System::TObject::TObject does nothing. Override this method when creating a class that takes some action after the object is created. For example, TCustomForm overrides

System::TObject::AfterConstruction to generate an OnCreate event.

See Also

System::TObject::BeforeDestruction (see page 22289)

OnCreate (see page 13951)

System::TObject::Create (see page 22287)

32.1.19.2.2 TDragObject.Assign Method

Copies the properties of another drag control object.

Pascal

```
procedure Assign(Source: TDragObject); virtual;
```

C++

```
virtual __fastcall Assign(TDragObject Source);
```

Description

Call Assign to copy the properties of another drag object. Assign changes the DragTarget (see page 6039), DragHandle (see page 6039), DragPos (see page 6039), DragTargetPos (see page 6040), MouseDeltaX (see page 6040) and MouseDeltaY (see page 6041) properties of the drag object to match those supplied by the Source parameter.

See Also

DragTarget (see page 6039)

DragHandle (see page 6039)

DragPos (see page 6039)

DragTargetPos (see page 6040)

MouseDeltaX (see page 6040)

MouseDeltaY (see page 6041)

32.1.19.2.3 TDragObject.BeforeDestruction Method

Responds before the first destructor executes.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

System::TObject::BeforeDestruction is called automatically before the object's first destructor executes. Do not call it explicitly in your applications.

The System::TObject::BeforeDestruction method implemented in System::TObject::TObject does nothing. Override this method when creating a class that takes some action before the object is destroyed. For example, TCustomForm overrides System::TObject::BeforeDestruction to generate an OnDestroy event.

Note: System::TObject::BeforeDestruction is not called when the object is destroyed before it is fully constructed. That is, if the object's constructor raises an exception, the destructor is called to dispose of the object, but System::TObject::BeforeDestruction

is not called.

See Also

System::TObject::AfterConstruction (see page 22289)

OnDestroy (see page 13953)

System::TObject::Destroy (see page 22287)

32.1.19.2.4 TDragObject.Finished Method

Responds when the mouse is released indicating the drag operation is complete.

Pascal

```
procedure Finished(Target: TObject; X: Integer; Y: Integer; Accepted: Boolean); virtual;
```

C++

```
virtual __fastcall Finished(TObject * Target, int X, int Y, Boolean Accepted);
```

Description

Finished does nothing as implemented in TDragObject (see page 6031). Override this method to provide more meaningful behavior. The Target is the object that accepted the drag. If the drag operation is canceled or a drag-and-dock operation ends with the dragged object in a free-floating position, Target is nil (Delphi) or NULL (C++). X and Y indicate the position where the drag ended. Accepted is true if the Target accepted the dragged object.

Finished is overridden and implemented in TBaseDragControlObject (see page 5719).

See Also

Finished (see page 5723)

32.1.19.2.5 TDragObject.GetDragCursor Method

Indicates which cursor should be displayed in response to mouse moves.

Pascal

```
function GetDragCursor(Accepted: Boolean; X: Integer; Y: Integer): TCursor; virtual;
```

C++

```
virtual __fastcall TCursor GetDragCursor(Boolean Accepted, int X, int Y);
```

Description

When the mouse is moved, GetDragCursor is called automatically. The Accepted parameter indicates whether the object under the mouse accepts the drag. The X and Y parameters represent the current position of the mouse. The TCursor (see page 6305) value returned by GetDragCursor is used to indicate the current drag cursor.

GetDragCursor returns crDrag (see page 6362) to when Accepted is true, crNoDrop (see page 6366) otherwise.

See Also

DragCursor (see page 5818)

32.1.19.2.6 TDragObject.GetDragImages Method

Returns an image list containing the image to be displayed while dragging.

Pascal

```
function GetDragImages: TDragImageList; virtual;
```

C++

```
virtual __fastcall TDragImageList GetDragImages();
```

Description

GetDragImages is called at the beginning of a drag and drop operation. As implemented in TDragObject (see page 6031), GetDragImages returns nil (Delphi) or NULL (C++), meaning that only the cursor is used to indicate the drag operation.

In descendant classes, the image list normally contains only one image, and the drag object automatically creates and maintains the image list.

See Also

TImageList (see page 6078)

32.1.19.2.7 TDragObject.GetName Method

Returns a string that identifies the drag operation.

Pascal

```
function GetName: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetName();
```

Description

By default GetName returns the name of the drag object class, but can be overridden to return a more meaningful string.

See Also

ClassName (see page 22290)

32.1.19.2.8 TDragObject.HideDragImage Method

Provides the interface for a method that hides the current drag image.

Pascal

```
procedure HideDragImage; virtual;
```

C++

```
virtual __fastcall HideDragImage();
```

Description

Because TDragObject (see page 6031) does not implement drag images (relying only on the cursor) HideDragImage does nothing. Descendant classes override HideDragImage to hide the drag image provided by the GetDragImages (see page 6035) method.

See Also

ShowDragImage (see page 6037)

GetDragCursor (see page 6035)

GetDragImages (see page 6035)

32.1.19.2.9 TDragObject.Instance Method

Returns the instance (module) handle of the EXE or DLL that created the drag object.

Pascal

```
function Instance: THandle; virtual;
```

C++

```
virtual __fastcall THandle Instance();
```

Description

Use Instance to obtain the instance handle for loading a resource, such as a cursor, associated with the drag object. See the example for the Cursors property of TScreen for an example of using the instance handle to load a cursor.

See Also

Cursors (see page 14212)

DragHandle (see page 6039)

32.1.19.2.10 TDragObject.MainWndProc Method

Pascal

```
procedure MainWndProc(var Message: TMessage);
```

C++

```
__fastcall MainWndProc(TMessage Message);
```

Description

This is MainWndProc, a member of class TDragObject.

32.1.19.2.11 TDragObject.ShowDragImage Method

Provides the interface for a method that hides the current drag image.

Pascal

```
procedure ShowDragImage; virtual;
```

C++

```
virtual __fastcall ShowDragImage();
```

Description

Because TDragObject (see page 6031) does not implement drag images (relying only on the cursor) ShowDragImage does nothing. Descendant classes override ShowDragImage to show the drag image.

See Also

HideDragImage (see page 6036)

GetDragCursor (see page 6035)

GetDragImages (see page 6035)

32.1.19.2.12 TDragObject.WndProc Method

Pascal

```
procedure WndProc(var Msg: TMessage); virtual;
```

C++

```
virtual __fastcall WndProc(TMessage Msg);
```

Description

This is WndProc, a member of class TDragObject.

32.1.19.3 TDragObject Properties

The properties of the TDragObject class are listed here.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.19.3.1 TDragObject.AlwaysShowDragImages Property

Pascal

```
property AlwaysShowDragImages: Boolean;
```

C++

```
__property Boolean AlwaysShowDragImages;
```

Description

This is AlwaysShowDragImages, a member of class TDragObject.

32.1.19.3.2 TDragObject.Cancelling Property

Specifies whether the drag operation is being canceled.

Pascal

```
property Cancelling: Boolean;
```

C++

```
__property Boolean Cancelling;
```

Description

Use Cancelling to specify whether the drag operation is being canceled. Cancelling is set to true in the global CancelDrag (see page 6247) procedure to prevent the canceling code from being executed more than once.

See Also

CancelDrag (see page 6247)

32.1.19.3.3 TDragObject.DragHandle Property

Specifies the window handle of the dragged object.

Pascal

```
property DragHandle: HWND;
```

C++

```
__property HWND DragHandle;
```

Description

Use DragHandle to get or set the window handle of the dragged object.

See Also

Handle (see page 6207)

32.1.19.3.4 TDragObject.DragPos Property

Specifies the position of the dragged object.

Pascal

```
property DragPos: TPoint;
```

C++

```
__property TPoint DragPos;
```

Description

Use DragPos to get the position of the dragged object.

See Also

DragTargetPos (see page 6040)

32.1.19.3.5 TDragObject.DragTarget Property

Specifies the dragged object's target.

Pascal

```
property DragTarget: Pointer;
```

C++

```
__property void * DragTarget;
```

Description

Use DragTarget to get the control (if any) that is the current drop target of the drag operation. If there is no control that will accept the dragged object if it is released, DragTarget is nil (Delphi) or NULL (C++).

See Also

DragTargetPos (see page 6040)

32.1.19.3.6 TDragObject.DragTargetPos Property

Specifies the position of the drag object relative to the drag target.

Pascal

```
property DragTargetPos: TPoint;
```

C++

```
__property TPoint DragTargetPos;
```

Description

Use DragTargetPos to get the position of the dragged object relative to the upper left corner of the drag target. To get the position of the dragged object in screen coordinates, use the DragPos (see page 6039) property instead.

See Also

DragTarget (see page 6039)

DragPos (see page 6039)

32.1.19.3.7 TDragObject.Dropped Property

Drag ended with drop.

Pascal

```
property Dropped: Boolean;
```

C++

```
__property Boolean Dropped;
```

Description

The Dropped property contains true if the last drag operation ended with a successful drop.

32.1.19.3.8 TDragObject.MouseDeltaX Property

Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.

Pascal

```
property MouseDeltaX: Double;
```

C++

```
__property Double MouseDeltaX;
```

Description

Use MouseDeltaX to determine the x-coordinate of the mouse position relative to the position where the dragged object would appear if released on the current target.

See Also

MouseDeltaY (see page 6041)

32.1.19.3.9 TDragObject.MouseDeltaY Property

Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.

Pascal

```
property MouseDeltaY: Double;
```

C++

```
__property Double MouseDeltaY;
```

Description

Use MouseDeltaY to determine the y-coordinate of the mouse position relative to the position where the dragged object would appear if released on the current target.

See Also

MouseDeltaX (see page 6040)

32.1.19.3.10 TDragObject.RightClickCancels Property

Pascal

```
property RightClickCancels: Boolean;
```

C++

```
__property Boolean RightClickCancels;
```

Description

This is RightClickCancels, a member of class TDragObject.

32.1.20 TDragObjectEx Class

TDragObjectEx is a base class used for managing drag operations.

Class Hierarchy

Pascal

```
TDragObjectEx = class(TDragObject);
```

C++

```
class TDragObjectEx : public TDragObject;
```

File

Controls

Description

Use TDragObjectEx as a base class when creating a custom drag object to manage drag-and-drop operations or drag-and-dock operations. Unlike its immediate ancestor, TDragObject (see page 6031), TDragObjectEx and its descendants are automatically freed at the end of a drag operation.

Applications can create the custom drag object in the OnStartDrag event of the dragged control. Use the public IsDragObject (see page 6259) function within a target's OnDragOver event when accepting a drag drop.

In Applications that do not need to override the virtual methods of TDragObjectEx, a drag object is created automatically to manage drag operations.

Drag objects allow more flexible drag operation handling. Normally, the Source parameter of the OnDragOver and OnDragDrop events is the control that starts the drag operation. If multiple controls of differing kinds need to start a drag of the same kind of data (for example, a file name, text, or a dollar amount), the source would need support for each kind of control. A drag object allows the target to handle drag sources as a single class of object, because each source control creates the same kind of drag object in their OnStartDrag events. The OnDragOver and OnDragDrop event handlers can tell if the source is a drag object, as opposed to the control, by calling IsDragObject (see page 6259).

Drag objects can be dragged between multiple .DLLs as well as inside the main .EXE. This is useful if you are not using packages but still want drag operations to function from forms implemented in .EXEs to forms implemented in .DLLs.

See Also

TDragControlObjectEx (see page 6007)

TDragDockObjectEx (see page 6018)

TControl (see page 5724)

IsDragObject (see page 6259)

TDragObject (see page 6031)

32.1.20.1 TDragObjectEx Members

The following tables list the members exposed by TDragObjectEx.

Protected Methods

	Name	Description
	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6043)	Allows the application to detect that the drag object needs to be freed.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetName (see page 6036)	Returns a string that identifies the drag operation.
V	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	Dropped (see page 6040)	Drag ended with drop.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

32.1.20.2 TDragObjectEx Methods

The methods of the TDragObjectEx class are listed here.

Public Methods

	Name	Description
V	BeforeDestruction (see page 6043)	Allows the application to detect that the drag object needs to be freed.

32.1.20.2.1 TDragObjectEx.BeforeDestruction Method

Allows the application to detect that the drag object needs to be freed.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

Do not call BeforeDestruction. This method is called automatically before any TDragObjectEx (see page 6041) destructors are called. It suppresses the inherited method, which prevents the drag object from being freed at the end of a drag operation.

32.1.21 TGraphicControl Class

TGraphicControl is the base class for all lightweight controls.

Class Hierarchy

Pascal

```
TGraphicControl = class(TControl);
```

C++

```
class TGraphicControl : public TControl;
```

File

Controls

Description

TGraphicControl supports simple lightweight controls that do not need the ability to accept keyboard input or contain other controls. Since lightweight controls do not wrap Windows screen objects, they are faster and user fewer resources than controls based on TWinControl (see page 6112).

TGraphicControl provides a Canvas (see page 6053) property for access to the control's drawing surface and a virtual Paint (see page 6052) method called in response to paint requests received by the parent control.

32.1.21.1 TGraphicControl Members

The following tables list the members exposed by TGraphicControl.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Paint (see page 6052)	Render control surface.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.

V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
R	Canvas (see page 6053)	Provides the drawing surface used by the graphic control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.

	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
V	Create (see page 6051)	Creates an instance of TGraphicControl (see page 6044).
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6052)	Destroys an instance of TGraphicControl (see page 6044).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EndDrag (see page 5757)	Stops a control from being dragged any further.

	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.

	Parent (see page 5832)	Indicates the parent of the control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.21.2 TGraphicControl.Create Constructor

Creates an instance of TGraphicControl (see page 6044).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TGraphicControl(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TGraphicControl (see page 6044). However, you should never attempt to instantiate a TGraphicControl (see page 6044). This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants.

AOwner is the component, typically a form, that is responsible for freeing the graphic control. It becomes the value of the Owner property. If you do not explicitly provide an Owner to the constructor (that is, if AOwner is nil (Delphi) or NULL (C++)), your application is responsible for explicitly freeing the graphic control.

Note: If a component's constructor allocates resources or memory, also override the destructor to free those resources.

Owner (see page 2807)

Create (see page 5731)

Destroy (see page 6052)

32.1.21.3 TGraphicControl.Destroy Destructor

Destroys an instance of TGraphicControl (see page 6044).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TGraphicControl();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the graphic control reference is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Frees the TCanvas object in its Canvas (see page 6053) property.

Override Destroy to free any memory or resources allocated in the Create (see page 6051) method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

Free (see page 22300)

32.1.21.4 TGraphicControl Methods

The methods of the TGraphicControl class are listed here.

Protected Methods

	Name	Description
V	Paint (see page 6052)	Render control surface.

32.1.21.4.1 TGraphicControl.Paint Method

Render control surface.

Pascal

```
procedure Paint; virtual;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when a lightweight control needs update its display area. Code in the Paint method uses the Canvas (see page 6053) property to render the control surface.

As implemented in TGraphicControl (see page 6044), Paint does nothing. Specific rendering logic is provided by Paint methods in descendant control classes.

See Also

Canvas (see page 6053)

32.1.21.5 TGraphicControl Properties

The properties of the TGraphicControl class are listed here.

Protected Properties

	Name	Description
	Canvas (see page 6053)	Provides the drawing surface used by the graphic control.

32.1.21.5.1 TGraphicControl.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl (see page 6044) instance does not have its own Windows screen object, it obtains its device context from its parent control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
```

```
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = (TLabel *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
```

```
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

32.1.22 THintWindow Class

THintWindow implements the small pop-up window that appears over a control at runtime when the control has its ShowHint (see page 5840) property set to true.

Class Hierarchy

Pascal

```
THintWindow = class(TCustomControl);
```

C++

```
class THintWindow : public TCustomControl;
```

File

Controls

Description

Use THintWindow to display a Help Hint (see page 5827) pop-up window directly from an application. Override THintWindow to customize the window that appears automatically for controls with their ShowHint (see page 5840) property set to true. After overriding THintWindow to create a new derived type, assign the new type to the global HintWindowClass variable at application startup, so that the new hint window type is used for Help Hints.

The hint window's BiDiMode (see page 6071) is always set to the BiDiMode (see page 6071) of the control that activates it. If the mode is bdRightToLeft, then the hint is left-aligned to the cursor.

Help and Hint Properties

32.1.22.1 THintWindow Members

The following tables list the members exposed by THintWindow.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.

	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.

	CreateParams (see page 6069)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	NCPaint (see page 6069)	This is NCPaint, a member of class THintWindow.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 6070)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.

	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.

	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WMPrint (see page 6071)	This is WMPrint, a member of class THintWindow.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.

	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	ActivateHint (see page 6067)	Displays the hint window.
V	ActivateHintData (see page 6067)	Displays the hint window using a provided data value.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
V	CalcHintRect (see page 6068)	Returns the size needed to display a given hint.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 6066)	Creates and initializes an instance of THintWindow (see page 6055).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.

	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
V	IsHintMsg (see page 6069)	Determines whether an application message requires hiding the hint window.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	ReleaseHandle (see page 6070)	Destroys the window displayed by THintWindow (see page 6055).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
V	ShouldHideHint (see page 6070)	This is ShouldHideHint, a member of class THintWindow.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 6071)	Specifies the bi-directional mode for the control.

	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 6072)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 6073)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 6076)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 6077)	Controls the attributes of text written on or in the control.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.

	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.22.2 THintWindow.Create Constructor

Creates and initializes an instance of THintWindow (see page 6055).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall THintWindow(TComponent * AOwner);
```

Description

Call Create to instantiate a hint window at runtime. Hint (see page 5827) windows activated by the application in response to the ShowHint (see page 5840) property of a control are created automatically.

See Also

ActivateHint (see page 6067)

ShowHint (see page 5840)

32.1.22.3 THintWindow Methods

The methods of the THintWindow class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 6069)	Initializes a window-creation parameter data structure.
	NCPaint (see page 6069)	This is NCPaint, a member of class THintWindow.
	Paint (see page 6070)	Renders the image of a custom control.
	WMPrint (see page 6071)	This is WMPrint, a member of class THintWindow.

Public Methods

	Name	Description
	ActivateHint (see page 6067)	Displays the hint window.
	ActivateHintData (see page 6067)	Displays the hint window using a provided data value.
	CalcHintRect (see page 6068)	Returns the size needed to display a given hint.
	IsHintMsg (see page 6069)	Determines whether an application message requires hiding the hint window.
	ReleaseHandle (see page 6070)	Destroys the window displayed by THintWindow (see page 6055).
	ShouldHideHint (see page 6070)	This is ShouldHideHint, a member of class THintWindow.

32.1.22.3.1 THintWindow.ActivateHint Method

Displays the hint window.

Pascal

```
procedure ActivateHint(Rect: TRect; const AHint: string); virtual;
```

C++

```
virtual __fastcall ActivateHint(TRect Rect, const AnsiString AHint);
```

Description

Call ActivateHint to display the hint window at the coordinates provided by the Rect parameter. If the Rect parameter appears off screen, ActivateHint moves the hint window to the closest approximation to the coordinates supplied by Rect that appears entirely on screen. ActivateHint sets the Caption (see page 6073) property to the AHint parameter before showing the window, so that the AHint string appears to the user.

After an application displays a hint window, it automatically deactivates it after a time period has elapsed, or when it receives a message that requires hiding the hint message. To hide the hint window that is brought up automatically by the application, use the HideHint method of the global Application object. To hide a hint window that is activated directly by calling ActivateHint, use the ReleaseHandle (see page 6070) method.

See Also

application

IsHintMsg (see page 6069)

ReleaseHandle (see page 6070)

HideHint (see page 13681)

Caption (see page 5806)

32.1.22.3.2 THintWindow.ActivateHintData Method

Displays the hint window using a provided data value.

Pascal

```
procedure ActivateHintData(Rect: TRect; const AHint: string; AData: Pointer); virtual;
```

C++

```
virtual __fastcall ActivateHintData(TRect Rect, const AnsiString AHint, void * AData);
```

Description

Call ActivateHintData to display the hint window at the coordinates provided by the Rect parameter. The ActivateHintData method for THintWindow (see page 6055) sets the Caption (see page 6073) property to the AHint parameter and ignores the AData parameter. Descendant classes can override this method to combine the AHint and AData parameters into a customized Hint (see page 5827) value.

After an application displays a hint window, it automatically deactivates it after a time period has elapsed, or when it receives a message that requires hiding the hint message. To hide the hint window that is brought up automatically by the application, use the HideHint method of the global Application object. To hide a hint window that is activated directly by calling ActivateHint (see page 6067), use the ReleaseHandle (see page 6070) method.

See Also

ActivateHint (see page 6067)

application

IsHintMsg (see page 6069)

ReleaseHandle (see page 6070)

HideHint (see page 13681)

Caption (see page 5806)

32.1.22.3.3 THintWindow.CalcHintRect Method

Returns the size needed to display a given hint.

Pascal

```
function CalcHintRect(MaxWidth: Integer; const AHint: string; AData: Pointer): TRect; virtual;
```

C++

```
virtual __fastcall TRect CalcHintRect(int MaxWidth, const AnsiString AHint, void * AData);
```

Description

Call CalcHintRect to determine the size needed to display a hint window for a specified string and data value. The MaxWidth parameter limits how wide the Hint (see page 5827) window can grow before the text wraps to a new line.

MaxWidth is the maximum length, in pixels, for the hint window. If the hint requires more than this width, the text in the hint window wraps to a new line.

AHint is the hint string that appears in the hint window.

AData is data associated with the AHint.

Note: CalcHintRect ignores the AData parameter. Descendant classes can override this method to make use of associated hint data.

See Also

ActivateHintData (see page 6067)

32.1.22.3.4 THintWindow.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

32.1.22.3.5 THintWindow.IsHintMsg Method

Determines whether an application message requires hiding the hint window.

Pascal

```
function IsHintMsg(var Msg: TMsg): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsHintMsg(TMsg Msg);
```

Description

Call IsHintMsg to determine whether the message specified by the Msg parameter requires hiding the hint window. Upon seeing a mouse, keyboard, command, or activation message, IsHintMsg returns true. The global Application object calls IsHintMsg to check messages while the hint window is on the screen, and hides the window if IsHintMsg returns true.

See Also

application

32.1.22.3.6 THintWindow.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); virtual;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class THintWindow.

32.1.22.3.7 THintWindow.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

See Also

Canvas (see page 5921)

PaintWindow (see page 5920)

GetDeviceContext (see page 6155)

ClipRect (see page 14486)

32.1.22.3.8 THintWindow.ReleaseHandle Method

Destroys the window displayed by THintWindow (see page 6055).

Pascal

```
procedure ReleaseHandle;
```

C++

```
__fastcall ReleaseHandle();
```

Description

Call ReleaseHandle to destroy a hint window that was activated by directly calling the ActivateHint (see page 6067) method. Hint (see page 5827) windows activated automatically by the application object are deactivated by the application as well.

See Also

ActivateHint (see page 6067)

32.1.22.3.9 THintWindow.ShouldHideHint Method

Pascal

```
function ShouldHideHint: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ShouldHideHint();
```

Description

This is ShouldHideHint, a member of class THintWindow.

32.1.22.3.10 THintWindow.WMPrint Method

Pascal

```
procedure WMPrint(var Message: TMessage); message WM_PRINT;
```

C++

```
__fastcall WMPrint(TMessage Message);
```

Description

This is WMPrint, a member of class THintWindow.

32.1.22.4 THintWindow Properties

The properties of the THintWindow class are listed here.

Public Properties

	Name	Description
	BiDiMode (see page 6071)	Specifies the bi-directional mode for the control.
	Canvas (see page 6072)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 6073)	Specifies a text string that identifies the control to the user.
	Color (see page 6076)	Specifies the background color of the control.
	Font (see page 6077)	Controls the attributes of text written on or in the control.

32.1.22.4.1 THintWindow.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

32.1.22.4.2 THintWindow.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = (TStringGrid *)ListBox1->Items->Objects[Index];
```

```
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TStringGrid) then
  begin
    myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
    with myStringGrid.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myStringGrid.Canvas.MoveTo(Left, Top);
      myStringGrid.Canvas.LineTo(Right, Bottom);
    end;
  myStringGrid:= nil;
  end;
```

See Also

Paint (see page 5920)

32.1.22.4.3 THintWindow.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
```

```
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
```

```
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

32.1.22.4.4 THintWindow.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

32.1.22.4.5 THintWindow.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
```

```
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i : Integer;
  begin
    for i := 0 to Screen.Fonts.Count - 1 do
     ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
  //  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
    RichEdit1.Lines.Text := 'How is it to be you?';
  end;

  procedure TForm1.ComboBox1Click(Sender: TObject);
  begin
    RichEdit1.Font.Name := ComboBox1.Text;
  end;
```

32.1.23 TImageList Class

TImageList represents a collection of same-sized images, each of which can be referred to by its index.

Class Hierarchy

Pascal

```
TImageList = class(TDragImageList);
```

C++

```
class TImageList : public TDragImageList;
```

File

Controls

Description

Image lists are used to efficiently manage large sets of icons or bitmaps. All images in an image list are contained in a single, wide bitmap in screen device format. An image list may also include a monochrome bitmap that contains masks used to draw images transparently (icon style).

The image list is capable of holding a large number of same sized images and retrieving them via their index within the range 0 to n - 1. The image list also has methods to facilitate storing, retrieving, and drawing of the stored images.

To add images to an image list at design time, right click and choose Image List Editor

Note: Image lists depend on Comctl32.dll. If the system does not have the latest version installed, there may be problems getting images to appear.

Adding Icons to Menus and Toolbars

32.1.23.1 TImageList Members

The following tables list the members exposed by TImageList.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 15370)	Copies the image list's properties to another image list.
	Change (see page 15371)	Generates an OnChange (see page 15393) event.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 15371)	Allows bitmap data to be saved and loaded.
V	DoDraw (see page 15372)	Draws the specified image onto the provided Canvas in the indicated style.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetImages (see page 15378)	Returns a specified image and its mask as bitmaps.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleNeeded (see page 15381)	This is HandleNeeded, a member of class TCustomImageList.
V	Initialize (see page 6028)	Sets numerous image list properties to their default values and creates instances of objects used internal to the image list.
V	Initialize (see page 15381)	Initializes a newly allocated image list.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadData (see page 15383)	This is ReadData, a member of class TCustomImageList.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.

	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteData (see page 15386)	This is WriteData, a member of class TCustomImageList.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	Add (see page 15368)	Adds an Image and its Mask (see page 15797) to the image list object.
	AddIcon (see page 15368)	Adds an icon to the image list object.
	AddImage (see page 15368)	Adds single image from another image list.
	AddImages (see page 15369)	Adds all images from another image list.
	AddMasked (see page 15369)	Adds an image to the image list along with a color which is used to generate the transparent mask.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 15370)	Copies the information from one image list to another.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 6026)	Starts the dragging of an image list.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 15371)	Clears all images from the image list.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 15365)	Creates an empty image list.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateSize (see page 15366)	Creates an empty image list of a specified size.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 15372)	Deletes a particular image from the image list.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 15366)	Destroys the image list and releases the memory allocated to it.
V	Destroy (see page 22287)	Disposes of an object instance.

	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DragLock (see page 6026)	Associates the drag image with the given Window handle and draws it at the position given by the parameters XPos and YPos while the window is in drag mode.
	DragMove (see page 6027)	Moves the drag image set by SetDragImage (see page 6029) to a new position specified by X and Y within its currently associated window while the window is in drag mode.
	DragUnlock (see page 6027)	Removes the association between the drag image and a window.
	Draw (see page 15373)	This is the overview for the Draw method overload.
	DrawOverlay (see page 15374)	This is the overview for the DrawOverlay method overload.
	EndDrag (see page 6028)	Ends the drag operation.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FileLoad (see page 15375)	Loads a resourced image into the image list.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetBitmap (see page 15376)	Retrieves a specified image as a bitmap.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetHotSpot (see page 6028)	Returns the hot spot location associated with the current drag image.
V	GetHotSpot (see page 15376)	Returns the hot spot location associated with the current drag image.
	GetIcon (see page 15377)	This is the overview for the GetIcon method overload.
	GetImageBitmap (see page 15378)	Returns a handle to a bitmap containing all of the images in the image list.
	GetInstRes (see page 15378)	This is the overview for the GetInstRes method overload.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetMaskBitmap (see page 15379)	Returns a handle to a bitmap containing all masks for images in the image list.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetResource (see page 15380)	Loads the specified bitmap, cursor, or icon resource into the image list.
	HandleAllocated (see page 15380)	Indicates whether a window handle exists for the image list.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HideDragImage (see page 6028)	Hides the current drag image if it was previously shown.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 15381)	Inserts a bitmap and its mask into the image list following a specified image.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertIcon (see page 15382)	Inserts an icon at a specified position in the image list.
	InsertMasked (see page 15382)	Inserts a bitmap at a specified position, creating the mask from a specified transparent color.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 15382)	Moves a specified image to another position.

V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Overlay (see page 15383)	Identifies an image in the list as an image that can be used as an overlay mask.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RegisterChanges (see page 15383)	Registers an object to be notified when changes occur in the image list.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Replace (see page 15384)	Replaces an image in the image list with a new image and mask.
	ReplaceIcon (see page 15384)	Replaces an image in the image list with an icon.
	ReplaceMasked (see page 15384)	Replaces an image in the image list with a new image and automatically-generated mask.
	ResInstLoad (see page 15385)	Loads a resource into the image list.
	ResourceLoad (see page 15385)	Loads a resource into the image list.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetDragImage (see page 6029)	Sets an image within the image list to be shown during a drag and drop operation.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	ShowDragImage (see page 6029)	Shows the current drag image if it was previously hidden.
	UnRegisterChanges (see page 15386)	Removes an object from the list of objects to be notified when the image list changes.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Count (see page 15388)	Indicates the number of images in the image list.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DragCursor (see page 6030)	Specifies the current drag cursor that is associated with the image list.
R	Dragging (see page 6030)	Indicates whether an image in the image list is being dragged.
	DragHotspot (see page 6030)	This is DragHotspot, a member of class TDragImageList.
	Handle (see page 15390)	Designates the handle for the image list.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 6087)	Occurs when the image list changes.

Published Properties

	Name	Description
	AllocBy (see page 6083)	Sets the number of images by which the image list grows when it needs to make room for new images.
	BkColor (see page 6083)	Determines which background color to use when drawing an image.
	BlendColor (see page 6084)	Determines which foreground color to use when drawing an image.
	DrawingStyle (see page 6084)	Specifies the style to be used when the image list is drawing an image.
	Height (see page 6085)	Specifies the height of images within the image list.

	ImageType (see page 6085)	Determines whether the image list uses the associated mask when drawing.
	Masked (see page 6086)	Specifies whether the image list includes masks that can be combined with the images.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ShareImages (see page 6086)	Specifies whether the image list destroys its handle when the image list is destroyed.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Width (see page 6086)	Specifies the width of all images within the image list.

32.1.23.2 TImageList Properties

The properties of the TImageList class are listed here.

Published Properties

	Name	Description
	AllocBy (see page 6083)	Sets the number of images by which the image list grows when it needs to make room for new images.
	BkColor (see page 6083)	Determines which background color to use when drawing an image.
	BlendColor (see page 6084)	Determines which foreground color to use when drawing an image.
	DrawingStyle (see page 6084)	Specifies the style to be used when the image list is drawing an image.
	Height (see page 6085)	Specifies the height of images within the image list.
	ImageType (see page 6085)	Determines whether the image list uses the associated mask when drawing.
	Masked (see page 6086)	Specifies whether the image list includes masks that can be combined with the images.
	ShareImages (see page 6086)	Specifies whether the image list destroys its handle when the image list is destroyed.
	Width (see page 6086)	Specifies the width of all images within the image list.

32.1.23.2.1 TImageList.AllocBy Property

Sets the number of images by which the image list grows when it needs to make room for new images.

Pascal

```
property AllocBy: Integer;
```

C++

```
__property int AllocBy;
```

Description

Use the AllocBy method to specify the number of new images that can be added to the resized image list.

See Also

Count (see page 15388)

Add (see page 15368)

AddIcon (see page 15368)

AddImages (see page 15369)

AddMasked (see page 15369)

32.1.23.2.2 TImageList.BkColor Property

Determines which background color to use when drawing an image.

Pascal

```
property BkColor: TColor;
```

C++

```
__property TColor BkColor;
```

Description

Use BkColor to specify the color used for the masked regions of the images in the list. When BkColor is clNone, the image is drawn transparently using the mask to define the transparent areas. Otherwise, the value of BkColor appears in the masked out portions.

Note: BkColor has no effect when the Masked property is false.

See Also

BlendColor (see page 15387)

Masked (see page 15392)

ImageType (see page 15391)

32.1.23.2.3 TImageList.BlendColor Property

Determines which foreground color to use when drawing an image.

Pascal

```
property BlendColor: TColor;
```

C++

```
__property TColor BlendColor;
```

Description

Set BlendColor to cause the images in the list to be combined with the specified color when the DrawingStyle is dsFocus or dsSelected. More of BlendColor is combined with the images when DrawingStyle is dsSelected. clNone specifies no blend color while clDefault specifies the system highlight .

See Also

BkColor (see page 15387)

DrawingStyle (see page 15390)

32.1.23.2.4 TImageList.DrawingStyle Property

Specifies the style to be used when the image list is drawing an image.

Pascal

```
property DrawingStyle: TDrawingStyle;
```

C++

```
__property TDrawingStyle DrawingStyle;
```

Description

Use the DrawingStyle property to control how the image is to appear. DrawingStyle controls how much of the blend color specified by BlendColor is combined with the foreground, or what background color to use.

See Also

Draw (see page 15373)

DrawOverlay (see page 15375)

ImageType (see page 15391)

BlendColor (see page 15387)

BkColor (see page 15387)

32.1.23.2.5 TImageList.Height Property

Specifies the height of images within the image list.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to specify the height of images before any are added to the image list. The image list is cleared when this value changes.

See Also

Width (see page 15392)

CreateSize (see page 15366)

Create (see page 15365)

32.1.23.2.6 TImageList.ImageType Property

Determines whether the image list uses the associated mask when drawing.

Pascal

```
property ImageType: TImageType;
```

C++

```
__property TImageType ImageType;
```

Description

Use the ImageType property to control whether the images are drawn using the image mask (itMask), or without the mask (itImage).

See Also

DrawingStyle (see page 15390)

Draw (see page 15373)

Masked (see page 15392)

DrawOverlay (see page 15375)

32.1.23.2.7 TImageList.Masked Property

Specifies whether the image list includes masks that can be combined with the images.

Pascal

```
property Masked: Boolean;
```

C++

```
__property Boolean Masked;
```

Description

Set the Masked property to true to combine the images with masks. The masked portion of the bitmap is drawn transparently, or replaced by the color specified by the BkColor property.

Masked indicates whether the image list stores masks to combine with the images. To use those masks, the ImageType property indicates whether to draw the image or the mask.

See Also

AddMasked (see page 15369)

InsertMasked (see page 15382)

BkColor (see page 15387)

ImageType (see page 15391)

32.1.23.2.8 TImageList.ShareImages Property

Specifies whether the image list destroys its handle when the image list is destroyed.

Pascal

```
property ShareImages: Boolean;
```

C++

```
__property Boolean ShareImages;
```

Description

Set the ShareImages property to false to ensure that the handle to the image list is freed when the image list is destroyed.

See Also

Destroy (see page 15366)

Handle (see page 15390)

32.1.23.2.9 TImageList.Width Property

Specifies the width of all images within the image list.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to specify the width of images before any are added to the image list. The image list is cleared when this

value changes.

See Also

Height (see page 15391)

Create (see page 15365)

CreateSize (see page 15366)

32.1.23.3 TImageList Events

The events of the TImageList class are listed here.

Published Events

	Name	Description
	OnChange (see page 6087)	Occurs when the image list changes.

32.1.23.3.1 TImageList.OnChange Event

Occurs when the image list changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to execute code when the image list changes. Any objects registered with the RegisterChanges method will also be notified.

See Also

RegisterChanges (see page 15383)

32.1.24 TMargins Class

Contains margins for the control.

Class Hierarchy

Pascal

```
TMargins = class(TPersistent);
```

C++

```
class TMargins : public TPersistent;
```

File

Controls

Description

TMargins is used in the Margins property of TControl (see page 5724) and its descendants. TMargins help define the relative position between components on a form, and between the edges of the form and the component. For example, when you set a left margin for a component to 10 pixels, the component will not come closer than 10 pixels to the edge of the container, or to another component on the left edge. The number of pixels by which two components are separated is the sum of the pixels of both components.

For example, if you place a component on the form with a left margin of 10 pixels, then add another component to it's left with a right margin of 20 pixels, the closed the two components can come together on those edges is 30 pixels.

You can define the amount of margin that should surround the component on the top, left, bottom, or right by changing the pixel value for the `Margins` property in the **Object Inspector**.

Note: For the Margins

settings to take effect on a component, you must also set its `AlignWithMargins` property to **True**.

32.1.24.1 TMargins Members

The following tables list the members exposed by TMargins.

Protected Methods

	Name	Description
	AssignTo (see page 6090)	Copies the properties of an object to a destination object.
	Change (see page 6091)	This is Change, a member of class TMargins.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetControlBound (see page 6091)	This is GetControlBound, a member of class TMargins.
	GetOwner (see page 2932)	Returns the owner of an object.
	InitDefaults (see page 6091)	This is InitDefaults, a member of class TMargins.

Protected Properties

	Name	Description
	Control (see page 6093)	This is Control, a member of class TMargins.

Public Events

	Name	Description
	OnChange (see page 6096)	Occurs when margins change.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6089)	This is Create, a member of class TMargins.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.

	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetBounds (see page 6091)	Sets the properties for the left, top, right, and bottom margins all at once.
	SetControlBounds (see page 6091)	This is the overview for the SetControlBounds method overload.

Public Properties

	Name	Description
	ControlHeight (see page 6093)	Sets the height of the control.
	ControlLeft (see page 6093)	Sets the starting point for the left side of the control.
	ControlTop (see page 6094)	Sets the starting point for the top of the control.
	ControlWidth (see page 6094)	Sets the width of the control.
	ExplicitHeight (see page 6094)	This is ExplicitHeight, a member of class TMargins.
	ExplicitLeft (see page 6094)	This is ExplicitLeft, a member of class TMargins.
	ExplicitTop (see page 6095)	This is ExplicitTop, a member of class TMargins.
	ExplicitWidth (see page 6095)	This is ExplicitWidth, a member of class TMargins.

Published Properties

	Name	Description
	Bottom (see page 6093)	Specifies the bottom edge of the margin.
	Left (see page 6095)	Specifies the left edge of the margin.
	Right (see page 6095)	Specifies the right edge of the margin.
	Top (see page 6095)	Specifies the top edge of the margin.

32.1.24.2 TMargins.Create Constructor

Pascal

```
constructor Create(Control: TControl); virtual;
```

C++

```
virtual __fastcall TMargins(TControl * Control);
```

Description

This is Create, a member of class TMargins.

32.1.24.3 TMargins Methods
