The methods of the TMargins class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 6090)	Copies the properties of an object to a destination object.
	Change (see page 6091)	This is Change, a member of class TMargins.
	GetControlBound (see page 6091)	This is GetControlBound, a member of class TMargins.
	InitDefaults (see page 6091)	This is InitDefaults, a member of class TMargins.

Public Methods

	Name	Description
	SetBounds (see page 6091)	Sets the properties for the left, top, right, and bottom margins all at once.
	SetControlBounds (see page 6091)	This is the overview for the SetControlBounds method overload.

32.1.24.3.1 TMargins.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

32.1.24.3.2 TMargins.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TMargins.

32.1.24.3.3 TMargins.GetControlBound Method

Pascal

```
function GetControlBound(Index: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int GetControlBound(int Index);
```

Description

This is GetControlBound, a member of class TMargins.

32.1.24.3.4 TMargins.InitDefaults Method

Pascal

```
class procedure InitDefaults(Margins: TMargins); virtual;
```

C++

```
virtual __fastcall InitDefaults(TMargins Margins);
```

Description

This is InitDefaults, a member of class TMargins.

32.1.24.3.5 TMargins.SetBounds Method

Sets the properties for the left, top, right, and bottom margins all at once.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; ARight: Integer; ABottom: Integer);
```

C++

```
__fastcall SetBounds(int ALeft, int ATop, int ARight, int ABottom);
```

Description

Use the SetBounds method to specify the values for the Left (see page 6095), Top (see page 6095), Right (see page 6095), andBottom properties as the value of the ALeft, ATop, ARight, and ABottom parameters, respectively.

32.1.24.3.6 SetControlBounds Method

This is the overview for the SetControlBounds method overload.

Overload List

	Name	Description
	TMargins.SetControlBounds (Integer, Integer, Integer, Integer, Boolean) (see page 6092)	This is SetControlBounds, a member of class TMargins.
	TMargins.SetControlBounds (TRect, Boolean) (see page 6092)	This is SetControlBounds, a member of class TMargins.

32.1.24.3.6.1 TMargins.SetControlBounds Method (Integer, Integer, Integer, Integer, Boolean)

Pascal

```
procedure SetControlBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer;
Aligning: Boolean = False); overload;
```

C++

```
__fastcall SetControlBounds(int ALeft, int ATop, int AWidth, int AHeight, Boolean Aligning =
False);
```

Description

This is SetControlBounds, a member of class TMargins.

32.1.24.3.6.2 TMargins.SetControlBounds Method (TRect, Boolean)

Pascal

```
procedure SetControlBounds(const ARect: TRect; Aligning: Boolean = False); overload;
```

C++

```
__fastcall SetControlBounds(const TRect ARect, Boolean Aligning = False);
```

Description

This is SetControlBounds, a member of class TMargins.

32.1.24.4 TMargins Properties

The properties of the TMargins class are listed here.

Protected Properties

	Name	Description
R	Control (see page 6093)	This is Control, a member of class TMargins.

Public Properties

	Name	Description
R	ControlHeight (see page 6093)	Sets the height of the control.
R	ControlLeft (see page 6093)	Sets the starting point for the left side of the control.
R	ControlTop (see page 6094)	Sets the starting point for the top of the control.
R	ControlWidth (see page 6094)	Sets the width of the control.
R	ExplicitHeight (see page 6094)	This is ExplicitHeight, a member of class TMargins.
R	ExplicitLeft (see page 6094)	This is ExplicitLeft, a member of class TMargins.
R	ExplicitTop (see page 6095)	This is ExplicitTop, a member of class TMargins.
R	ExplicitWidth (see page 6095)	This is ExplicitWidth, a member of class TMargins.

Published Properties

	Name	Description
	Bottom (see page 6093)	Specifies the bottom edge of the margin.
	Left (see page 6095)	Specifies the left edge of the margin.
	Right (see page 6095)	Specifies the right edge of the margin.
	Top (see page 6095)	Specifies the top edge of the margin.

32.1.24.4.1 TMargins.Bottom Property

Specifies the bottom edge of the margin.

Pascal

```
property Bottom: TMarginSize;
```

C++

```
__property TMarginSize Bottom;
```

Description

Use the Bottom property to specify the bottom edge of the margin.

32.1.24.4.2 TMargins.Control Property

Pascal

```
property Control: TControl;
```

C++

```
__property TControl * Control;
```

Description

This is Control, a member of class TMargins.

32.1.24.4.3 TMargins.ControlHeight Property

Sets the height of the control.

Pascal

```
property ControlHeight: Integer;
```

C++

```
__property int ControlHeight;
```

Description

Use the ControlHeight property to set the height of the control. This height includes the height of the margins.

32.1.24.4.4 TMargins.ControlLeft Property

Sets the starting point for the left side of the control.

Pascal

```
property ControlLeft: Integer;
```

C++

```
__property int ControlLeft;
```

Description

Use the ControlLeft property to set the starting point of the left side of the control. This value includes the margins.

32.1.24.4.5 TMargins.ControlTop Property

Sets the starting point for the top of the control.

Pascal

```
property ControlTop: Integer;
```

C++

```
__property int ControlTop;
```

Description

Use the ControlTop property to set the starting point of the top of the control. This value includes the margins.

32.1.24.4.6 TMargins.ControlWidth Property

Sets the width of the control.

Pascal

```
property ControlWidth: Integer;
```

C++

```
__property int ControlWidth;
```

Description

Use the ControlWidth property to set the width of the control. This width includes the width of the margins.

32.1.24.4.7 TMargins.ExplicitHeight Property

Pascal

```
property ExplicitHeight: Integer;
```

C++

```
__property int ExplicitHeight;
```

Description

This is ExplicitHeight, a member of class TMargins.

32.1.24.4.8 TMargins.ExplicitLeft Property

Pascal

```
property ExplicitLeft: Integer;
```

C++

```
__property int ExplicitLeft;
```

Description

This is ExplicitLeft, a member of class TMargins.

32.1.24.4.9 TMargins.ExplicitTop Property

Pascal

```
property ExplicitTop: Integer;
```

C++

```
__property int ExplicitTop;
```

Description

This is ExplicitTop, a member of class TMargins.

32.1.24.4.10 TMargins.ExplicitWidth Property

Pascal

```
property ExplicitWidth: Integer;
```

C++

```
__property int ExplicitWidth;
```

Description

This is ExplicitWidth, a member of class TMargins.

32.1.24.4.11 TMargins.Left Property

Specifies the left edge of the margin.

Pascal

```
property Left: TMarginSize;
```

C++

```
__property TMarginSize Left;
```

Description

Use the Left property to specify the left edge of the margin.

32.1.24.4.12 TMargins.Right Property

Specifies the right edge of the margin.

Pascal

```
property Right: TMarginSize;
```

C++

```
__property TMarginSize Right;
```

Description

Use the Right property to specify the right edge of the margin.

32.1.24.4.13 TMargins.Top Property

Specifies the top edge of the margin.

Pascal

```
property Top: TMarginSize;
```

C++

```
__property TMarginSize Top;
```

Description

Use the Top property to specify the top edge of the margin.

32.1.24.5 TMargins Events

The events of the TMargins class are listed here.

Public Events

	Name	Description
	OnChange (see page 6096)	Occurs when margins change.

32.1.24.5.1 TMargins.OnChange Event

Occurs when margins change.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Use OnChange to write a handler to perform an action then the margin changes.

32.1.25 TMouse Class

TMouse surfaces information about the mouse and specifies how the application responds to mouse messages.

Class Hierarchy

Controls.TMouse

Pascal

```
TMouse = class;
```

C++

```
class TMouse;
```

File

Controls

Description

Use the global Mouse (see page 6321) variable, which is a TMouse object, to get information about the mouse.

TControl (see page 5724) descendants surface several events that let you respond to actions users make with the mouse. Typically, the event handlers for these events provide most of the information about the mouse that you need and you do not

need to use the global Mouse (see page 6321) variable. Instead, use the Mouse (see page 6321) variable to obtain similar information outside of a mouse-related event or to specify more global aspects of how your application responds to mouse messages, such as how much the user must move the mouse to start a drag operation.

See Also

Mouse (see page 6321)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

32.1.25.1 TMouse Members

The following tables list the members exposed by TMouse.

Public Methods

	Name	Description
	Create (see page 6097)	Creates and initializes a TMouse (see page 6096) object.
	CreatePanningWindow (see page 6098)	Creates a panning window.
V	Destroy (see page 6098)	Destroys an instance of TMouse (see page 6096).
	SettingChanged (see page 6098)	Responds when a Mouse (see page 6321) setting is changed.

Public Properties

	Name	Description
	Capture (see page 6099)	Specifies the handle of the window that is capturing mouse events.
	CursorPos (see page 6100)	Specifies the position of the mouse cursor.
	DragImmediate (see page 6100)	Specifies whether clicking the left mouse button starts a drag event immediately.
	DragThreshold (see page 6101)	Specifies the number of pixels that the left mouse button must be moved in order to cause a drag operation.
R	IsDragging (see page 6101)	Is there an active dragging operation?
R	IsPanning (see page 6101)	Returns the Boolean value True if the panning window is actively panning. .
R	MousePresent (see page 6101)	Specifies whether a mouse is present on the system.
	PanningWindow (see page 6102)	Returns a reference to the active panning window. .
	PanningWindowClass (see page 6102)	The class type used for creating the panning window class.
R	RegWheelMessage (see page 6102)	Indicates the windows message that is sent when the user scrolls the mouse wheel.
R	WheelPresent (see page 6103)	Specifies whether the mouse has a wheel.
R	WheelScrollLines (see page 6103)	Specifies the number of lines that are scrolled for each notch that the mouse wheel is rotated.

32.1.25.2 TMouse.Create Constructor

Creates and initializes a TMouse (see page 6096) object.

Pascal

```
constructor Create;
```

C++

```
__fastcall TMouse();
```

Description

Do not create instances of TMouse (see page 6096). A single instance of TMouse (see page 6096) is available as the global Mouse (see page 6321) variable.

32.1.25.3 TMouse.Destroy Destructor

Destroys an instance of TMouse (see page 6096).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMouse();
```

Description

Do not destroy the global instance of TMouse (see page 6096). This object is automatically destroyed when the application shuts down.

32.1.25.4 TMouse Methods

The methods of the TMouse class are listed here.

Public Methods

	Name	Description
	CreatePanningWindow (see page 6098)	Creates a panning window.
	SettingChanged (see page 6098)	Responds when a Mouse (see page 6321) setting is changed.

32.1.25.4.1 TMouse.CreatePanningWindow Method

Creates a panning window.

Pascal

```
function CreatePanningWindow: TCustomPanningWindow;
```

C++

```
__fastcall TCustomPanningWindow CreatePanningWindow();
```

Description

Creates a panning window when a panning operation is requested on a control that supports the csPanning ControlStyle. The window created is of the TCustomPanningWindow (see page 5958) class.

32.1.25.4.2 TMouse.SettingChanged Method

Responds when a Mouse (see page 6321) setting is changed.

Pascal

```
procedure SettingChanged(Setting: Integer);
```

C++

```
__fastcall SettingChanged(int Setting);
```

Description

SettingChanged is called automatically when the application receives notification from Windows that the control panel settings have changed. It updates the Mouse (see page 6321) object to reflect the current control panel settings.

Applications should not need to call this method.

32.1.25.5 TMouse Properties

The properties of the TMouse class are listed here.

Public Properties

	Name	Description
	Capture (see page 6099)	Specifies the handle of the window that is capturing mouse events.
	CursorPos (see page 6100)	Specifies the position of the mouse cursor.
	DragImmediate (see page 6100)	Specifies whether clicking the left mouse button starts a drag event immediately.
	DragThreshold (see page 6101)	Specifies the number of pixels that the left mouse button must be moved in order to cause a drag operation.
R	IsDragging (see page 6101)	Is there an active dragging operation?
R	IsPanning (see page 6101)	Returns the Boolean value True if the panning window is actively panning. .
R	MousePresent (see page 6101)	Specifies whether a mouse is present on the system.
	PanningWindow (see page 6102)	Returns a reference to the active panning window. .
	PanningWindowClass (see page 6102)	The class type used for creating the panning window class.
R	RegWheelMessage (see page 6102)	Indicates the windows message that is sent when the user scrolls the mouse wheel.
R	WheelPresent (see page 6103)	Specifies whether the mouse has a wheel.
R	WheelScrollLines (see page 6103)	Specifies the number of lines that are scrolled for each notch that the mouse wheel is rotated.

32.1.25.5.1 TMouse.Capture Property

Specifies the handle of the window that is capturing mouse events.

Pascal

```
property Capture: HWND;
```

C++

```
__property HWND Capture;
```

Description

Read Capture to get the handle of the window that receives all mouse messages. This is the window that is currently responding to the user's mouse actions.

Set Capture to the Handle property of a control to let it "capture" the mouse. When a window captures the mouse, it receives all mouse messages until it releases the mouse.

Typically, applications do not need to explicitly set the Capture property. Individual controls automatically capture the mouse in response to mouse clicks. They then translate incoming mouse message into events such as OnMouseDown or OnMouseMove. You only need to set Capture to override this default behavior. For example, when writing an object that creates a child control in response to a mouse click, you might set Capture to the child control's Handle property so that it receives subsequent mouse messages until the mouse button is released.

See Also

MouseCapture (see page 5831)

Handle (see page 6207)

OnMouseDown (see page 5862)

OnMouseMove (see page 5865)

OnMouseUp (see page 5867)

OnMouseWheel (see page 5869)

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

32.1.25.5.2 TMouse.CursorPos Property

Specifies the position of the mouse cursor.

Pascal

```
property CursorPos: TPoint;
```

C++

```
__property TPoint CursorPos;
```

Description

Use CursorPos to get the position of the mouse cursor in global coordinates. Use this position to position UI elements in relation to the mouse. For example, the position of popup menus or the display of the drag rectangle during drag-and-dock operations is based on the value of CursorPos.

TMouse (see page 6096). CursorPos can raise an exception. The property getter API call is wrapped with Win32Check, which raises the exception, EOSException, if the function fails. The API call is shown in the following code:

```
function TMouse.GetCursorPos: TPoint;
begin
  Win32Check(Windows.GetCursorPos(Result));
end;
```

32.1.25.5.3 TMouse.DragImmediate Property

Specifies whether clicking the left mouse button starts a drag event immediately.

Pascal

```
property DragImmediate: Boolean;
```

C++

```
__property Boolean DragImmediate;
```

Description

Use DragImmediate to determine whether clicking the left mouse button starts a drag event immediately. If DragImmediate is false, then drag events are delayed until the mouse cursor is moved the number of pixels specified in the DragThreshold (see page 6101) property.

See Also

DragThreshold (see page 6101)

32.1.25.5.4 TMouse.DragThreshold Property

Specifies the number of pixels that the left mouse button must be moved in order to cause a drag operation.

Pascal

```
property DragThreshold: Integer;
```

C++

```
__property int DragThreshold;
```

Description

Use DragThreshold to specify the number of pixels that the mouse cursor must be moved with the left mouse button down in order to initiate a drag operation. DragThreshold only has an effect if the DragImmediate (see page 6100) property is false.

Note: DragThreshold must be greater than or equal to zero. Negative values are treated as 0.

See Also

DragImmediate (see page 6100)

32.1.25.5.5 TMouse.IsDragging Property

Is there an active dragging operation?

Pascal

```
property IsDragging: Boolean;
```

C++

```
__property Boolean IsDragging;
```

Description

Use IsDragging to determine whether a dragging operation is in progress.

32.1.25.5.6 TMouse.IsPanning Property

Returns the Boolean value True if the panning window is actively panning. .

Pascal

```
property IsPanning: Boolean;
```

C++

```
__property Boolean IsPanning;
```

Description

If a False value is returned, no panning is currently occurring.

32.1.25.5.7 TMouse.MousePresent Property

Specifies whether a mouse is present on the system.

Pascal

```
property MousePresent: Boolean;
```

C++

```
__property Boolean MousePresent;
```

Description

Use MousePresent to determine whether a mouse is present on the system.

See Also

WheelPresent (see page 6103)

32.1.25.5.8 TMouse.PanningWindow Property

Returns a reference to the active panning window. .

Pascal

```
property PanningWindow: TCustomPanningWindow;
```

C++

```
__property TCustomPanningWindow PanningWindow;
```

Description

Add this property to your code to return a reference to the active panning window.

32.1.25.5.9 TMouse.PanningWindowClass Property

The class type used for creating the panning window class.

Pascal

```
property PanningWindowClass: TPanningWindowClass;
```

C++

```
__property TPanningWindowClass PanningWindowClass;
```

Description

This class type is used for creating the panning window class.

32.1.25.5.10 TMouse.RegWheelMessage Property

Indicates the windows message that is sent when the user scrolls the mouse wheel.

Pascal

```
property RegWheelMessage: UINT;
```

C++

```
__property UINT RegWheelMessage;
```

Description

Use RegWheelMessage to get the windows message that is sent when the user scrolls the mouse wheel. Typically, applications do not need to use RegWheelMessage. TWinControl (see page 6112) checks for this value when it receives window messages, and translates it into appropriate Mouse (see page 6321) Wheel events.

RegWheelMessage is used in Windows 95, but not NT or later versions of Windows. (Mouse (see page 6321) support is built into the later operating systems.)

See Also

WheelPresent (see page 6103)

32.1.25.5.11 TMouse.WheelPresent Property

Specifies whether the mouse has a wheel.

Pascal

```
property WheelPresent: Boolean;
```

C++

```
__property Boolean WheelPresent;
```

Description

Use WheelPresent to determine whether the mouse has a wheel.

See Also

MousePresent (see page 6101)

RegWheelMessage (see page 6102)

32.1.25.5.12 TMouse.WheelScrollLines Property

Specifies the number of lines that are scrolled for each notch that the mouse wheel is rotated.

Pascal

```
property WheelScrollLines: Integer;
```

C++

```
__property int WheelScrollLines;
```

Description

Use WheelScrollLines to get the number of lines that are scrolled for each notch that the mouse wheel is rotated.

WheelScrollLines can be set under Mouse (see page 6321) in the Windows Control Panel.

See Also

WheelPresent (see page 6103)

32.1.26 TPadding Class

Contains the padding for the control.

Class Hierarchy

Pascal

```
TPadding = class(TMargins);
```

C++

```
class TPadding : public TMargins;
```

File

Controls

Description

TPadding is used in the Padding property of TControl (see page 5724) and its descendants. It specifies the padding of a control.

32.1.26.1 TPadding Members

The following tables list the members exposed by TPadding.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 6090)	Copies the properties of an object to a destination object.
	Change (see page 6091)	This is Change, a member of class TMargins.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetControlBound (see page 6091)	This is GetControlBound, a member of class TMargins.
	GetOwner (see page 2932)	Returns the owner of an object.
	InitDefaults (see page 6105)	This is InitDefaults, a member of class TPadding.

Protected Properties

	Name	Description
	Control (see page 6093)	This is Control, a member of class TMargins.

Public Events

	Name	Description
	OnChange (see page 6096)	Occurs when margins change.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6089)	This is Create, a member of class TMargins.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetBounds (see page 6091)	Sets the properties for the left, top, right, and bottom margins all at once.
	SetControlBounds (see page 6091)	This is the overview for the SetControlBounds method overload.

Public Properties

	Name	Description
R	ControlHeight (see page 6093)	Sets the height of the control.
R	ControlLeft (see page 6093)	Sets the starting point for the left side of the control.
R	ControlTop (see page 6094)	Sets the starting point for the top of the control.
R	ControlWidth (see page 6094)	Sets the width of the control.
R	ExplicitHeight (see page 6094)	This is ExplicitHeight, a member of class TMargins.
R	ExplicitLeft (see page 6094)	This is ExplicitLeft, a member of class TMargins.
R	ExplicitTop (see page 6095)	This is ExplicitTop, a member of class TMargins.
R	ExplicitWidth (see page 6095)	This is ExplicitWidth, a member of class TMargins.

Published Properties

	Name	Description
	Bottom (see page 6106)	Specifies the bottom edge of the padding.
	Left (see page 6106)	Specifies the left edge of the padding.
	Right (see page 6106)	Specifies the right edge of the padding.
	Top (see page 6107)	Specifies the top edge of the padding.

32.1.26.2 TPadding Methods

The methods of the TPadding class are listed here.

Protected Methods

	Name	Description
V	InitDefaults (see page 6105)	This is InitDefaults, a member of class TPadding.

32.1.26.2.1 TPadding.InitDefaults Method

Pascal

```
class procedure InitDefaults(Margins: TMargins); override;
```

C++

```
virtual __fastcall InitDefaults(TMargins Margins);
```

Description

This is InitDefaults, a member of class TPadding.

32.1.26.3 TPadding Properties

The properties of the TPadding class are listed here.

Published Properties

	Name	Description
	Bottom (see page 6106)	Specifies the bottom edge of the padding.
	Left (see page 6106)	Specifies the left edge of the padding.
	Right (see page 6106)	Specifies the right edge of the padding.
	Top (see page 6107)	Specifies the top edge of the padding.

32.1.26.3.1 TPadding.Bottom Property

Specifies the bottom edge of the padding.

Pascal

```
property Bottom: TMarginSize;
```

C++

```
__property TMarginSize Bottom;
```

Description

Use the Bottom property to specify the bottom edge of the padding.

32.1.26.3.2 TPadding.Left Property

Specifies the left edge of the padding.

Pascal

```
property Left: TMarginSize;
```

C++

```
__property TMarginSize Left;
```

Description

Use the Left property to specify the left edge of the padding.

32.1.26.3.3 TPadding.Right Property

Specifies the right edge of the padding.

Pascal

```
property Right: TMarginSize;
```

C++

```
__property TMarginSize Right;
```

Description

Use the Right property to specify the right edge of the padding.

32.1.26.3.4 TPadding.Top Property

Specifies the top edge of the padding.

Pascal

```
property Top: TMarginSize;
```

C++

```
__property TMarginSize Top;
```

Description

Use the Top property to specify the top edge of the padding.

32.1.27 TSizeConstraints Class

Contains size constraints for a control.

Class Hierarchy

Pascal

```
TSizeConstraints = class(TPersistent);
```

C++

```
class TSizeConstraints : public TPersistent;
```

File

Controls

Description

TSizeConstraints is used in the Constraints property of TControl (see page 5724) and its descendants. It specifies the minimum and maximum sizes of a control, preventing the control from being resized larger than the maximum or smaller than the minimum.

See Also

TControl (see page 5724)

32.1.27.1 TSizeConstraints Members

The following tables list the members exposed by TSizeConstraints.

Protected Methods

	Name	Description
	AssignTo (see page 6109)	Handles assignments for TSizeConstraint objects.
	Change (see page 6109)	Called when the size constraints change.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Protected Properties

	Name	Description
R	Control (see page 6110)	Specifies the control to which the size constraints apply.

Public Events

	Name	Description
	OnChange (see page 6112)	Occurs when the size constraints change.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6109)	Creates and initializes an instance of TSizeConstraints (see page 6107).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Published Properties

	Name	Description
	MaxHeight (see page 6110)	Specifies the maximum height for the control.
	MaxWidth (see page 6111)	Specifies the maximum width for the control.
	MinHeight (see page 6111)	Specifies the minimum height for the control.
	MinWidth (see page 6111)	Specifies the minimum width for the control.

32.1.27.2 TSizeConstraints.Create Constructor

Creates and initializes an instance of TSizeConstraints (see page 6107).

Pascal

```
constructor Create(Control: TControl); virtual;
```

C++

```
virtual __fastcall TSizeConstraints(TControl * Control);
```

Description

Do not create instances of TSizeContraints. This object is created automatically by controls to implement their Constraints property.

Create sets the Control (see page 6110) property to Control (see page 6110) and then calls the inherited constructor.

See Also

Control (see page 6110)

Constraints (see page 5812)

32.1.27.3 TSizeConstraints Methods

The methods of the TSizeConstraints class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 6109)	Handles assignments for TSizeConstraint objects.
	Change (see page 6109)	Called when the size constraints change.

32.1.27.3.1 TSizeConstraints.AssignTo Method

Handles assignments for TSizeConstraint objects.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Call AssignTo to copy the values of one TSizeConstraints (see page 6107) object to another.

AssignTo overrides the inherited method in order to handle assignments specific to TSizeConstraints (see page 6107) objects.

See Also

Assign (see page 2930)

32.1.27.3.2 TSizeConstraints.Change Method

Called when the size constraints change.

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

Override Change in a derived class to perform actions when the size constraints change.

By default, Change calls the OnChange (see page 6112) event handler.

32.1.27.4 TSizeConstraints Properties

The properties of the TSizeConstraints class are listed here.

Protected Properties

	Name	Description
R	Control (see page 6110)	Specifies the control to which the size constraints apply.

Published Properties

	Name	Description
	MaxHeight (see page 6110)	Specifies the maximum height for the control.
	MaxWidth (see page 6111)	Specifies the maximum width for the control.
	MinHeight (see page 6111)	Specifies the minimum height for the control.
	MinWidth (see page 6111)	Specifies the minimum width for the control.

32.1.27.4.1 TSizeConstraints.Control Property

Specifies the control to which the size constraints apply.

Pascal

```
property Control: TControl;
```

C++

```
__property TControl * Control;
```

Description

Use Control to determine the control to which the size constraints apply.

Control is set automatically when a TSizeConstraints (see page 6107) object is created for the Constraints property of a control.

See Also

Constraints (see page 5812)

32.1.27.4.2 TSizeConstraints.MaxHeight Property

Specifies the maximum height for the control.

Pascal

```
property MaxHeight: TConstraintSize;
```

C++

```
__property TConstraintSize MaxHeight;
```

Description

Use MaxHeight to get or set the maximum height for the control.

32.1.27.4.3 TSizeConstraints.MaxWidth Property

Specifies the maximum width for the control.

Pascal

```
property MaxWidth: TConstraintSize;
```

C++

```
__property TConstraintSize MaxWidth;
```

Description

Use MaxWidth to get or set the maximum width for the control.

32.1.27.4.4 TSizeConstraints.MinHeight Property

Specifies the minimum height for the control.

Pascal

```
property MinHeight: TConstraintSize;
```

C++

```
__property TConstraintSize MinHeight;
```

Description

Use MinHeight to get or set the minimum height for the control.

32.1.27.4.5 TSizeConstraints.MinWidth Property

Specifies the minimum width for the control.

Pascal

```
property MinWidth: TConstraintSize;
```

C++

```
__property TConstraintSize MinWidth;
```

Description

Use MinWidth to get or set the minimum width for the control.

32.1.27.5 TSizeConstraints Events

The events of the TSizeConstraints class are listed here.

Public Events

	Name	Description
	OnChange (see page 6112)	Occurs when the size constraints change.

32.1.27.5.1 TSizeConstraints.OnChange Event

Occurs when the size constraints change.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Use OnChange to perform actions when the size constraints change.

32.1.28 TWinControl Class

TWinControl is the base class for all controls that are wrappers for Microsoft Windows screen objects.

Class Hierarchy

Pascal

```
TWinControl = class(TControl);
```

C++

```
class TWinControl : public TControl;
```

File

Controls

Description

TWinControl provides the common functionality for all controls that act as wrappers for Microsoft Windows screen objects ("windows"). Controls (see page 6197) that are wrap underlying windows have the following features:

The control can incorporate the functionality of an underlying window. For example, if the underlying screen object is a text editor, the control can incorporate the editor ability to manage and display a text buffer.

The control can receive user input focus. The focused control can handle keyboard input events. Some controls change their appearance when they have the focus. For example, button controls typically indicate the focus by drawing a rectangle around the caption.

The control can serve as a container for other controls, referred to as child controls. This relationship is signified by the child's Parent (see page 5832) property. Container controls provide important services to their children, including display services for controls that do not implement their own canvases. Examples of container controls include forms, panels, and toolbars.

Controls (see page 6197) based on TWinControl can display standard screen objects provided by Microsoft Windows, or customized screen objects developed by the VCL programmer.

Descendants of TWinControl include abstract base classes that support most kinds of user interface objects. The most significant descendant is TCustomControl (see page 5908), which provides code to implement a canvas and handle paint messages. Other important abstract descendants include TScrollingWinControl, TButtonControl, TCustomComboBox,

TCustomEdit, and TCustomListBox. When defining new control classes, consider these descendants before deriving directly from TWinControl.

Every TWinControl object has a Handle (see page 6207) property which provides the window handle for the underlying Microsoft Windows screen object. Use the Handle (see page 6207) property to bypass the VCL API and directly access the underlying window.

32.1.28.1 TWinControl Members

The following tables list the members exposed by TWinControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.

	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.

	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.

	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.

	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.

	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.

R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

32.1.28.2 TWinControl.Create Constructor

Creates an instance of TWinControl (see page 6112).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWinControl(TComponent * AOwner);
```

Description

Call Create to construct and initialize a new control and insert the newly-constructed control into its owner, as specified by the AOwner parameter. Create inserts the control in the owner by calling the owner's InsertComponent method.

Most controls override Create to initialize their unique properties. Objects that override the Create method must always call the inherited Create method first, and then proceed with the component-specific initialization. Specify the override directive when overriding the Create method.

If a component's Create method allocates resources or memory, override the Destroy (see page 6124) method to free those resources.

See Also

Brush (see page 6195)

TabOrder (see page 6211)

CreateParented (see page 6123)

InsertComponent (see page 2780)

Create (see page 5731)

Owner (see page 2807)

32.1.28.3 TWinControl.CreateParented Constructor

Creates and initializes a control as the child of a specified non-VCL container.

Pascal

```
constructor CreateParented(ParentWindow: HWnd);
```

C++

```
__fastcall TWinControl(HWnd ParentWindow);
```

Description

Call CreateParented to embed a new control in a non-VCL parent window. TActiveXControl objects call CreateParented to create an ActiveX control as a child of the host application's client site window.

32.1.28.4 TWinControl.Destroy Destructor

Destroys an instance of TWinControl (see page 6112).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWinControl();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TWinControl (see page 6112) reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

Destroy (see page 5732)

32.1.28.5 TWinControl Fields

The fields of the TWinControl class are listed here.

Protected Fields

	Name	Description
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.

32.1.28.5.1 TWinControl.FDesignSize Field

Pascal

```
FDesignSize: TPoint;
```

C++

```
TPoint FDesignSize;
```

Description

This is FDesignSize, a member of class TWinControl.

32.1.28.5.2 TWinControl.FDoubleBuffered Field

Pascal

```
FDoubleBuffered: Boolean;
```

C++

```
Boolean FDoubleBuffered;
```

Description

This is FDoubleBuffered, a member of class TWinControl.

32.1.28.5.3 TWinControl.FInImeComposition Field

Pascal

```
FInImeComposition: Boolean;
```

C++

```
Boolean FInImeComposition;
```

Description

This is FInImeComposition, a member of class TWinControl.

32.1.28.6 TWinControl Methods

The methods of the TWinControl class are listed here.

Protected Methods

	Name	Description
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.

	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	WndProc (see page 6187)	Provides specific message responses for the control.

Public Methods

	Name	Description
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	Invalidate (see page 6161)	Schedules a control repaint.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Realign (see page 6171)	Forces the control to realign children.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	Repaint (see page 6174)	Repaints the entire control.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScrollBy (see page 6176)	Scroll control contents.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.
	Update (see page 6183)	Forces the control to update.
	UpdateControlState (see page 6186)	Respond to state change.

32.1.28.6.1 TWinControl.ActionChange Method

Updates the control to reflect changes in its associated action.

Pascal

```
procedure ActionChange(Sender: TObject; CheckDefaults: Boolean); override;
```

C++

```
virtual __fastcall ActionChange(TObject * Sender, Boolean CheckDefaults);
```

Description

ActionChange is called automatically when the associated action changes. It updates the control to reflect the action's current Caption (see page 5806), Enabled (see page 5821), Hint (see page 5827), Visible (see page 5847), and HelpContext (see page 5826) properties and its OnClick (see page 5851) event handler.

The Sender parameter is the associated action. The CheckDefaults parameter specifies whether properties and event handlers

should be changed if they differ from the default values. When CheckDefaults is true, properties and event handlers are only changed when the current values are the default values (that is, when the values have not been previously changed). When CheckDefaults is false, properties and event handlers are changed, regardless of their current values.

See Also

RegisterChanges (see page 2713)

32.1.28.6.2 TWinControl.AddBiDiModeExStyle Method

Sets control's window style according to its bi-directional support.

Pascal

```
procedure AddBiDiModeExStyle(var ExStyle: DWORD);
```

C++

```
__fastcall AddBiDiModeExStyle(DWORD ExStyle);
```

Description

The CreateParams (see page 6135) method calls AddBiDiModeExStyle to update the control's style flags (passed as the ExStyle parameter) according the control's bi-directional support. AddBiDiModeExStyle uses the UseRightToLeftReading (see page 5790), UseRightToLeftScrollbar, UseRightToLeftAlignment (see page 5790), and GetControlsAlignment (see page 5759) methods to determine the current bi-directional support.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftScrollBar (see page 5791)

UseRightToLeftReading (see page 5790)

GetControlsAlignment (see page 5759)

CreateParams (see page 6135)

32.1.28.6.3 TWinControl.AdjustClientRect Method

Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.

Pascal

```
procedure AdjustClientRect(var Rect: TRect); virtual;
```

C++

```
virtual __fastcall AdjustClientRect(TRect Rect);
```

Description

AdjustClientRect is called internally when the control needs accurate information on where to place child controls within the client area. As implemented in TWinControl (see page 6112), AdjustClientRect does nothing. Override this method in descendants such as TTabControl where the ClientRect (see page 5810) property is not the same as the region in which child objects can appear.

See Also

ClientRect

Controls (see page 6197)

32.1.28.6.4 TWinControl.AdjustSize Method

Adjusts the control's size according to its contents and constraints.

Pascal

```
procedure AdjustSize; override;
```

C++

```
virtual __fastcall AdjustSize();
```

Description

If the AutoSize (see page 5803) property is true, AdjustSize is called automatically when the control needs to automatically resize itself to its contents. As implemented in TWinControl (see page 6112), AdjustSize calls SetBounds (see page 6178) with the values of its Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties. This call can result in a change of size if these values are altered in the control's OnCanResize (see page 5851) or OnConstrainedResize (see page 5853) event handlers, or if the control's OnResize (see page 5870) event handler makes any final adjustments.

Descendant classes override AdjustSize to change the size of the control to adjust to its contents.

Component writers may call AdjustSize when making changes to a control's contents.

See Also

OnCanResize (see page 5851)

OnConstrainedResize (see page 5853)

OnResize (see page 5870)

SetBounds (see page 6178)

AutoSize (see page 5803)

CanAutoSize (see page 6131)

32.1.28.6.5 TWinControl.AlignControls Method

Aligns any controls for which the control is the parent within a specified area of the control.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); virtual;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of a form, panel, group box, scroll box, or any container control. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align (see page 5798) property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly-aligned controls.

See Also

Align (see page 5798)

32.1.28.6.6 TWinControl.ArrangeControl Method

Pascal

```
procedure ArrangeControl(AControl: TControl; const ParentSize: TPoint; AAlign: TAlign;
AAlignInfo: TAlignInfo; var Rect: TRect; UpdateAnchorOrigin: Boolean = False);
```

C++

```
__fastcall ArrangeControl(TControl * AControl, const TPoint ParentSize, TAlign AAlign,
TAlignInfo AAlignInfo, TRect Rect, Boolean UpdateAnchorOrigin = False);
```

Description

This is ArrangeControl, a member of class TWinControl.

32.1.28.6.7 TWinControl.AssignTo Method

Copies the properties of the windowed control to another object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Do not call the protected AssignTo method. Instead, applications call the Assign method to copy the properties of another object. If the object's Assign method does not include the ability to copy from the source object, the Assign method calls the source object's protected AssignTo method, to copy the source objects properties to the object specified by the Dest parameter. This allows objects to expand the abilities of another object's Assign method to copy from additional sources.

The AssignTo method implemented in TWinControl (see page 6112) copies the Caption (see page 5806), Enabled (see page 5821), Hint (see page 5827), Visible (see page 5847), and HelpContext (see page 5826) properties and the OnClick (see page 5851) event handler to a TCustomAction object.

See Also

Assign (see page 2930)

TCustomAction (see page 297)

Caption (see page 5806)

Enabled (see page 5821)

Hint (see page 5827)

Visible (see page 5847)

HelpContext (see page 5826)

OnClick (see page 5851)

32.1.28.6.8 TWinControl.Broadcast Method

Sends a message to each of the child controls.

Pascal

```
procedure Broadcast(var Message);
```

C++

```
__fastcall Broadcast( Message);
```

Description

Use Broadcast when you want to send the same message to each of the child controls contained within the windowed control. Specify the message to be passed as the value of the Message parameter.

See Also

NotifyControls (see page 6165)

Broadcasting a Message to All Controls in a Form

32.1.28.6.9 TWinControl.CanAutoSize Method

Indicates how the control can be resized.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize (see page 5803) property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize (see page 5803) property before the resize sequence that begins with the OnCanResize (see page 5851) and OnConstrainedResize (see page 5853) events and ends with the OnResize (see page 5870) event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width (see page 5849) and Height (see page 5825), CanAutoSize returns false, and the resize sequence is aborted.

As implemented in TWinControl (see page 6112), CanAutoSize returns true, adjusting NewWidth and NewHeight so that all the control's children fit.

See Also

Constraints (see page 5812)

ConstrainedResize (see page 6133)

AdjustSize (see page 6129)

32.1.28.6.10 TWinControl.CanFocus Method

Indicates whether a control can receive focus.

Pascal

```
function CanFocus: Boolean; dynamic;
```

C++

```
__fastcall Boolean CanFocus();
```

Description

Call CanFocus to find out if the control can receive input from the user.

CanFocus returns true if both the control and its parent(s) have their Visible (see page 5847) and Enabled (see page 5821) properties set to true. If any of the Visible (see page 5847) and Enabled (see page 5821) properties of the control or the controls in which it is contained are not true, then CanFocus returns false.

See Also

Enabled (see page 5821)

Parent (see page 5832)

Visible (see page 5847)

32.1.28.6.11 TWinControl.CanResize Method

Indicates how the control can respond to a resize attempt.

Pascal

```
function CanResize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanResize(int NewWidth, int NewHeight);
```

Description

CanResize is called automatically when an attempt is made to resize the control. The NewWidth and NewHeight parameters specify the attempted new values for the control's height and width. CanResize returns true if the control can be resized to the returned values of NewWidth and NewHeight. CanResize returns false if the control can't be resized.

CanResize generates an OnCanResize (see page 5851) event. An OnCanResize (see page 5851) event handler may change the values of NewHeight and NewWidth.

See Also

OnCanResize (see page 5851)

32.1.28.6.12 TWinControl.ChangeScale Method

Resize (see page 5780) and reposition children and self.

Pascal

```
procedure ChangeScale(M: Integer; D: Integer); override;
```

C++

```
virtual __fastcall ChangeScale(int M, int D);
```

Description

ChangeScale rescales the control in the same manner as the ChangeScale method in TControl (see page 5724). If the control contains any children, their ChangeScale methods are called before the parent itself is rescaled.

To rescale the control's children without rescaling the control itself, use ScaleControls (see page 6176). To rescale the control without repositioning, use ScaleBy (see page 6175).

See Also

ScaleBy (see page 6175)

ChangeScale (see page 5743)

32.1.28.6.13 TWinControl.ConstrainedResize Method

Generates an OnConstrainedResize (see page 5853) event.

Pascal

```
procedure ConstrainedResize(var MinWidth: Integer; var MinHeight: Integer; var MaxWidth:
Integer; var MaxHeight: Integer); override;
```

C++

```
virtual __fastcall ConstrainedResize(int MinWidth, int MinHeight, int MaxWidth, int MaxHeight);
```

Description

ConstrainedResize is called automatically as part of a control's resize sequence. It generates an OnConstrainedResize (see page 5853) event, passing in the MinWidth, MinHeight, MaxWidth, and MaxHeight parameters, which can be altered by the event handler before they are applied to the attempted resize.

See Also

OnConstrainedResize (see page 5853)

CanResize (see page 5742)

Constraints (see page 5812)

32.1.28.6.14 TWinControl.ContainsControl Method

Indicates whether a specified control exists within the control.

Pascal

```
function ContainsControl(Control: TControl): Boolean;
```

C++

```
__fastcall Boolean ContainsControl(TControl * Control);
```

Description

Use ContainsControl to find out if a particular control exists within this control. ContainsControl returns true if the specified value of the Control parameter is a child control of this control. The Control parameter need not be an immediate child (in the Controls (see page 6197) property), but may be contained in a child of the control, or in a child of a child of the control, for indefinitely many levels deep.

If the method returns false, the specified control is not within the control.

See Also

ControlAtPos (see page 6133)

Controls (see page 6197)

Parent (see page 5832)

32.1.28.6.15 TWinControl.ControlAtPos Method

Returns the child control located at a specified position within the control.

Pascal

```
function ControlAtPos(const Pos: TPoint; AllowDisabled: Boolean; AllowWinControls: Boolean =
False; AllLevels: Boolean = False): TControl;
```

C++

```
__fastcall TControl * ControlAtPos(const TPoint Pos, Boolean AllowDisabled, Boolean
AllowWinControls = False, Boolean AllLevels = False);
```

Description

Use ControlAtPos to determine which child control is at the specified location within the control. ControlAtPos returns an immediate child of the control; that is, one of the entries of the Controls (see page 6197) property, that has this control for its Parent (see page 5832) property.

Specify the position in client coordinates as the value of the Pos parameter. Pos can be anywhere within the boundaries of the child control, not just the upper left corner.

The AllowDisabled parameter determines whether the search for controls includes disabled controls.

The AllowWinControls parameter determines whether descendants of TWinControl (see page 6112) are considered when looking for the child control.

If there is no control that matches the AllowDisabled and AllowWinControls parameters at the specified position, ControlAtPos returns nil (Delphi) or NULL (C++).

See Also

ContainsControl (see page 6133)

Controls (see page 6197)

Parent (see page 5832)

ScreenToClient (see page 5781)

FindVCLWindow (see page 6250)

32.1.28.6.16 TWinControl.ControlsAligned Method

Pascal

```
procedure ControlsAligned; dynamic;
```

C++

```
__fastcall ControlsAligned();
```

Description

This is ControlsAligned, a member of class TWinControl.

32.1.28.6.17 TWinControl.CreateDockManager Method

Creates the dock manager for the control.

Pascal

```
function CreateDockManager: IDockManager; dynamic;
```

C++

```
__fastcall IDockManager CreateDockManager();
```

Description

CreateDockManager is called automatically during drag-and-dock operations when the UseDockManager (see page 6212) property is true. CreateDockManager creates the object that implements the DockManager (see page 6202) property.

Override CreateDockManager to create a custom dock manager for the control.

See Also

DockSite (see page 6204)

UseDockManager (see page 6212)

DockManager (see page 6202)

32.1.28.6.18 TWinControl.CreateHandle Method

Creates underlying screen object.

Pascal

```
procedure CreateHandle; virtual;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

CreateHandle creates the Microsoft Windows screen object that underlies the control. if it does not already exist. The new window handle becomes the value of the Handle (see page 6207) property.

CreateHandle creates or locates the parent control's window before it creates a window for the control itself.

Note: If the Parent (see page 5832) property is nil (Delphi) or NULL (C++), CreateHandle raises an exception.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

Handle (see page 6207)

Parent (see page 5832)

32.1.28.6.19 TWinControl.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); virtual;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 6137) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 6137). Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams (see page 6280) record become the

parameters to a call to the CreateWindowEx API function.

TWinControl (see page 6112) implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

32.1.28.6.20 TWinControl.CreateParentedControl Method

Creates and initializes a control as the child of a specified non-VCL window.

Pascal

```
class function CreateParentedControl(ParentWindow: HWnd): TWinControl;
```

C++

```
__fastcall TWinControl * CreateParentedControl(HWnd ParentWindow);
```

Description

Call CreateParentedControl to embed a new control in a non-VCL parent.

CreateParentedControl allocates memory for a new instance of the same class as the control (Delphi) or is the class specified by the vmt parameter (C++), sets its ParentWindow (see page 6210) property to ParentWindow (see page 6210), and calls the constructor, passing in nil (Delphi) or NULL (C++) for the Owner parameter. CreateParentedControl returns the newly created control.

CreateParentedControl has the same purpose as CreateParented (see page 6123), but is a simple class function instead of a constructor. Unlike CreateParented (see page 6123), CreateParentedControl can be called from C++ code.

See Also

CreateParented (see page 6123)

ParentWindow (see page 6210)

32.1.28.6.21 TWinControl.CreateSubClass Method

Creates a windowed control derived from an existing Windows window class.

Pascal

```
procedure CreateSubClass(var Params: TCreateParams; ControlClassName: PChar);
```

C++

```
__fastcall CreateSubClass(TCreateParams Params, const char * ControlClassName);
```

Description

Call CreateSubClass in the CreateParams (see page 6135) method of a subclassed control, after calling the inherited CreateParams (see page 6135). Specify the parameter record as the value of the Params parameter. CreateSubClass allows VCL controls to create registered Windows controls.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

32.1.28.6.22 TWinControl.CreateWindowHandle Method

Creates a Windows control to represent the control.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); virtual;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

The CreateWnd (see page 6137) method calls CreateWindowHandle to create the window for a control. CreateWindowHandle creates the window by calling the CreateWindowEx API function, passing parameters from the record passed in the Params parameter. Once the window is created, its handle is available as the Handle (see page 6207) property.

See Also

CreateParams (see page 6135)

CreateWnd (see page 6137)

Handle (see page 6207)

32.1.28.6.23 TWinControl.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; virtual;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

32.1.28.6.24 TWinControl.CustomAlignInsertBefore Method

Returns placement order of custom-aligned child control.

Pascal

```
function CustomAlignInsertBefore(C1: TControl; C2: TControl): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CustomAlignInsertBefore(TControl * C1, TControl * C2);
```

Description

CustomAlignInsertBefore determines the order in which custom-aligned child controls are placed. The control calls CustomAlignInsertBefore once for each pair of child controls with an Align (see page 5798) property of **alCustom**. CustomAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise.

Once the custom-aligned child controls are sorted, their specific positions are determined by calls to CustomAlignPosition (see page 6138).

CustomAlignInsertBefore triggers the OnAlignInsertBefore (see page 6213) event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore (see page 6213). Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

As implemented in TWinControl (see page 6112), CustomAlignInsertBefore returns false if OnAlignInsertBefore (see page 6213) is not implemented, so the controls are placed in the order they appear in the Controls (see page 6197) property.

See Also

CustomAlignPosition (see page 6138)

Align (see page 5798)

Controls (see page 6197)

OnAlignInsertBefore (see page 6213)

32.1.28.6.25 TWinControl.CustomAlignPosition Method

Returns aligned position of custom-aligned child control.

Pascal

```
procedure CustomAlignPosition(Control: TControl; var NewLeft: Integer; var NewTop: Integer;
var NewWidth: Integer; var NewHeight: Integer; var AlignRect: TRect; AlignInfo: TAlignInfo);
virtual;
```

C++

```
virtual __fastcall CustomAlignPosition(TControl * Control, int NewLeft, int NewTop, int
NewWidth, int NewHeight, TRect AlignRect, TAlignInfo AlignInfo);
```

Description

CustomAlignPosition determines the specific position of custom-aligned child controls. CustomAlignPosition is called once for each child control with an Align (see page 5798) property of **alCustom**, in an order previously determined by calls to CustomAlignInsertBefore (see page 6137).

CustomAlignPosition triggers the OnAlignPosition (see page 6214) event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition (see page 6214). Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition.

These are the parameters:

Control	The child control being placed.
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors (see page 5802) TControl_Anchors constraints for the control. CustomAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. CustomAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo (see page 6269).

As implemented in TWinControl (see page 6112), CustomAlignPosition does nothing.	

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

OnAlignPosition (see page 6214)

TAlignInfo (see page 6269)

32.1.28.6.26 TWinControl.DefaultHandler Method

Provides message handling for all messages that the control does not fully process itself.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to change the default message handling for the control. The Message parameter can be cast to a TMessage type, to obtain the WParam, LParam, and Result of the message. If the Result of the message is non-zero, the message has already been handled. Set the Result field to a non-zero value to prevent further processing of the message by the inherited method.

Note: In Delphi code, calling inherited in a message-handling method results in a call to the ancestor's DefaultHandler method unless that ancestor specifies an explicit handler for the message.

TWinControl (see page 6112) overrides the TControl (see page 5724) DefaultHandler method to handle messages for all its descendant types. DefaultHandler passes any otherwise-unhandled messages to the control's window procedure using the CallWindowProc API function.

See Also

WindowProc (see page 5872)

DefWndProc (see page 6199)

32.1.28.6.27 TWinControl.DefineProperties Method

Provides methods to read and write the IsControl property to a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties is called automatically by the streaming system that loads and saves VCL components. It allows persistent objects to read and write properties that are not published. Published properties are loaded and stored automatically.

DefineProperties uses the methods of the filer passed as the Filer parameter to assign methods that can load and save the IsControl property.

Override DefineProperties to persist unpublished properties. Call the DefineBinaryProperty or DefineProperty method of the Filer parameter to assign methods that load or save property values.

Note: When overriding this method, call the parent class's DefineProperties method first.

See Also

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

DefineProperties (see page 2771)

IsControl (see page 5829)

32.1.28.6.28 TWinControl.DestroyHandle Method

Destroys the control's window without destroying the control.

Pascal

```
procedure DestroyHandle; virtual;
```

C++

```
virtual __fastcall DestroyHandle();
```

Description

Call DestroyHandle to dispose of the window, but leave the control intact. The control can later recreate the window if needed. DestroyHandle is the converse operation to CreateHandle (see page 6135). Applications should call the high-level CreateHandle (see page 6135) and DestroyHandle methods, rather than the lower-level methods of CreateWnd (see page 6137) and DestroyWnd (see page 6141), whenever possible.

If the control has TWinControl (see page 6112) objects as child controls, DestroyHandle calls each of their DestroyHandle methods before calling DestroyWnd (see page 6141) to destroy its own handle.

See Also

CreateHandle (see page 6135)

DestroyWnd (see page 6141)

32.1.28.6.29 TWinControl.DestroyWindowHandle Method

Destroys the window created in the CreateWindowHandle (see page 6137) method.

Pascal

```
procedure DestroyWindowHandle; virtual;
```

C++

```
virtual __fastcall DestroyWindowHandle();
```

Description

Call DestroyWindowHandle to dispose of the window for the control.

TWinControl (see page 6112)'s Destroy (see page 6124) method calls DestroyWindowHandle to destroy any window associated with a windowed control before destroying the object. The DestroyWnd (see page 6141) method also calls DestroyWindowHandle.

See Also

CreateWindowHandle (see page 6137)

Destroy (see page 6124)

DestroyWnd (see page 6141)

32.1.28.6.30 TWinControl.DestroyWnd Method

Destroys the control's window.

Pascal

```
procedure DestroyWnd; virtual;
```

C++

```
virtual __fastcall DestroyWnd();
```

Description

DestroyWnd is called when the control needs to replace its window. For example, changing properties that are implemented by window parameter settings require the control to be destroyed and then recreated using the CreateWnd (see page 6137) method.

Before the window is destroyed, DestroyWnd saves a copy of the control's text in memory, frees any device contexts, and finally calls DestroyWindowHandle (see page 6140). When the window is recreated, the stored copy of the control's text is assigned to the new window.

See Also

DestroyWindowHandle (see page 6140)

RecreateWnd (see page 6171)

32.1.28.6.31 TWinControl.DisableAlign Method

Disables the realignment of child controls.

Pascal

```
procedure DisableAlign;
```

C++

```
__fastcall DisableAlign();
```

Description

Call DisableAlign to temporarily prevent child controls from realigning. For example, while performing multiple manipulations of controls, such as reading from a form file or scaling, performance improves if child controls are not realigned until all manipulations are complete. The EnableAlign (see page 6148) method restores normal child realignment.

Every call to DisableAlign must be followed by a matching call to EnableAlign (see page 6148). If an exception could be raised after the call to DisableAlign, use an exception block to ensure that EnableAlign (see page 6148) will always be called.

DisableAlign/EnableAlign (see page 6148) call sequences can be nested. An internal counter records the level of nesting. As long as the counter is positive, realignment is disabled and the AlignDisabled (see page 6192) property returns true. Once the counter returns to zero, realignment is enabled and AlignDisabled (see page 6192) returns false.

See Also

EnableAlign (see page 6148)

AlignDisabled (see page 6192)

32.1.28.6.32 TWinControl.DoAddDockClient Method

Performs actions when a control is docked to the windowed control.

Pascal

```
procedure DoAddDockClient(Client: TControl; const ARect: TRect); dynamic;
```

C++

```
__fastcall DoAddDockClient(TControl * Client, const TRect ARect);
```

Description

DoAddDockClient is called automatically when a client control is docked to the windowed control. As implemented in TWinControl (see page 6112), DoAddDockClient sets the client's Parent (see page 5832) property to the control.

Client is the control that has been docked.

ARect describes the boundaries of the region where Client has been docked.

Override DoAddDockClient to perform actions when a control is docked to the windowed control.

Note: DoAddDockClient is called in response to a message sent by the DockDrop (see page 6142) method, before the OnDockDrop (see page 6214) event.

See Also

Parent (see page 5832)

DockClients (see page 6201)

ManualDock (see page 5771)

DoRemoveDockClient (see page 6147)

DockDrop (see page 6142)

OnDockDrop (see page 6214)

32.1.28.6.33 TWinControl.DockDrop Method

Generates an OnDockDrop (see page 6214) event.

Pascal

```
procedure DockDrop(Source: TDragDockObject; X: Integer; Y: Integer); dynamic;
```

C++

```
__fastcall DockDrop(TDragDockObject Source, int X, int Y);
```

Description

DockDrop is called automatically when a control is docked to the windowed control. It instructs the control that is being dropped to prepare for the dock operation and then generates an OnDockDrop (see page 6214) event.

Although you can override DockDrop to perform actions in addition to the generated OnDockDrop (see page 6214) event, typically descendant classes override the DoAddDockClient (see page 6142) method instead. This is because DoAddDockClient (see page 6142) is called by the client after it has performed its own preparations, but before the OnDockDrop (see page 6214) event.

DockDrop is called only if DockSite (see page 6204) is true.

See Also

OnDockDrop (see page 6214)

DockSite (see page 6204)

DoAddDockClient (see page 6142)

32.1.28.6.34 TWinControl.DockOver Method

Responds when a docking client is dragged over the windowed control.

Pascal

```
procedure DockOver(Source: TDragDockObject; X: Integer; Y: Integer; State: TDragState; var
Accept: Boolean); dynamic;
```

C++

```
__fastcall DockOver(TDragDockObject Source, int X, int Y, TDragState State, Boolean Accept);
```

Description

DockOver is called automatically for dock sites when a dockable object is dragged over them. As implemented in TWinControl (see page 6112), DockOver positions the docking rectangle and then calls DoDockOver (see page 6143) to generate an OnDockOver (see page 6216) event.

Override DockOver to perform additional actions when another control is dragged over the control.

DockOver is called only if DockSite (see page 6204) is true.

See Also

OnDockOver (see page 6216)

DockSite (see page 6204)

DoDockOver (see page 6143)

32.1.28.6.35 TWinControl.DockReplaceDockClient Method

Pascal

```
function DockReplaceDockClient(Client: TControl; NewDockSite: TWinControl; DropControl:
TControl; ControlSide: TAlign; ReplacementClient: TControl): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DockReplaceDockClient(TControl * Client, TWinControl * NewDockSite,
TControl * DropControl, TAlign ControlSide, TControl * ReplacementClient);
```

Description

This is DockReplaceDockClient, a member of class TWinControl.

32.1.28.6.36 TWinControl.DoDockOver Method

Generates an OnDockOver (see page 6216) event.

Pascal

```
procedure DoDockOver(Source: TDragDockObject; X: Integer; Y: Integer; State: TDragState; var
Accept: Boolean); dynamic;
```

C++

```
__fastcall DoDockOver(TDragDockObject Source, int X, int Y, TDragState State, Boolean Accept);
```

Description

DoDockOver is called by the DockOver (see page 6143) method to generate an OnDockOver (see page 6216) event when the user drags a dockable control over the windowed control. Override this method to perform some other action or to suppress the event.

See Also

OnDockOver (see page 6216)

DockOver (see page 6143)

32.1.28.6.37 TWinControl.DoEnter Method

Respond to receiving input focus.

Pascal

```
procedure DoEnter; dynamic;
```

C++

```
__fastcall DoEnter();
```

Description

DoEnter is called automatically when the control receives the input focus. As implemented in TWinControl (see page 6112), DoEnter calls the OnEnter (see page 6219) event handler, if defined.

Descendant classes that override DoEnter should always call the inherited method.

See Also

DoExit (see page 6144)

OnEnter (see page 6219)

32.1.28.6.38 TWinControl.DoExit Method

Respond to losing input focus

Pascal

```
procedure DoExit; dynamic;
```

C++

```
__fastcall DoExit();
```

Description

DoExit is called automatically when the control receives the input focus. As implemented in TWinControl (see page 6112), DoExit calls the OnExit (see page 6221) event handler, if defined.

Descendant classes that override DoExit should always call the inherited method.

See Also

DoEnter (see page 6144)

OnExit (see page 6221)

32.1.28.6.39 TWinControl.DoFlipChildren Method

Flips the control's children.

Pascal

```
procedure DoFlipChildren; dynamic;
```

C++

```
__fastcall DoFlipChildren();
```

Description

The FlipChildren (see page 6150) method calls DoFlipChildren to reverse the positions of child controls. DoFlipChildren moves the control's children to opposite positions on the control; that is, children on the left side of the control are moved to the right side of the control and vice versa.

Override FlipChildren (see page 6150) to control how the control's children are flipped.

Note: DoFlipChildren is a protected helper method for the public FlipChildren (see page 6150) method. Unlike FlipChildren (see page 6150), DoFlipChildren does not adjust the alignment of controls that are aligned to one of the edges of the windowed control.

See Also

BiDiMode (see page 5803)

FlipChildren (see page 6150)

32.1.28.6.40 TWinControl.DoKeyDown Method

Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

Pascal

```
function DoKeyDown(var Message: TWMKey): Boolean;
```

C++

```
__fastcall Boolean DoKeyDown(TWMKey Message);
```

Description

The return value from DoKeyDown determines if the control should continue processing key-down messages passed in the Message parameter. A return value of true indicates that the key-down occurrence has been handled completely, and no further processing is needed. A return value of false indicates that the application should continue passing the key-down message through the inherited processing.

DoKeyDown checks whether the KeyPreview property of the parent form is true; if so, it allows the form to preemptively process key-down messages before they are handled by the windowed control. If the form does not handle the message, DoKeyDown translates the message parameters into the appropriate types and calls KeyDown (see page 6163), which in turn calls the OnKeyDown (see page 6225) event handler, if any.

See Also

DoKeyPress (see page 6146)

DoKeyUp (see page 6146)

KeyDown (see page 6163)

OnKeyDown (see page 6225)

KeyPreview (see page 13918)

32.1.28.6.41 TWinControl.DoKeyPress Method

Performs some preprocessing before generating an OnKeyPress (see page 6227) event.

Pascal

```
function DoKeyPress(var Message: TWMKey): Boolean;
```

C++

```
__fastcall Boolean DoKeyPress(TWMKey Message);
```

Description

The return value from DoKeyPress determines whether the control should continue processing the key-press message passed in the Message parameter. A return value of true indicates that the key-press occurrence has been handled completely, and no further processing is needed. A return value of false indicates that the application should continue passing the key-press message through the inherited processing.

DoKeyPress checks whether the KeyPreview property of the parent form is true, and if so, allows the form to preemptively process key-press messages before they are handled by the windowed control. If the form does not handle the message, DoKeyPress translates the message parameters into the appropriate types and calls KeyPress (see page 6163), which in turn calls the OnKeyPress (see page 6227) event handler, if any.

See Also

DoKeyDown (see page 6145)

DoKeyUp (see page 6146)

KeyPress (see page 6163)

OnKeyPress (see page 6227)

KeyPreview (see page 13918)

32.1.28.6.42 TWinControl.DoKeyUp Method

Performs some preprocessing before generating an OnKeyUp (see page 6228) event.

Pascal

```
function DoKeyUp(var Message: TWMKey): Boolean;
```

C++

```
__fastcall Boolean DoKeyUp(TWMKey Message);
```

Description

The return value from DoKeyUp determines whether the control should continue processing the key-up message passed in the Message parameter. A return value of true indicates that the key-up occurrence has been handled completely, and no further processing is needed. A return value of false indicates that the application should continue passing the key-up message through the inherited processing.

DoKeyUp checks whether the KeyPreview property of the parent form is true, and if so, allows the form to preemptively process key-up messages before they are handled by the windowed control. If the form does not handle the message, DoKeyUp translates the message parameters into the appropriate types and calls KeyUp (see page 6164), which in turn calls the OnKeyUp (see page 6228) event handler, if any.

See Also

DoKeyDown (see page 6145)

KeyUp (see page 6164)

OnKeyUp (see page 6228)

KeyPreview (see page 13918)

32.1.28.6.43 TWinControl.DoRemoveDockClient Method

Responds when a control is undocked from the windowed control.

Pascal

```
procedure DoRemoveDockClient(Client: TControl); dynamic;
```

C++

```
__fastcall DoRemoveDockClient(TControl * Client);
```

Description

DoRemoveDockClient is called automatically when a client control is undocked from the windowed control. As implemented in TWinControl (see page 6112), DoRemoveDockClient does nothing.

Client is the control that has been undocked.

Override DoRemoveDockClient to perform any necessary adjustments when a control is undocked from the windowed control.

Note: DoRemoveDockClient occurs at the end of the undocking process. To make changes when undocking starts, override the DoUnDock (see page 6147) method instead.

See Also

DockClients (see page 6201)

ManualDock (see page 5771)

DoAddDockClient (see page 6142)

DoUnDock (see page 6147)

32.1.28.6.44 TWinControl.DoUnDock Method

Undocks a control that is currently docked to the windowed control.

Pascal

```
function DoUnDock(NewTarget: TWinControl; Client: TControl): Boolean; dynamic;
```

C++

```
__fastcall Boolean DoUnDock(TWinControl * NewTarget, TControl * Client);
```

Description

DoUnDock is called automatically when a control is undocked from the windowed control. It handles all necessary changes to the windowed control to accomplish the undocking. These are

1.Generates an OnUnDock (see page 6230) event.

2.If there is no OnUnDock (see page 6230) event handler, or if the event handler indicates that the client can be undocked, it removes the client from the DockClients (see page 6201) property list.

The NewTarget parameter indicates the new host to which the undocked control is moving.

The Client parameter indicates the control to be undocked from the windowed control.

DoUnDock returns true if the client is successfully undocked, false if the undocking attempt was blocked by an OnUnDock (see page 6230) event handler.

Override DoUnDock to change the way controls are undocked from the windowed control.

Note: DoUnDock occurs at the start of the undocking process. To handle changes when undocking is complete, override the DoRemoveDockClient (see page 6147) method instead.

See Also

OnUnDock (see page 6230)

DockClients (see page 6201)

DoRemoveDockClient (see page 6147)

32.1.28.6.45 TWinControl.EnableAlign Method

Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.

Pascal

```
procedure EnableAlign;
```

C++

```
__fastcall EnableAlign();
```

Description

Call EnableAlign to allow child controls within the control to realign again after they were prevented from realigning by a call to DisableAlign (see page 6141).

Each time the DisableAlign (see page 6141) method is called, it increments a reference count. Each time EnableAlign is called, it decrements the same reference count. When the reference count reaches zero, EnableAlign calls the Realign (see page 6171) method to perform any pending realignments.

Be sure to pair each call to DisableAlign (see page 6141) with a call to EnableAlign. If an exception could be raised after the call to DisableAlign (see page 6141), use an exception block to ensure that the corresponding call to EnableAlign is executed.

See Also

DisableAlign (see page 6141)

32.1.28.6.46 TWinControl.FindChildControl Method

Returns a child control given its name.

Pascal

```
function FindChildControl(const ControlName: string): TControl;
```

C++

```
__fastcall TControl * FindChildControl(const AnsiString ControlName);
```

Description

Call FindChildControl to locate a specified child control. FindChildControl searches the control's children and returns the control with the specified name. If no child controls match the specified name, FindChildControl returns nil (Delphi) or NULL (C++).

Note: FindChildControl only locates immediate children of the control. It can't find a control that is a child of one of the control's children.

See Also

FindNextControl (see page 6149)

Controls (see page 6197)

FindVCLWindow (see page 6250)

FindControl (see page 6249)

32.1.28.6.47 TWinControl.FindNextControl Method

Returns the control's next child in the tab order after the specified control.

Pascal

```
function FindNextControl(CurControl: TWinControl; GoForward: Boolean; CheckTabStop: Boolean;
CheckParent: Boolean): TWinControl;
```

C++

```
__fastcall TWinControl * FindNextControl(TWinControl * CurControl, Boolean GoForward, Boolean
CheckTabStop, Boolean CheckParent);
```

Description

Call FindNextControl to find the next child control in the tab order after CurControl. If CurControl is not a child of the control, FindNextControl returns the first child control in the tab order.

The GoForward parameter controls the direction of the search. If GoForward is true, FindNextControl searches forward through the child controls in tab order. If Go Forward is false, FindNextControl searches backward through the controls.

The CheckTabStop and CheckParent parameters control whether FindNextControl performs certain checks on the controls it finds. If CheckTabStop is true, the returned control must have its TabStop (see page 6211) property set to true. If CheckParent is true, the returned control's Parent (see page 5832) property must indicate the parent control.

FindNextControl calls the GetTabOrderList (see page 6158) method to build its list of possible "next" controls.

See Also

GetTabOrderList (see page 6158)

TabOrder (see page 6211)

TabStop (see page 6211)

SelectNext (see page 6177)

32.1.28.6.48 TWinControl.FixupTabList Method

Sorts the child controls by their tab order.

Pascal

```
procedure FixupTabList;
```

C++

```
__fastcall FixupTabList();
```

Description

Applications should not call FixupTabList directly. The ReadState (see page 6171) method calls FixupTabList to initialize the

tab order list based on the TabOrder (see page 6211) properties of the child controls being read from a stream.

See Also

ReadState (see page 6171)

TabOrder (see page 6211)

32.1.28.6.49 TWinControl.FlipChildren Method

Reverses the positions of child controls.

Pascal

```
procedure FlipChildren(AllLevels: Boolean); dynamic;
```

C++

```
__fastcall FlipChildren(Boolean AllLevels);
```

Description

Call FlipChildren to flip the control's children; that is, to move children on the left side of the control to the right side and vice versa. FlipChildren reverses the position of all child controls and adjusts their Align (see page 5798) properties, if necessary, to enforce the new position.

AllLevels specifies whether FlipChildren should be called recursively on the control's children.

FlipChildren can be used to reverse the layout of an application when it is running in Middle Eastern locales where users read from right to left instead of left to right: Call UseRightToLeftAlignment (see page 5790) to determine whether the BiDiMode (see page 5803) property dictates a reversal of alignment based on the system locale.

Note: FlipChildren does the same thing as the Flip Children command on the control's context menu in the IDE.

See Also

BiDiMode (see page 5803)

UseRightToLeftAlignment (see page 5790)

32.1.28.6.50 TWinControl.Focused Method

Determines whether the control has input focus.

Pascal

```
function Focused: Boolean; dynamic;
```

C++

```
__fastcall Boolean Focused();
```

Description

Use the Focused method to see if the control is the active control. When Focused returns true, the control has the input focus. If Focused returns false, the user cannot interact with the control.

C++ Examples:

```
/*
This example uses the OnActiveControlChange event to detect
when focus changes on the form. When focus changes, the hint
for the active control is displayed on the status bar. To use
this example, you must add a status bar to the form and set
its SimplePanel property to true.  Add a new public procedure,
ActiveControlChanged, to the TForm1 class declaration.
```

```
*/
void _fastcall TForm1::ActiveControlChanged(System::TObject *Sender)
{
  TWinControl *Active = NULL;
  for (int I = 0; I < Form1->ControlCount; I++)
  {
    TWinControl *Temp = dynamic_cast<TWinControl *>(Form1->Controls[I]);
    if (Temp && Temp->Focused())
      Active = Temp;
  }
  if ((Active != NULL) && (Active->Hint != ""))
    StatusBar2->SimpleText = GetLongHint(Active->Hint) + " focus";
}

void __fastcall TForm1::MouseOverChanged(TObject *Sender)
{
  TWinControl *Active = dynamic_cast<TWinControl *>(Sender);
  if (Active != NULL)
    StatusBar1->SimpleText = GetLongHint(Active->Hint) + " mouse over";
}

/*
Assign this method as the OnActiveControlChange event
handler by setting it from the form's OnCreate event handler:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Screen->OnActiveControlChange = ActiveControlChanged;
}

/*
Make sure you clean up the screen object when the form is
freed by adding this OnDestroy event handler to the form:
*/
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  Screen->OnActiveControlChange = 0;
}
```

Delphi Examples:

```
{
This example uses the OnActiveControlChange event to detect
when focus changes on the form. When focus changes, the hint
for the active control is displayed on the status bar. To use
this example, you must add a status bar to the form and set
its SimplePanel property to true.  Add a new public procedure,
ActiveControlChanged, to the TForm1 class declaration.
}

type
  TForm1 = class(TForm)
    StatusBar1, StatusBar2: TStatusBar;
    Button1: TButton;
    RadioButton1: TRadioButton;
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
    procedure MouseOverChanged(Sender: TObject);
  private
    { Private declarations }
  public
    procedure ActiveControlChanged(Sender: TObject);
  end;

var
  Active : TWinControl;
  I: Integer;
```

```
    Form1: TForm1;

  implementation

  {$R *.dfm}

  procedure TForm1.ActiveControlChanged(Sender: TObject);
  var
    Active : TWinControl;
    I: Integer;
  begin
    Active := nil;
    for I:= 0 to ControlCount -1 do
    begin
      if (Controls[I] is TWinControl) then
        if (Controls[I] as TWinControl).Focused then
          Active := TWinControl(Controls[I]);
    end;
    if ((Active <> nil) and (Active.Hint <> '')) then
    begin
      StatusBar2.SimpleText := GetLongHint(Active.Hint) + ' focus';
    end
  end;

  procedure TForm1.MouseOverChanged(Sender: TObject);
  var
    Active : TWinControl;
    I: Integer;
  begin
    if (Sender is TWinControl) then
    begin
      Active := TWinControl(Sender);
      StatusBar1.SimpleText := GetLongHint(Active.Hint) + ' mouse over';
    end;
  end;

  {
  Assign this method as the OnActiveControlChange event
  handler by setting it from the form's OnCreate event handler:
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Screen.OnActiveControlChange := ActiveControlChanged;
  end;

  {
  Make sure you clean up the screen object when the form is
  freed by adding this OnDestroy event handler to the form:
  }
  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    Screen.OnActiveControlChange := nil;
  end;
```

See Also

ActiveControl (see page 13896)

ActiveControl (see page 14206)

32.1.28.6.51 TWinControl.GetActionLinkClass Method

Returns the associated action link class.

Pascal

```
function GetActionLinkClass: TControlActionLinkClass; override;
```

C++

```
virtual __fastcall TControlActionLinkClass GetActionLinkClass();
```

Description

GetActionLinkClass returns the appropriate class type for the action link used with a control. This class is used internally to create an action link object for the control when it has an associated action. The action link links the action to the control client. Each Action (see page 5797) link class is designed to link specific properties and event handlers of the action to its client, based on the types of properties the client supports.

As implemented in TWinControl (see page 6112), GetActionLinkClass returns the TWinControlActionLink (see page 6233) class type, which associates the HelpContext (see page 5826), ShowHint (see page 5840), Caption (see page 5806), Enabled (see page 5821) and Visible (see page 5847) properties and the OnClick (see page 5851) event handler. Descendants of TWinControl (see page 6112) override this method to specify a descendant of TControlActionLink (see page 5892) that handles their configuration of properties and events.

See Also

TWinControlActionLink (see page 6233)

ActionLink (see page 5798)

Action (see page 5797)

32.1.28.6.52 TWinControl.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls (see page 6197) property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls (see page 6197)

Owner (see page 2807)

32.1.28.6.53 TWinControl.GetClientOrigin Method

Returns the value of the ClientOrigin (see page 5809) property.

Pascal

```
function GetClientOrigin: TPoint; override;
```

C++

```
virtual __fastcall TPoint GetClientOrigin();
```

Description

GetClientOrigin is the protected implementation of the ClientOrigin (see page 5809) property.

GetClientOrigin returns a point indicating the position of the top-left corner of the control in screen coordinates.

See Also

ClientOrigin

ClientToScreen (see page 5744)

GetClientRect (see page 6154)

32.1.28.6.54 TWinControl.GetClientRect Method

Returns the value of the ClientRect (see page 5810) property.

Pascal

```
function GetClientRect: TRect; override;
```

C++

```
virtual __fastcall TRect GetClientRect();
```

Description

GetClientRect is the protected implementation of the ClientRect (see page 5810) property. GetClientRect returns a rectangle with the rectangle's Top (see page 5844) and Left (see page 5830) fields set to zero, and its Bottom and Right fields set to the control's ClientHeight (see page 5808) and ClientWidth (see page 5811), respectively.

See Also

ClientHeight (see page 5808)

ClientWidth (see page 5811)

GetClientOrigin (see page 6153)

32.1.28.6.55 TWinControl.GetControlExtents Method

Returns the smallest rectangle in which all the control's children fit.

Pascal

```
function GetControlExtents: TRect; virtual;
```

C++

```
virtual __fastcall TRect GetControlExtents();
```

Description

Call GetControlExtents to determine the smallest rectangle in which all the control's children fit. Windowed controls call GetControlExtents when implementing the AutoSize (see page 5803) property.

See Also

CanAutoSize (see page 6131)

AutoSize (see page 5803)

32.1.28.6.56 TWinControl.GetDeviceContext Method

Provides access to a device context for the control.

Pascal

```
function GetDeviceContext(var WindowHandle: HWnd): HDC; override;
```

C++

```
virtual __fastcall HDC GetDeviceContext(HWnd WindowHandle);
```

Description

Call GetDeviceContext to obtain a handle to a device context for the control.

GetDeviceContext calls the Windows API function GetDC, passing the windowed control's Handle (see page 6207) property. It returns the window's handle in the WindowHandle (see page 6212) parameter and the HDC as the return value. If the call is unsuccessful, the EOutOfResources exception is raised.

C++ Examples:

```
/*
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
*/
class TMyControl : public TColorListBox
{
__published:    // IDE-managed Components
    void __fastcall SaveAsBmp(TFileName fileName);
private:    // User declarations
public:     // User declarations
    __fastcall TMyControl(TComponent* Owner);
};

TForm1 *Form1;
TMyControl *MyControl1;

__fastcall TForm1::TForm1(TComponent* Owner)
    : TForm(Owner)
{
}
__fastcall TMyControl::TMyControl(TComponent* Owner)
    : TColorListBox(Owner)
{
}

typedef struct {
  TLogPalette lpal;
  TPaletteEntry dummy[256];
} LogPal;

void __fastcall TMyControl::SaveAsBmp(TFileName fileName)
{
  TCanvas *tempCanvas = new TCanvas;
  try
  {
    HWND notUsed;
    tempCanvas->Handle = GetDeviceContext(notUsed);
    TImage *image2save = new TImage(Form1);
    try
```

```
      {
        image2save->Height = Height;
        image2save->Width = Width;
        TRect destRect = Rect(0,0,Width,Height);
        TRect sourceRect = destRect;
        image2save->Canvas->CopyRect(destRect, tempCanvas, sourceRect);
        LogPal SysPal;
        SysPal.lpal.palVersion = 0x300;
        SysPal.lpal.palNumEntries = 256;
        GetSystemPaletteEntries(tempCanvas->Handle,0,256,SysPal.lpal.palPalEntry);
        image2save->Picture->Bitmap->Palette = CreatePalette((const tagLOGPALETTE
*)&SysPal.lpal);
        image2save->Picture->SaveToFile(fileName);
      }
      __finally
      {
       delete image2save;
      }
    }
    __finally
    {
      delete tempCanvas;
    }
  }

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    MyControl1->SaveAsBmp("../foo.bmp");
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    MyControl1 = new TMyControl(Form1);
    MyControl1->Parent = Form1;
    MyControl1->Visible  = true;
  }
```

Delphi Examples:

```
  {
  The GetFormImage allows you to easily obtain a bitmap of a
  form. The following method can be added to a custom
  TWinControl descendant to save itself as a bitmap.  Check the
  produced BMP file to confirm.  Click the button and them
  double click on the newly created foo.bmp file to view.
  }
  type
    TMyControl = class(TColorListBox)
      procedure SaveAsBmp(fileName: TFileName);
    end;
    TForm1 = class(TForm)
      Button1: TButton;
      procedure Button1Click(Sender: TObject);
      procedure FormCreate(Sender: TObject);
    private
      { Private declarations }
    public
      { Public declarations }
    end;

  var
    Form1: TForm1;
    MyControl1: TMyControl;
  implementation

  {$R *.dfm}
```

```
type
  LogPal = record
  lpal : TLogPalette;
  dummy:Array[0..255] of TPaletteEntry;
  end;

procedure TMyControl.SaveAsBmp(fileName: TFileName);
var
  Source: TComponent;
  SysPal : LogPal;
  tempCanvas: TCanvas;
  sourceRect, destRect: TRect;
  image2save: TImage;
  notUsed: HWND;
begin
  tempCanvas := TCanvas.Create;
  try
    tempCanvas.Handle := GetDeviceContext(notUsed);
    image2save:=TImage.create(self);
    try
      with image2save do
      begin
        Height := Self.Height;
        Width :=  Self.Width;
        destRect := Rect(0,0,Width,Height);
        sourceRect := destRect;
        Canvas.CopyRect(destRect,tempCanvas,sourceRect);
        SysPal.lPal.palVersion:=$300;
        SysPal.lPal.palNumEntries:=256;
        GetSystemPaletteEntries(
          tempCanvas.Handle,0,256,SysPal.lpal.palPalEntry);
        Picture.Bitmap.Palette:= CreatePalette(Syspal.lpal);
      end;
      image2save.Picture.SaveToFile(fileName);
    finally
     image2save.Free;
    end;
  finally
    tempCanvas.Free;
  end;
end;

begin
  MyControl1.SaveAsBmp('foo.bmp');
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  MyControl1:= TMyControl.Create(Form1);
  MyControl1.Parent:= Form1;
  MyControl1.visible := true;
end;
```

See Also

EOutOfResources (see page 2702)

Handle (see page 6207)

32.1.28.6.57 TWinControl.GetParentHandle Method

Returns the window handle for the window of the control's parent.

Pascal

```
function GetParentHandle: HWnd;
```

C++

```
__fastcall HWnd GetParentHandle();
```

Description

Use the handle returned by GetParentHandle as a parameter to Windows API function calls that need the window handle for the parent window of the control. If the Parent (see page 5832) property is not nil (Delphi) or NULL (C++), GetParentHandle returns the Handle (see page 6207) property of the parent control. If the Parent (see page 5832) property is nil (Delphi) or NULL (C++), GetParentHandle returns the value of ParentWindow (see page 6210).

See Also

GetTopParentHandle (see page 6159)

Handle (see page 6207)

Parent (see page 5832)

ParentWindow (see page 6210)

32.1.28.6.58 TWinControl.GetSiteInfo Method

Generates an OnGetSiteInfo (see page 6223) event

Pascal

```
procedure GetSiteInfo(Client: TControl; var InfluenceRect: TRect; MousePos: TPoint; var
CanDock: Boolean); dynamic;
```

C++

```
__fastcall GetSiteInfo(TControl * Client, TRect InfluenceRect, TPoint MousePos, Boolean
CanDock);
```

Description

GetSiteInfo is called automatically during drag-and-dock operations to initialize a TDragDockObject (see page 6009) with information about where a dragged object can be docked, if at all.

Client is a potential docking client.

InfluenceRect returns the area in which the client would be docked.

MousePos is the current mouse position.

CanDock returns whether the client can dock to the windowed control.

As implemented in TWinControl (see page 6112), GetSiteInfo generates an influence rectangle equal to BoundsRect (see page 5803) expanded by 10 pixels on every side, and then calls the OnGetSiteInfo (see page 6223) event handler.

See Also

OnGetSiteInfo (see page 6223)

BoundsRect (see page 5803)

32.1.28.6.59 TWinControl.GetTabOrderList Method

Builds a list of controls in tab order.

Pascal

```
procedure GetTabOrderList(List: TList); dynamic;
```

C++

```
__fastcall GetTabOrderList(TList List);
```

Description

Call GetTabOrderList to construct a list of child controls in tab order.

GetTabOrderList iterates through the control's internal tab-order list, adding each of the child controls to List, including any controls contained in those controls. The result is a list of all the controls and their owned controls, in tab order.

The FindNextControl (see page 6149) method calls GetTabOrderList to build a complete list of the controls that FindNextControl (see page 6149) uses to locate the next control in the tab order.

See Also

FindNextControl (see page 6149)

TabOrder (see page 6211)

32.1.28.6.60 TWinControl.GetTopParentHandle Method

Returns the window handle of the first window not associated with a VCL control that contains the windowed control.

Pascal

```
function GetTopParentHandle: HWnd;
```

C++

```
__fastcall HWnd GetTopParentHandle();
```

Description

Use GetTopParentHandle to access the handle of the window that is hosting the windowed control. GetTopParentHandle walks up the containers of the windowed control until it finds a control whose Parent (see page 5832) property is nil (Delphi) or NULL (C++). If that topmost parent is contained in a non-VCL window (its ParentWindow (see page 6210) is nonzero), GetTopParentHandle returns the non-VCL window. If the windowed control is not contained in a non-VCL window, GetTopParentHandle returns the windowed control's own window handle.

See Also

GetParentHandle (see page 6157)

Handle (see page 6207)

Parent (see page 5832)

ParentWindow (see page 6210)

32.1.28.6.61 TWinControl.HandleAllocated Method

Reports whether a screen object handle exists for the control.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Query HandleAllocated to find out if the control's underlying screen object has been generated.

If the screen object exists, HandleAllocated returns true. If the screen object does not exist, HandleAllocated returns false. Testing the Handle (see page 6207) property of a control directly causes the window to be created if it does not already exist. Call the HandleAllocated method to determine whether a window exists without creating one as a side effect.

See Also

Handle (see page 6207)

HandleNeeded (see page 6160)

32.1.28.6.62 TWinControl.HandleNeeded Method

Creates a screen object for the control if it doesn't already exist.

Pascal

```
procedure HandleNeeded;
```

C++

```
__fastcall HandleNeeded();
```

Description

Call HandleNeeded to create a screen object for the control.

If the screen object does not exist, HandleNeeded calls the CreateHandle (see page 6135) method for the parent of the control before it creates a screen object for this control.

See Also

Handle (see page 6207)

HandleAllocated (see page 6159)

32.1.28.6.63 TWinControl.InsertControl Method

Inserts a control into the Controls (see page 6197) array property.

Pascal

```
procedure InsertControl(AControl: TControl);
```

C++

```
__fastcall InsertControl(TControl * AControl);
```

Description

Applications should not need to call InsertControl directly. Child controls are automatically inserted and removed when added or deleted at design time. At runtime, use the Parent (see page 5832) property of the child control to insert it in the Controls (see page 6197) array. If the child control is already the child of another control, setting the Parent (see page 5832) property ensures that the child is removed from the Controls (see page 6197) of the original parent.

InsertControl makes the inserted control a child, and the containing control the parent. The AControl parameter is the child control that is inserted into the Controls (see page 6197) array.

C++ Examples:

```
/*
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  if (Button1->Parent != GroupBox1) // second click?
  {
    RemoveControl(Button1);
    GroupBox1->InsertControl(Button1);
  }
}

/*
Note that it was necessary to remove the button from the Controls
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
*/

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Button2->Parent = GroupBox1;
}
```

Delphi Examples:

```
{
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (Button1.Parent <> GroupBox1) then // second click?
  begin
    RemoveControl(Button1);
    GroupBox1.InsertControl(Button1);
  end;
end;

{
Note that it was necessary to remove the button from the Controls
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
}

procedure TForm1.Button2Click(Sender: TObject);
begin
  Button2.Parent := GroupBox1;
end;
```

See Also

Controls (see page 6197)

Parent (see page 5832)

RemoveControl (see page 6172)

32.1.28.6.64 TWinControl.Invalidate Method

Schedules a control repaint.

Pascal

```
procedure Invalidate; override;
```

C++

```
virtual __fastcall Invalidate();
```

Description

Invalidate informs a control that its entire surface needs to be repainted. Calling Invalidate can prevent flicker caused by a series of partial repaints. There is no performance penalty for calling Invalidate multiple times before the control is actually repainted.

The actual repaint does not occur until the control is updated. To force an immediate repaint, call Repaint (see page 6174) instead.

See Also

Repaint (see page 6174)

Update (see page 6183)

32.1.28.6.65 TWinControl.InvalidateDockHostSite Method

Pascal

```
procedure InvalidateDockHostSite(FocusLost: Boolean);
```

C++

```
__fastcall InvalidateDockHostSite(Boolean FocusLost);
```

Description

This is InvalidateDockHostSite, a member of class TWinControl.

32.1.28.6.66 TWinControl.IsControlActivateMsg Method

Pascal

```
function IsControlActivateMsg(var Message: TWMMouseActivate; Control: TControl = nil): Boolean;
```

C++

```
__fastcall Boolean IsControlActivateMsg(TWMMouseActivate Message, TControl * Control = nil);
```

Description

This is IsControlActivateMsg, a member of class TWinControl.

32.1.28.6.67 TWinControl.IsControlMouseMsg Method

Indicates whether a specified mouse message is directed to one of the windowed control's child controls.

Pascal

```
function IsControlMouseMsg(var Message: TWMMouse): Boolean;
```

C++

```
__fastcall Boolean IsControlMouseMsg(TWMMouse Message);
```

Description

Call IsControlMouseMsg to find out if a mouse message is directed to one of the control's child controls. Specify the mouse message as the value of the Message parameter.

Windows takes care of sending messages to windowed child controls, but for nonwindowed child controls, Windows sends the messages to the parent control, which must then determine which, if any, of its child controls should receive the message.

The WndProc (see page 6187) method of a windowed control calls IsControlMouseMsg to process all mouse message sent to the windowed control.

See Also

WndProc (see page 6187)

32.1.28.6.68 TWinControl.IsQualifyingSite Method

Pascal

```
function IsQualifyingSite(const Client: TControl): Boolean; dynamic;
```

C++

```
__fastcall Boolean IsQualifyingSite(const TControl * Client);
```

Description

This is IsQualifyingSite, a member of class TWinControl.

32.1.28.6.69 TWinControl.KeyDown Method

Respond to key press events.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); dynamic;
```

C++

```
__fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-down message (WM_KEYDOWN) from Windows, its message handler calls the DoKeyDown (see page 6145) method. If DoKeyDown (see page 6145) determines that the control should, in fact, process the character, it calls KeyDown, passing the key code and shift-key state in the Key and Shift parameters, respectively.

KeyDown calls any event handler attached to the OnKeyDown (see page 6225) event. Override KeyDown to provide other responses in addition to the event-handler call.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use WinAPI virtual key codes to determine the key pressed. For more information, search for virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

Either KeyDown or the OnKeyDown (see page 6225) event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

See Also

KeyUp (see page 6164)

OnKeyDown (see page 6225)

DoKeyDown (see page 6145)

DoKeyPress (see page 6146)

DoKeyUp (see page 6146)

32.1.28.6.70 TWinControl.KeyPress Method

Respond to keyboard input.

Pascal

```
procedure KeyPress(var Key: Char); dynamic;
```

C++

```
__fastcall KeyPress(Char Key);
```

Description

When a windowed control receives a key-press message (WM_CHAR) from Windows, its message handler calls the DoKeyPress (see page 6146) method. If DoKeyPress (see page 6146) determines that the control should, in fact, process the character, it calls KeyPress, passing the key code in the Key parameter.

KeyPress calls any event handler attached to the OnKeyPress (see page 6227) event. Override KeyPress to provide other responses in addition to the event-handler call.

Either KeyPress or the OnKeyPress (see page 6227) event handler it calls can suppress further processing of a character by setting the Key parameter to zero.

Note: The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

KeyDown (see page 6163)

KeyUp (see page 6164)

OnKeyPress (see page 6227)

32.1.28.6.71 TWinControl.KeyUp Method

Respond to released key.

Pascal

```
procedure KeyUp(var Key: Word; Shift: TShiftState); dynamic;
```

C++

```
__fastcall KeyUp(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-up message (WM_KEYUP) from Windows, its message handler calls the DoKeyUp (see page 6146) method. If DoKeyUp (see page 6146) determines that the control should, in fact, process the character, it calls KeyUp, passing the key code and shift-key state to KeyUp in the Key and Shift parameters, respectively.

KeyUp calls any event handler attached to the OnKeyUp (see page 6228) event. Override KeyUp to provide other responses in addition to the event-handler call.

Either KeyUp or the OnKeyUp (see page 6228) event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use WinAPI virtual key codes to determine the key pressed. For more information, search virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

See Also

KeyDown (see page 6163)

KeyPress (see page 6163)

OnKeyUp (see page 6228)

32.1.28.6.72 TWinControl.MainWndProc Method

Receives Windows messages for the control.

Pascal

```
procedure MainWndProc(var Message: TMessage);
```

C++

```
__fastcall MainWndProc(TMessage Message);
```

Description

MainWndProc is the window procedure for the control that is associated with the control's window when it is created. When Windows sends a message to the control's window, MainWndProc receives it.

MainWndProc does not process or dispatch the messages itself, but rather calls the method specified by WindowProc (see page 5872) to do that. MainWndProc provides an exception-handling block around WindowProc (see page 5872), ensuring that if any unhandled exceptions occur during the processing of a message, the application's HandleException method will handle them.

See Also

HandleException (see page 13674)

WindowProc (see page 5872)

32.1.28.6.73 TWinControl.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

32.1.28.6.74 TWinControl.NotifyControls Method

Sends a message to all the child controls.

Pascal

```
procedure NotifyControls(Msg: Word);
```

C++

```
__fastcall NotifyControls(Word Msg);
```

Description

NotifyControls sends a message with the message ID passed in the Msg parameter to all the controls in the windowed control's Controls (see page 6197) array property. NotifyControls is used to update all the controls in a form of such occurrences as changes in the parent color or font.

NotifyControls constructs a generic message record, filling its message ID field with the value of Msg and setting its parameter and result fields to zeros, then calls the Broadcast (see page 6130) method to send the message to all the child controls.

See Also

Broadcast (see page 6130)

Controls (see page 6197)

32.1.28.6.75 TWinControl.PaintControls Method

Paints each of the child controls in a windowed control using the specified device context.

Pascal

```
procedure PaintControls(DC: HDC; First: TControl);
```

C++

```
__fastcall PaintControls(HDC DC, TControl * First);
```

Description

Call PaintControls to paint all the child controls of this control. Pass the device context as the value of the DC parameter. The First parameter indicates the starting point in the windowed control's child-control list to paint. If First is nil (Delphi) or NULL (C++) or does not indicate one of the child controls, PaintControls paints all the child controls.

The Repaint (see page 6174) method calls PaintControls for the control's parent, passing the control in First to repaint the control and any controls it might intersect. PaintHandler (see page 6166) also calls PaintControls after calling PaintWindow (see page 6169).

See Also

PaintHandler (see page 6166)

PaintWindow (see page 6169)

Repaint (see page 6174)

32.1.28.6.76 TWinControl.PaintHandler Method

Responds to WM_PAINT messages.

Pascal

```
procedure PaintHandler(var Message: TWMPaint);
```

C++

```
__fastcall PaintHandler(TWMPaint Message);
```

Description

PaintHandler is called automatically when the control receives a WM_PAINT message. It calls the BeginPaint and EndPaint API functions, and between them paints the control's background by calling PaintWindow (see page 6169) and any child controls by calling PaintControls (see page 6166).

See Also

PaintControls (see page 6166)

PaintWindow (see page 6169)

32.1.28.6.77 PaintTo Method

This is the overview for the PaintTo method overload.

Overload List

	Name	Description
	TWinControl.PaintTo (HDC, Integer, Integer) (see page 6167)	Draws the windowed control to a device context.
	TWinControl.PaintTo (TCanvas, Integer, Integer) (see page 6167)	Draws the windowed control to a device context.

32.1.28.6.77.1 TWinControl.PaintTo Method (HDC, Integer, Integer)

Draws the windowed control to a device context.

Pascal

```
procedure PaintTo(DC: HDC; X: Integer; Y: Integer); overload;
procedure PaintTo(Canvas: TCanvas; X: Integer; Y: Integer); overload;
```

C++

```
__fastcall PaintTo(HDC DC, int X, int Y);
__fastcall PaintTo(TCanvas Canvas, int X, int Y);
```

Description

Call PaintTo to draw the control on a device context. Specify the device context as the value of the DC parameter and specify the X and Y coordinates on the device context where the top-left corner of the windowed control is to be drawn. PaintTo first erases the background of the device context and then paints the control.

PaintTo is useful for drawing an image of the control into a bitmap DC.

Warning: When using PaintTo to draw on a canvas, you must lock the canvas first (and unlock it after the call to PaintTo. If you do not lock the canvas, Windows calls that occur while the control is painting can cause the canvas to lose its handle.

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PrintDialog1->Options.Clear();
  PrintDialog1->Options << poPageNums << poSelection;
  PrintDialog1->FromPage = 1;
  PrintDialog1->MinPage = 1;
  PrintDialog1->ToPage = PageControl1->PageCount;
  PrintDialog1->MaxPage = PageControl1->PageCount;
  if (PrintDialog1->Execute())
  {
    int Start, Stop;
    // determine the range the user wants to print
    switch (PrintDialog1->PrintRange)
    {
      case prSelection:
        Start = PageControl1->ActivePage->PageIndex;
        Stop = Start;
        break;
      case prPageNums:
        Start = PrintDialog1->FromPage - 1;
        Stop =  PrintDialog1->ToPage - 1;
        break;
      default:  // prAllPages
        Start = PrintDialog1->MinPage - 1;
        Stop = PrintDialog1->MaxPage - 1;
        break;
    }
    // now, print the pages
    Printer()->BeginDoc();
    for (int i = Start; i <= Stop; i++)
    {
      PageControl1->Pages[i]->PaintTo(Printer()->Handle, 10, 10);
      if (i != Stop)
        Printer()->NewPage();
    }
    Printer()->EndDoc();
  }
}
```

Delphi Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
}
procedure TForm1.Button1Click(Sender:TObject);
var
  I, Start, Stop: Integer;
begin
PrintDialog1.Options := [poPageNums, poSelection];
PrintDialog1.FromPage := 1;
PrintDialog1.MinPage := 1;
PrintDialog1.ToPage := PageControl1.PageCount;
PrintDialog1.MaxPage := PageControl1.PageCount;

if PrintDialog1.Execute() then
  begin
    { determine the range the user wants to print }
    with PrintDialog1 do
    begin
```

```
        if PrintRange = prAllPages then
          begin
          Start := MinPage - 1;
          Stop := MaxPage - 1;
        end
        else if PrintRange = prSelection then
        begin
          Start := PageControl1.ActivePage.PageIndex;
          Stop := Start;
          end
        else  { PrintRange = prPageNums }
        begin
          Start := FromPage - 1;
          Stop := ToPage - 1;
        end;
      end;
      { now, print the pages }
      with Printer do
      begin
        BeginDoc;
        for I := Start to Stop do
        begin
          PageControl1.Pages[I].PaintTo(Handle, 10, 10);
          if I <> Stop then
            NewPage;
        end;
        EndDoc;
      end;
    end;
  end;
```

See Also

PaintWindow (see page 6169)

DoubleBuffered (see page 6205)

Lock (see page 14463)

32.1.28.6.78 TWinControl.PaintWindow Method

Renders the image of a windowed control.

Pascal

```
procedure PaintWindow(DC: HDC); virtual;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

Call PaintWindow to repaint the control. PaintWindow sends a WM_PAINT message to the windowed control's DefaultHandler (see page 6139) method, setting the message record's WParam field to the value passed in DC and the other parameter and result fields to zeros.

See Also

DefaultHandler (see page 6139)

PaintTo (see page 6167)

DoubleBuffered (see page 6205)

32.1.28.6.79 TWinControl.PaletteChanged Method

Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.

Pascal

```
function PaletteChanged(Foreground: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean PaletteChanged(Boolean Foreground);
```

Description

PaletteChanged is called automatically when the Windows system palette changes. TWinControl (see page 6112) responds to these notifications by trying to realize the windowed control's palette, if any, into the current device context, and then passing on the PaletteChanged notification to each of the child controls in turn. If the change in the system palette causes the actual value of the control's palette to change, PaletteChanged will invalidate the control so that it can repaint with the new palette.

Windows paints the active window with a foreground palette, while other windows are forced to use background palettes. Background palettes are approximate matches to the colors specified by the control's logical palette, given the limitations imposed by implementing the foreground palette. Windows only allows a single foreground palette.

PaletteChanged allows the control to obtain a new realization of its palette when the system palette changes. When Foreground is true, the form has been activated and the control is specifying the new foreground palette. When Foreground is false, another application or form has changed the foreground palette, and controls that are sensitive to the available palette should realize new background palettes to best match their logical palettes.

If the control does not have a logical palette to be realized into the current device context, GetPalette (see page 5765) will return a handle of 0, and PaletteChanged will not try to realize a palette for the windowed control. Instead, it simply passes the notification on to the child controls. If the windowed control or any of its child controls realize a palette into the current device context in response to PaletteChanged, this method returns true.

Override PaletteChanged to change the way in which controls are given an opportunity to realize a new palette when the Windows system palette changes. For example, override PaletteChanged to change the order in which child controls realize their palettes, giving a particular control the foreground palette when the form is activated, or to pass palette change notification to custom controls implemented outside of the VCL, such as in DLLs.

Override GetPalette (see page 5765) instead to affect whether the windowed control actually has a palette to realize, or to change the value of the control's logical palette.

Note: PaletteChanged is called only when the run-time video mode requires palette support, such as for 256 color mode, but not 16 million color mode.

See Also

GetDeviceContext (see page 6155)

GetPalette (see page 5765)

32.1.28.6.80 TWinControl.PreProcessMessage Method

Pascal

```
function PreProcessMessage(var Msg: TMsg): Boolean; dynamic;
```

C++

```
__fastcall Boolean PreProcessMessage(TMsg Msg);
```

Description

This is PreProcessMessage, a member of class TWinControl.

32.1.28.6.81 TWinControl.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl (see page 6112), ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

See Also

Parent (see page 5832)

ReadState (see page 5778)

32.1.28.6.82 TWinControl.Realign Method

Forces the control to realign children.

Pascal

```
procedure Realign;
```

C++

```
__fastcall Realign();
```

Description

The EnableAlign (see page 6148) method calls Realign when the reference count reaches zero. It adjusts the size and position of any child controls according to their Align (see page 5798) properties.

If all of the child controls have their Align (see page 5798) properties set to alNone, Realign has no effect.

See Also

Align (see page 5798)

DisableAlign (see page 6141)

EnableAlign (see page 6148)

32.1.28.6.83 TWinControl.RecreateWnd Method

Recreate underlying Windows screen object.

Pascal

```
procedure RecreateWnd;
```

C++

```
__fastcall RecreateWnd();
```

Description

Call RecreateWnd to recreate the control from scratch. RecreateWnd destroys the underlying Windows screen object. The next time the Handle (see page 6207) property is referenced (when the object is repainted, for example), a new Windows screen object is created. Some changes in control properties are not implemented until this re-creation occurs.

See Also

DestroyHandle (see page 6140)

Handle (see page 6207)

HandleNeeded (see page 6160)

32.1.28.6.84 TWinControl.ReloadDockedControl Method

Reloads a docked control.

Pascal

```
procedure ReloadDockedControl(const AControlName: string; var AControl: TControl); dynamic;
```

C++

```
__fastcall ReloadDockedControl(const AnsiString AControlName, TControl * AControl);
```

Description

Use ReloadDockedControl to obtain a reference to control given its name. The AControlName parameter is the name of the child control. The corresponding control is returned as the AControl parameter. ReloadDockedControl can only locate a control if it has the same Owner as the windowed control.

The dock manager calls ReloadDockedControl to obtain a control reference that it then docks to the windowed control.

See Also

DockManager (see page 6202)

FindChildControl (see page 6148)

FindComponent (see page 2772)

Owner (see page 2807)

32.1.28.6.85 TWinControl.RemoveControl Method

Removes a specified control from the Controls (see page 6197) array.

Pascal

```
procedure RemoveControl(AControl: TControl);
```

C++

```
__fastcall RemoveControl(TControl * AControl);
```

Description

RemoveControl removes a child control from the Controls (see page 6197) property. After calling RemoveControl, the control

is no longer the parent of the child specified by the AControl parameter.

Applications should not call RemoveControl directly. Child controls are automatically inserted and removed when added or deleted at design time. At runtime, use the Parent (see page 5832) property of the child control to remove it from the Controls (see page 6197) array.

C++ Examples:

```
/*
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (Button1->Parent != GroupBox1) // second click?
  {
    RemoveControl(Button1);
    GroupBox1->InsertControl(Button1);
  }
}

/*
Note that it was necessary to remove the button from the Controls
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
*/

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Button2->Parent = GroupBox1;
}
```

Delphi Examples:

```
{
This example uses a button placed next to a group box. When the
user clicks the button, the group box becomes the parent of the
button, so the button moves inside the group box.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (Button1.Parent <> GroupBox1) then // second click?
  begin
    RemoveControl(Button1);
    GroupBox1.InsertControl(Button1);
  end;
end;

{
Note that it was necessary to remove the button from the Controls
property of the form before the button actually moves into the
group box. This code accomplishes the same thing:
}

procedure TForm1.Button2Click(Sender: TObject);
begin
  Button2.Parent := GroupBox1;
end;
```

See Also

Controls (see page 6197)

InsertControl (see page 6160)

Parent (see page 5832)

32.1.28.6.86 TWinControl.RemoveWindowProps Method

Pascal

```
procedure RemoveWindowProps;
```

C++

```
__fastcall RemoveWindowProps();
```

Description

This is RemoveWindowProps, a member of class TWinControl.

32.1.28.6.87 TWinControl.Repaint Method

Repaints the entire control.

Pascal

```
procedure Repaint; override;
```

C++

```
virtual __fastcall Repaint();
```

Description

Call Repaint to repaint the control.

As implemented in TWinControl (see page 6112), Repaint calls the Invalidate (see page 6161) method and then the Update (see page 6183) method to repaint the control.

See Also

Invalidate (see page 6161)

Update (see page 6183)

32.1.28.6.88 TWinControl.ResetIme Method

Restores the input method editor (IME) that was active when the application started.

Pascal

```
procedure ResetIme;
```

C++

```
__fastcall ResetIme();
```

Description

For controls that specify the ImeName (see page 6208) property, call ResetIme to revert to the IME that was active when the application started. If the IME was deactivated by setting the ImeMode (see page 6207) property to imDisable, ResetIme restarts the default IME.

Applications cannot call ResetIme. ResetIme is called automatically when the control loses input focus. It is exposed as a protected method so descendant objects can restore the default IME at other times.

See Also

ImeMode (see page 6207)

ImeName (see page 6208)

SetIme (see page 6181)

DefaultIme (see page 14216)

32.1.28.6.89 TWinControl.ResetImeComposition Method

Directs the composition window of the input method editor (IME) to perform a specific action.

Pascal

```
function ResetImeComposition(Action: DWORD): Boolean;
```

C++

```
__fastcall Boolean ResetImeComposition(DWORD Action);
```

Description

Call ResetImeComposition to direct what the composition window does with the input typed by the user. The composition window is the window displayed by the IME that provides feedback to the user about what keystrokes have been typed, and how they are converted into asian characters.

The Action (see page 5797) parameter indicates what the composition window should do with its current contents. Action (see page 5797) can have one of the following values:

Value	Meaning
CPS_CANCEL	Clear the composition string and set the status to no composition string.
CPS_COMPLETE	Set the composition string as the result string.
CPS_CONVERT	Convert the composition string.
CPS_REVERT	Cancel the current composition string and revert to the unconverted string.

ResetImeComposition returns true if the composition window performs the requested action.

ImeMode (see page 6207)

ImeName (see page 6208)

SetImeCompositionWindow (see page 6181)

32.1.28.6.90 TWinControl.ScaleBy Method

Rescale control and its children.

Pascal

```
procedure ScaleBy(M: Integer; D: Integer);
```

C++

```
__fastcall ScaleBy(int M, int D);
```

Description

ScaleBy resizes a control without moving its upper left corner. This is similar to changing the Height (see page 5825) and Width (see page 5849) properties, but the control also attempts to rescale and rearrange any child controls to maintain their relative size and placement.

The M and D parameters define a multiplier and divisor by which to scale the control. For example, to make a control 75% of its original size, specify the value of M as 75, and the value of D as 100. Any pair of values that has the same ratio has the same

effect. Thus M = 3 and D = 4 also makes the control 75% of its previous size.

To rescale the control's children without rescaling the control itself, use ScaleControls (see page 6176).

See Also

ChangeScale (see page 6132)

ScaleControls (see page 6176)

Height (see page 5825)

Width (see page 5849)

Considerations When Dynamically Resizing Forms and Controls

32.1.28.6.91 TWinControl.ScaleControls Method

Rescale child controls only.

Pascal

```
procedure ScaleControls(M: Integer; D: Integer);
```

C++

```
__fastcall ScaleControls(int M, int D);
```

Description

Call ScaleControls to rescale only the children of the control, while leaving the control itself the same size. The parameters have the same meaning as in the ScaleBy (see page 6175) method.

See Also

ChangeScale (see page 6132)

ScaleBy (see page 6175)

32.1.28.6.92 TWinControl.ScrollBy Method

Scroll control contents.

Pascal

```
procedure ScrollBy(DeltaX: Integer; DeltaY: Integer);
```

C++

```
__fastcall ScrollBy(int DeltaX, int DeltaY);
```

Description

Call ScrollBy to scroll the contents within the control. While ScrollBy can be used for any TWinControl (see page 6112), it makes the most sense to use it for descendants of TScrollingWinControl.

Applications seldom need to call the ScrollBy method unless they implement their own scrolling interface rather than relying on a scroll bar.

The DeltaX parameter is the change in pixels along the X axis. A positive DeltaX value scrolls the contents to the right; a negative value scrolls the contents to the left. The DeltaY parameter is the change in pixels along the Y axis. A positive DeltaY value scrolls the contents down; a negative value scrolls the contents up.

See Also

HorzScrollBar (see page 14329)

ScrollInView (see page 14328)

VertScrollBar (see page 14330)

32.1.28.6.93 TWinControl.SelectFirst Method

Locates first selectable child control.

Pascal

```
procedure SelectFirst;
```

C++

```
__fastcall SelectFirst();
```

Description

Call SelectFirst to find the first child that can be selected within the control's tab order. SelectFirst calls the FindNextControl (see page 6149) method, passing nil (Delphi) or NULL (C++) as the current control. Once the first selectable control is found, SelectFirst makes the control the active control on the form.

See Also

FindNextControl (see page 6149)

SelectNext (see page 6177)

ActiveControl (see page 13896)

32.1.28.6.94 TWinControl.SelectNext Method

Moves the input focus from the current child control to the next one in the tab order.

Pascal

```
procedure SelectNext(CurControl: TWinControl; GoForward: Boolean; CheckTabStop: Boolean);
```

C++

```
__fastcall SelectNext(TWinControl * CurControl, Boolean GoForward, Boolean CheckTabStop);
```

Description

Call SelectNext to move the child control focus. SelectNext selects the first child that follows or precedes CurControl in the tab order and that meets the criteria specified in the other parameters.

The GoForward parameter controls the direction of the search. If GoForward is true, FindNextControl (see page 6149) searches forward through the child controls in tab order. If GoForward is false, SelectNext searches backward through the controls. The search wraps past the end of the collection back to CurControl.

The CheckTabStop parameter controls whether the control SelectNext finds must be a tab stop. If CheckTabStop is true, the returned control must have its TabStop (see page 6211) property set to true, or the search for the next control continues.

If a child control matches the search criteria, that control obtains the focus. If no such child control is found, the focus remains unchanged.

See Also

SelectFirst (see page 6177)

TabOrder (see page 6211)

32.1.28.6.95 TWinControl.SetBounds Method

Sets the windowed control's boundary properties all at once.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer);
override;
```

C++

```
virtual __fastcall SetBounds(int ALeft, int ATop, int AWidth, int AHeight);
```

Description

Use SetBounds to change all of the control's boundary properties at once. The same effect can be achieved by setting the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties separately. By setting all four properties at once, SetBounds ensures that the control will not repaint between changes

Specify the values for the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties as the value of the ALeft, ATop, AWidth, and AHeight parameters, respectively.

See Also

Height (see page 5825)

Left (see page 5830)

Top (see page 5844)

Width (see page 5849)

32.1.28.6.96 TWinControl.SetChildOrder Method

Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.

Pascal

```
procedure SetChildOrder(Child: TComponent; Order: Integer); override;
```

C++

```
virtual __fastcall SetChildOrder(TComponent * Child, int Order);
```

Description

Use SetChildOrder when you want to change the order in which child objects are streamed in. Specify the child component whose order you want to change as the value of the Child parameter. Indicate the position you want the component to be in as the value of the Order parameter.

When SetChildOrder is called, items previously below the child's old position move up, and those below the new position move down.

See Also

GetChildren (see page 6153)

32.1.28.6.97 TWinControl.SetDesignVisible Method

Makes a control visible at design time.

Pascal

```
procedure SetDesignVisible(Value: Boolean); override;
```

C++

```
virtual __fastcall SetDesignVisible(Boolean Value);
```

Description

SetDesignVisible is used internally by Delphi during form design.

See Also

TComponentState

32.1.28.6.98 TWinControl.SetFocus Method

Gives the input focus to the control.

Pascal

```
procedure SetFocus; virtual;
```

C++

```
virtual __fastcall SetFocus();
```

Description

Use SetFocus to change input focus to the control. When a control has focus, it receives keyboard events.

C++ Examples:

```
/*
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
*/
void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  for (int I = 0; I < Memo1->Lines->Count; I++)
  {
    int PosReturn = Memo1->Lines->Strings[I].Pos(FindDialog1->FindText);
    if (PosReturn) //found!
    {
      int Skipchars = 0;
      for (int J = 0; J < I; J++)
        Skipchars += Memo1->Lines->Strings[J].Length();
      Skipchars += I*2; // add CR/LF for all skipped lines
      Skipchars += PosReturn - 1;
      Memo1->SetFocus();
      Memo1->SelStart = Skipchars;
      Memo1->SelLength = FindDialog1->FindText.Length();
      break;
    }
  }
}
/*
The following example demonstrates the use of the Perform method
to send a windows message. The EM_SCROLLCARET message scrolls the
```

```
caret in the rich edit into view. The caret position is set to the
contents of the mask edit prior to calling Perform.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    RichEdit1->SelStart = StrToInt(MaskEdit1->Text);
    Edit1->Text = IntToStr(RichEdit1->SelStart);
    RichEdit1->Perform(EM_SCROLLCARET, 0, 0);
    RichEdit1->SetFocus();
}
```

Delphi Examples:

```
{
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
}
procedure TForm1.FindDialog1Find(Sender: TObject);
var
  I, J, PosReturn, SkipChars: Integer;
begin
  for I := 0 to Memo1.Lines.Count do
  begin
    PosReturn := Pos(FindDialog1.FindText,Memo1.Lines[I]);
    if PosReturn <> 0 then {found!}
    begin
      SkipChars := 0;
      for J := 0 to I - 1 do
        SkipChars := SkipChars + Length(Memo1.Lines[J]);
      SkipChars := SkipChars + (I*2);
      SkipChars := SkipChars + PosReturn - 1;
      Memo1.SetFocus;
      Memo1.SelStart := SkipChars;
      Memo1.SelLength := Length(FindDialog1.FindText);
      Break;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'country.list';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
{
The following example demonstrates the use of the Perform method
to send a windows message. The EM_SCROLLCARET message scrolls the
caret in the rich edit into view. The caret position is set to the
contents of the mask edit prior to calling Perform.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
with RichEdit1 do
  Begin
    SelStart := StrToInt(MaskEdit1.Text);
    Edit1.Text := InttoStr(SelStart);
    RichEdit1.Perform(EM_SCROLLCARET, 0, 0);
    RichEdit1.SetFocus;
  end;
```

```
end;
```

See Also

CanFocus (see page 6131)

FocusControl (see page 13875)

Focused (see page 6150)

32.1.28.6.99 TWinControl.SetIme Method

Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.

Pascal

```
procedure SetIme;
```

C++

```
__fastcall SetIme();
```

Description

Applications cannot call SetIme. SetIme is called automatically when the control receives input focus. It is exposed as a protected method so that descendant objects can cause the ImeMode (see page 6207) and ImeName (see page 6208) properties to take effect at other times.

See Also

ImeMode (see page 6207)

ImeName (see page 6208)

32.1.28.6.100 TWinControl.SetImeCompositionWindow Method

Sets the position and font of the composition window.

Pascal

```
function SetImeCompositionWindow(Font: TFont; XPos: Integer; YPos: Integer): Boolean;
```

C++

```
__fastcall Boolean SetImeCompositionWindow(TFont Font, int XPos, int YPos);
```

Description

Call SetImeComposition to change the position or font of the composition window. The composition window is the window displayed by the input method editor (IME) that provides feedback to the user about what keystrokes have been typed, and how they are converted into asian characters.

The Font (see page 5823) parameter describes the font that the composition window should use. Setting the Font (see page 5823) parameter to nil (Delphi) or NULL (C++) repositions the composition window without changing the font. XPos and YPos specify the desired global coordinates for the composition window.

SetImeCompositionWindow returns true if the font and position are successfully assigned.

See Also

ImeMode (see page 6207)

ImeName (see page 6208)

TFont (see page 14497)

32.1.28.6.101 TWinControl.SetParent Method

Sets the parent of the control.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent property. Override SetParent to execute additional code when the value of the Parent property changes.

The AParent parameter specifies the new parent of the control.

If the control already has a parent, SetParent removes the control from that parent's list of controls by calling the parent's RemoveControl method. If AParent is not nil (Delphi) or NULL (C++), SetParent calls its InsertControl method to add the control to its list of controls.

The TControl destructor calls SetParent(nil (Delphi) or NULL (C++)) to remove the control from its parent's control list before destroying the component.

See Also

Destroy (see page 5732)

InsertControl (see page 6160)

Parent (see page 5832)

RemoveControl (see page 6172)

32.1.28.6.102 TWinControl.SetParentBackground Method

Pascal

```
procedure SetParentBackground(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetParentBackground(Boolean Value);
```

Description

This is SetParentBackground, a member of class TWinControl.

32.1.28.6.103 TWinControl.SetZOrder Method

Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.

Pascal

```
procedure SetZOrder(TopMost: Boolean); override;
```

C++

```
virtual __fastcall SetZOrder(Boolean TopMost);
```

Description

Use SetZOrder to rearrange overlapping controls within a parent control or (if the control has no parent) overlapping windows on

the screen. If the TopMost parameter is true, the control becomes the top control; otherwise, it becomes the bottom control.

TWinControl (see page 6112) controls always stack on top of other controls, regardless of the Z order.

After changing the order, SetZOrder invalidates the control to ensure repainting to reflect the new order.

See Also

BringToFront (see page 5740)

Invalidate (see page 6161)

Parent (see page 5832)

SendToBack (see page 5782)

32.1.28.6.104 TWinControl.ShowControl Method

Ensures that a specified child control is visible.

Pascal

```
procedure ShowControl(AControl: TControl); virtual;
```

C++

```
virtual __fastcall ShowControl(TControl * AControl);
```

Description

Call ShowControl to display a child control. Specify the control you want to ensure will be visible as the value of the AControl parameter.

As implemented in TWinControl (see page 6112), ShowControl simply calls the ShowControl method of the control's parent. Derived objects override ShowControl to perform whatever actions are necessary to allow the indicated child object to be visible. Possible actions include scrolling the particular child object into view, or changing to the appropriate notebook page.

See Also

Show (see page 5788)

Parent (see page 5832)

32.1.28.6.105 TWinControl.Update Method

Forces the control to update.

Pascal

```
procedure Update; override;
```

C++

```
virtual __fastcall Update();
```

Description

Update repaints any part of the control surface that is out of date. Normally, updates occur automatically, but an Update call may be necessary before lengthy processing that might interfere with automatic updates. Calling Update unnecessarily can increase overhead and cause screen flicker.

Update only repaints areas of the control the have been determined to be out of date. To force immediate repainting of the entire control, call the Repaint (see page 6174) method. To notify a control that it is out of date (without forcing an immediate repaint), call the Invalidate (see page 6161) method.

C++ Examples:

```
/*
StepBy, CreateForm, Run, Show, Update, Initialize example
This example shows progress of loading forms as an application starts up. The code example is
placed in the project source (*.dpr) file. To see project source, select the View | Project
Source menu item.
You will need to set up your project with the following steps before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place Form5 on the available forms
list.
o          Change the code of your project (*.dpr) file to look like the example.
*/

Invalidate (see page 6161)

Repaint (see page 6174)

32.1.28.6.106 TWinControl.UpdateBounds Method

Pascal

```
procedure UpdateBounds;
```

C++

```
__fastcall UpdateBounds();
```

Description

This is UpdateBounds, a member of class TWinControl.

32.1.28.6.107 TWinControl.UpdateControlOriginalParentSize Method

Pascal

```
procedure UpdateControlOriginalParentSize(AControl: TControl; var AOriginalParentSize:
TPoint); virtual;
```

C++

```
virtual __fastcall UpdateControlOriginalParentSize(TControl * AControl, TPoint
AOriginalParentSize);
```

Description

This is UpdateControlOriginalParentSize, a member of class TWinControl.

32.1.28.6.108 TWinControl.UpdateControlState Method

Respond to state change.

Pascal

```
procedure UpdateControlState;
```

C++

```
__fastcall UpdateControlState();
```

Description

UpdateControlState is called automatically when any display change occurs that might affect the internal state of the control.

As implemented in TWinControl (see page 6112), UpdateControlState climbs the chain of parent controls to verify that each control in the chain has Showing (see page 6210) equal to true. If this is the case, UpdateControlState makes sure that the Showing (see page 6210) property is accurate for this control and for all its descendants. Descendant classes can extend this behavior.

See Also

Handle (see page 6207)

Show (see page 5788)

ShowControl (see page 6183)

Showing (see page 6210)

32.1.28.6.109 TWinControl.UpdateRecreatingFlag Method

Pascal

```
procedure UpdateRecreatingFlag(Recreating: Boolean);
```

C++

```
__fastcall UpdateRecreatingFlag(Boolean Recreating);
```

Description

This is UpdateRecreatingFlag, a member of class TWinControl.

32.1.28.6.110 TWinControl.UpdateUIState Method

Updates form User Interface State as needed

Pascal

```
procedure UpdateUIState(CharCode: Word);
```

C++

```
__fastcall UpdateUIState(Word CharCode);
```

Description

UpdateUIState is called in component code to ensure that the User Interface State is consistently updated. User Interface State determinates whether keyboard accelerators and focus indicators are hidden or shown. A control should call UpdateUIState whenever it receives a keyboard event that might invalidate the User Interface State. CharCode is the virtual key code of the keyboard event.

32.1.28.6.111 TWinControl.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc (see page 5872) property is initialized to point to the WndProc method.

WndProc for TWinControl (see page 6112) overrides the inherited method to define responses for focus, mouse, and keyboard messages. It sends all others to its inherited WndProc.

When overriding WndProc to provide specialized responses to messages, call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/
class TMyListBoxDescendant : public TListBox
{
__published:    // IDE-managed Components
    void __fastcall SubClassWndProc(Messages::TMessage &Message);
    void __fastcall ToggleSubClass(bool On);
    void __fastcall OnDrawItemProc(
      TWinControl *Control, int Index, const TRect &Rect,
      TOwnerDrawState State);
private:    // User declarations
public:     // User declarations
    __fastcall TMyListBoxDescendant(TComponent* Owner);
};

TForm1 *Form1;
TMyListBoxDescendant *MyListBoxDescendant1;
Graphics::TBitmap *bitmap0;

const WM_STYLEMESSAGE = WM_USER + 2000;
```

```
__fastcall TForm1::TForm1(TComponent* Owner)
    : TForm(Owner)
{
}

__fastcall TMyListBoxDescendant::TMyListBoxDescendant(TComponent* Owner)
    : TListBox(Owner)
{
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PostMessage(
    MyListBoxDescendant1->Handle,
    WM_STYLEMESSAGE,
    Integer(lbOwnerDrawFixed),
    0);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  PostMessage(
    MyListBoxDescendant1->Handle,
    WM_STYLEMESSAGE,
    Integer(lbStandard),
    0);
}

void __fastcall TForm1::SubClassRadioGroup1Click(TObject *Sender)
{
  MyListBoxDescendant1->ToggleSubClass(SubClassRadioGroup1->ItemIndex == 0);
}

void __fastcall TMyListBoxDescendant::SubClassWndProc(Messages::TMessage &Message)
{
  if (Message.Msg == WM_STYLEMESSAGE)
    Style = (TListBoxStyle)Message.WParam;
  else
    WndProc(Message);
}

void __fastcall TMyListBoxDescendant::ToggleSubClass(bool On)
{
  if (On)
    WindowProc = SubClassWndProc;
  else
    WindowProc = WndProc;
}

void __fastcall TMyListBoxDescendant::OnDrawItemProc(TWinControl *Control, int Index,
      const TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *bitmap; // temporary variable for item's bitmap
  int Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *canvas = ((TListBox *)Control)->Canvas;
  canvas->FillRect(Rect); // clear the rectangle
  bitmap = (Graphics::TBitmap *)((TListBox *)Control)->Items->Objects[Index];
  if (bitmap)
  {
    canvas->BrushCopy(
      Bounds(Rect.Left + Offset, Rect.Top, bitmap->Width, bitmap->Height),
      bitmap, Bounds(0, 0, bitmap->Width, bitmap->Height), clRed); // render bitmap
    Offset += bitmap->Width + 4;   // add four pixels between bitmap and text
  }
```

```
  // display the text

  SubClassRadioGroup1->Items->Add("WndProc");
  SubClassRadioGroup1->ItemIndex = 2;
}
```

Delphi Examples:

```
{
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
}

32.1.28.7 TWinControl Properties

The properties of the TWinControl class are listed here.

Protected Properties

	Name	Description
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.

	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.

Public Properties

	Name	Description
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	Padding (see page 6209)	Specifies the padding of a control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

32.1.28.7.1 TWinControl.AlignDisabled Property

Indicates child control realignment disabled.

Pascal

```
property AlignDisabled: Boolean;
```

C++

```
__property Boolean AlignDisabled;
```

Description

AlignDisabled returns true if child control realignment has been temporarily disabled by a call to DisableAlign (see page 6141).

See Also

DisableAlign (see page 6141)

EnableAlign (see page 6148)

32.1.28.7.2 TWinControl.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner (see page 6193), BevelOuter (see page 6194), and BevelKind (see page 6193) properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

32.1.28.7.3 TWinControl.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter (see page 6194) is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

32.1.28.7.4 TWinControl.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth (see page 6194) and the cut of the bevel specified by BevelInner (see page 6193) or BevelOuter (see page 6194), can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

32.1.28.7.5 TWinControl.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner (see page 6193) to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

32.1.28.7.6 TWinControl.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

32.1.28.7.7 TWinControl.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics (see page 14387) or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter (see page 6194)

32.1.28.7.8 TWinControl.Brush Property

Determines the color and pattern used for painting the background of the control.

Pascal

```
property Brush: TBrush;
```

C++

```
__property TBrush Brush;
```

Description

The Brush property accesses the TBrush object that determines pattern and color for the control background. Brush is a read-only property, but an application can manipulate the TBrush object by setting its properties or by using its Assign method.

See Also

Assign (see page 14433)

Color (see page 14437)

Style (see page 14438)

Bitmap (see page 14436)

Color (see page 14437)

Assign (see page 14433)

32.1.28.7.9 TWinControl.ControlCount Property

Returns the number of child controls.

Pascal

```
property ControlCount: Integer;
```

C++

```
__property int ControlCount;
```

Description

Read ControlCount when iterating over all the children of this control. The children of the control are listed in the Controls (see page 6197) property array.

ControlCount is a read-only property.

Note: The value of ControlCount is always 1 greater than the highest Controls (see page 6197) index, because the first Controls (see page 6197) index is 0.

C++ Examples:

```
/*
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
*/
void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  int I;
  TControl *ChildControl;

  for (I = 0; I < GroupBox1->ControlCount; I++)
  {
    ChildControl = GroupBox1->Controls[I];
    if (Button == btNext)
      ChildControl->Top = ChildControl->Top + 15;
    else
      ChildControl->Top = ChildControl->Top - 15;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorarray[5] = {clYellow, clGreen, clBlue, clLime, clFuchsia};
  GroupBox1->Brush->Color = clRed;
  for (int i = 0; i < GroupBox1->ControlCount; i++)
    ((TWinControl *)GroupBox1->Controls[i])->Brush->Color = colorarray[i];
}
```

Delphi Examples:

```
{
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
const
  colorarray : Array[0..4] of TColor = (clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
   GroupBox1.Brush.Color := clRed;
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    TWinControl(GroupBox1.Controls[I]).Brush.Color := colorarray[I];
  end;
end;

procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
var
```

```
  I: Integer;
  ChildControl: TControl;
begin
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    ChildControl := GroupBox1.Controls[I];
    if Button = btNext then
      ChildControl.Top := ChildControl.Top + 15
    else
      ChildControl.Top := ChildControl.Top - 15;
  end;
end;
```

See Also

Controls (see page 6197)

32.1.28.7.10 TWinControl.Controls Property

Lists all child controls.

Pascal

```
property Controls [Index: Integer]: TControl;
```

C++

```
__property TControl * Controls[int Index];
```

Description

Controls is an array of all the child controls. These are all controls that list this control as their Parent (see page 5832) property. The Controls property is convenient for referring to the children of a control by number rather than name. For example, Controls may be used to iterate over all the child controls.

Don't confuse the Controls property with the Components property. The Controls property lists all the controls that are child windows of the control, while the Components property lists all components that it owns. The form owns all components put on it, and therefore, they appear in the form's Components property list, even when they are child windows of a control on the form.

Controls is a read-only property. To add or delete a child control, use the InsertControl (see page 6160) or RemoveControl (see page 6172) methods. To move a child control from one parent to another, set the Parent (see page 5832) of the child control, as that will handle both the RemoveControl (see page 6172) from the original parent and the InsertControl (see page 6160) to the new parent.

C++ Examples:

```
/*
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
*/
void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  int I;
  TControl *ChildControl;

  for (I = 0; I < GroupBox1->ControlCount; I++)
  {
    ChildControl = GroupBox1->Controls[I];
    if (Button == btNext)
      ChildControl->Top = ChildControl->Top + 15;
    else
      ChildControl->Top = ChildControl->Top - 15;
  }
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorarray[5] = {clYellow, clGreen, clBlue, clLime, clFuchsia};
  GroupBox1->Brush->Color = clRed;
  for (int i = 0; i < GroupBox1->ControlCount; i++)
    ((TWinControl *)GroupBox1->Controls[i])->Brush->Color = colorarray[i];
}
```

Delphi Examples:

```
{
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
const
  colorarray : Array[0..4] of TColor = (clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
   GroupBox1.Brush.Color := clRed;
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    TWinControl(GroupBox1.Controls[I]).Brush.Color := colorarray[I];
  end;
end;

procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
var
  I: Integer;
  ChildControl: TControl;
begin
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    ChildControl := GroupBox1.Controls[I];
    if Button = btNext then
      ChildControl.Top := ChildControl.Top + 15
    else
      ChildControl.Top := ChildControl.Top - 15;
  end;
end;
```

See Also

Components (see page 2799)

ControlCount (see page 6195)

InsertControl (see page 6160)

Parent (see page 5832)

RemoveControl (see page 6172)

32.1.28.7.11 TWinControl.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

32.1.28.7.12 TWinControl.DefWndProc Property

Specifies the default window procedure for the windowed control.

Pascal

```
property DefWndProc: Pointer;
```

C++

```
__property void * DefWndProc;
```

Description

Windowed controls use the Windows API function CallWindowProc with DefWndProc to invoke the standard Windows message handling for a window message. Using DefWndProc instead of the WndProc (see page 6187) method bypasses any message processing introduced by the WndProc (see page 6187) method.

DefWndProc fills the role for windowed controls that DefaultHandler (see page 6139) fills for all objects. The DefaultHandler (see page 6139) for TWinControl (see page 6112) uses DefWndProc to pass messages to Windows for processing.

For windowed controls, DefWndProc is initially set to the window procedure of the window class specified in the Params parameter in the CreateParams (see page 6135) method. Change DefWndProc to subclass the window class of a windowed control.

See Also

CreateParams (see page 6135)

DefaultHandler (see page 6139)

WndProc (see page 6187)

32.1.28.7.13 TWinControl.DockClientCount Property

Specifies the number of controls that are docked on the windowed control.

Pascal

```
property DockClientCount: Integer;
```

C++

```
__property int DockClientCount;
```

Description

Use DockClientCount to get the number of controls that are docked to the windowed control. This value can be used as an upper bound when iterating through the DockClients (see page 6201) property.

Note: The DockClients (see page 6201) property can contain controls that are not visible. To get the number of docked clients that are visible, use the VisibleDockClientCount (see page 6212) property instead.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

See Also

DockClients (see page 6201)

VisibleDockClientCount (see page 6212)

32.1.28.7.14 TWinControl.DockClients Property

Lists the controls that are docked to the windowed control.

Pascal

```
property DockClients [Index: Integer]: TControl;
```

C++

```
__property TControl * DockClients[int Index];
```

Description

Use DockClients to access any control that is docked to the windowed control.

C++ Examples:

```
{
This example shows how to undock a dockable object.  This example
is part of the Docking Demo.
}

void __fastcall TTabDockHost::FormClose(TObject *Sender, TCloseAction &Action)
{
  TRect ARect;
  TPoint point;
  if (PageControl1->DockClientCount == 1)
  {
    point =  PageControl1->DockClients[0]->ClientToScreen(Point(0, 0));
    ARect.left = point.x;
    ARect.top = point.y;
    point = PageControl1->DockClients[0]->ClientToScreen(
      Point(PageControl1->DockClients[0]->UndockWidth,
PageControl1->DockClients[0]->UndockHeight));
    ARect.right = point.x;
    ARect.bottom = point.y;
    PageControl1->DockClients[0]->ManualFloat(ARect);
    Action = caFree;
  }
  else
    Action = caHide;
}
```

Delphi Examples:

```
procedure TTabDockHost.FormClose(Sender: TObject;
  var Action: TCloseAction);
var
  ARect: TRect;
begin
  if PageControl1.DockClientCount = 1 then
  begin
    with PageControl1.DockClients[0] do
    begin
      ARect.TopLeft := ClientToScreen(Point(0, 0));
      ARect.BottomRight := ClientToScreen(Point(UndockWidth, UndockHeight));
      ManualFloat(ARect);
    end;
    Action := caFree;
  end else
    Action := caHide;
end;
```

VisibleDockClientCount (see page 6212)

32.1.28.7.15 TWinControl.DockManager Property

Specifies the control's docking manager interface.

Pascal

```
property DockManager: IDockManager;
```

C++

```
__property IDockManager DockManager;
```

Description

Use DockManager to specify the control's docking manager. The docking manager handles the layout of docking zones (where controls are docked) and any painting associated with docking zones.

If you set DockSite (see page 6204) and UseDockManager (see page 6212) to true, but do not assign a value to DockManager, the windowed control generates a default docking manager, using the global DefaultDockTreeClass (see page 6321) variable.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
```

```
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
```

```
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

See Also

DockSite (see page 6204)

UseDockManager (see page 6212)

DefaultDockTreeClass (see page 6321)

32.1.28.7.16 TWinControl.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite: Boolean;
```

C++

```
__property Boolean DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

32.1.28.7.17 TWinControl.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered: Boolean;
```

C++

```
__property Boolean DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
```

```
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

DockManager (see page 6202)

PaintWindow (see page 6169)

32.1.28.7.18 TWinControl.Handle Property

Provides access to the underlying Windows screen object for the control.

Pascal

```
property Handle: HWnd;
```

C++

```
__property HWnd Handle;
```

Description

The Handle property returns the window handle for the underlying Microsoft Windows screen object. Use the Handle property to bypass the VCL API and directly access the underlying window.

Do not refer to the Handle property during component creation or streaming. The underlying window does not exist until the first time the Handle property is referenced. When this occurs, the HandleNeeded (see page 6160) method is called automatically.

Handle is a read-only property.

C++ Examples:

```
/*
The following code uses the Windows API function ShowWindow
to display Form2 as an icon, but does not activate it.
*/

#include "Unit2.h"

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ShowWindow(Form2->Handle, SW_SHOWMINNOACTIVE);
}
```

Delphi Examples:

```
{
The following code uses the Windows API function ShowWindow
to display Form2 as an icon, but does not activate it.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowWindow(Form2.Handle, SW_SHOWMINNOACTIVE);
end;
```

See Also

HandleNeeded (see page 6160)

32.1.28.7.19 TWinControl.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted

characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme (see page 6181) method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

32.1.28.7.20 TWinControl.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme (see page 6181) method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

32.1.28.7.21 TWinControl.MouseInClient Property

Pascal

```
property MouseInClient: Boolean;
```

C++

```
__property Boolean MouseInClient;
```

Description

This is MouseInClient, a member of class TWinControl.

32.1.28.7.22 TWinControl.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding: TPadding;
```

C++

```
__property TPadding Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding (see page 6103).

See Also

TPadding (see page 6103)

32.1.28.7.23 TWinControl.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground: Boolean;
```

C++

```
__property Boolean ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

32.1.28.7.24 TWinControl.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D (see page 6198) property.

See Also

Ctl3D (see page 6198)

32.1.28.7.25 TWinControl.ParentWindow Property

Reference to parent's underlying control.

Pascal

```
property ParentWindow: HWnd;
```

C++

```
__property HWnd ParentWindow;
```

Description

ParentWindow refers to the window handle that underlies the parent control. To designate a non-VCL control as a parent, assign that control's handle to ParentWindow. This assignment causes the control to be moved into the parent's screen area. Setting ParentWindow has no effect if Parent (see page 5832) is not nil (Delphi) or NULL (C++).

TActiveXControl objects use ParentWindow to insert a control in an ActiveX container window. ParentWindow is set automatically when a control is constructed with a call to CreateParented (see page 6123) (Delphi) or the appropriate overloaded constructor (C++).

Use ParentWindow with windowed controls that are packaged in a DLL. This allows references to the control by applications based on other applications.

See Also

CreateParented (see page 6123)

CreateParentedControl (see page 6136)

Create (see page 6123)

Parent (see page 5832)

TActiveXControl (see page 1517)

32.1.28.7.26 TWinControl.Showing Property

Indicates whether the control is showing on the screen.

Pascal

```
property Showing: Boolean;
```

C++

```
__property Boolean Showing;
```

Description

Showing is used internally to optimize the allocation of Windows resources. Use Showing to determine when you must allocate resources that are required when the control is visible. When Showing is false, the control is not visible and you can delay the allocation of resources.

If the Visible (see page 5847) properties of a component and all the parents in its parent hierarchy are true, Showing is guaranteed to be true. If one of the parents containing the control has a Visible (see page 5847) property value of false, Showing may be either true or false.

Showing is a read-only property.

See Also

Visible (see page 5847)

32.1.28.7.27 TWinControl.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop (see page 6211) property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop (see page 6211) property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

32.1.28.7.28 TWinControl.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

32.1.28.7.29 TWinControl.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager: Boolean;
```

C++

```
__property Boolean UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

See Also

DockManager (see page 6202)

32.1.28.7.30 TWinControl.VisibleDockClientCount Property

Specifies the number of visible controls that are docked on the windowed control.

Pascal

```
property VisibleDockClientCount: Integer;
```

C++

```
__property int VisibleDockClientCount;
```

Description

Use VisibleDockClientCount to determine the number of controls in the DockClients (see page 6201) list that have a Visible (see page 5847) property value of true. This value is less than or equal to the value of DockClientCount (see page 6199).

See Also

DockClientCount (see page 6199)

DockClients (see page 6201)

Visible (see page 5847)

32.1.28.7.31 TWinControl.WindowHandle Property

Provides access to a window handle for the control.

Pascal

```
property WindowHandle: HWnd;
```

C++

```
__property HWnd WindowHandle;
```

Description

The WindowHandle property provides access to the same window handle as the Handle (see page 6207) property, but WindowHandle is protected, and therefore only accessible to code inside the control.

The advantage to using WindowHandle is that it can be written to, while the Handle (see page 6207) property is read-only. Use WindowHandle when implementing methods that need to change the value of the control's window handle. Unlike the Handle (see page 6207) property, reading the value of WindowHandle doesn't automatically create a valid handle. Reading WindowHandle can return a zero value.

See Also

Handle (see page 6207)

HandleNeeded (see page 6160)

32.1.28.8 TWinControl Events

The events of the TWinControl class are listed here.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

32.1.28.8.1 TWinControl.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align (see page 5798) property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent (see page 6293) type.

CustomAlignInsertBefore (see page 6137) triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore (see page 6137) returns the value returned by OnAlignInsertBefore. Defining this event allows users

to define the order of control alignment without overriding CustomAlignInsertBefore (see page 6137).

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

32.1.28.8.2 TWinControl.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align (see page 5798) property of **alCustom** are aligned.

CustomAlignPosition (see page 6138) triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition (see page 6138) uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition (see page 6138). It holds a TAlignPositionEvent (see page 6293) type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors (see page 5802) TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo (see page 6269).
As implemented in TWinControl (see page 6112), OnAlignPosition does nothing.	

See Also

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

32.1.28.8.3 TWinControl.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop: TDockDropEvent;
```

C++

```
__property TDockDropEvent OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite (see page 6204) is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

32.1.28.8.4 TWinControl.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver: TDockOverEvent;
```

C++

```
__property TDockOverEvent OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject (see page 6009) has been initialized by an OnGetSiteInfo (see page 6223) event.

OnDockOver occurs only if DockSite (see page 6204) is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
```

```
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

32.1.28.8.5 TWinControl.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit (see page 6221) event of the container occurs after the OnExit (see page 6221) event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit (see page 6221) event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit (see page 6221) event for the radio button occurs followed by an OnExit (see page 6221) event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
```

```
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
```

```
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

32.1.28.8.6 TWinControl.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter (see page 6219) event of the container occurs before the OnEnter (see page 6219) event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter (see page 6219) event on the group box, and finally an OnEnter (see page 6219) event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter (see page 6219) event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

32.1.28.8.7 TWinControl.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo: TGetSiteInfoEvent;
```

C++

```
__property TGetSiteInfoEvent OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject (see page 6009) with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver (see page 6216) event.

OnGetSiteInfo occurs only if DockSite (see page 6204) is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
```

```
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

32.1.28.8.8 TWinControl.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent (see page 6311) type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress (see page 6227) event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress (see page 6227) event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
```

```
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin

32.1.28.8.9 TWinControl.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown (see page 6225) or OnKeyUp (see page 6228) event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown (see page 6225) event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown (see page 6225) event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown (see page 6225) event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

32.1.28.8.10 TWinControl.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent (see page 6311) type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
```

```
event to FormKeyUp.  Set the KeyPreview on the form to True.
}

32.1.28.8.11 TWinControl.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock: TUnDockEvent;
```

C++

```
__property TUnDockEvent OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
```

```
  undocked (if it is a dockable form). In addition, when the
  next to last docked control is undocked, the conjoinment
  docking site sends itself a close message so that the last
  docked control is undocked to its old position and size.
  */
  void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
        TWinControl *NewTarget, bool &Allow)
  {
    // Only 2 dock clients means the host must be destroyed and
    // the remaining window undocked to its old position and size.
    // Recall that OnUnDock gets called before the undocking
    // actually occurs.
    if (Client->ClassNameIs("TDockableForm"))
      dynamic_cast<TDockableForm *>(Client)->DockSite = True;
    if ((DockClientCount == 2) && (NewTarget != this))        // Self?
      PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
    UpdateCaption(Client);
  }
  /*
  The following example is taken from the docking demo. It
  shows how set permissions to dock dockable objects onto a
  docking site.
  */

  void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
        TDragDockObject *Source, int X, int Y)
  {
    //OnDockDrop gets called AFTER the client has actually docked,
    //so we check for DockClientCount = 1 before making the dock panel visible.
    TPanel *panel = dynamic_cast<TPanel *>(Sender);
    if (panel->DockClientCount == 1)
      ShowDockPanel(panel, True, NULL);
    panel->DockManager->ResetBounds(True);
    //Make DockManager repaints it's clients.
  }

  void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
        TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
    if (Accept)
    {
      // Modify the DockRect to preview dock area.
      Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
      Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
        Point(this->ClientWidth/3, LeftDockPanel->Height));
      Source->DockRect = Types::TRect(TopLeft, BottomRight);
    }
  }

  void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
        TControl *Client, TWinControl *NewTarget, bool &Allow)
  {
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    TPanel *panel = dynamic_cast<TPanel *>(Sender);
    if (panel->DockClientCount == 1)
      ShowDockPanel(panel, False, NULL);
  }

  void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
        TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
        bool &CanDock)
  {

32.1.29 TWinControlActionLink Class

TWinControlActionLink is an action link used by descendants of TWinControl (see page 6112).

Class Hierarchy

System::TObject → Classes.TBasicActionLink → ActnList.TActionLink → Controls.TControlActionLink → Controls.TWinControlActionLink

Pascal

```
TWinControlActionLink = class(TControlActionLink);
```

C++

```
class TWinControlActionLink : public TControlActionLink;
```

File

Controls

Description

TWinControlActionLink is designed to link actions to controls based on TWinControl (see page 6112). TWinControlActionLink inherits support for linking actions with the properties of components and controls and adds support for linking the help context.

32.1.29.1 TWinControlActionLink Members

The following tables list the members exposed by TWinControlActionLink.

Protected Fields

	Name	Description
	FAction (see page 2722)	This is FAction, a member of class TBasicActionLink.
	FClient (see page 6236)	This is FClient, a member of class TWinControlActionLink.

Protected Methods

	Name	Description
V	AssignClient (see page 6236)	Specifies the client control.
V	Change (see page 2723)	This is Change, a member of class TBasicActionLink.

	DoShowHint (see page 5896)	Indicates whether the hint is shown, and modified.
	IsCaptionLinked (see page 268)	Indicates whether the Caption properties for the action and client are linked.
	IsCaptionLinked (see page 5896)	Indicates whether the caption for the action and the client are linked.
	IsCheckedLinked (see page 269)	Indicates whether the Checked properties for the action and client are linked.
	IsDropdownMenuLinked (see page 5896)	This is IsDropdownMenuLinked, a member of class TControlActionLink.
	IsEnabledLinked (see page 269)	Indicates whether the Enabled properties for the action and client are linked.
	IsEnabledLinked (see page 5897)	Indicates whether the enabled state for the action and the client are linked.
	IsEnableDropdownLinked (see page 5897)	This is IsEnableDropdownLinked, a member of class TControlActionLink.
	IsGroupIndexLinked (see page 270)	Indicates whether the GroupIndex property for the action controls client behavior.
	IsHelpContextLinked (see page 6236)	Indicates whether the Help context for the action and the client are linked.
	IsHelpLinked (see page 271)	Indicates whether the help properties for the action and client are linked.
	IsHelpLinked (see page 5897)	Indicates whether the help properties for the action and the client are linked.
	IsHintLinked (see page 271)	Indicates whether the Hint properties for the action and client are linked.
	IsHintLinked (see page 5898)	Indicates whether the Hint property for the action and the client are linked.
	IsImageIndexLinked (see page 272)	Indicates whether the image index for the action and the client are linked.
	IsOnExecuteLinked (see page 2723)	This is IsOnExecuteLinked, a member of class TBasicActionLink.
	IsOnExecuteLinked (see page 5898)	Indicates whether the OnExecute event handler for the action and the client are linked.
	IsPopupMenuLinked (see page 5898)	This is IsPopupMenuLinked, a member of class TControlActionLink.
	IsShortCutLinked (see page 272)	Indicates whether the ShortCut properties for the action and client are linked.
	IsVisibleLinked (see page 273)	Indicates whether the Visible properties for the action and client are linked.
	IsVisibleLinked (see page 5899)	Indicates whether the visible state for the action and the client are linked.
	SetAction (see page 2724)	This is SetAction, a member of class TBasicActionLink.
	SetAutoCheck (see page 274)	Introduces an interface for setting the AutoCheck property of a client.
	SetCaption (see page 274)	Introduces an interface for setting the caption on a client.
	SetCaption (see page 5899)	Sets the caption of a control if the client is linked to the action for this event.
	SetChecked (see page 274)	Introduces an interface for setting the checked state of a client.
	SetDropdownMenu (see page 5899)	This is SetDropdownMenu, a member of class TControlActionLink.
	SetEnabled (see page 275)	Introduces an interface for setting the enabled state of a client.
	SetEnabled (see page 5900)	Sets the enabled state of a control if the client is linked to the action for this event.
	SetEnableDropdown (see page 5900)	This is SetEnableDropdown, a member of class TControlActionLink.
	SetGroupIndex (see page 275)	Introduces an interface for setting the GroupIndex property of a client.
	SetHelpContext (see page 6237)	Sets the Help context of a windowed control if the client is linked to the action for this event.
	SetHelpKeyword (see page 276)	Introduces an interface for setting the help keyword of a client.
	SetHelpKeyword (see page 5901)	Sets the HelpKeyword of a control if the client is linked to the action help properties.
	SetHelpType (see page 277)	Introduces an interface for setting the HelpType property of a client.
	SetHelpType (see page 5901)	Sets the HelpType of a control if the client is linked to the action help properties.
	SetHint (see page 278)	Introduces an interface for setting the hint for a client.
	SetHint (see page 5901)	Sets the hint of a control if the client is linked to the action for this event.
	SetImageIndex (see page 278)	Introduces an interface for setting the image index for a client.
	SetOnExecute (see page 2724)	This is SetOnExecute, a member of class TBasicActionLink.
	SetOnExecute (see page 5902)	Sets the execution event handler for a control if the client is linked to the action for this event.
	SetPopupMenu (see page 5902)	This is SetPopupMenu, a member of class TControlActionLink.
	SetShortCut (see page 279)	Introduces an interface for setting the shortcut for a client.
	SetVisible (see page 279)	Introduces an interface for setting the visible state of a client.
	SetVisible (see page 5902)	Sets the visible state of a control if the client is linked to the action for this event.

Public Events

	Name	Description
	OnChange (see page 2725)	Occurs when an OnChange event is triggered on the action.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2721)	Instantiates and initializes a TBasicActionLink (see page 2720) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2722)	Destroys an instance of an action link object.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 2723)	Invokes the action's Execute method.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Update (see page 2724)	Invokes the action's Update method.

Public Properties

	Name	Description
	Action (see page 2725)	Indicates which action the link connects to its client.

32.1.29.2 TWinControlActionLink Fields

The fields of the TWinControlActionLink class are listed here.

Protected Fields

	Name	Description
	FClient (see page 6236)	This is FClient, a member of class TWinControlActionLink.

32.1.29.2.1 TWinControlActionLink.FClient Field

Pascal

```
FClient: TWinControl;
```

C++

```
TWinControl * FClient;
```

Description

This is FClient, a member of class TWinControlActionLink.

32.1.29.3 TWinControlActionLink Methods

The methods of the TWinControlActionLink class are listed here.

Protected Methods

	Name	Description
	AssignClient (see page 6236)	Specifies the client control.
	IsHelpContextLinked (see page 6236)	Indicates whether the Help context for the action and the client are linked.
	SetHelpContext (see page 6237)	Sets the Help context of a windowed control if the client is linked to the action for this event.

32.1.29.3.1 TWinControlActionLink.AssignClient Method

Specifies the client control.

Pascal

```
procedure AssignClient(AClient: TObject); override;
```

C++

```
virtual __fastcall AssignClient(TObject * AClient);
```

Description

TWinControlActionLink (see page 6233) overrides AssignClient to ensure that the client is a TWinControl (see page 6112) object.

32.1.29.3.2 TWinControlActionLink.IsHelpContextLinked Method

Indicates whether the Help context for the action and the client are linked.

Pascal

```
function IsHelpContextLinked: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsHelpContextLinked();
```

Description

IsHelpContextLinked indicates whether HelpContext property is linked to the appropriate client property. IsHelpContextLinked returns true if the client requests that the action control this property, false otherwise.

See Also

HelpContext (see page 16148)

HelpContext (see page 5826)

HelpContext (see page 311)

32.1.29.3.3 TWinControlActionLink.SetHelpContext Method

Sets the Help context of a windowed control if the client is linked to the action for this event.

Pascal

```
procedure SetHelpContext(Value: THelpContext); override;
```

C++

```
virtual __fastcall SetHelpContext(THelpContext Value);
```

Description

SetHelpContext sets the help context of a client windowed control, and is called only if the client is linked for this event. Value specifies whether what the help context should be.

See Also

IsHelpContextLinked (see page 6236)

32.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDockManager (see page 6238)	IDockManager is the interface for docking managers.

32.2.1 IDockManager Interface

IDockManager is the interface for docking managers.

Class Hierarchy

Controls.IDockManager

Pascal

```
IDockManager = interface;
```

C++

```
__interface IDockManager;
```

File

Controls

Description

IDockManager handles the tasks of inserting and removing controls when they are docked to or undocked from a container control, including details such as positioning controls and any painting that is associated with docking operations. IDockManager is the type of a container control's DockManager property.

Each docking manager is associated with a single TWinControl (see page 6112) object. To use a docking manager, set the container control's UseDockManager property to true. An application can explicitly assign an object that implements the IDockManager interface as the value of a container control's DockManager property, or it can let the container control create its own docking manager.

Note: C++ declarations that use IDockManager use the _di_IDockManager type instead. This type is a DelphiInterface wrapper around the IDockManager interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IDockManager >  _di_IDockManager;
```

See Also

TWinControl (see page 6112)

TWinControl (see page 6112)

TDockTree (see page 5983)

32.2.1.1 IDockManager Members

The following tables list the members exposed by IDockManager.

Public Methods

	Name	Description
	BeginUpdate (see page 6239)	Responds when the docked controls are about to change.
	EndUpdate (see page 6240)	Responds when the docked controls have finished changing.
	GetControlBounds (see page 6240)	Returns the dimensions allotted to a control that is already docked.
	InsertControl (see page 6240)	Handles the docking of a control into the associated container control.
	LoadFromStream (see page 6241)	Lays out a set of docked controls read from a stream.
	PaintSite (see page 6241)	Paints the elements that surround all docked controls.
	PositionDockRect (see page 6242)	Computes the dimensions of a new docking zone.
	RemoveControl (see page 6242)	Handles the undocking of a control from the associated container control.
	ResetBounds (see page 6243)	Recomputes the layout of docked controls.
	SaveToStream (see page 6245)	Saves a list of the set of docked controls and their positions to a stream.
	SetReplacingControl (see page 6245)	This is SetReplacingControl, a member of class IDockManager.

32.2.1.2 IDockManager Methods

The methods of the IDockManager class are listed here.

Public Methods

	Name	Description
	BeginUpdate (see page 6239)	Responds when the docked controls are about to change.
	EndUpdate (see page 6240)	Responds when the docked controls have finished changing.
	GetControlBounds (see page 6240)	Returns the dimensions allotted to a control that is already docked.
	InsertControl (see page 6240)	Handles the docking of a control into the associated container control.
	LoadFromStream (see page 6241)	Lays out a set of docked controls read from a stream.
	PaintSite (see page 6241)	Paints the elements that surround all docked controls.
	PositionDockRect (see page 6242)	Computes the dimensions of a new docking zone.
	RemoveControl (see page 6242)	Handles the undocking of a control from the associated container control.
	ResetBounds (see page 6243)	Recomputes the layout of docked controls.
	SaveToStream (see page 6245)	Saves a list of the set of docked controls and their positions to a stream.
	SetReplacingControl (see page 6245)	This is SetReplacingControl, a member of class IDockManager.

32.2.1.2.1 IDockManager.BeginUpdate Method

Responds when the docked controls are about to change.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

BeginUpdate is called before controls are docked or undocked.

Once all docking or undocking is complete, the EndUpdate (see page 6240) method is called so that the dock manager can make any final adjustments to reflect the final set of docked controls. Every call to BeginUpdate should be paired with a call to EndUpdate (see page 6240). BeginUpdate/EndUpdate (see page 6240) pairs can be nested.

See Also

EndUpdate (see page 6240)

32.2.1.2.2 IDockManager.EndUpdate Method

Responds when the docked controls have finished changing.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

EndUpdate is called after a series of changes to the docked controls is completed. It checks that every previous call to the BeginUpdate (see page 6239) method has been matched with an EndUpdate call. If so, it performs any final adjustments to the docked controls, now that they are all in place.

Each call to EndUpdate should be paired by a call to BeginUpdate (see page 6239), which is made before docking or undocking controls. BeginUpdate (see page 6239)/EndUpdate pairs can be nested.

See Also

BeginUpdate (see page 6239)

32.2.1.2.3 IDockManager.GetControlBounds Method

Returns the dimensions allotted to a control that is already docked.

Pascal

```
procedure GetControlBounds(Control: TControl; out CtlBounds: TRect);
```

C++

```
__fastcall GetControlBounds(TControl * Control, TRect CtlBounds);
```

Description

GetControlBounds returns the dimensions of the zone in which a control is currently docked.

Control is the currently docked control.

CtlBounds returns the dimensions of the zone in which Control is docked. If Control does not specify an object that is currently docked in the container control that uses this dock manager, CtlBounds returns (0,0,0,0).

See Also

PositionDockRect (see page 6242)

ResetBounds (see page 6243)

32.2.1.2.4 IDockManager.InsertControl Method

Handles the docking of a control into the associated container control.

Pascal

```
procedure InsertControl(Control: TControl; InsertAt: TAlign; DropCtl: TControl);
```

C++

```
__fastcall InsertControl(TControl * Control, TAlign InsertAt, TControl * DropCtl);
```

Description

InsertControl is called immediately after the container control that uses the dock manager adds a new control to its list of docked controls.

Control is the newly docked control.

InsertAt indicates where Control was docked within the container control.

DropCtl is the container control in which Control was docked.

InsertControl handles any tasks the dock manager needs to manage the layout and appearance of docked controls, forcing a repaint of the container control if necessary.

See Also

RemoveControl (see page 6242)

32.2.1.2.5 IDockManager.LoadFromStream Method

Lays out a set of docked controls read from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

LoadFromStream updates the dock manager to reflect the set of docked controls it reads from a stream. The stream must reflect the same format as is written by the SaveToStream (see page 6245) method.

Stream is the stream object to use for reading the docked controls.

See Also

SaveToStream (see page 6245)

32.2.1.2.6 IDockManager.PaintSite Method

Paints the elements that surround all docked controls.

Pascal

```
procedure PaintSite(DC: HDC);
```

C++

```
__fastcall PaintSite(HDC DC);
```

Description

Container controls that use a docking manager call PaintSite when they need to paint their docked child controls.

DC is the handle to the device context to use when rendering the visual elements that surround the docked controls.

PaintSite paints the visual elements associated with the docked controls other than the docked controls themselves.

See Also

PaintControls (see page 6166)

UseDockManager (see page 6212)

32.2.1.2.7 IDockManager.PositionDockRect Method

Computes the dimensions of a new docking zone.

Pascal

```
procedure PositionDockRect(Client: TControl; DropCtl: TControl; DropAlign: TAlign; var
DockRect: TRect);
```

C++

```
__fastcall PositionDockRect(TControl * Client, TControl * DropCtl, TAlign DropAlign, TRect
DockRect);
```

Description

The control that is being dragged calls PositionDockRect from its own PositionDockRect method when it is being docked to a container control that uses a dock manager. It allows the dock manager to indicate where a specified control would appear if the user released the mouse.

Client is the control that is being dragged to a docking position.

DropCtl is the container control into which Client will be docked.

DropAlign indicates where Control is to be docked within the container control.

DockRect returns the boundaries of the docking zone where Control can be docked.

See Also

PositionDockRect (see page 5777)

UseDockManager (see page 6212)

32.2.1.2.8 IDockManager.RemoveControl Method

Handles the undocking of a control from the associated container control.

Pascal

```
procedure RemoveControl(Control: TControl);
```

C++

```
__fastcall RemoveControl(TControl * Control);
```

Description

The container control that uses the dock manager calls RemoveControl when one of its docked controls is undocked.

Control is the control that was just undocked.

RemoveControl performs any internal adjustments that are needed now that the control is no longer docked, forcing a repaint of the container control if necessary.

See Also

InsertControl (see page 6240)

32.2.1.2.9 IDockManager.ResetBounds Method

Recomputes the layout of docked controls.

Pascal

```
procedure ResetBounds(Force: Boolean);
```

C++

```
__fastcall ResetBounds(Boolean Force);
```

Description

ResetBounds updates the layout of the docked controls and their surrounding docking zones, based on the current dimensions of the associated container control. It is used to update the dock manager to reflect current conditions (for example, when the container control that uses the dock manager is resized).

Force indicates whether ResetBounds should recompute the layout if the dimensions of the associated container control have not changed. When Force is false, ResetBounds only updates the layout of docked controls if the dimensions of DockSite have changed. When Force is true, ResetBounds updates the layout of docked controls even if the dimensions of the associated container control have not changed.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
```

```
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

32.2.1.2.10 IDockManager.SaveToStream Method

Saves a list of the set of docked controls and their positions to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

SaveToStream writes enough information to a stream that the dock manager can reconstruct the docking zone structure when it reads that information back at a later time.

Stream is the stream object to use for writing the information.

Note: To reconstruct the docking structure at a later time, use the LoadFromStream (see page 6241) method.

See Also

LoadFromStream (see page 6241)

32.2.1.2.11 IDockManager.SetReplacingControl Method

Pascal

```
procedure SetReplacingControl(Control: TControl);
```

C++

```
__fastcall SetReplacingControl(TControl * Control);
```

Description

This is SetReplacingControl, a member of class IDockManager.

32.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CancelDrag (see page 6247)	Cancels a drag-and-drop or drag-and-dock operation that is in progress.
	ChangeBiDiModeAlignment (see page 6247)	This is function Controls.ChangeBiDiModeAlignment.
	CursorToIdent (see page 6247)	Returns the name of the predefined constant that corresponds to a cursor.
	CursorToString (see page 6248)	Returns the AnsiString representation of a cursor.
	DragDone (see page 6249)	This is function Controls.DragDone.
	FindControl (see page 6249)	Returns the windowed control (Windows) or widget (cross-platform) whose window is identified by the specifiedhandle or which appears at a specified position.
	FindDragTarget (see page 6249)	Returns the control at a specified screen coordinate.
	FindVCLWindow (see page 6250)	Returns the windowed control, if any, at the specified location.
	GetCaptureControl (see page 6251)	Returns the control, if any, that currently receives all mouse messages.
	GetCursorValues (see page 6251)	Passes the name of every predefined cursor constant to a callback.
	GetLongHint (see page 6252)	Returns the second part of a two-part hint string.
	GetShortHint (see page 6253)	Returns the first part of a two-part hint string.
	IdentToCursor (see page 6254)	Translates a predefined cursor constant into a cursor.
	Imm32GetCompositionString (see page 6254)	This is function Controls.Imm32GetCompositionString.
	Imm32GetContext (see page 6255)	This is function Controls.Imm32GetContext.
	Imm32GetConversionStatus (see page 6255)	This is function Controls.Imm32GetConversionStatus.
	Imm32IsIME (see page 6255)	This is function Controls.Imm32IsIME.
	Imm32NotifyIME (see page 6256)	This is function Controls.Imm32NotifyIME.
	Imm32ReleaseContext (see page 6256)	This is function Controls.Imm32ReleaseContext.
	Imm32SetCompositionFont (see page 6256)	This is function Controls.Imm32SetCompositionFont.
	Imm32SetCompositionWindow (see page 6257)	This is function Controls.Imm32SetCompositionWindow.
	Imm32SetConversionStatus (see page 6257)	This is function Controls.Imm32SetConversionStatus.
	Imm32SetOpenStatus (see page 6257)	This is function Controls.Imm32SetOpenStatus.
	InitWndProc (see page 6258)	This is function Controls.InitWndProc.
	IsAbortResult (see page 6258)	Checks the return value from a modal form dialog and indicates whether the user selected Abort or Cancel.
	IsAnAllResult (see page 6259)	Checks the return value from a modal form dialog and indicates whether the user selected All, Yes to All, or No to All.
	IsDragObject (see page 6259)	Indicates whether a specified object is a TDragObject (see page 6031) descendant.
	IsNegativeResult (see page 6260)	Checks the return value from a modal form dialog and indicates whether the user selected No or No to All.
	IsPositiveResult (see page 6260)	Checks the return value from a modal form dialog and indicates whether the user selected Ok, Yes, Yes to All, or All.
	IsVCLControl (see page 6261)	IsVCLControl returns true if a control is a VCL control.
	MoveWindowOrg (see page 6262)	Changes the location of the point (0,0) within a device context.
	PerformEraseBackground (see page 6262)	This is function Controls.PerformEraseBackground.
	SendAppMessage (see page 6262)	Sends a Windows message to the application.
	SetCaptureControl (see page 6263)	Causes the specified control to receive all mouse messages.
	SetImeMode (see page 6264)	This is function Controls.SetImeMode.
	SetImeName (see page 6264)	This is function Controls.SetImeName.
	StringToCursor (see page 6264)	Returns a TCursor (see page 6305) value given its string representation.
	StripAllFromResult (see page 6265)	Converts a TModalResult (see page 6312) value from a constant that refers to "all" to the corresponding simple constant.
	Win32NLSEnableIME (see page 6266)	This is function Controls.Win32NLSEnableIME.

32.3.1 Controls.CancelDrag Function

Cancels a drag-and-drop or drag-and-dock operation that is in progress.

Pascal

```
procedure CancelDrag;
```

C++

```
CancelDrag();
```

File

Controls

Description

Call CancelDrag to terminate the current drag-and-drop or drag-and-dock operation without dropping or docking the dragged object.

32.3.2 Controls.ChangeBiDiModeAlignment Function

Pascal

```
procedure ChangeBiDiModeAlignment(var Alignment: TAlignment);
```

C++

```
ChangeBiDiModeAlignment(TAlignment Alignment);
```

File

Controls

Description

This is function Controls.ChangeBiDiModeAlignment.

32.3.3 Controls.CursorToIdent Function

Returns the name of the predefined constant that corresponds to a cursor.

Pascal

```
function CursorToIdent(Cursor: Longint; var Ident: string): Boolean;
```

C++

```
Boolean CursorToIdent(Longint Cursor, AnsiString Ident);
```

File

Controls

Description

Use CursorToIdent to convert the cursor used by a control or one of the cursors made available by the global screen variable into the name of the corresponding constant. Pass the cursor value as the Cursor parameter. CursorToIdent returns the constant

name as the Ident parameter. If the cursor does not have an associated constant (for example, a custom cursor), CursorToIdent returns false.

To obtain a string representation of the cursor, even if there is no built-in cursor constant for it, use the CursorToString (see page 6248) function.

CursorToIdent can be used to identify the current cursor in a list of possible cursor constants that is built using GetCursorValues (see page 6251).

See Also

TControl (see page 5724)

CursorToString (see page 6248)

IdentToCursor (see page 6254)

TScreen

GetCursorValues (see page 6251)

32.3.4 Controls.CursorToString Function

Returns the AnsiString representation of a cursor.

Pascal

```
function CursorToString(Cursor: TCursor): string;
```

C++

```
AnsiString CursorToString(TCursor Cursor);
```

File

Controls

Description

Use CursorToString to convert the cursor used by a control or one of the cursors made available by the global screen variable into a string that can be displayed to the user. Pass the cursor value as the Cursor parameter. If there is a predefined constant for the cursor, CursorToString returns the constant name. If the cursor does not have an associated constant (for example, a custom cursor), CursorToString returns a string representation of the cursor's numeric value.

To obtain a string representation of the cursor only if there is a built-in cursor constant, use CursorToIdent (see page 6247).

See Also

TControl (see page 5724)

CursorToIdent (see page 6247)

StringToCursor (see page 6264)

TScreen

32.3.5 Controls.DragDone Function

Pascal

```
procedure DragDone(Drop: Boolean);
```

C++

```
DragDone(Boolean Drop);
```

File

Controls

Description

This is function Controls.DragDone.

32.3.6 Controls.FindControl Function

Returns the windowed control (Windows) or widget (cross-platform) whose window is identified by the specifiedhandle or which appears at a specified position.

Pascal

```
function FindControl(Handle: HWnd): TWinControl;
```

C++

```
TWinControl * FindControl(HWnd Handle);
```

File

Controls

Description

Call FindControl to access the control whose underlying screen object is identified by the Handle parameter or which appears at the position specified by the Pos parameter. If Handle is not the handle of a screen object or if there is no widget at the specified position, FindControl returns nil (Delphi) or NULL (C++).

See Also

TWinControl (see page 6112)

FindVCLWindow (see page 6250)

TWidgetControl

32.3.7 Controls.FindDragTarget Function

Returns the control at a specified screen coordinate.

Pascal

```
function FindDragTarget(const Pos: TPoint; AllowDisabled: Boolean): TControl;
```

C++

```
TControl * FindDragTarget(const TPoint Pos, Boolean AllowDisabled);
```

File

Controls

Description

Call FindDragTarget to determine the potential drag-and-drop or drag-and-dock target currently under the mouse. FindDragTarget returns the control at the position specified by the Pos parameter. If there is not control at the specified position, FindDragTarget returns nil (Delphi) or NULL (C++). The AllowDisabled parameter determines whether the search includes disabled controls.

If FindDragTarget returns a control, this does not mean that the control will necessarily accept the dragged object. The control will only accept the dragged object if it has an OnDragOver or OnDockOver event handler that accepts the object or if its DockSite property is true.

See Also

TControl (see page 5724)

TWinControl (see page 6112)

TWincontrol

32.3.8 Controls.FindVCLWindow Function

Returns the windowed control, if any, at the specified location.

Pascal

```
function FindVCLWindow(const Pos: TPoint): TWinControl;
```

C++

```
TWinControl * FindVCLWindow(const TPoint Pos);
```

File

Controls

Description

Call FindVCLWindow to locate the windowed control under a certain point. For example, use FindVCLWindow to identify the windowed control that is under the mouse from another control that has captured the mouse. The Pos parameter specifies the location that must be over the returned windowed control. If there is no windowed control under the Pos parameter, FindVCLWindow returns nil (Delphi) or NULL (C++).

See Also

FindControl (see page 6249)

SetCaptureControl (see page 6263)

TControl (see page 5724)

32.3.9 Controls.GetCaptureControl Function

Returns the control, if any, that currently receives all mouse messages.

Pascal

```
function GetCaptureControl: TControl;
```

C++

```
TControl * GetCaptureControl();
```

File

Controls

Description

Call GetCaptureControl to determine which control is currently processing mouse messages. When a control has captured the mouse, it receives all mouse messages, even if the mouse is not over the control.

GetCaptureControl is equivalent to GetMouseGrabControl.

See Also

SetCaptureControl (see page 6263)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

GetMouseGrabControl

32.3.10 Controls.GetCursorValues Function

Passes the name of every predefined cursor constant to a callback.

Pascal

```
procedure GetCursorValues(Proc: TGetStrProc);
```

C++

```
GetCursorValues(TGetStrProc Proc);
```

File

Controls

Description

Call GetCursorValues to execute a callback for every built-in cursor constant in the VCL. The Proc parameter is the callback function that is called for every cursor constant name.

Note: To convert the strings that are passed to the callback into actual cursors, use IdentToCursor (see page 6254). To convert a cursor into a constant name that can be compared with the string passed to the callback, use CursorToIdent (see page 6247).

See Also

CursorToIdent (see page 6247)

IdentToCursor (see page 6254)

32.3.11 Controls.GetLongHint Function

Returns the second part of a two-part hint string.

Pascal

```
function GetLongHint(const Hint: string): string;
```

C++

```
AnsiString GetLongHint(const AnsiString Hint);
```

File

Controls

Description

Call GetLongHint to obtain the long version of the hint specified as the value of a Hint property. The second part of the hint is the text following the | character. If the Hint string value is not separated into two parts, GetLongHint returns the entire string.

C++ Examples:

```
/*
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
*/

/*
Here is the code to add to the unit file.  It provides the
implementation of the DisplayHint method and assigns it to
the Application in the form's OnCreate event handler.
Note:   It is not actually necessary to write an OnHint event
handler to display hints on the status bar. This can be
accomplished more simply by setting the status bar's AutoHint
property.
*/
void __fastcall TForm1::DisplayHint(TObject *Sender)
{
  StatusBar1->SimpleText = GetLongHint(Application->Hint);
}

// Here is the form's OnCreate event handler.
// It assigns the application's OnHint event handler at
// runtime because the Application is not available in the
// Object Inspector
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHint = DisplayHint;
}
```

Delphi Examples:

```
{
```

```
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    StatusBar1: TStatusBar;
    Edit1: TEdit;
    procedure FormCreate(Sender: TObject);
  private
    { Private declarations }
  public
    procedure DisplayHint(Sender: TObject);
  end;
var
  Form1: TForm1;
implementation
{$R *.dfm}

{ Here is the implementation of the OnHint event handler }
{ It displays the application's current hint in the status bar }
procedure TForm1.DisplayHint(Sender: TObject);
begin
  StatusBar1.SimpleText := GetLongHint(Application.Hint);
end;
{ Here is the form's OnCreate event handler. }
{ It assign's the application's OnHint event handler at runtime }
{ because the Application is not available in the Object Inspector }
{ at design time }
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnHint := DisplayHint;
end;
```

32.3.12 Controls.GetShortHint Function

Returns the first part of a two-part hint string.

Pascal

```
function GetShortHint(const Hint: string): string;
```

C++

```
AnsiString GetShortHint(const AnsiString Hint);
```

File

Controls

Description

Call GetShortHint to obtain the short version of the hint specified as the value of a Hint property. The first part of the hint is the text preceding the | character. If the Hint string value is not separated into two parts, GetShortHint returns the entire string.

See Also

GetLongHint (see page 6252)

TApplication

TApplication

TControl (see page 5724)

32.3.13 Controls.IdentToCursor Function

Translates a predefined cursor constant into a cursor.

Pascal

```
function IdentToCursor(const Ident: string; var Cursor: Longint): Boolean;
```

C++

```
Boolean IdentToCursor(const AnsiString Ident, Longint Cursor);
```

File

Controls

Description

Call IdentToCursor to reverse the translation performed by the CursorToIdent (see page 6247) function. This method is useful for converting the strings generated by GetCursorValues (see page 6251) into useable cursors. IdentToCursor returns true if the Ident parameter is successfully converted into a cursor. IdentToCursor returns false if the Ident parameter is not the name of one of the built-in cursor constants.

Note: If the string identifier for a cursor may represent either a numeric value or a cursor constant, use the StringToCursor (see page 6264) function instead.

See Also

TControl (see page 5724)

CursorToIdent (see page 6247)

StringToCursor (see page 6264)

GetCursorValues (see page 6251)

32.3.14 Controls.Imm32GetCompositionString Function

Pascal

```
function Imm32GetCompositionString(hImc: HIMC; dWord1: DWORD; lpBuf: pointer; dwBufLen:
DWORD): Longint;
```

C++

```
Longint Imm32GetCompositionString(HIMC hImc, DWORD dWord1, void * lpBuf, DWORD dwBufLen);
```

File

Controls

Description

This is function Controls.Imm32GetCompositionString.

32.3.15 Controls.Imm32GetContext Function

Pascal

```
function Imm32GetContext(hWnd: HWND): HIMC;
```

C++

```
HIMC Imm32GetContext(HWND hWnd);
```

File

Controls

Description

This is function Controls.Imm32GetContext.

32.3.16 Controls.Imm32GetConversionStatus Function

Pascal

```
function Imm32GetConversionStatus(hImc: HIMC; var Conversion: DWORD; var Sentence: DWORD):
Boolean;
```

C++

```
Boolean Imm32GetConversionStatus(HIMC hImc, DWORD Conversion, DWORD Sentence);
```

File

Controls

Description

This is function Controls.Imm32GetConversionStatus.

32.3.17 Controls.Imm32IsIME Function

Pascal

```
function Imm32IsIME(hKl: HKL): Boolean;
```

C++

```
Boolean Imm32IsIME(HKL hKl);
```

File

Controls

Description

This is function Controls.Imm32IsIME.

32.3.18 Controls.Imm32NotifyIME Function

Pascal

```
function Imm32NotifyIME(hImc: HIMC; dwAction: DWORD; dwIndex: DWORD; dwValue: DWORD): Boolean;
```

C++

```
Boolean Imm32NotifyIME(HIMC hImc, DWORD dwAction, DWORD dwIndex, DWORD dwValue);
```

File

Controls

Description

This is function Controls.Imm32NotifyIME.

32.3.19 Controls.Imm32ReleaseContext Function

Pascal

```
function Imm32ReleaseContext(hWnd: HWND; hImc: HIMC): Boolean;
```

C++

```
Boolean Imm32ReleaseContext(HWND hWnd, HIMC hImc);
```

File

Controls

Description

This is function Controls.Imm32ReleaseContext.

32.3.20 Controls.Imm32SetCompositionFont Function

Pascal

```
function Imm32SetCompositionFont(hImc: HIMC; lpLogfont: PLOGFONTA): Boolean;
```

C++

```
Boolean Imm32SetCompositionFont(HIMC hImc, PLOGFONTA lpLogfont);
```

File

Controls

Description

This is function Controls.Imm32SetCompositionFont.

32.3.21 Controls.Imm32SetCompositionWindow Function

Pascal

```
function Imm32SetCompositionWindow(hImc: HIMC; lpCompForm: PCOMPOSITIONFORM): Boolean;
```

C++

```
Boolean Imm32SetCompositionWindow(HIMC hImc, PCOMPOSITIONFORM lpCompForm);
```

File

Controls

Description

This is function Controls.Imm32SetCompositionWindow.

32.3.22 Controls.Imm32SetConversionStatus Function

Pascal

```
function Imm32SetConversionStatus(hImc: HIMC; Conversion: DWORD; Sentence: DWORD): Boolean;
```

C++

```
Boolean Imm32SetConversionStatus(HIMC hImc, DWORD Conversion, DWORD Sentence);
```

File

Controls

Description

This is function Controls.Imm32SetConversionStatus.

32.3.23 Controls.Imm32SetOpenStatus Function

Pascal

```
function Imm32SetOpenStatus(hImc: HIMC; fOpen: Boolean): Boolean;
```

C++

```
Boolean Imm32SetOpenStatus(HIMC hImc, Boolean fOpen);
```

File

Controls

Description

This is function Controls.Imm32SetOpenStatus.

32.3.24 Controls.InitWndProc Function

Pascal

```
function InitWndProc(HWindow: HWnd; Message: Longint; WParam: Longint; LParam: Longint):
Longint; stdcall;
```

C++

```
__stdcall Longint InitWndProc(HWnd HWindow, Longint Message, Longint WParam, Longint LParam);
```

File

Controls

Description

This is function Controls.InitWndProc.

32.3.25 Controls.IsAbortResult Function

Checks the return value from a modal form dialog and indicates whether the user selected Abort or Cancel.

Pascal

```
function IsAbortResult(const AModalResult: TModalResult): Boolean;
```

C++

```
Boolean IsAbortResult(const TModalResult AModalResult);
```

File

Controls

Description

Call IsAbortResult to check whether the user clicked "Abort" or "Cancel" to close a modal form. Pass the return value from the form's ShowModal method as the AModalResult argument. IsAbortResult returns true if AModalResult is mrAbort (see page 6372) or mrCancel (see page 6373), false otherwise.

32.3.26 Controls.IsAnAllResult Function

Checks the return value from a modal form dialog and indicates whether the user selected All, Yes to All, or No to All.

Pascal

```
function IsAnAllResult(const AModalResult: TModalResult): Boolean;
```

C++

```
Boolean IsAnAllResult(const TModalResult AModalResult);
```

File

Controls

Description

Call IsAnAllResult to check whether the user closed a modal form by indicating a response that applies to "all". Pass the return value from the form's ShowModal method as the AModalResult argument. IsAnAllResult returns true if AModalResult is mrAll (see page 6372), mrNoToAll (see page 6375), or mrYesToAll (see page 6376), false otherwise.

Note: If IsAnAllResult returns

true, you can convert the result to a simple Ok, No, or Yes result by calling StripAllFromResult (see page 6265).

32.3.27 Controls.IsDragObject Function

Indicates whether a specified object is a TDragObject (see page 6031) descendant.

Pascal

```
function IsDragObject(Sender: TObject): Boolean;
```

C++

```
Boolean IsDragObject(TObject * Sender);
```

File

Controls

Description

Use IsDragObject to determine whether the object being dragged in a drag-and-drop or drag-and-dock operation is a specialized TDragObject (see page 6031) that represents the dragged control's data rather then the control itself. Use IsDragObject on the

Source parameter in an OnDragOver or OnDockOver event handler to determine the type of object being dragged and whether it should be accepted. Use IsDragObject on the Source parameter of an OnDragDrop or OnDockDrop event handler to determine how to interpret the dragged object's data.

Customizing Drag and Drop with a Drag Object

32.3.28 Controls.IsNegativeResult Function

Checks the return value from a modal form dialog and indicates whether the user selected No or No to All.

Pascal

```
function IsNegativeResult(const AModalResult: TModalResult): Boolean;
```

C++

```
Boolean IsNegativeResult(const TModalResult AModalResult);
```

File

Controls

Description

Call IsNegativeResult to check whether the user closed a modal form by indicating a "No" response. Pass the return value from the form's ShowModal method as the AModalResult argument. IsNegativeResult returns true if AModalResult is mrNo (see page 6374) or mrNoToAll (see page 6375), false otherwise.

32.3.29 Controls.IsPositiveResult Function

Checks the return value from a modal form dialog and indicates whether the user selected Ok, Yes, Yes to All, or All.

Pascal

```
function IsPositiveResult(const AModalResult: TModalResult): Boolean;
```

C++

```
Boolean IsPositiveResult(const TModalResult AModalResult);
```

File

Controls

Description

Call IsPositiveResult to check whether the user closed a modal form by indicating a "Yes" or "Ok" response. Pass the return value from the form's ShowModal method as the AModalResult argument. IsPositiveResult returns true if AModalResult is mrYes (see page 6376), mrOk (see page 6375), mrYesToAll (see page 6376) or mrAll (see page 6372), false otherwise.

TCustomForm

32.3.30 Controls.IsVCLControl Function

IsVCLControl returns true if a control is a VCL control.

Pascal

```
function IsVCLControl(Handle: HWnd): Boolean;
```

C++

```
Boolean IsVCLControl(HWnd Handle);
```

File

Controls

Description

IsVCLControl returns true if the visual control specified by the Windows **Handle** is a VCL component. Otherwise, false is returned.

Use FindControl (see page 6249) to get a reference to the control via its handle.

See Also

FindControl (see page 6249)

32.3.31 Controls.MoveWindowOrg Function

Changes the location of the point (0,0) within a device context.

Pascal

```
procedure MoveWindowOrg(DC: HDC; DX: Integer; DY: Integer);
```

C++

```
MoveWindowOrg(HDC DC, int DX, int DY);
```

File

Controls

Description

Call MoveWindowOrg to change the location of where items are drawn on the canvas of an object. When drawing to a canvas, objects specify the location of the image they draw as a set of coordinates, which are offsets from the upper left corner. MoveWindowOrg allows the same drawing code to draw its image in a different location. The DC parameter is a handle to the device context of the canvas, printer, or window where the image is to be drawn. The DX and DY parameters specify the number of pixels to move the location of the (0,0) point on that drawing surface.

MoveWindowOrg is especially useful when playing metafiles, which draw to a particular position on a canvas, because it provides the ability to play the metafile to a different location on the canvas.

TWinControl (see page 6112)

32.3.32 Controls.PerformEraseBackground Function

Pascal

```
procedure PerformEraseBackground(Control: TControl; DC: HDC);
```

C++

```
PerformEraseBackground(TControl * Control, HDC DC);
```

File

Controls

Description

This is function Controls.PerformEraseBackground.

32.3.33 Controls.SendAppMessage Function

Sends a Windows message to the application.

Pascal

```
function SendAppMessage(Msg: Cardinal; WParam: Longint; LParam: Longint): Longint;
```

C++

```
Longint SendAppMessage(unsigned Msg, Longint WParam, Longint LParam);
```

File

Controls

Description

Call SendAppMessage to send a Windows message to the global application object.

Msg represents the Windows Message code.

WParam represents the WParam of the message. Its interpretation depends on the value of Msg.

LParam represents the LParam of the message. Its interpretation depends on the value of Msg.

SendAppMessage returns the result provided by the application's window procedure. If the application did not handle the message, SendAppMessage returns 0.

32.3.34 Controls.SetCaptureControl Function

Causes the specified control to receive all mouse messages.

Pascal

```
procedure SetCaptureControl(Control: TControl);
```

C++

```
SetCaptureControl(TControl * Control);
```

File

Controls

Description

Call SetCaptureControl to allow a control to capture the mouse. When the control has the mouse captured, it receives all mouse messages until another control captures the mouse.

SetCaptureControl is equivalent to SetMouseGrabControl.

Note: Many controls capture the mouse in response to mouse events. Application code should avoid explicitly capturing the mouse.

See Also

GetCaptureControl (see page 6251)

TControl (see page 5724)

TControl (see page 5724)

TControl (see page 5724)

SetMouseGrabControl

32.3.35 Controls.SetImeMode Function

Pascal

```
procedure SetImeMode(hWnd: HWND; Mode: TImeMode);
```

C++

```
SetImeMode(HWND hWnd, TImeMode Mode);
```

File

Controls

Description

This is function Controls.SetImeMode.

32.3.36 Controls.SetImeName Function

Pascal

```
procedure SetImeName(Name: TImeName);
```

C++

```
SetImeName(TImeName Name);
```

File

Controls

Description

This is function Controls.SetImeName.

32.3.37 Controls.StringToCursor Function

Returns a TCursor (see page 6305) value given its string representation.

Pascal

```
function StringToCursor(const S: string): TCursor;
```

C++

```
TCursor StringToCursor(const AnsiString S);
```

File

Controls

Description

Call StringToCursor to reverse the translation performed by CursorToString (see page 6248). This method is useful for converting the strings entered by the user into useable TCursor (see page 6305) values.

The S parameter can be either the name of a built-in cursor constant such as "crHelp (see page 6363)", or the string representation of a valid TCursor (see page 6305) value such as "10". StringToCursor returns the TCursor (see page 6305) value that corresponds to the S parameter.

Note: The value returned by StringToCursor is not guaranteed to be a valid cursor. If the Cursors property of the global Screen variable does not include a corresponding entry, the value returned by StringToCursor can not be used to set the Cursor property of a control.

See Also

TControl (see page 5724)

IdentToCursor (see page 6254)

CursorToString (see page 6248)

TScreen

32.3.38 Controls.StripAllFromResult Function

Converts a TModalResult (see page 6312) value from a constant that refers to "all" to the corresponding simple constant.

Pascal

```
function StripAllFromResult(const AModalResult: TModalResult): TModalResult;
```

C++

```
TModalResult StripAllFromResult(const TModalResult AModalResult);
```

File

Controls

Description

Call StripAllFromResult to remove the "all" interpretation from a TModalResult (see page 6312) value. For example, after checking the result from a form's ShowModal method with the IsAnAllResult (see page 6259) function, you can call StripAllFromResult to allow common code to process results that apply to a single selected item or all items.

StripAllFromResult makes the following conversions:

AModalResult	Return value
mrAll (see page 6372)	mrOk (see page 6375)
mrNoToAll (see page 6375)	mrNo (see page 6374)
mrYesToAll (see page 6376)	mrYes (see page 6376)

32.3.39 Controls.Win32NLSEnableIME Function

Pascal

```
function Win32NLSEnableIME(hWnd: HWND; Enable: Boolean): Boolean;
```

C++

```
Boolean Win32NLSEnableIME(HWND hWnd, Boolean Enable);
```

File

Controls

Description

This is function Controls.Win32NLSEnableIME.

32.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAlign (see page 6268)	TAlign specifies the alignment of a control within its parent.
	TAnchorKind (see page 6269)	TAnchorKind and TAnchors (see page 6294) specify how a control is anchored to its parent.
	TBevelCut (see page 6270)	TBevelCut specifies a bevel's cut.
	TBevelEdge (see page 6270)	TBevelEdge and TBevelEdges (see page 6295) specify which edges of a window are beveled.
	TBevelKind (see page 6271)	TBevelKind specifies the kind of bevel that appears on a control.
	TDockOrientation (see page 6282)	TDockOrientation specifies the orientation of controls in a docking zone.
	TDragKind (see page 6282)	TDragKind indicates the type of operation that occurs when the user drags a control.
	TDragMessage (see page 6283)	This is record Controls.TDragMessage.
	TDragMode (see page 6283)	TDragMode indicates how a control initiates drag operations.
	TDragState (see page 6284)	TDragState is used to specify how the mouse is moving in relation to a control.
	TImeMode (see page 6285)	TImeMode represents the current mode of an Input Method Editor (IME).
	TMouseActivate (see page 6287)	TMouseActivate defines values for the OnMouseActivate event.
	TMouseButton (see page 6288)	TMouseButton identifies a mouse button in a mouse-event handler.

Records

	Name	Description
	TAlignInfo (see page 6269)	This is record Controls.TAlignInfo.
	TCMCancelMode (see page 6272)	This is record Controls.TCMCancelMode.
	TCMChanged (see page 6272)	This is record Controls.TCMChanged.
	TCMChildKey (see page 6273)	This is record Controls.TCMChildKey.
	TCMControlChange (see page 6273)	This is record Controls.TCMControlChange.
	TCMControlListChange (see page 6274)	This is record Controls.TCMControlListChange.
	TCMControlListChanging (see page 6274)	This is record Controls.TCMControlListChanging.
	TCMCreatePopup (see page 6275)	This is record Controls.TCMCreatePopup.
	TCMDockClient (see page 6275)	This is record Controls.TCMDockClient.
	TCMDockNotification (see page 6276)	This is record Controls.TCMDockNotification.
	TCMDrag (see page 6276)	This is record Controls.TCMDrag.
	TCMFloat (see page 6277)	This is record Controls.TCMFloat.
	TCMFocusChanged (see page 6277)	This is record Controls.TCMFocusChanged.
	TCMMouseActivate (see page 6278)	This is record Controls.TCMMouseActivate.
	TCMMouseWheel (see page 6278)	This is record Controls.TCMMouseWheel.
	TCMPopupHWndDestroy (see page 6279)	This is record Controls.TCMPopupHWndDestroy.
	TCMUnDockClient (see page 6279)	This is record Controls.TCMUnDockClient.
	TControlListItem (see page 6280)	This is record Controls.TControlListItem.
	TCreateParams (see page 6280)	TCreateParams is the window-creation parameter record used to specify the type of window to create for a windowed control.
	TDockNotifyRec (see page 6281)	TDockNotifyRec represents the information from a Windows docking notification message, and PDockNotifyRec (see page 6291) is a pointer to a TDockNotifyRec value.
	TDragRec (see page 6284)	This is record Controls.TDragRec.
	TMouseActivateRec (see page 6288)	This is record Controls.TMouseActivateRec.
	TPopupFormInfo (see page 6289)	This is record Controls.TPopupFormInfo.

32.4.1 Controls.TAlign Enumeration

TAlign specifies the alignment of a control within its parent.

Pascal

```
TAlign = (
  alNone,
  alTop,
  alBottom,
  alLeft,
  alRight,
  alClient,
  alCustom
);
```

C++

```
enum TAlign {
  alNone,
  alTop,
  alBottom,
  alLeft,
  alRight,
  alClient,
  alCustom
};
```

File

Controls

Description

TAlign specifies how a control is placed relative to its parent. It can have one of the following values:

Value	Meaning
alNone	The control remains where it was placed. This is the default value.
alTop	The control moves to the top of its parent and resizes to fill the width of its parent. The height of the control is not affected.
alBottom	The control moves to the bottom of its parent and resizes to fill the width of its parent. The height of the control is not affected.
alLeft	The control moves to the left side of its parent and resizes to fill the height of its parent. The width of the control is not affected.
alRight	The control moves to the right side of its parent and resizes to fill the height of its parent. The width of the control is not affected.
alClient	The control resizes to fill the client area of its parent. If another control already occupies part of the client area, the control resizes to fit within the remaining client area.
alCustom	The control's positioning is determined by calls to its parent's CustomAlignInsertBefore and CustomAlignPosition methods.

See Also

CustomAlignInsertBefore

CustomAlignPosition

32.4.2 Controls.TAlignInfo Record

Pascal

```
TAlignInfo = record
  AlignList: TList;
  ControlIndex: Integer;
  Align: TAlign;
  Scratch: Integer;
end;
```

C++

```
struct TAlignInfo {
  TList AlignList;
  int ControlIndex;
  TAlign Align;
  int Scratch;
};
```

File

Controls

Description

This is record Controls.TAlignInfo.

32.4.3 Controls.TAnchorKind Enumeration

TAnchorKind and TAnchors (see page 6294) specify how a control is anchored to its parent.

Pascal

```
TAnchorKind = (
  akLeft,
  akTop,
  akRight,
  akBottom
);
```

C++

```
enum TAnchorKind {
  akLeft,
  akTop,
  akRight,
  akBottom
};
```

File

Controls

Description

TAnchors (see page 6294) is a set of TAnchorKind values. TAnchorKind can have one or more of the following values:

Value	Meaning
akTop	The control's position is fixed with respect to the top edge of its parent.

akLeft	The control's position is fixed with respect to the left edge of its parent.
akRight	The control's position is fixed with respect to the right edge of its parent.
akBottom	The control's position is fixed with respect to the bottom edge of its parent.

32.4.4 Controls.TBevelCut Enumeration

TBevelCut specifies a bevel's cut.

Pascal

```
TBevelCut = (
  bvNone,
  bvLowered,
  bvRaised,
  bvSpace
);
```

C++

```
enum TBevelCut {
  bvNone,
  bvLowered,
  bvRaised,
  bvSpace
};
```

File

Controls

Description

TBevelCut can have one of the following values:

Value	Meaning
bvNone	The bevel does not exist.
bvLowered	The bevel appears lowered.
bvRaised	The bevel appears raised.
bvSpace	The bevel appears as a space if its kind is not bkTile. Otherwise, the bevel appears raised.

See Also

TWinControl

TWinControl

32.4.5 Controls.TBevelEdge Enumeration

TBevelEdge and TBevelEdges (see page 6295) specify which edges of a window are beveled.

Pascal

```
TBevelEdge = (
  beLeft,
```

```
    beTop,
    beRight,
    beBottom
  );
```

C++

```
  enum TBevelEdge {
    beLeft,
    beTop,
    beRight,
    beBottom
  };
```

File

Controls

Description

TBevelEdges (see page 6295) can have one or more of the following values:

Value	Meaning
beLeft	The left edge is beveled.
beTop	The top edge is beveled.
beRight	The right edge is beveled.
beBottom	The bottom edge is beveled.

32.4.6 Controls.TBevelKind Enumeration

TBevelKind specifies the kind of bevel that appears on a control.

Pascal

```
  TBevelKind = (
    bkNone,
    bkTile,
    bkSoft,
    bkFlat
  );
```

C++

```
  enum TBevelKind {
    bkNone,
    bkTile,
    bkSoft,
    bkFlat
  };
```

File

Controls

Description

TBevelKind can have one of the following values:

Value	Meaning
bkNone	No bevel is added.

bkTile	The bevel appears sharply defined.
bkSoft	The bevel uses softer contrasts than bkTile.
bkFlat	The bevel has a broad, flat appearance.

32.4.7 Controls.TCMCancelMode Record

Pascal

```
TCMCancelMode = record
  Msg: Cardinal;
  Unused: Integer;
  Sender: TControl;
  Result: Longint;
end;
```

C++

```
struct TCMCancelMode {
  unsigned Msg;
  int Unused;
  TControl * Sender;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMCancelMode.

32.4.8 Controls.TCMChanged Record

Pascal

```
TCMChanged = record
  Msg: Cardinal;
  Unused: Longint;
  Child: TControl;
  Result: Longint;
end;
```

C++

```
struct TCMChanged {
  unsigned Msg;
  Longint Unused;
  TControl * Child;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMChanged.

32.4.9 Controls.TCMChildKey Record

Pascal

```
TCMChildKey = record
  Msg: Cardinal;
  CharCode: Word;
  Unused: Word;
  Sender: TWinControl;
  Result: Longint;
end;
```

C++

```
struct TCMChildKey {
  unsigned Msg;
  Word CharCode;
  Word Unused;
  TWinControl * Sender;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMChildKey.

32.4.10 Controls.TCMControlChange Record

Pascal

```
TCMControlChange = record
  Msg: Cardinal;
  Control: TControl;
  Inserting: LongBool;
  Result: Longint;
end;
```

C++

```
struct TCMControlChange {
  unsigned Msg;
  TControl * Control;
  LongBool Inserting;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMControlChange.

32.4.11 Controls.TCMControlListChange Record

Pascal

```
TCMControlListChange = record
  Msg: Cardinal;
  Control: TControl;
  Inserting: LongBool;
  Result: Longint;
end;
```

C++

```
struct TCMControlListChange {
  unsigned Msg;
  TControl * Control;
  LongBool Inserting;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMControlListChange.

32.4.12 Controls.TCMControlListChanging Record

Pascal

```
TCMControlListChanging = record
  Msg: Cardinal;
  ControlListItem: PControlListItem;
  Inserting: LongBool;
  Result: Longint;
end;
```

C++

```
struct TCMControlListChanging {
  unsigned Msg;
  PControlListItem ControlListItem;
  LongBool Inserting;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMControlListChanging.

32.4.13 Controls.TCMCreatePopup Record

Pascal

```
TCMCreatePopup = packed record
  Msg: Cardinal;
  PopupID: Integer;
  OwnerWnd: HWND;
  Result: Integer;
end;
```

C++

```
struct TCMCreatePopup {
  unsigned Msg;
  int PopupID;
  HWND OwnerWnd;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMCreatePopup.

32.4.14 Controls.TCMDockClient Record

Pascal

```
TCMDockClient = packed record
  Msg: Cardinal;
  DockSource: TDragDockObject;
  MousePos: TSmallPoint;
  Result: Integer;
end;
```

C++

```
struct TCMDockClient {
  unsigned Msg;
  TDragDockObject DockSource;
  TSmallPoint MousePos;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMDockClient.

32.4.15 Controls.TCMDockNotification Record

Pascal

```
TCMDockNotification = packed record
  Msg: Cardinal;
  Client: TControl;
  NotifyRec: PDockNotifyRec;
  Result: Integer;
end;
```

C++

```
struct TCMDockNotification {
  unsigned Msg;
  TControl * Client;
  PDockNotifyRec NotifyRec;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMDockNotification.

32.4.16 Controls.TCMDrag Record

Pascal

```
TCMDrag = packed record
  Msg: Cardinal;
  DragMessage: TDragMessage;
  Reserved1: Byte;
  Reserved2: Word;
  DragRec: PDragRec;
  Result: Longint;
end;
```

C++

```
struct TCMDrag {
  unsigned Msg;
  TDragMessage DragMessage;
  Byte Reserved1;
  Word Reserved2;
  PDragRec DragRec;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMDrag.

32.4.17 Controls.TCMFloat Record

Pascal

```
TCMFloat = packed record
  Msg: Cardinal;
  Reserved: Integer;
  DockSource: TDragDockObject;
  Result: Integer;
end;
```

C++

```
struct TCMFloat {
  unsigned Msg;
  int Reserved;
  TDragDockObject DockSource;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMFloat.

32.4.18 Controls.TCMFocusChanged Record

Pascal

```
TCMFocusChanged = record
  Msg: Cardinal;
  Unused: Integer;
  Sender: TWinControl;
  Result: Longint;
end;
```

C++

```
struct TCMFocusChanged {
  unsigned Msg;
  int Unused;
  TWinControl * Sender;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMFocusChanged.

32.4.19 Controls.TCMMouseActivate Record

Pascal

```
TCMMouseActivate = packed record
  Msg: Cardinal;
  Reserved: Integer;
  MouseActivateRec: PMouseActivateRec;
  Result: Integer;
end;
```

C++

```
struct TCMMouseActivate {
  unsigned Msg;
  int Reserved;
  PMouseActivateRec MouseActivateRec;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMMouseActivate.

32.4.20 Controls.TCMMouseWheel Record

Pascal

```
TCMMouseWheel = record
  Msg: Cardinal;
  ShiftState: TShiftState;
  Unused: Byte;
  WheelDelta: SmallInt;
  case Integer of
    0: (XPos: Smallint;
        YPos: Smallint;);
    1: (Pos: TSmallPoint;
        Result: Longint;);
end;
```

C++

```
struct TCMMouseWheel {
  unsigned Msg;
  TShiftState ShiftState;
  Byte Unused;
  SmallInt WheelDelta;
  Smallint XPos;
  Smallint YPos;
  TSmallPoint Pos;
  Longint Result;
};
```

File

Controls

Description

This is record Controls.TCMMouseWheel.

32.4.21 Controls.TCMPopupHWndDestroy Record

Pascal

```
TCMPopupHWndDestroy = packed record
  Msg: Cardinal;
  PopupFormInfo: PPopupFormInfo;
  PopupControlWnd: HWND;
  Result: Integer;
end;
```

C++

```
struct TCMPopupHWndDestroy {
  unsigned Msg;
  PPopupFormInfo PopupFormInfo;
  HWND PopupControlWnd;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMPopupHWndDestroy.

32.4.22 Controls.TCMUnDockClient Record

Pascal

```
TCMUnDockClient = packed record
  Msg: Cardinal;
  NewTarget: TControl;
  Client: TControl;
  Result: Integer;
end;
```

C++

```
struct TCMUnDockClient {
  unsigned Msg;
  TControl * NewTarget;
  TControl * Client;
  int Result;
};
```

File

Controls

Description

This is record Controls.TCMUnDockClient.

32.4.23 Controls.TControlListItem Record

Pascal

```
TControlListItem = record
  Control: TControl;
  Parent: TWinControl;
end;
```

C++

```
struct TControlListItem {
  TControl * Control;
  TWinControl * Parent;
};
```

File

Controls

Description

This is record Controls.TControlListItem.

32.4.24 Controls.TCreateParams Record

TCreateParams is the window-creation parameter record used to specify the type of window to create for a windowed control.

Pascal

```
TCreateParams = record
  Caption: PChar;
  Style: DWORD;
  ExStyle: DWORD;
  X: Integer;
  Y: Integer;
  Height: Integer;
  Width: Integer;
  WndParent: HWnd;
  Param: Pointer;
  WindowClass: TWndClass;
  WinClassName: array[0..63] of Char;
end;
```

C++

```
struct TCreateParams {
  const char * Caption;
  DWORD Style;
  DWORD ExStyle;
  int X;
  int Y;
  int Height;
  int Width;
  HWnd WndParent;
  void * Param;
  TWndClass WindowClass;
  array[0..63] of Char WinClassName;
};
```

File

Controls

Description

TCreateParams is a data structure for holding information needed when telling Windows to create a window. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function. TCreateParams contains the following fields:

Field	Meaning
Caption	The window caption. This is usually the value of the Caption or Text property of the control.
Style	The Windows style for the window. This is a bit array of flags such as WS_CHILD or WS_DISABLED. See the Microsoft Windows documentation for possible flags.
ExStyle	The extended Windows style for the window. This is one of the Windows predefined extended style constants such as WS_EX_TOOLWINDOW or WS_EX_CONTROLPARENT. See the Microsoft Windows documentation for possible values.
X	The x coordinate of the left side of the window. This is usually the same as the Left property.
Y	The y coordinate of the top of the window. This is usually the same as the Top property.
Width	The width, in pixels, of the window. This is usually the same as the Width property.
Height	The height, in pixels, of the window. This is usually the same as the Height property.
WndParent	The window handle of the parent window. This is the same as the Handle property of the parent control.
Param	A pointer to the windows creation parameter that is passed as the LParam of the WM_CREATE message.
WindowClass	The WindowClass record that describes the class of window being created. The WindowClass record includes information about the window procedure, style, default cursor, background brush, associated menus, and so on.
WinClassName	The window class name. This must be the name of a window class that has already been registered. Windows provides several built-in window classes with predefined names. Applications may also register their own custom window classes.

TWinControl

32.4.25 Controls.TDockNotifyRec Record

TDockNotifyRec represents the information from a Windows docking notification message, and PDockNotifyRec (see page 6291) is a pointer to a TDockNotifyRec value.

Pascal

```
TDockNotifyRec = record
  ClientMsg: Cardinal;
  MsgWParam: Integer;
  MsgLParam: Integer;
end;
```

C++

```
struct TDockNotifyRec {
  unsigned ClientMsg;
  int MsgWParam;
  int MsgLParam;
```

```
};
```

File

Controls

Description

ClientMsg is the Windows message ID.

MsgWParam is the message's WParam.

MsgLParam is the message's LParam.

32.4.26 Controls.TDockOrientation Enumeration

TDockOrientation specifies the orientation of controls in a docking zone.

Pascal

```
TDockOrientation = (
  doNoOrient,
  doHorizontal,
  doVertical
);
```

C++

```
enum TDockOrientation {
  doNoOrient,
  doHorizontal,
  doVertical
};
```

File

Controls

Description

TDockOrientation can have one of the following values:

Value	Meaning
doNoOrient	The zone contains a control instead of child zones.
doHorizontal	The zone's children are arranged top to bottom.
doVertical	The zone's children are arranged left to right.

32.4.27 Controls.TDragKind Enumeration

TDragKind indicates the type of operation that occurs when the user drags a control.

Pascal

```
TDragKind = (
  dkDrag,
  dkDock
);
```

C++

```
enum TDragKind {
  dkDrag,
  dkDock
};
```

File

Controls

Description

TDragKind can have one of the following values:

Value	Meaning
dkDrag	The object is being dragged for a drag-and-drop operation.
dkDock	The object is being dragged for a drag-and-dock operation.

32.4.28 Controls.TDragMessage Enumeration

Pascal

```
TDragMessage = (
  dmDragEnter,
  dmDragLeave,
  dmDragMove,
  dmDragDrop,
  dmDragCancel,
  dmFindTarget
);
```

C++

```
enum TDragMessage {
  dmDragEnter,
  dmDragLeave,
  dmDragMove,
  dmDragDrop,
  dmDragCancel,
  dmFindTarget
};
```

File

Controls

Description

This is record Controls.TDragMessage.

32.4.29 Controls.TDragMode Enumeration

TDragMode indicates how a control initiates drag operations.

Pascal

```
TDragMode = (
```

```
    dmManual,
    dmAutomatic
  );
```

C++

```
  enum TDragMode {
    dmManual,
    dmAutomatic
  };
```

File

Controls

Description

TDragMode can have one of the following values:

Value	Meaning
dmAutomatic	The control begins a drag operation automatically when the user clicks and drags it.
dmManual	The control can't be dragged until the application calls the BeginDrag method.

32.4.30 Controls.TDragRec Record

Pascal

```
  TDragRec = record
    Pos: TPoint;
    Source: TDragObject;
    Target: Pointer;
    Docking: Boolean;
  end;
```

C++

```
  struct TDragRec {
    TPoint Pos;
    TDragObject Source;
    void * Target;
    Boolean Docking;
  };
```

File

Controls

Description

This is record Controls.TDragRec.

32.4.31 Controls.TDragState Enumeration

TDragState is used to specify how the mouse is moving in relation to a control.

Pascal

```
  TDragState = (
    dsDragEnter,
```

```
    dsDragLeave,
    dsDragMove
  );
```

C++

```
  enum TDragState {
    dsDragEnter,
    dsDragLeave,
    dsDragMove
  };
```

File

Controls

Description

TDragState describes how the mouse is moving in relation to a control that it is passing over. It has one of the following values:

Value	Meaning
dsDragEnter	The mouse just moved over the control.
dsDragLeave	The mouse is moving off of the control.
dsDragMove	The mouse is moving while over the control.

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
```

32.4.32 Controls.TImeMode Enumeration

TImeMode represents the current mode of an Input Method Editor (IME).

Pascal

```
  TImeMode = (
    imDisable,
```

```
    imClose,
    imOpen,
    imDontCare,
    imSAlpha,
    imAlpha,
    imHira,
    imSKata,
    imKata,
    imChinese,
    imSHanguel,
    imHanguel
  );
```

C++

```
  enum TImeMode {
    imDisable,
    imClose,
    imOpen,
    imDontCare,
    imSAlpha,
    imAlpha,
    imHira,
    imSKata,
    imKata,
    imChinese,
    imSHanguel,
    imHanguel
  };
```

File

Controls

Description

TImeMode represents the way an Input Method Editor operates to convert keyboard input typed on an Asian version of Windows. TImeMode has the following values:

Value	Meaning
imDisable	Shut down the IME. imDisable has no effect on Chinese, Taiwanese, or Korean IMEs.
imClose	Close the IME conversion window, but leave the IME running in the background. The IME can be reactivated by a hot key combination.
imOpen	Open the IME conversion window. The conversion mode is the last conversion mode used by the IME.
imDontCare	Launch the IME if it is disabled. The conversion mode is the last conversion mode used by the IME.
imSAlpha	Open the IME conversion window and set the conversion mode to accept single-width Roman alphabet input.
imAlpha	Open the IME conversion window and set the conversion mode to accept double-width Roman alphabet input.
imHira	Open the IME conversion window and set the conversion mode to double-width Hiragana. imHira is only available for Japanese IMEs.
imSKata	Open the IME conversion window and set the conversion mode to single-width Katakana (Hankaku Katakana). imSKata is only available for Japanese IMEs.
imKata	Open the IME conversion window and set the conversion mode to double-width Katakana (Zenkaku Katakana). imKata is only available for Japanese IMEs.
imChinese	Open the IME conversion window and set the conversion mode to double-width Chinese. imChinese is only available for Chinese IMEs.
imSHanguel	Open the IME conversion window and set the conversion mode to single-width Hanguel. imSHanguel is only available for Korean IMEs.

imHanguel	Open the IME conversion window and set the conversion mode to double-width Hanguel. imHanguel is only available for Korean IMEs.

32.4.33 Controls.TMouseActivate Enumeration

TMouseActivate defines values for the OnMouseActivate event.

Pascal

```
TMouseActivate = (
  maDefault,
  maActivate,
  maActivateAndEat,
  maNoActivate,
  maNoActivateAndEat
);
```

C++

```
enum TMouseActivate {
  maDefault,
  maActivate,
  maActivateAndEat,
  maNoActivate,
  maNoActivateAndEat
};
```

File

Controls

Description

The TMouseActivate type provides the following values to the OnMouseActivate event.

Type	Description
maDefault	Allows the parent control to process the OnMouseActivate event.
maActivate	Activates the top level form and allows the mouse button down message to go through. No Parent window processing occurs.
maActivateAndEat	Same as maActivate, except that the button down message is suppressed.
maNoActivate	Does not activate the top-level window, but allows the mouse button down message to continue to be processed.
maNoActivateAndEat	Same as maNoActivate, except that the button down message is suppressed.

TControl

TControl

32.4.34 Controls.TMouseActivateRec Record

Pascal

```
TMouseActivateRec = record
  MousePos: TPoint;
  HitTest: Integer;
  Button: TMouseButton;
  ShiftState: TShiftState;
  TopLevel: HWND;
end;
```

C++

```
struct TMouseActivateRec {
  TPoint MousePos;
  int HitTest;
  TMouseButton Button;
  TShiftState ShiftState;
  HWND TopLevel;
};
```

File

Controls

Description

This is record Controls.TMouseActivateRec.

32.4.35 Controls.TMouseButton Enumeration

TMouseButton identifies a mouse button in a mouse-event handler.

Pascal

```
TMouseButton = (
  mbLeft,
  mbRight,
  mbMiddle
);
```

C++

```
enum TMouseButton {
  mbLeft,
  mbRight,
  mbMiddle
};
```

File

Controls

Description

The TMouseButton type defines the mouse-button constants used by mouse-event handlers to distinguish which button generated the mouse event.

32.4.36 Controls.TPopupFormInfo Record

Pascal

```
TPopupFormInfo = record
  PopupID: Integer;
  PopupWnd: HWND;
  IsPopup: Boolean;
end;
```

C++

```
struct TPopupFormInfo {
  int PopupID;
  HWND PopupWnd;
  Boolean IsPopup;
};
```

File

Controls

Description

This is record Controls.TPopupFormInfo.

32.5 Types

The following table lists types in this documentation.

Types

Name	Description
PControlListItem (see page 6291)	This is type Controls.PControlListItem.
PDockNotifyRec (see page 6291)	This is type Controls.PDockNotifyRec.
PDragRec (see page 6292)	This is type Controls.PDragRec.
PMouseActivateRec (see page 6292)	This is type Controls.PMouseActivateRec.
PPopupFormInfo (see page 6292)	This is type Controls.PPopupFormInfo.
TAlignInsertBeforeEvent (see page 6293)	TAlignInsertBeforeEvent is the function type for an OnAlignInsertBefore event.
TAlignPositionEvent (see page 6293)	TAlignPositionEvent is the function type for an OnAlignPosition event.
TAlignSet (see page 6294)	TAlignSet specifies the alignment of a child control within its parent.
TAnchors (see page 6294)	TBorderWidth (see page 6296) defines the distance, in pixels, between the outer and inner bevels of a control.
TAnimateWindowProc (see page 6295)	This is type Controls.TAnimateWindowProc.
TBevelEdges (see page 6295)	TBevelEdge (see page 6270) and TBevelEdges specify which edges of a window are beveled.
TBevelWidth (see page 6296)	This is type Controls.TBevelWidth.
TBorderWidth (see page 6296)	This is type Controls.TBorderWidth.
TCanResizeEvent (see page 6296)	TCanResizeEvent is the type of the OnCanResize event handler.
TCaption (see page 6297)	TCaption is the type of the Caption property.
TCMActivate (see page 6297)	This is type Controls.TCMActivate.
TCMDeactivate (see page 6297)	This is type Controls.TCMDeactivate.
TCMDesignHitTest (see page 6298)	This is type Controls.TCMDesignHitTest.
TCMDialogChar (see page 6298)	This is type Controls.TCMDialogChar.
TCMDialogKey (see page 6298)	This is type Controls.TCMDialogKey.
TCMEnter (see page 6299)	This is type Controls.TCMEnter.
TCMExit (see page 6299)	This is type Controls.TCMExit.
TCMGotFocus (see page 6299)	This is type Controls.TCMGotFocus.
TCMHitTest (see page 6300)	This is type Controls.TCMHitTest.
TCMLostFocus (see page 6300)	This is type Controls.TCMLostFocus.
TCMWantSpecialKey (see page 6300)	This is type Controls.TCMWantSpecialKey.
TConstrainedResizeEvent (see page 6301)	This is type Controls.TConstrainedResizeEvent.
TConstraintSize (see page 6301)	This is type Controls.TConstraintSize.
TContextPopupEvent (see page 6301)	This is type Controls.TContextPopupEvent.
TControlActionLinkClass (see page 6302)	TControlActionLinkClass defines the metaclass for TControlActionLink (see page 5892).
TControlClass (see page 6302)	TControlClass defines the metaclass for TControl (see page 5724).
TControlState (see page 6302)	TControlState describes the current state of a control.
TControlStyle (see page 6303)	The TControlStyle type describes the current style of the control.
TCursor (see page 6305)	TCursor identifies the cursor type.
TDate (see page 6306)	TDate is used to represent a date.
TDockDropEvent (see page 6307)	TDockDropEvent is the type of the OnDockDrop event handler.
TDockOverEvent (see page 6307)	TDockOverEvent is the type of the OnDockOver event handler.
TDockTreeClass (see page 6308)	TDockTreeClass defines the metaclass for TDockTree (see page 5983).
TDragDropEvent (see page 6308)	This is type Controls.TDragDropEvent.
TDragObjectClass (see page 6308)	TDragObjectClass defines the metaclass for TDragObject (see page 6031).
TDragOverEvent (see page 6309)	This is type Controls.TDragOverEvent.
TEndDragEvent (see page 6309)	This is type Controls.TEndDragEvent.

TForEachZoneProc (see page 6309)	This is type Controls.TForEachZoneProc.
TGetSiteInfoEvent (see page 6310)	TGetSiteInfoEvent is the type of the OnGetSiteInfo event handler.
THintWindowClass (see page 6310)	THintWindowClass defines the metaclass for THintWindow (see page 6055).
TImeName (see page 6311)	TImeName is the type that represents the name of an Input Method Editor.
TKeyEvent (see page 6311)	This is type Controls.TKeyEvent.
TKeyPressEvent (see page 6311)	This is type Controls.TKeyPressEvent.
TMarginSize (see page 6312)	This is type Controls.TMarginSize.
TModalResult (see page 6312)	TModalResult represents the return value from a modal dialog.
TMouseActivateEvent (see page 6313)	This is type Controls.TMouseActivateEvent.
TMouseEvent (see page 6313)	This is type Controls.TMouseEvent.
TMouseMoveEvent (see page 6314)	This is type Controls.TMouseMoveEvent.
TMouseWheelEvent (see page 6314)	This is type Controls.TMouseWheelEvent.
TMouseWheelUpDownEvent (see page 6314)	This is type Controls.TMouseWheelUpDownEvent.
TPanningWindowClass (see page 6315)	TPanningWindowClass defines the metaclass for TPanningWindow.
TScalingFlags (see page 6315)	TScalingFlags describes the way controls are scaled.
TStartDockEvent (see page 6316)	TStartDockEvent is the type of the OnStartDock event handler.
TStartDragEvent (see page 6316)	This is type Controls.TStartDragEvent.
TTabOrder (see page 6317)	TTabOrder defines the tab order of a control.
TTime (see page 6317)	TTime is used to represent a time.
TUnDockEvent (see page 6317)	TUnDockEvent is the type of the OnUnDock event handler.
TWinControlActionLinkClass (see page 6318)	TWinControlActionLinkClass defines the metaclass for TWinControlActionLink (see page 6233).
TWinControlClass (see page 6318)	TWinControlClass defines the metaclass for TWinControl (see page 6112).
TWndMethod (see page 6319)	TWndMethod is the type for Windows message procedures.

32.5.1 Controls.PControlListItem Type

Pascal

```
PControlListItem = ^TControlListItem;
```

C++

```
^TControlListItem PControlListItem;
```

File

Controls

Description

This is type Controls.PControlListItem.

32.5.2 Controls.PDockNotifyRec Type

Pascal

```
PDockNotifyRec = ^TDockNotifyRec;
```

C++

```
^TDockNotifyRec PDockNotifyRec;
```

File

Controls

Description

This is type Controls.PDockNotifyRec.

32.5.3 Controls.PDragRec Type

Pascal

```
PDragRec = ^TDragRec;
```

C++

```
^TDragRec PDragRec;
```

File

Controls

Description

This is type Controls.PDragRec.

32.5.4 Controls.PMouseActivateRec Type

Pascal

```
PMouseActivateRec = ^TMouseActivateRec;
```

C++

```
^TMouseActivateRec PMouseActivateRec;
```

File

Controls

Description

This is type Controls.PMouseActivateRec.

32.5.5 Controls.PPopupFormInfo Type

Pascal

```
PPopupFormInfo = ^TPopupFormInfo;
```

C++

```
^TPopupFormInfo PPopupFormInfo;
```

File

Controls

Description

This is type Controls.PPopupFormInfo.

32.5.6 Controls.TAlignInsertBeforeEvent Type

TAlignInsertBeforeEvent is the function type for an OnAlignInsertBefore event.

Pascal

```
TAlignInsertBeforeEvent = function (Sender: TWinControl; C1, C2: TControl): Boolean of object;
```

C++

```
(Sender: TWinControl; C1, C2: TControl): Boolean ( TAlignInsertBeforeEvent)();
```

File

Controls

Description

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**. It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise.

TAlignInsertBeforeEvent has the following parameters:

Value	Meaning
Sender	Parent control.
C1	First control to be ordered.
C2	Second control to be ordered.

See Also

CustomAlignInsertBefore (see page 6137)

OnAlignInsertBefore (see page 6213)

32.5.7 Controls.TAlignPositionEvent Type

TAlignPositionEvent is the function type for an OnAlignPosition event.

Pascal

```
TAlignPositionEvent = procedure (Sender: TWinControl; Control: TControl; var NewLeft, NewTop,
NewWidth, NewHeight: Integer; var AlignRect: TRect; AlignInfo: TAlignInfo) of object;
```

C++

```
(Sender: TWinControl; Control: TControl; var NewLeft, NewTop, NewWidth, NewHeight: Integer;
var AlignRect: TRect; AlignInfo: TAlignInfo) ( TAlignPositionEvent)();
```

File

Controls

Description

CustomAlignPosition triggers the OnAlignPosition event. OnAlignPosition occurs for each child control with an Align property of **alCustom** when it is aligned. It can determine where the control is placed by specifying the alignment parameters.

TAlignPositionEvent has the following parameters:

Parameter	Meaning
Sender	Parent control.
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo (see page 6269).

See Also

CustomAlignPosition (see page 6138)

OnAlignPosition (see page 6214)

TAlignInfo (see page 6269)

32.5.8 Controls.TAlignSet Type

TAlignSet specifies the alignment of a child control within its parent.

Pascal

```
TAlignSet = set of TAlign;
```

C++

```
TAlign TAlignSet;
```

File

Controls

32.5.9 Controls.TAnchors Type

TBorderWidth (see page 6296) defines the distance, in pixels, between the outer and inner bevels of a control.

Pascal

```
TAnchors = set of TAnchorKind;
```

C++

```
TAnchorKind TAnchors;
```

File

Controls

Description

TBorderWidth (see page 6296) is used to specify the border width of a control via its BorderWidth property.

Note: Do not confuse the border of the panel with line drawn around the panel itself. The line around the panel is specified by the BorderStyle property.

See Also

BevelWidth (see page 13052)

BorderStyle (see page 13054)

32.5.10 Controls.TAnimateWindowProc Type

Pascal

```
TAnimateWindowProc = function (hWnd: HWND; dwTime: DWORD; dwFlags: DWORD): BOOL;
```

C++

```
(hWnd: HWND; dwTime: DWORD; dwFlags: DWORD): BOOL ( TAnimateWindowProc)();
```

File

Controls

Description

This is type Controls.TAnimateWindowProc.

32.5.11 Controls.TBevelEdges Type

TBevelEdge (see page 6270) and TBevelEdges specify which edges of a window are beveled.

Pascal

```
TBevelEdges = set of TBevelEdge;
```

C++

```
TBevelEdge TBevelEdges;
```

File

Controls

Description

TBevelEdges can have one or more of the following values:

Value	Meaning
beLeft	The left edge is beveled.
beTop	The top edge is beveled.
beRight	The right edge is beveled.
beBottom	The bottom edge is beveled.

32.5.12 Controls.TBevelWidth Type

Pascal

```
TBevelWidth = 1..MaxInt;
```

C++

```
1..MaxInt TBevelWidth;
```

File

Controls

Description

This is type Controls.TBevelWidth.

32.5.13 Controls.TBorderWidth Type

Pascal

```
TBorderWidth = 0..MaxInt;
```

C++

```
0..MaxInt TBorderWidth;
```

File

Controls

Description

This is type Controls.TBorderWidth.

32.5.14 Controls.TCanResizeEvent Type

TCanResizeEvent is the type of the OnCanResize event handler.

Pascal

```
TCanResizeEvent = procedure (Sender: TObject; var NewWidth, NewHeight: Integer; var Resize:
Boolean) of object;
```

C++

```
(Sender: TObject; var NewWidth, NewHeight: Integer; var Resize: Boolean) ( TCanResizeEvent)();
```

File

Controls

Description

Sender is the object that is being resized.

NewWidth returns the new width of the object.

NewHeight returns the new height of the object.

Resize returns true if the resize attempt can proceed and false if the attempt to resize should be aborted.

32.5.15 Controls.TCaption Type

TCaption is the type of the Caption property.

Pascal

```
TCaption = type string;
```

C++

```
type string TCaption;
```

File

Controls

Description

TCaption is the string that represents the caption or text of a control.

32.5.16 Controls.TCMActivate Type

Pascal

```
TCMActivate = TWMNoParams;
```

C++

```
TWMNoParams TCMActivate;
```

File

Controls

Description

This is type Controls.TCMActivate.

32.5.17 Controls.TCMDeactivate Type

Pascal

```
TCMDeactivate = TWMNoParams;
```

C++

```
TWMNoParams TCMDeactivate;
```

File

Controls

Description

This is type Controls.TCMDeactivate.

32.5.18 Controls.TCMDesignHitTest Type

Pascal

```
TCMDesignHitTest = TWMMouse;
```

C++

```
TWMMouse TCMDesignHitTest;
```

File

Controls

Description

This is type Controls.TCMDesignHitTest.

32.5.19 Controls.TCMDialogChar Type

Pascal

```
TCMDialogChar = TWMKey;
```

C++

```
TWMKey TCMDialogChar;
```

File

Controls

Description

This is type Controls.TCMDialogChar.

32.5.20 Controls.TCMDialogKey Type

Pascal

```
TCMDialogKey = TWMKey;
```

C++

```
TWMKey TCMDialogKey;
```

File

Controls

Description

This is type Controls.TCMDialogKey.

32.5.21 Controls.TCMEnter Type

Pascal

```
TCMEnter = TWMNoParams;
```

C++

```
TWMNoParams TCMEnter;
```

File

Controls

Description

This is type Controls.TCMEnter.

32.5.22 Controls.TCMExit Type

Pascal

```
TCMExit = TWMNoParams;
```

C++

```
TWMNoParams TCMExit;
```

File

Controls

Description

This is type Controls.TCMExit.

32.5.23 Controls.TCMGotFocus Type

Pascal

```
TCMGotFocus = TWMNoParams;
```

C++

```
TWMNoParams TCMGotFocus;
```

File

Controls

Description

This is type Controls.TCMGotFocus.

32.5.24 Controls.TCMHitTest Type

Pascal

```
TCMHitTest = TWMNCHitTest;
```

C++

```
TWMNCHitTest TCMHitTest;
```

File

Controls

Description

This is type Controls.TCMHitTest.

32.5.25 Controls.TCMLostFocus Type

Pascal

```
TCMLostFocus = TWMNoParams;
```

C++

```
TWMNoParams TCMLostFocus;
```

File

Controls

Description

This is type Controls.TCMLostFocus.

32.5.26 Controls.TCMWantSpecialKey Type

Pascal

```
TCMWantSpecialKey = TWMKey;
```

C++

```
TWMKey TCMWantSpecialKey;
```

File

Controls

Description

This is type Controls.TCMWantSpecialKey.

32.5.27 Controls.TConstrainedResizeEvent Type

Pascal

```
TConstrainedResizeEvent = procedure (Sender: TObject; var MinWidth, MinHeight, MaxWidth,
MaxHeight: Integer) of object;
```

C++

```
(Sender: TObject; var MinWidth, MinHeight, MaxWidth, MaxHeight: Integer) (
TConstrainedResizeEvent)();
```

File

Controls

Description

This is type Controls.TConstrainedResizeEvent.

32.5.28 Controls.TConstraintSize Type

Pascal

```
TConstraintSize = 0..MaxInt;
```

C++

```
0..MaxInt TConstraintSize;
```

File

Controls

Description

This is type Controls.TConstraintSize.

32.5.29 Controls.TContextPopupEvent Type

Pascal

```
TContextPopupEvent = procedure (Sender: TObject; MousePos: TPoint; var Handled: Boolean) of
object;
```

C++

```
(Sender: TObject; MousePos: TPoint; var Handled: Boolean) ( TContextPopupEvent)();
```

File

Controls

Description

This is type Controls.TContextPopupEvent.

32.5.30 Controls.TControlActionLinkClass Type

TControlActionLinkClass defines the metaclass for TControlActionLink (see page 5892).

Pascal

```
TControlActionLinkClass = class of TControlActionLink;
```

C++

```
TControlActionLink TControlActionLinkClass;
```

File

Controls

Description

TControlActionLinkClass is the metaclass for TControlActionLink (see page 5892). Its value is a class reference for TControlActionLink (see page 5892) or one of its descendants.

32.5.31 Controls.TControlClass Type

TControlClass defines the metaclass for TControl (see page 5724).

Pascal

```
TControlClass = class of TControl;
```

C++

```
TControl * TControlClass;
```

File

Controls

Description

TControlClass is the metaclass for TControl (see page 5724). Its value is the class reference for TControl (see page 5724) or for one of its descendants.

See Also

TControl (see page 5724)

32.5.32 Controls.TControlState Type

TControlState describes the current state of a control.

Pascal

```
TControlState = set of (csLButtonDown, csClicked, csPalette, csReadingState,
csAlignmentNeeded, csFocusing, csCreating, csPaintCopy, csCustomPaint, csDestroyingHandle,
csDocking, csDesignerHide, csPanning, csRecreating, csAligning);
```

C++

```
(csLButtonDown, csClicked, csPalette, csReadingState, csAlignmentNeeded, csFocusing,
csCreating, csPaintCopy, csCustomPaint, csDestroyingHandle, csDocking, csDesignerHide,
csPanning, csRecreating, csAligning) TControlState;
```

File

Controls

Description

TControlState defines a set of flags used to defined the state of a control:

Flag	Meaning
csLButtonDown	The left mouse button was clicked and not yet released. This is set for all mouse-down events.
csClicked	The same as csLButtonDown, but only set if ControlStyle contains csClickEvents, meaning that mouse-down events are interpreted as clicks.
csPalette	The palette has changed and the control or one of its descendants has not finished adjusting by realizing its palette.
csReadingState	The control is reading its state from a stream.
csAlignmentNeeded	The control needs to realign itself when alignment is re-enabled.
csFocusing	The application is processing messages intended to give the control focus. This does not guarantee the control will receive focus, but prevents recursive calls.
csCreating	The control and/or its owner and subcontrols are being created. This flag clears when all have finished creating.
csPaintCopy	The control is being replicated, meaning a copy of the control is being painted. The ControlStyle flag csReplicatable must be set for this state to occur.
csCustomPaint	The control is processing custom paint messages.
csDestroyingHandle	The control's window is being destroyed.
csDocking	The control is being docked.
csPanning	Set if the control is actively being panned.
csRecreating	The control and/or its owner and subcontrols are being recreated. This flag clears when all have finished recreating.

32.5.33 Controls.TControlStyle Type

The TControlStyle type describes the current style of the control.

Pascal

```
TControlStyle = set of (csAcceptsControls, csCaptureMouse, csDesignInteractive, csClickEvents,
csFramed, csSetCaption, csOpaque, csDoubleClicks, csFixedWidth, csFixedHeight,
csNoDesignVisible, csReplicatable, csNoStdEvents, csDisplayDragImage, csReflector,
csActionClient, csMenuEvents, csNeedsBorderPaint, csParentBackground, csPannable,
csAlignWithMargins);
```

C++

```
(csAcceptsControls, csCaptureMouse, csDesignInteractive, csClickEvents, csFramed,
csSetCaption, csOpaque, csDoubleClicks, csFixedWidth, csFixedHeight, csNoDesignVisible,
csReplicatable, csNoStdEvents, csDisplayDragImage, csReflector, csActionClient, csMenuEvents,
csNeedsBorderPaint, csParentBackground, csPannable, csAlignWithMargins) TControlStyle;
```

File

Controls

Description

TControlStyle defines a set of style flags indicating control attributes:

The following table lists the flags and their meanings:

Flag	Meaning
csAcceptsControls	The control becomes the parent of any controls dropped on it at design time.
csCaptureMouse	The control captures mouse events when it is clicked.
csDesignInteractive	The control maps right mouse-button clicks at design time into left mouse-button clicks to manipulate the control.
csClickEvents	The control can receive and respond to mouse clicks.
csFramed	The control has a 3D frame.
csSetCaption	The control's Caption should match the Name property if it has not been explicitly set to something else.
csOpaque	The control completely fills its client rectangle.
csDoubleClicks	The control can receive and respond to double-click messages. Otherwise, map double-clicks into clicks.
csFixedWidth	The width of the control does not vary or scale.
csFixedHeight	The height of the control does not vary or scale.
csNoDesignVisible	The control is not visible at design time.
csReplicatable	The control can be copied using the PaintTo method to draw its image to an arbitrary canvas.
csNoStdEvents	Standard events such as mouse, key, and click events are ignored. This flag allows an application to run faster when there is no need respond to these events.
csDisplayDragImage	If some control that has an associated drag image list is dragged across a control with this setting, then the image list is used to enhance the drag cursor while the cursor is over it. Otherwise, the drag cursor is used on its own.
csReflector	The control responds to Windows dialog messages, focus messages, or size change messages. Use this setting if the control can be used as an ActiveX control, so that it receives notification of these events.
csActionClient	The control is linked to an action object. This flag is set when the Action property is set, and cleared if the Action property is cleared.
csMenuEvents	The control responds to system menu commands.
csPannable	Set this In your control style if it is to support mouse panning.
csNeedsBorderPaint	Only applicable when Themes are Enabled in applications on Windows XP. Causes the ThemeServices to paint the border of a control with the current theme.
csParentBackground	Only applicable when Themes are Enabled in applications on Windows XP. Causes the parent to draw its background into the Control's background. This is useful for controls which need to show their parent's theme elements, such as a TPanel or TFrame that appear on a TPageControl. TWinControl (see page 6112) introduces a protected ParentBackground property that includes/excludes the **csParentBackground** control style.
csAlignWithMargins	Use the Margins property of the control to govern the spacing relative to other controls that are aligned with this one. The controls are not allowed to be any closer than the spacing specified in Margins. This spacing is maintained as controls are moved when the parent control resizes.

See Also

TFrame (see page 14114)

TMargins (see page 6087)

TPageControl (see page 4459)

TPanel (see page 13032)

TWinControl (see page 6112)

ParentBackground (see page 6209)

TControl (see page 5724)

Margins (see page 5831)

32.5.34 Controls.TCursor Type

TCursor identifies the cursor type.

Pascal

```
TCursor = -32768..32767;
```

C++

```
-32768..32767 TCursor;
```

File

Controls

Description

TCursor type defines a cursor ident (integer). It may have one of the following values :

Value	Meaning
crDefault (see page 6362)	Default cursor : thikc arrow pointing up and left.
crArrow (see page 6361)	Same as the default cursor
crCross (see page 6361)	Fine cross shaped cursor used in graphic applications for precise positioning.
crIBeam (see page 6365)	Text insert cursor in the form of a thin capital I.
crSizeNESW (see page 6368)	Resizing cursor from North-East to South-West resizing.
crSizeNS (see page 6369)	Vertical resizing cursor.
crSizeNWSE (see page 6369)	Resizing cursor from North-West to South-East resizing.
crSizeWE (see page 6370)	Horizontal resizing cursor.
crUpArrow (see page 6371)	Thin upward pointing cursor.

crHourGlass (see page 6364)	Hour glass cursor to indicate a busy process.
crDrag (see page 6362)	Drag cursor for single items being dragged.
crNoDrop (see page 6366)	Whit cross in a white circle indicating that a drag operation is hovering over an invalid drop target.
crHSplit (see page 6364)	Cursor shown when the mouse is over a Horizontal splitter.
crVSplit (see page 6371)	Cursor shown when the mouse is over a Veryical splitter.
crMultiDrag (see page 6365)	Drag cursor for multiple items being dragged.
crSQLWait (see page 6370)	Hour glass cursor to indicate a busy SQL database operation.
crNo (see page 6366)	Black cross in a black circle indicating invalid mouse target location.
crAppStart (see page 6360)	Hour glass and standard pointer combination cursor show at application startup.
crHelp (see page 6363)	Question mark and standard pointer operation
crHandPoint (see page 6363)	An upward pointing hand cursor. This is normally used to identify a selectable item, such as a web page link.
crSizeAll (see page 6368)	Cursor for resizing up, down, left and right.

Use the Screen Cursor property to set the cursor type to one of the TCursor values.

See Also

Cursor (see page 14209)

32.5.35 Controls.TDate Type

TDate is used to represent a date.

Pascal

```
TDate = type TDateTime;
```

C++

```
type TDateTime TDate;
```

File

Controls

Description

TDate represents a special type of TDateTime value that has no decimal part. A TDate value represents the number of days that have elapsed since 12/30/1899.

See Also

TTimeStamp (see page 23009)

32.5.36 Controls.TDockDropEvent Type

TDockDropEvent is the type of the OnDockDrop event handler.

Pascal

```
TDockDropEvent = procedure (Sender: TObject; Source: TDragDockObject; X, Y: Integer) of object;
```

C++

```
(Sender: TObject; Source: TDragDockObject; X, Y: Integer) ( TDockDropEvent)();
```

File

Controls

Description

Sender is the object on which another object is being dropped.

Source is information about the object that is being dropped.

X and Y are the coordinates of the mouse pointer.

32.5.37 Controls.TDockOverEvent Type

TDockOverEvent is the type of the OnDockOver event handler.

Pascal

```
TDockOverEvent = procedure (Sender: TObject; Source: TDragDockObject; X, Y: Integer; State:
TDragState; var Accept: Boolean) of object;
```

C++

```
(Sender: TObject; Source: TDragDockObject; X, Y: Integer; State: TDragState; var Accept:
Boolean) ( TDockOverEvent)();
```

File

Controls

Description

Sender is the object over which another object is being dragged.

Source is information about the object that is being dragged.

X and Y are the coordinates of the mouse pointer.

DragState is the current drag state.

Accept returns whether or not the control accepts the dragged object for docking.

32.5.38 Controls.TDockTreeClass Type

TDockTreeClass defines the metaclass for TDockTree (see page 5983).

Pascal

```
TDockTreeClass = class of TDockTree;
```

C++

```
TDockTree TDockTreeClass;
```

File

Controls

Description

TDockTreeClass is the metaclass for TDockTree (see page 5983). Its value is the class reference for TDockTree (see page 5983) or for one of its descendants.

See Also

TDockTree (see page 5983)

32.5.39 Controls.TDragDropEvent Type

Pascal

```
TDragDropEvent = procedure (Sender, Source: TObject; X, Y: Integer) of object;
```

C++

```
(Sender, Source: TObject; X, Y: Integer) ( TDragDropEvent)();
```

File

Controls

Description

This is type Controls.TDragDropEvent.

32.5.40 Controls.TDragObjectClass Type

TDragObjectClass defines the metaclass for TDragObject (see page 6031).

Pascal

```
TDragObjectClass = class of TDragObject;
```

C++

```
TDragObject TDragObjectClass;
```

File

Controls

Description

TDragObjectClass is the metaclass for TDragObject (see page 6031). Its value is the class reference for TDragObject (see page 6031) or for one of its descendants.

See Also

TDragObject (see page 6031)

32.5.41 Controls.TDragOverEvent Type

Pascal

```
TDragOverEvent = procedure (Sender, Source: TObject; X, Y: Integer; State: TDragState; var
Accept: Boolean) of object;
```

C++

```
(Sender, Source: TObject; X, Y: Integer; State: TDragState; var Accept: Boolean) (
TDragOverEvent)();
```

File

Controls

Description

This is type Controls.TDragOverEvent.

32.5.42 Controls.TEndDragEvent Type

Pascal

```
TEndDragEvent = procedure (Sender, Target: TObject; X, Y: Integer) of object;
```

C++

```
(Sender, Target: TObject; X, Y: Integer) ( TEndDragEvent)();
```

File

Controls

Description

This is type Controls.TEndDragEvent.

32.5.43 Controls.TForEachZoneProc Type

Pascal

```
TForEachZoneProc = procedure (Zone: TDockZone) of object;
```

C++

```
(Zone: TDockZone) ( TForEachZoneProc)();
```

File

Controls

Description

This is type Controls.TForEachZoneProc.

32.5.44 Controls.TGetSiteInfoEvent Type

TGetSiteInfoEvent is the type of the OnGetSiteInfo event handler.

Pascal

```
TGetSiteInfoEvent = procedure (Sender: TObject; DockClient: TControl; var InfluenceRect:
TRect; MousePos: TPoint; var CanDock: Boolean) of object;
```

C++

```
(Sender: TObject; DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint; var
CanDock: Boolean) ( TGetSiteInfoEvent)();
```

File

Controls

Description

Sender is the dock site.

DockClient is the control being dragged.

InfluenceRect is the rectangle in which the mouse must be positioned for the dock site to accept a dragged control. By default, InfluenceRect is the area of the target control, expanded by 10 pixels on each side. This can be adjusted by the event handler.

MousePos is the position of the mouse pointer.

CanDock returns whether the dragged control can be docked to the dock site.

32.5.45 Controls.THintWindowClass Type

THintWindowClass defines the metaclass for THintWindow (see page 6055).

Pascal

```
THintWindowClass = class of THintWindow;
```

C++

```
THintWindow THintWindowClass;
```

File

Controls

Description

THintWindowClass is the metaclass for THintWindow (see page 6055). Its value is the class reference for THintWindow (see page 6055) or for one of its descendants.

See Also

THintWindow (see page 6055)

32.5.46 Controls.TImeName Type

TImeName is the type that represents the name of an Input Method Editor.

Pascal

```
TImeName = type string;
```

C++

```
type string TImeName;
```

File

Controls

Description

TImeName is the string that identifies an IME.

32.5.47 Controls.TKeyEvent Type

Pascal

```
TKeyEvent = procedure (Sender: TObject; var Key: Word; Shift: TShiftState) of object;
```

C++

```
(Sender: TObject; var Key: Word; Shift: TShiftState) ( TKeyEvent)();
```

File

Controls

Description

This is type Controls.TKeyEvent.

32.5.48 Controls.TKeyPressEvent Type

Pascal

```
TKeyPressEvent = procedure (Sender: TObject; var Key: Char) of object;
```

C++

```
(Sender: TObject; var Key: Char) ( TKeyPressEvent)();
```

File

Controls

Description

This is type Controls.TKeyPressEvent.

32.5.49 Controls.TMarginSize Type

Pascal

```
TMarginSize = 0..MaxInt;
```

C++

```
0..MaxInt TMarginSize;
```

File

Controls

Description

This is type Controls.TMarginSize.

32.5.50 Controls.TModalResult Type

TModalResult represents the return value from a modal dialog.

Pascal

```
TModalResult = Low(Integer)..High(Integer);
```

C++

```
Low(Integer)..High(Integer) TModalResult;
```

File

Controls

Description

TModalResult represents the value returned by a modal dialog. An application can use any integer value as a modal result value. Although TModalResult can take any integer value, the following constants are defined for commonly used TModalResult values:

Constant	Value	Meaning
mrNone (see page 6374)	0	None. Used as a default value before the user exits.
mrOk (see page 6375)	idOK	The user exited with OK button.
mrCancel (see page 6373)	idCancel	The user exited with the CANCEL button.
mrAbort (see page 6372)	idAbort	The user exited with the ABORT button.
mrRetry (see page 6375)	idRetry	The user exited with the RETRY button.
mrIgnore (see page 6373)	idIgnore	The user exited with the IGNORE button.
mrYes (see page 6376)	idYes	The user exited with the YES button.

mrNo (see page 6374)	idNo	The user exited with the NO button.
mrAll (see page 6372)	mrNo (see page 6374) + 1	The user exited with the ALL button.
mrNoToAll (see page 6375)	mrAll (see page 6372) + 1	The user exited with the NO TO ALL button.
mrYesToAll (see page 6376)	mrNoToAll (see page 6375) + 1	The user exited with the YES TO ALL button.

TCustomForm (see page 13849)

TDBEngineErrorDlg

TButton (see page 20909)

IsAbortResult (see page 6258)

IsAnALlResult

IsNegativeResult (see page 6260)

IsPositiveResult (see page 6260)

StripAllFromResult (see page 6265)

32.5.51 Controls.TMouseActivateEvent Type

Pascal

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

C++

```
(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y: Integer; HitTest: Integer;
var MouseActivate: TMouseActivate) ( TMouseActivateEvent)();
```

File

Controls

Description

This is type Controls.TMouseActivateEvent.

32.5.52 Controls.TMouseEvent Type

Pascal

```
TMouseEvent = procedure (Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer) of object;
```

C++

```
(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y: Integer) ( TMouseEvent)();
```

File

Controls

Description

This is type Controls.TMouseEvent.

32.5.53 Controls.TMouseMoveEvent Type

Pascal

```
TMouseMoveEvent = procedure (Sender: TObject; Shift: TShiftState; X, Y: Integer) of object;
```

C++

```
(Sender: TObject; Shift: TShiftState; X, Y: Integer) ( TMouseMoveEvent)();
```

File

Controls

Description

This is type Controls.TMouseMoveEvent.

32.5.54 Controls.TMouseWheelEvent Type

Pascal

```
TMouseWheelEvent = procedure (Sender: TObject; Shift: TShiftState; WheelDelta: Integer;
MousePos: TPoint; var Handled: Boolean) of object;
```

C++

```
(Sender: TObject; Shift: TShiftState; WheelDelta: Integer; MousePos: TPoint; var Handled:
Boolean) ( TMouseWheelEvent)();
```

File

Controls

Description

This is type Controls.TMouseWheelEvent.

32.5.55 Controls.TMouseWheelUpDownEvent Type

Pascal

```
TMouseWheelUpDownEvent = procedure (Sender: TObject; Shift: TShiftState; MousePos: TPoint; var
Handled: Boolean) of object;
```

C++

```
(Sender: TObject; Shift: TShiftState; MousePos: TPoint; var Handled: Boolean) (
TMouseWheelUpDownEvent)();
```

File

Controls

Description

This is type Controls.TMouseWheelUpDownEvent.

32.5.56 Controls.TPanningWindowClass Type

TPanningWindowClass defines the metaclass for TPanningWindow.

Pascal

```
TPanningWindowClass = class of TCustomPanningWindow;
```

C++

```
TCustomPanningWindow TPanningWindowClass;
```

File

Controls

Description

TPanningWindowClass is the metaclass for TPanningWindow. Its value is the class reference for TPanningWindow or for one of its descendants.

See Also

TPanningWindow

32.5.57 Controls.TScalingFlags Type

TScalingFlags describes the way controls are scaled.

Pascal

```
TScalingFlags = set of (sfLeft, sfTop, sfWidth, sfHeight, sfFont, sfDesignSize);
```

C++

```
(sfLeft, sfTop, sfWidth, sfHeight, sfFont, sfDesignSize) TScalingFlags;
```

File

Controls

Description

TScalingFlags describes a set of flags used in scaling inherited forms and their controls.

Flag	Meaning
sfLeft	Left side of control not yet scaled.

sfTop	Top of control not yet scaled.
sfWidth	Width of control not yet scaled.
sfHeight	Height of control not yet scaled.
sfFont	Font of control not yet scaled.
sfDesignSize	Design-time dimensions of control not yet scaled.

See Also

TControl

32.5.58 Controls.TStartDockEvent Type

TStartDockEvent is the type of the OnStartDock event handler.

Pascal

```
TStartDockEvent = procedure (Sender: TObject; var DragObject: TDragDockObject) of object;
```

C++

```
(Sender: TObject; var DragObject: TDragDockObject) ( TStartDockEvent)();
```

File

Controls

Description

Sender is the object on which a control is being docked.

DragObject is information about the control that is being docked.

See Also

OnStartDock

32.5.59 Controls.TStartDragEvent Type

Pascal

```
TStartDragEvent = procedure (Sender: TObject; var DragObject: TDragObject) of object;
```

C++

```
(Sender: TObject; var DragObject: TDragObject) ( TStartDragEvent)();
```

File

Controls

Description

This is type Controls.TStartDragEvent.

32.5.60 Controls.TTabOrder Type

TTabOrder defines the tab order of a control.

Pascal

```
TTabOrder = -1..32767;
```

C++

```
-1..32767 TTabOrder;
```

File

Controls

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears. Subsequent controls in the tab sequence have value 1, 2, 3 and so on.

TTabOrder is the data type used by the TabOrder property.

See Also

TabOrder (see page 6211)

32.5.61 Controls.TTime Type

TTime is used to represent a time.

Pascal

```
TTime = type TDateTime;
```

C++

```
type TDateTime TTime;
```

File

Controls

Description

TTime is simply a TDateTime type.

See Also

TDateTime (see page 22612)

32.5.62 Controls.TUnDockEvent Type

TUnDockEvent is the type of the OnUnDock event handler.

Pascal

```
TUnDockEvent = procedure (Sender: TObject; Client: TControl; NewTarget: TWinControl; var
Allow: Boolean) of object;
```

C++

```
(Sender: TObject; Client: TControl; NewTarget: TWinControl; var Allow: Boolean) (
TUnDockEvent)();
```

File

Controls

Description

Sender is the object from which a control is being undocked.

Client is the control that is being undocked.

NewTarget is the control to which Client is being docked.

Allow is whether to allow the undocking.

See Also

OnUnDock

32.5.63 Controls.TWinControlActionLinkClass Type

TWinControlActionLinkClass defines the metaclass for TWinControlActionLink (see page 6233).

Pascal

```
TWinControlActionLinkClass = class of TWinControlActionLink;
```

C++

```
TWinControlActionLink TWinControlActionLinkClass;
```

File

Controls

Description

TWinControlActionLinkClass is the metaclass for TWinControlActionLink (see page 6233). Its value is the class reference for TWinControlActionLink (see page 6233) or for one of its descendants.

See Also

TWinControlActionLink (see page 6233)

32.5.64 Controls.TWinControlClass Type

TWinControlClass defines the metaclass for TWinControl (see page 6112).

Pascal

```
TWinControlClass = class of TWinControl;
```

C++

```
TWinControl * TWinControlClass;
```

File

Controls

Description

TWinControlClass is the metaclass for TWinControl (see page 6112). Its value is the class reference for TWinControl (see page 6112) or for one of its descendants.

32.5.65 Controls.TWndMethod Type

TWndMethod is the type for Windows message procedures.

Pascal

```
TWndMethod = Classes.TWndMethod;
```

C++

```
Classes.TWndMethod TWndMethod;
```

File

Controls

Description

Each Window has a message procedure that responds to calls from Windows. These calls can originate from Windows (such as paint messages), from user actions (such as mouse messages), or from your messages that you send in your own code.

TWndMethod is the type for VCL-based message procedures. Message procedures of this type can be assigned to controls using the WindowProc method. In addition, a window that implements this procedure but which is not associated with a control can be created using the AllocateHWnd function.

The Message parameter encapsulates the message to which the procedure responds. It contains fields for the incoming message parameters and a result field that holds the return value.

See Also

TControl (see page 5724)

AllocateHWnd (see page 3217)

32.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AnimateWindowProc (see page 6320)	This is variable Controls.AnimateWindowProc.
CreationControl (see page 6320)	This is variable Controls.CreationControl.
DefaultDockTreeClass (see page 6321)	Provides the default implementation class for the DockManager property of container controls.
IsVCLControlHook (see page 6321)	This is variable Controls.IsVCLControlHook.
Mouse (see page 6321)	Contains information about the system's mouse.
NewStyleControls (see page 6322)	Determines whether controls are drawn using the Windows 3.x "look".

32.6.1 Controls.AnimateWindowProc Variable

Pascal

```
AnimateWindowProc: TAnimateWindowProc = nil;
```

C++

```
TAnimateWindowProc AnimateWindowProc = nil;
```

File

Controls

Description

This is variable Controls.AnimateWindowProc.

32.6.2 Controls.CreationControl Variable

Pascal

```
CreationControl: TWinControl = nil;
```

C++

```
TWinControl * CreationControl = nil;
```

File

Controls

Description

This is variable Controls.CreationControl.

32.6.3 Controls.DefaultDockTreeClass Variable

Provides the default implementation class for the DockManager property of container controls.

Pascal

```
DefaultDockTreeClass: TDockTreeClass = TDockTree;
```

C++

```
TDockTreeClass DefaultDockTreeClass = TDockTree;
```

File

Controls

Description

When you set the UseDockManager property of a container control to true, it uses the value of its DockManager property to manage docking operations. If the application does not explicitly assign a value to DockManager, the control generates a dock manager by instantiating the class specified by DefaultDockTreeClass.

The Controls (see page 5711) unit sets DefaultDockTreeClass to TDockTree (see page 5983). Change this value to provide a different default implementation of the dock manager that container controls use when the DockManager property is not explicitly assigned. The class specified by DefaultDockTreeClass must be a descendant of TDockTree (see page 5983).

See Also

IDockManager (see page 6238)

TWinControl (see page 6112)

TWinControl (see page 6112)

TDockTree (see page 5983)

32.6.4 Controls.IsVCLControlHook Variable

Pascal

```
IsVCLControlHook: function (Handle: HWnd): Boolean of object;
```

C++

```
function (Handle: HWnd): Boolean of object IsVCLControlHook;
```

File

Controls

Description

This is variable Controls.IsVCLControlHook.

32.6.5 Controls.Mouse Variable

Contains information about the system's mouse.

Pascal

```
Mouse: TMouse;
```

C++

```
TMouse Mouse;
```

File

Controls

Description

Use Mouse to get information about the system's mouse, including which window (if any) has captured the mouse, the position of the mouse, and mouse settings from the Control panel. Mouse can also be used to specify global aspects of how your application responds to mouse messages, such as how much the user must move the mouse to start a drag operation.

32.6.6 Controls.NewStyleControls Variable

Determines whether controls are drawn using the Windows 3.x "look".

Pascal

```
NewStyleControls: Boolean;
```

C++

```
Boolean NewStyleControls;
```

File

Controls

Description

NewStyleControls determines whether controls in the application are drawn using the effects that were introduced with Windows 95. When NewStyleControls is false, controls have a flatter look.

By default, NewStyleControls is true unless the application is running on a Windows 3.x system with Win32S. To change this value to false, set the value of NewStyleControls in the project file, before the call to the Application object's Run method.

32.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
AnchorAlign (see page 6325)	Defines the default sets of anchor types for all component alignment values.
CM_ACTIONEXECUTE (see page 6326)	This is constant Controls.CM_ACTIONEXECUTE.
CM_ACTIONUPDATE (see page 6327)	This is constant Controls.CM_ACTIONUPDATE.
CM_ACTIVATE (see page 6327)	This is constant Controls.CM_ACTIVATE.
CM_ALLCHILDRENFLIPPED (see page 6327)	This is constant Controls.CM_ALLCHILDRENFLIPPED.
CM_APPKEYDOWN (see page 6328)	This is constant Controls.CM_APPKEYDOWN.
CM_APPSYSCOMMAND (see page 6328)	This is constant Controls.CM_APPSYSCOMMAND.
CM_BASE (see page 6328)	This is constant Controls.CM_BASE.
CM_BIDIMODECHANGED (see page 6329)	This is constant Controls.CM_BIDIMODECHANGED.
CM_BORDERCHANGED (see page 6329)	This is constant Controls.CM_BORDERCHANGED.
CM_BUTTONPRESSED (see page 6329)	This is constant Controls.CM_BUTTONPRESSED.
CM_CANCELMODE (see page 6330)	This is constant Controls.CM_CANCELMODE.
CM_CHANGED (see page 6330)	This is constant Controls.CM_CHANGED.
CM_CHILDKEY (see page 6330)	This is constant Controls.CM_CHILDKEY.
CM_COLORCHANGED (see page 6331)	This is constant Controls.CM_COLORCHANGED.
CM_CONTROLCHANGE (see page 6331)	This is constant Controls.CM_CONTROLCHANGE.
CM_CONTROLLISTCHANGE (see page 6331)	This is constant Controls.CM_CONTROLLISTCHANGE.
CM_CONTROLLISTCHANGING (see page 6332)	This is constant Controls.CM_CONTROLLISTCHANGING.
CM_CREATEPOPUP (see page 6332)	This is constant Controls.CM_CREATEPOPUP.
CM_CTL3DCHANGED (see page 6332)	This is constant Controls.CM_CTL3DCHANGED.
CM_CTLCOLOREDITGLASS (see page 6333)	This is constant Controls.CM_CTLCOLOREDITGLASS.
CM_CURSORCHANGED (see page 6333)	This is constant Controls.CM_CURSORCHANGED.
CM_DEACTIVATE (see page 6333)	This is constant Controls.CM_DEACTIVATE.
CM_DESIGNHITTEST (see page 6334)	This is constant Controls.CM_DESIGNHITTEST.
CM_DESTROYHANDLE (see page 6334)	This is constant Controls.CM_DESTROYHANDLE.
CM_DIALOGCHAR (see page 6334)	This is constant Controls.CM_DIALOGCHAR.
CM_DIALOGHANDLE (see page 6335)	This is constant Controls.CM_DIALOGHANDLE.
CM_DIALOGKEY (see page 6335)	This is constant Controls.CM_DIALOGKEY.
CM_DOCKCLIENT (see page 6335)	This is constant Controls.CM_DOCKCLIENT.
CM_DOCKNOTIFICATION (see page 6336)	This is constant Controls.CM_DOCKNOTIFICATION.
CM_DOCWINDOWACTIVATE (see page 6336)	This is constant Controls.CM_DOCWINDOWACTIVATE.
CM_DRAG (see page 6336)	This is constant Controls.CM_DRAG.
CM_ENABLEDCHANGED (see page 6337)	This is constant Controls.CM_ENABLEDCHANGED.
CM_ENTER (see page 6337)	This is constant Controls.CM_ENTER.
CM_EXIT (see page 6337)	This is constant Controls.CM_EXIT.
CM_FLOAT (see page 6338)	This is constant Controls.CM_FLOAT.
CM_FOCUSCHANGED (see page 6338)	This is constant Controls.CM_FOCUSCHANGED.
CM_FONTCHANGE (see page 6338)	This is constant Controls.CM_FONTCHANGE.
CM_FONTCHANGED (see page 6339)	This is constant Controls.CM_FONTCHANGED.
CM_GETDATALINK (see page 6339)	This is constant Controls.CM_GETDATALINK.
CM_GOTFOCUS (see page 6339)	This is constant Controls.CM_GOTFOCUS.
CM_HINTSHOW (see page 6340)	This is constant Controls.CM_HINTSHOW.
CM_HINTSHOWPAUSE (see page 6340)	This is constant Controls.CM_HINTSHOWPAUSE.
CM_HITTEST (see page 6340)	This is constant Controls.CM_HITTEST.

CM_ICONCHANGED (see page 6341)	This is constant Controls.CM_ICONCHANGED.
CM_INVALIDATE (see page 6341)	This is constant Controls.CM_INVALIDATE.
CM_INVALIDATEDOCKHOST (see page 6341)	This is constant Controls.CM_INVALIDATEDOCKHOST.
CM_INVOKEHELP (see page 6342)	This is constant Controls.CM_INVOKEHELP.
CM_ISSHORTCUT (see page 6342)	This is constant Controls.CM_ISSHORTCUT.
CM_ISTOOLCONTROL (see page 6342)	This is constant Controls.CM_ISTOOLCONTROL.
CM_LOSTFOCUS (see page 6343)	This is constant Controls.CM_LOSTFOCUS.
CM_MENUCHANGED (see page 6343)	This is constant Controls.CM_MENUCHANGED.
CM_MOUSEACTIVATE (see page 6343)	This is constant Controls.CM_MOUSEACTIVATE.
CM_MOUSEENTER (see page 6344)	This is constant Controls.CM_MOUSEENTER.
CM_MOUSELEAVE (see page 6344)	This is constant Controls.CM_MOUSELEAVE.
CM_MOUSEWHEEL (see page 6344)	This is constant Controls.CM_MOUSEWHEEL.
CM_PARENTBIDIMODECHANGED (see page 6345)	This is constant Controls.CM_PARENTBIDIMODECHANGED.
CM_PARENTCOLORCHANGED (see page 6345)	This is constant Controls.CM_PARENTCOLORCHANGED.
CM_PARENTCTL3DCHANGED (see page 6345)	This is constant Controls.CM_PARENTCTL3DCHANGED.
CM_PARENTFONTCHANGED (see page 6346)	This is constant Controls.CM_PARENTFONTCHANGED.
CM_PARENTSHOWHINTCHANGED (see page 6346)	This is constant Controls.CM_PARENTSHOWHINTCHANGED.
CM_POPUPHWNDDESTROY (see page 6346)	This is constant Controls.CM_POPUPHWNDDESTROY.
CM_RECREATEWND (see page 6347)	This is constant Controls.CM_RECREATEWND.
CM_RELEASE (see page 6347)	This is constant Controls.CM_RELEASE.
CM_SETACTIVECONTROL (see page 6347)	This is constant Controls.CM_SETACTIVECONTROL.
CM_SHOWHINTCHANGED (see page 6348)	This is constant Controls.CM_SHOWHINTCHANGED.
CM_SHOWINGCHANGED (see page 6348)	This is constant Controls.CM_SHOWINGCHANGED.
CM_SYSCOLORCHANGE (see page 6348)	This is constant Controls.CM_SYSCOLORCHANGE.
CM_SYSFONTCHANGED (see page 6349)	This is constant Controls.CM_SYSFONTCHANGED.
CM_TABSTOPCHANGED (see page 6349)	This is constant Controls.CM_TABSTOPCHANGED.
CM_TEXTCHANGED (see page 6349)	This is constant Controls.CM_TEXTCHANGED.
CM_TIMECHANGE (see page 6350)	This is constant Controls.CM_TIMECHANGE.
CM_UIACTIVATE (see page 6350)	This is constant Controls.CM_UIACTIVATE.
CM_UIDEACTIVATE (see page 6350)	This is constant Controls.CM_UIDEACTIVATE.
CM_UNDOCKCLIENT (see page 6351)	This is constant Controls.CM_UNDOCKCLIENT.
CM_VISIBLECHANGED (see page 6351)	This is constant Controls.CM_VISIBLECHANGED.
CM_WANTSPECIALKEY (see page 6351)	This is constant Controls.CM_WANTSPECIALKEY.
CM_WINDOWHOOK (see page 6352)	This is constant Controls.CM_WINDOWHOOK.
CM_WININICHANGE (see page 6352)	This is constant Controls.CM_WININICHANGE.
CN_BASE (see page 6352)	This is constant Controls.CN_BASE.
CN_CHAR (see page 6353)	This is constant Controls.CN_CHAR.
CN_CHARTOITEM (see page 6353)	This is constant Controls.CN_CHARTOITEM.
CN_COMMAND (see page 6353)	This is constant Controls.CN_COMMAND.
CN_COMPAREITEM (see page 6354)	This is constant Controls.CN_COMPAREITEM.
CN_CTLCOLORBTN (see page 6354)	This is constant Controls.CN_CTLCOLORBTN.
CN_CTLCOLORDLG (see page 6354)	This is constant Controls.CN_CTLCOLORDLG.
CN_CTLCOLOREDIT (see page 6355)	This is constant Controls.CN_CTLCOLOREDIT.
CN_CTLCOLORLISTBOX (see page 6355)	This is constant Controls.CN_CTLCOLORLISTBOX.
CN_CTLCOLORMSGBOX (see page 6355)	This is constant Controls.CN_CTLCOLORMSGBOX.
CN_CTLCOLORSCROLLBAR (see page 6356)	This is constant Controls.CN_CTLCOLORSCROLLBAR.
CN_CTLCOLORSTATIC (see page 6356)	This is constant Controls.CN_CTLCOLORSTATIC.
CN_DELETEITEM (see page 6356)	This is constant Controls.CN_DELETEITEM.
CN_DRAWITEM (see page 6357)	This is constant Controls.CN_DRAWITEM.
CN_HSCROLL (see page 6357)	This is constant Controls.CN_HSCROLL.
CN_KEYDOWN (see page 6357)	This is constant Controls.CN_KEYDOWN.
CN_KEYUP (see page 6358)	This is constant Controls.CN_KEYUP.
CN_MEASUREITEM (see page 6358)	This is constant Controls.CN_MEASUREITEM.
CN_NOTIFY (see page 6358)	This is constant Controls.CN_NOTIFY.

CN_PARENTNOTIFY (see page 6359)	This is constant Controls.CN_PARENTNOTIFY.
CN_SYSCHAR (see page 6359)	This is constant Controls.CN_SYSCHAR.
CN_SYSKEYDOWN (see page 6359)	This is constant Controls.CN_SYSKEYDOWN.
CN_VKEYTOITEM (see page 6360)	This is constant Controls.CN_VKEYTOITEM.
CN_VSCROLL (see page 6360)	This is constant Controls.CN_VSCROLL.
crAppStart (see page 6360)	Identifies the default cursor.
crArrow (see page 6361)	Identifies an arrow cursor.
crCross (see page 6361)	Identifies an cross cursor.
crDefault (see page 6362)	Identifies the default cursor.
crDrag (see page 6362)	Identifies a drag cursor.
crHandPoint (see page 6363)	Identifies a pointing hand cursor.
crHelp (see page 6363)	Identifies a help cursor.
crHourGlass (see page 6364)	Identifies an hour glass cursor.
crHSplit (see page 6364)	Identifies a horizontal split cursor.
crIBeam (see page 6365)	Identifies a text insert cursor.
crMultiDrag (see page 6365)	Identifies a multiple item drag cursor.
crNo (see page 6366)	Identifies a not allowed cursor.
crNoDrop (see page 6366)	Identifies a not allowed to drop cursor.
crNone (see page 6367)	Identifies an invisible cursor.
crSize (see page 6367)	Identifies an obsolete cursor.
crSizeAll (see page 6368)	Identifies a size in all directions cursor.
crSizeNESW (see page 6368)	Identifies a North-East to South-West sizing cursor.
crSizeNS (see page 6369)	Identifies a vertical sizing cursor.
crSizeNWSE (see page 6369)	Identifies a North-West to South-East sizing cursor.
crSizeWE (see page 6370)	Identifies a horizontal sizing cursor.
crSQLWait (see page 6370)	Identifies an SQL wait hour glass cursor.
crUpArrow (see page 6371)	Identifies an upwards pointing arrow cursor.
crVSplit (see page 6371)	Identifies a vertical split cursor.
CTL3D_ALL (see page 6372)	This is constant Controls.CTL3D_ALL.
mrAbort (see page 6372)	Indicates that Abort was selected in a modal dialog.
mrAll (see page 6372)	This is constant Controls.mrAll.
mrCancel (see page 6373)	Indicates that Cancel was selected in a modal dialog.
mrIgnore (see page 6373)	Indicates that Ignore was selected in a modal dialog.
mrNo (see page 6374)	Indicates that No was selected in a modal dialog.
mrNone (see page 6374)	The default modal dialog return value.
mrNoToAll (see page 6375)	Indicates that 'No To All' was selected in a modal dialog.
mrOk (see page 6375)	This is constant Controls.mrOk.
mrRetry (see page 6375)	Indicates that Retry was selected in a modal dialog.
mrYes (see page 6376)	Indicates that Yes was selected in a modal dialog.
mrYesToAll (see page 6376)	Indicates that 'Yes To All' was selected in a modal dialog.
NullDockSite (see page 6377)	This is constant Controls.NullDockSite.

32.7.1 Controls.AnchorAlign Constant

Defines the default sets of anchor types for all component alignment values.

Pascal

```
AnchorAlign: array[TAlign] of TAnchors = ( [akLeft, akTop], [akLeft, akTop, akRight], [akLeft,
akRight, akBottom], [akLeft, akTop, akBottom], [akRight, akTop, akBottom], [akLeft, akTop,
akRight, akBottom], [akLeft, akTop] );
```

C++

```
array[TAlign] of TAnchors AnchorAlign = ( [akLeft, akTop], [akLeft, akTop, akRight], [akLeft,
```

```
akRight, akBottom], [akLeft, akTop, akBottom], [akRight, akTop, akBottom], [akLeft, akTop,
akRight, akBottom], [akLeft, akTop] );
```

File

Controls

Description

Component alignment and anchoring are closely related. Setting an anchor to true means that a side of a component will remain the designed distance from the edge of the container at run time. Alignment simply forces this distance to be zero at design time (if we disregard margin and padding values).

For example, a component with Align set to alLeft in the Object Inspector will hug the left side of its container regardless of any effort to reposition it. You can, however, adjust its width since the right side position is not forced to align with the right side of the container - the akRight anchor value is false.

AnchorAlign defines the default set of TAnchorKind (see page 6269) anchor values for each possible TAlign (see page 6268) value :

TAlign (see page 6268) value	TAnchorKind (see page 6269) values set	Meaning
alNone	akLeft, akTop	No design time forced alignment is performed.
alTop	akLeft, akTop, akRight	Component is forced to align with top of the container - along with the left and right.
alBottom	akLeft, akRight, akBottom	Component is forced to align with bottom of the container - along with the left and right.
alLeft	akLeft, akTop, akBottom	Component is forced to align with left of the container - along with the top and bottom.
alRight	akRight, akTop, akBottom	Component is forced to align with right of the container - along with the top and bottom.
alClient	akLeft, akTop, akRight, akBottom	Component is forced to align with all sides of the container. If another control already occupies part of the container, the control resizes to fit within the remaining client area.
alCustom	akLeft, akTop	The control's positioning is determined by calls to its parent's CustomAlignInsertBefore and CustomAlignPosition methods.

Note: In the above, the container is the parent component inside which the current component is being positioned. If that parent already has aligned component(s), the current component respects them. For example, a 2nd alLeft aligned component will align to the immediate right of the first component.

TAlign (see page 6268)

TAnchorKind (see page 6269)

32.7.2 Controls.CM_ACTIONEXECUTE Constant

Pascal

```
CM_ACTIONEXECUTE = CM_BASE + 64;
```

C++

```
CM_ACTIONEXECUTE = CM_BASE + 64;
```

File

Controls

Description

This is constant Controls.CM_ACTIONEXECUTE.

32.7.3 Controls.CM_ACTIONUPDATE Constant

Pascal

```
CM_ACTIONUPDATE = CM_BASE + 63;
```

C++

```
CM_ACTIONUPDATE = CM_BASE + 63;
```

File

Controls

Description

This is constant Controls.CM_ACTIONUPDATE.

32.7.4 Controls.CM_ACTIVATE Constant

Pascal

```
CM_ACTIVATE = CM_BASE + 0;
```

C++

```
CM_ACTIVATE = CM_BASE + 0;
```

File

Controls

Description

This is constant Controls.CM_ACTIVATE.

32.7.5 Controls.CM_ALLCHILDRENFLIPPED Constant

Pascal

```
CM_ALLCHILDRENFLIPPED = CM_BASE + 62;
```

C++

```
CM_ALLCHILDRENFLIPPED = CM_BASE + 62;
```

File

Controls

Description

This is constant Controls.CM_ALLCHILDRENFLIPPED.

32.7.6 Controls.CM_APPKEYDOWN Constant

Pascal

```
CM_APPKEYDOWN = CM_BASE + 22;
```

C++

```
CM_APPKEYDOWN = CM_BASE + 22;
```

File

Controls

Description

This is constant Controls.CM_APPKEYDOWN.

32.7.7 Controls.CM_APPSYSCOMMAND Constant

Pascal

```
CM_APPSYSCOMMAND = CM_BASE + 23;
```

C++

```
CM_APPSYSCOMMAND = CM_BASE + 23;
```

File

Controls

Description

This is constant Controls.CM_APPSYSCOMMAND.

32.7.8 Controls.CM_BASE Constant

Pascal

```
CM_BASE = $B000;
```

C++

```
CM_BASE = 0xB000;
```

File

Controls

Description

This is constant Controls.CM_BASE.

32.7.9 Controls.CM_BIDIMODECHANGED Constant

Pascal

```
CM_BIDIMODECHANGED = CM_BASE + 60;
```

C++

```
CM_BIDIMODECHANGED = CM_BASE + 60;
```

File

Controls

Description

This is constant Controls.CM_BIDIMODECHANGED.

32.7.10 Controls.CM_BORDERCHANGED Constant

Pascal

```
CM_BORDERCHANGED = CM_BASE + 59;
```

C++

```
CM_BORDERCHANGED = CM_BASE + 59;
```

File

Controls

Description

This is constant Controls.CM_BORDERCHANGED.

32.7.11 Controls.CM_BUTTONPRESSED Constant

Pascal

```
CM_BUTTONPRESSED = CM_BASE + 24;
```

C++

```
CM_BUTTONPRESSED = CM_BASE + 24;
```

File

Controls

Description

This is constant Controls.CM_BUTTONPRESSED.

32.7.12 Controls.CM_CANCELMODE Constant

Pascal

```
CM_CANCELMODE = CM_BASE + 4;
```

C++

```
CM_CANCELMODE = CM_BASE + 4;
```

File

Controls

Description

This is constant Controls.CM_CANCELMODE.

32.7.13 Controls.CM_CHANGED Constant

Pascal

```
CM_CHANGED = CM_BASE + 55;
```

C++

```
CM_CHANGED = CM_BASE + 55;
```

File

Controls

Description

This is constant Controls.CM_CHANGED.

32.7.14 Controls.CM_CHILDKEY Constant

Pascal

```
CM_CHILDKEY = CM_BASE + 46;
```

C++

```
CM_CHILDKEY = CM_BASE + 46;
```

File

Controls

Description

This is constant Controls.CM_CHILDKEY.

32.7.15 Controls.CM_COLORCHANGED Constant

Pascal

```
CM_COLORCHANGED = CM_BASE + 13;
```

C++

```
CM_COLORCHANGED = CM_BASE + 13;
```

File

Controls

Description

This is constant Controls.CM_COLORCHANGED.

32.7.16 Controls.CM_CONTROLCHANGE Constant

Pascal

```
CM_CONTROLCHANGE = CM_BASE + 54;
```

C++

```
CM_CONTROLCHANGE = CM_BASE + 54;
```

File

Controls

Description

This is constant Controls.CM_CONTROLCHANGE.

32.7.17 Controls.CM_CONTROLLISTCHANGE Constant

Pascal

```
CM_CONTROLLISTCHANGE = CM_BASE + 44;
```

C++

```
CM_CONTROLLISTCHANGE = CM_BASE + 44;
```

File

Controls

Description

This is constant Controls.CM_CONTROLLISTCHANGE.

32.7.18 Controls.CM_CONTROLLISTCHANGING Constant

Pascal

```
CM_CONTROLLISTCHANGING = CM_BASE + 76;
```

C++

```
CM_CONTROLLISTCHANGING = CM_BASE + 76;
```

File

Controls

Description

This is constant Controls.CM_CONTROLLISTCHANGING.

32.7.19 Controls.CM_CREATEPOPUP Constant

Pascal

```
CM_CREATEPOPUP = CM_BASE + 73;
```

C++

```
CM_CREATEPOPUP = CM_BASE + 73;
```

File

Controls

Description

This is constant Controls.CM_CREATEPOPUP.

32.7.20 Controls.CM_CTL3DCHANGED Constant

Pascal

```
CM_CTL3DCHANGED = CM_BASE + 16;
```

C++

```
CM_CTL3DCHANGED = CM_BASE + 16;
```

File

Controls

Description

This is constant Controls.CM_CTL3DCHANGED.

32.7.21 Controls.CM_CTLCOLOREDITGLASS Constant

Pascal

```
CM_CTLCOLOREDITGLASS = CM_BASE + 77;
```

C++

```
CM_CTLCOLOREDITGLASS = CM_BASE + 77;
```

File

Controls

Description

This is constant Controls.CM_CTLCOLOREDITGLASS.

32.7.22 Controls.CM_CURSORCHANGED Constant

Pascal

```
CM_CURSORCHANGED = CM_BASE + 15;
```

C++

```
CM_CURSORCHANGED = CM_BASE + 15;
```

File

Controls

Description

This is constant Controls.CM_CURSORCHANGED.

32.7.23 Controls.CM_DEACTIVATE Constant

Pascal

```
CM_DEACTIVATE = CM_BASE + 1;
```

C++

```
CM_DEACTIVATE = CM_BASE + 1;
```

File

Controls

Description

This is constant Controls.CM_DEACTIVATE.

32.7.24 Controls.CM_DESIGNHITTEST Constant

Pascal

```
CM_DESIGNHITTEST = CM_BASE + 28;
```

C++

```
CM_DESIGNHITTEST = CM_BASE + 28;
```

File

Controls

Description

This is constant Controls.CM_DESIGNHITTEST.

32.7.25 Controls.CM_DESTROYHANDLE Constant

Pascal

```
CM_DESTROYHANDLE = CM_BASE + 74;
```

C++

```
CM_DESTROYHANDLE = CM_BASE + 74;
```

File

Controls

Description

This is constant Controls.CM_DESTROYHANDLE.

32.7.26 Controls.CM_DIALOGCHAR Constant

Pascal

```
CM_DIALOGCHAR = CM_BASE + 6;
```

C++

```
CM_DIALOGCHAR = CM_BASE + 6;
```

File

Controls

Description

This is constant Controls.CM_DIALOGCHAR.

32.7.27 Controls.CM_DIALOGHANDLE Constant

Pascal

```
CM_DIALOGHANDLE = CM_BASE + 49;
```

C++

```
CM_DIALOGHANDLE = CM_BASE + 49;
```

File

Controls

Description

This is constant Controls.CM_DIALOGHANDLE.

32.7.28 Controls.CM_DIALOGKEY Constant

Pascal

```
CM_DIALOGKEY = CM_BASE + 5;
```

C++

```
CM_DIALOGKEY = CM_BASE + 5;
```

File

Controls

Description

This is constant Controls.CM_DIALOGKEY.

32.7.29 Controls.CM_DOCKCLIENT Constant

Pascal

```
CM_DOCKCLIENT = CM_BASE + 56;
```

C++

```
CM_DOCKCLIENT = CM_BASE + 56;
```

File

Controls

Description

This is constant Controls.CM_DOCKCLIENT.

32.7.30 Controls.CM_DOCKNOTIFICATION Constant

Pascal

```
CM_DOCKNOTIFICATION = CM_BASE + 66;
```

C++

```
CM_DOCKNOTIFICATION = CM_BASE + 66;
```

File

Controls

Description

This is constant Controls.CM_DOCKNOTIFICATION.

32.7.31 Controls.CM_DOCWINDOWACTIVATE Constant

Pascal

```
CM_DOCWINDOWACTIVATE = CM_BASE + 43;
```

C++

```
CM_DOCWINDOWACTIVATE = CM_BASE + 43;
```

File

Controls

Description

This is constant Controls.CM_DOCWINDOWACTIVATE.

32.7.32 Controls.CM_DRAG Constant

Pascal

```
CM_DRAG = CM_BASE + 47;
```

C++

```
CM_DRAG = CM_BASE + 47;
```

File

Controls

Description

This is constant Controls.CM_DRAG.

32.7.33 Controls.CM_ENABLEDCHANGED Constant

Pascal

```
CM_ENABLEDCHANGED = CM_BASE + 12;
```

C++

```
CM_ENABLEDCHANGED = CM_BASE + 12;
```

File

Controls

Description

This is constant Controls.CM_ENABLEDCHANGED.

32.7.34 Controls.CM_ENTER Constant

Pascal

```
CM_ENTER = CM_BASE + 26;
```

C++

```
CM_ENTER = CM_BASE + 26;
```

File

Controls

Description

This is constant Controls.CM_ENTER.

32.7.35 Controls.CM_EXIT Constant

Pascal

```
CM_EXIT = CM_BASE + 27;
```

C++

```
CM_EXIT = CM_BASE + 27;
```

File

Controls

Description

This is constant Controls.CM_EXIT.

32.7.36 Controls.CM_FLOAT Constant

Pascal

```
CM_FLOAT = CM_BASE + 58;
```

C++

```
CM_FLOAT = CM_BASE + 58;
```

File

Controls

Description

This is constant Controls.CM_FLOAT.

32.7.37 Controls.CM_FOCUSCHANGED Constant

Pascal

```
CM_FOCUSCHANGED = CM_BASE + 7;
```

C++

```
CM_FOCUSCHANGED = CM_BASE + 7;
```

File

Controls

Description

This is constant Controls.CM_FOCUSCHANGED.

32.7.38 Controls.CM_FONTCHANGE Constant

Pascal

```
CM_FONTCHANGE = CM_BASE + 38;
```

C++

```
CM_FONTCHANGE = CM_BASE + 38;
```

File

Controls

Description

This is constant Controls.CM_FONTCHANGE.

32.7.39 Controls.CM_FONTCHANGED Constant

Pascal

```
CM_FONTCHANGED = CM_BASE + 14;
```

C++

```
CM_FONTCHANGED = CM_BASE + 14;
```

File

Controls

Description

This is constant Controls.CM_FONTCHANGED.

32.7.40 Controls.CM_GETDATALINK Constant

Pascal

```
CM_GETDATALINK = CM_BASE + 45;
```

C++

```
CM_GETDATALINK = CM_BASE + 45;
```

File

Controls

Description

This is constant Controls.CM_GETDATALINK.

32.7.41 Controls.CM_GOTFOCUS Constant

Pascal

```
CM_GOTFOCUS = CM_BASE + 2;
```

C++

```
CM_GOTFOCUS = CM_BASE + 2;
```

File

Controls

Description

This is constant Controls.CM_GOTFOCUS.

32.7.42 Controls.CM_HINTSHOW Constant

Pascal

```
CM_HINTSHOW = CM_BASE + 48;
```

C++

```
CM_HINTSHOW = CM_BASE + 48;
```

File

Controls

Description

This is constant Controls.CM_HINTSHOW.

32.7.43 Controls.CM_HINTSHOWPAUSE Constant

Pascal

```
CM_HINTSHOWPAUSE = CM_BASE + 65;
```

C++

```
CM_HINTSHOWPAUSE = CM_BASE + 65;
```

File

Controls

Description

This is constant Controls.CM_HINTSHOWPAUSE.

32.7.44 Controls.CM_HITTEST Constant

Pascal

```
CM_HITTEST = CM_BASE + 10;
```

C++

```
CM_HITTEST = CM_BASE + 10;
```

File

Controls

Description

This is constant Controls.CM_HITTEST.

32.7.45 Controls.CM_ICONCHANGED Constant

Pascal

```
CM_ICONCHANGED = CM_BASE + 29;
```

C++

```
CM_ICONCHANGED = CM_BASE + 29;
```

File

Controls

Description

This is constant Controls.CM_ICONCHANGED.

32.7.46 Controls.CM_INVALIDATE Constant

Pascal

```
CM_INVALIDATE = CM_BASE + 52;
```

C++

```
CM_INVALIDATE = CM_BASE + 52;
```

File

Controls

Description

This is constant Controls.CM_INVALIDATE.

32.7.47 Controls.CM_INVALIDATEDOCKHOST Constant

Pascal

```
CM_INVALIDATEDOCKHOST = CM_BASE + 70;
```

C++

```
CM_INVALIDATEDOCKHOST = CM_BASE + 70;
```

File

Controls

Description

This is constant Controls.CM_INVALIDATEDOCKHOST.

32.7.48 Controls.CM_INVOKEHELP Constant

Pascal

```
CM_INVOKEHELP = CM_BASE + 31;
```

C++

```
CM_INVOKEHELP = CM_BASE + 31;
```

File

Controls

Description

This is constant Controls.CM_INVOKEHELP.

32.7.49 Controls.CM_ISSHORTCUT Constant

Pascal

```
CM_ISSHORTCUT = CM_BASE + 68;
```

C++

```
CM_ISSHORTCUT = CM_BASE + 68;
```

File

Controls

Description

This is constant Controls.CM_ISSHORTCUT.

32.7.50 Controls.CM_ISTOOLCONTROL Constant

Pascal

```
CM_ISTOOLCONTROL = CM_BASE + 50;
```

C++

```
CM_ISTOOLCONTROL = CM_BASE + 50;
```

File

Controls

Description

This is constant Controls.CM_ISTOOLCONTROL.

32.7.51 Controls.CM_LOSTFOCUS Constant

Pascal

```
CM_LOSTFOCUS = CM_BASE + 3;
```

C++

```
CM_LOSTFOCUS = CM_BASE + 3;
```

File

Controls

Description

This is constant Controls.CM_LOSTFOCUS.

32.7.52 Controls.CM_MENUCHANGED Constant

Pascal

```
CM_MENUCHANGED = CM_BASE + 21;
```

C++

```
CM_MENUCHANGED = CM_BASE + 21;
```

File

Controls

Description

This is constant Controls.CM_MENUCHANGED.

32.7.53 Controls.CM_MOUSEACTIVATE Constant

Pascal

```
CM_MOUSEACTIVATE = CM_BASE + 75;
```

C++

```
CM_MOUSEACTIVATE = CM_BASE + 75;
```

File

Controls

Description

This is constant Controls.CM_MOUSEACTIVATE.

32.7.54 Controls.CM_MOUSEENTER Constant

Pascal

```
CM_MOUSEENTER = CM_BASE + 19;
```

C++

```
CM_MOUSEENTER = CM_BASE + 19;
```

File

Controls

Description

This is constant Controls.CM_MOUSEENTER.

32.7.55 Controls.CM_MOUSELEAVE Constant

Pascal

```
CM_MOUSELEAVE = CM_BASE + 20;
```

C++

```
CM_MOUSELEAVE = CM_BASE + 20;
```

File

Controls

Description

This is constant Controls.CM_MOUSELEAVE.

32.7.56 Controls.CM_MOUSEWHEEL Constant

Pascal

```
CM_MOUSEWHEEL = CM_BASE + 67;
```

C++

```
CM_MOUSEWHEEL = CM_BASE + 67;
```

File

Controls

Description

This is constant Controls.CM_MOUSEWHEEL.

32.7.57 Controls.CM_PARENTBIDIMODECHANGED Constant

Pascal

```
CM_PARENTBIDIMODECHANGED = CM_BASE + 61;
```

C++

```
CM_PARENTBIDIMODECHANGED = CM_BASE + 61;
```

File

Controls

Description

This is constant Controls.CM_PARENTBIDIMODECHANGED.

32.7.58 Controls.CM_PARENTCOLORCHANGED Constant

Pascal

```
CM_PARENTCOLORCHANGED = CM_BASE + 9;
```

C++

```
CM_PARENTCOLORCHANGED = CM_BASE + 9;
```

File

Controls

Description

This is constant Controls.CM_PARENTCOLORCHANGED.

32.7.59 Controls.CM_PARENTCTL3DCHANGED Constant

Pascal

```
CM_PARENTCTL3DCHANGED = CM_BASE + 17;
```

C++

```
CM_PARENTCTL3DCHANGED = CM_BASE + 17;
```

File

Controls

Description

This is constant Controls.CM_PARENTCTL3DCHANGED.

32.7.60 Controls.CM_PARENTFONTCHANGED Constant

Pascal

```
CM_PARENTFONTCHANGED = CM_BASE + 8;
```

C++

```
CM_PARENTFONTCHANGED = CM_BASE + 8;
```

File

Controls

Description

This is constant Controls.CM_PARENTFONTCHANGED.

32.7.61 Controls.CM_PARENTSHOWHINTCHANGED Constant

Pascal

```
CM_PARENTSHOWHINTCHANGED = CM_BASE + 35;
```

C++

```
CM_PARENTSHOWHINTCHANGED = CM_BASE + 35;
```

File

Controls

Description

This is constant Controls.CM_PARENTSHOWHINTCHANGED.

32.7.62 Controls.CM_POPUPHWNDDESTROY Constant

Pascal

```
CM_POPUPHWNDDESTROY = CM_BASE + 72;
```

C++

```
CM_POPUPHWNDDESTROY = CM_BASE + 72;
```

File

Controls

Description

This is constant Controls.CM_POPUPHWNDDESTROY.

32.7.63 Controls.CM_RECREATEWND Constant

Pascal

```
CM_RECREATEWND = CM_BASE + 51;
```

C++

```
CM_RECREATEWND = CM_BASE + 51;
```

File

Controls

Description

This is constant Controls.CM_RECREATEWND.

32.7.64 Controls.CM_RELEASE Constant

Pascal

```
CM_RELEASE = CM_BASE + 33;
```

C++

```
CM_RELEASE = CM_BASE + 33;
```

File

Controls

Description

This is constant Controls.CM_RELEASE.

32.7.65 Controls.CM_SETACTIVECONTROL Constant

Pascal

```
CM_SETACTIVECONTROL = CM_BASE + 71;
```

C++

```
CM_SETACTIVECONTROL = CM_BASE + 71;
```

File

Controls

Description

This is constant Controls.CM_SETACTIVECONTROL.

32.7.66 Controls.CM_SHOWHINTCHANGED Constant

Pascal

```
CM_SHOWHINTCHANGED = CM_BASE + 34;
```

C++

```
CM_SHOWHINTCHANGED = CM_BASE + 34;
```

File

Controls

Description

This is constant Controls.CM_SHOWHINTCHANGED.

32.7.67 Controls.CM_SHOWINGCHANGED Constant

Pascal

```
CM_SHOWINGCHANGED = CM_BASE + 25;
```

C++

```
CM_SHOWINGCHANGED = CM_BASE + 25;
```

File

Controls

Description

This is constant Controls.CM_SHOWINGCHANGED.

32.7.68 Controls.CM_SYSCOLORCHANGE Constant

Pascal

```
CM_SYSCOLORCHANGE = CM_BASE + 36;
```

C++

```
CM_SYSCOLORCHANGE = CM_BASE + 36;
```

File

Controls

Description

This is constant Controls.CM_SYSCOLORCHANGE.

32.7.69 Controls.CM_SYSFONTCHANGED Constant

Pascal

```
CM_SYSFONTCHANGED = CM_BASE + 53;
```

C++

```
CM_SYSFONTCHANGED = CM_BASE + 53;
```

File

Controls

Description

This is constant Controls.CM_SYSFONTCHANGED.

32.7.70 Controls.CM_TABSTOPCHANGED Constant

Pascal

```
CM_TABSTOPCHANGED = CM_BASE + 40;
```

C++

```
CM_TABSTOPCHANGED = CM_BASE + 40;
```

File

Controls

Description

This is constant Controls.CM_TABSTOPCHANGED.

32.7.71 Controls.CM_TEXTCHANGED Constant

Pascal

```
CM_TEXTCHANGED = CM_BASE + 18;
```

C++

```
CM_TEXTCHANGED = CM_BASE + 18;
```

File

Controls

Description

This is constant Controls.CM_TEXTCHANGED.

32.7.72 Controls.CM_TIMECHANGE Constant

Pascal

```
CM_TIMECHANGE = CM_BASE + 39;
```

C++

```
CM_TIMECHANGE = CM_BASE + 39;
```

File

Controls

Description

This is constant Controls.CM_TIMECHANGE.

32.7.73 Controls.CM_UIACTIVATE Constant

Pascal

```
CM_UIACTIVATE = CM_BASE + 41;
```

C++

```
CM_UIACTIVATE = CM_BASE + 41;
```

File

Controls

Description

This is constant Controls.CM_UIACTIVATE.

32.7.74 Controls.CM_UIDEACTIVATE Constant

Pascal

```
CM_UIDEACTIVATE = CM_BASE + 42;
```

C++

```
CM_UIDEACTIVATE = CM_BASE + 42;
```

File

Controls

Description

This is constant Controls.CM_UIDEACTIVATE.

32.7.75 Controls.CM_UNDOCKCLIENT Constant

Pascal

```
CM_UNDOCKCLIENT = CM_BASE + 57;
```

C++

```
CM_UNDOCKCLIENT = CM_BASE + 57;
```

File

Controls

Description

This is constant Controls.CM_UNDOCKCLIENT.

32.7.76 Controls.CM_VISIBLECHANGED Constant

Pascal

```
CM_VISIBLECHANGED = CM_BASE + 11;
```

C++

```
CM_VISIBLECHANGED = CM_BASE + 11;
```

File

Controls

Description

This is constant Controls.CM_VISIBLECHANGED.

32.7.77 Controls.CM_WANTSPECIALKEY Constant

Pascal

```
CM_WANTSPECIALKEY = CM_BASE + 30;
```

C++

```
CM_WANTSPECIALKEY = CM_BASE + 30;
```

File

Controls

Description

This is constant Controls.CM_WANTSPECIALKEY.

32.7.78 Controls.CM_WINDOWHOOK Constant

Pascal

```
CM_WINDOWHOOK = CM_BASE + 32;
```

C++

```
CM_WINDOWHOOK = CM_BASE + 32;
```

File

Controls

Description

This is constant Controls.CM_WINDOWHOOK.

32.7.79 Controls.CM_WININICHANGE Constant

Pascal

```
CM_WININICHANGE = CM_BASE + 37;
```

C++

```
CM_WININICHANGE = CM_BASE + 37;
```

File

Controls

Description

This is constant Controls.CM_WININICHANGE.

32.7.80 Controls.CN_BASE Constant

Pascal

```
CN_BASE = $BC00;
```

C++

```
CN_BASE = 0xBC00;
```

File

Controls

Description

This is constant Controls.CN_BASE.

32.7.81 Controls.CN_CHAR Constant

Pascal

```
CN_CHAR = CN_BASE + WM_CHAR;
```

C++

```
CN_CHAR = CN_BASE + WM_CHAR;
```

File

Controls

Description

This is constant Controls.CN_CHAR.

32.7.82 Controls.CN_CHARTOITEM Constant

Pascal

```
CN_CHARTOITEM = CN_BASE + WM_CHARTOITEM;
```

C++

```
CN_CHARTOITEM = CN_BASE + WM_CHARTOITEM;
```

File

Controls

Description

This is constant Controls.CN_CHARTOITEM.

32.7.83 Controls.CN_COMMAND Constant

Pascal

```
CN_COMMAND = CN_BASE + WM_COMMAND;
```

C++

```
CN_COMMAND = CN_BASE + WM_COMMAND;
```

File

Controls

Description

This is constant Controls.CN_COMMAND.

32.7.84 Controls.CN_COMPAREITEM Constant

Pascal

```
CN_COMPAREITEM = CN_BASE + WM_COMPAREITEM;
```

C++

```
CN_COMPAREITEM = CN_BASE + WM_COMPAREITEM;
```

File

Controls

Description

This is constant Controls.CN_COMPAREITEM.

32.7.85 Controls.CN_CTLCOLORBTN Constant

Pascal

```
CN_CTLCOLORBTN = CN_BASE + WM_CTLCOLORBTN;
```

C++

```
CN_CTLCOLORBTN = CN_BASE + WM_CTLCOLORBTN;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORBTN.

32.7.86 Controls.CN_CTLCOLORDLG Constant

Pascal

```
CN_CTLCOLORDLG = CN_BASE + WM_CTLCOLORDLG;
```

C++

```
CN_CTLCOLORDLG = CN_BASE + WM_CTLCOLORDLG;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORDLG.

32.7.87 Controls.CN_CTLCOLOREDIT Constant

Pascal

```
CN_CTLCOLOREDIT = CN_BASE + WM_CTLCOLOREDIT;
```

C++

```
CN_CTLCOLOREDIT = CN_BASE + WM_CTLCOLOREDIT;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLOREDIT.

32.7.88 Controls.CN_CTLCOLORLISTBOX Constant

Pascal

```
CN_CTLCOLORLISTBOX = CN_BASE + WM_CTLCOLORLISTBOX;
```

C++

```
CN_CTLCOLORLISTBOX = CN_BASE + WM_CTLCOLORLISTBOX;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORLISTBOX.

32.7.89 Controls.CN_CTLCOLORMSGBOX Constant

Pascal

```
CN_CTLCOLORMSGBOX = CN_BASE + WM_CTLCOLORMSGBOX;
```

C++

```
CN_CTLCOLORMSGBOX = CN_BASE + WM_CTLCOLORMSGBOX;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORMSGBOX.

32.7.90 Controls.CN_CTLCOLORSCROLLBAR Constant

Pascal

```
CN_CTLCOLORSCROLLBAR = CN_BASE + WM_CTLCOLORSCROLLBAR;
```

C++

```
CN_CTLCOLORSCROLLBAR = CN_BASE + WM_CTLCOLORSCROLLBAR;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORSCROLLBAR.

32.7.91 Controls.CN_CTLCOLORSTATIC Constant

Pascal

```
CN_CTLCOLORSTATIC = CN_BASE + WM_CTLCOLORSTATIC;
```

C++

```
CN_CTLCOLORSTATIC = CN_BASE + WM_CTLCOLORSTATIC;
```

File

Controls

Description

This is constant Controls.CN_CTLCOLORSTATIC.

32.7.92 Controls.CN_DELETEITEM Constant

Pascal

```
CN_DELETEITEM = CN_BASE + WM_DELETEITEM;
```

C++

```
CN_DELETEITEM = CN_BASE + WM_DELETEITEM;
```

File

Controls

Description

This is constant Controls.CN_DELETEITEM.

32.7.93 Controls.CN_DRAWITEM Constant

Pascal

```
CN_DRAWITEM = CN_BASE + WM_DRAWITEM;
```

C++

```
CN_DRAWITEM = CN_BASE + WM_DRAWITEM;
```

File

Controls

Description

This is constant Controls.CN_DRAWITEM.

32.7.94 Controls.CN_HSCROLL Constant

Pascal

```
CN_HSCROLL = CN_BASE + WM_HSCROLL;
```

C++

```
CN_HSCROLL = CN_BASE + WM_HSCROLL;
```

File

Controls

Description

This is constant Controls.CN_HSCROLL.

32.7.95 Controls.CN_KEYDOWN Constant

Pascal

```
CN_KEYDOWN = CN_BASE + WM_KEYDOWN;
```

C++

```
CN_KEYDOWN = CN_BASE + WM_KEYDOWN;
```

File

Controls

Description

This is constant Controls.CN_KEYDOWN.

32.7.96 Controls.CN_KEYUP Constant

Pascal

```
CN_KEYUP = CN_BASE + WM_KEYUP;
```

C++

```
CN_KEYUP = CN_BASE + WM_KEYUP;
```

File

Controls

Description

This is constant Controls.CN_KEYUP.

32.7.97 Controls.CN_MEASUREITEM Constant

Pascal

```
CN_MEASUREITEM = CN_BASE + WM_MEASUREITEM;
```

C++

```
CN_MEASUREITEM = CN_BASE + WM_MEASUREITEM;
```

File

Controls

Description

This is constant Controls.CN_MEASUREITEM.

32.7.98 Controls.CN_NOTIFY Constant

Pascal

```
CN_NOTIFY = CN_BASE + WM_NOTIFY;
```

C++

```
CN_NOTIFY = CN_BASE + WM_NOTIFY;
```

File

Controls

Description

This is constant Controls.CN_NOTIFY.

32.7.99 Controls.CN_PARENTNOTIFY Constant

Pascal

```
CN_PARENTNOTIFY = CN_BASE + WM_PARENTNOTIFY;
```

C++

```
CN_PARENTNOTIFY = CN_BASE + WM_PARENTNOTIFY;
```

File

Controls

Description

This is constant Controls.CN_PARENTNOTIFY.

32.7.100 Controls.CN_SYSCHAR Constant

Pascal

```
CN_SYSCHAR = CN_BASE + WM_SYSCHAR;
```

C++

```
CN_SYSCHAR = CN_BASE + WM_SYSCHAR;
```

File

Controls

Description

This is constant Controls.CN_SYSCHAR.

32.7.101 Controls.CN_SYSKEYDOWN Constant

Pascal

```
CN_SYSKEYDOWN = CN_BASE + WM_SYSKEYDOWN;
```

C++

```
CN_SYSKEYDOWN = CN_BASE + WM_SYSKEYDOWN;
```

File

Controls

Description

This is constant Controls.CN_SYSKEYDOWN.

32.7.102 Controls.CN_VKEYTOITEM Constant

Pascal

```
CN_VKEYTOITEM = CN_BASE + WM_VKEYTOITEM;
```

C++

```
CN_VKEYTOITEM = CN_BASE + WM_VKEYTOITEM;
```

File

Controls

Description

This is constant Controls.CN_VKEYTOITEM.

32.7.103 Controls.CN_VSCROLL Constant

Pascal

```
CN_VSCROLL = CN_BASE + WM_VSCROLL;
```

C++

```
CN_VSCROLL = CN_BASE + WM_VSCROLL;
```

File

Controls

Description

This is constant Controls.CN_VSCROLL.

32.7.104 Controls.crAppStart Constant

Identifies the default cursor.

Pascal

```
crAppStart = TCursor(-19);
```

C++

```
crAppStart = TCursor(-19);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -19 identifies the Application Start cursor, a combination of arrow and hourglass.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.105 Controls.crArrow Constant

Identifies an arrow cursor.

Pascal

```
crArrow = TCursor(-2);
```

C++

```
crArrow = TCursor(-2);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -2 identifies a cursor that is an arrow pointing up and to the left.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.106 Controls.crCross Constant

Identifies an cross cursor.

Pascal

```
crCross = TCursor(-3);
```

C++

```
crCross = TCursor(-3);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -3 identifies a cross cursor. This is principally used for precise screen work.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.107 Controls.crDefault Constant

Identifies the default cursor.

Pascal

```
crDefault = TCursor(0);
```

C++

```
crDefault = TCursor(0);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The default value of 0 represents the default cursor, an arrow pointing up and to the left.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.108 Controls.crDrag Constant

Identifies a drag cursor.

Pascal

```
crDrag = TCursor(-12);
```

C++

```
crDrag = TCursor(-12);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -12 identifies a drag cursor. It is deployed when a user clicks, holds and then drags a screen item that supports dragging. It is shown as an arrow and document combination.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.109 Controls.crHandPoint Constant

Identifies a pointing hand cursor.

Pascal

```
crHandPoint = TCursor(-21);
```

C++

```
crHandPoint = TCursor(-21);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -21 identifies an upward pointing hand cursor. This is normally used to identify a selectable item, such as a web page link.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.110 Controls.crHelp Constant

Identifies a help cursor.

Pascal

```
crHelp = TCursor(-20);
```

C++

```
crHelp = TCursor(-20);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -20 identifies a help cursor, comprising the default arrow pointing up and to the left combined with a question mark.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.111 Controls.crHourGlass Constant

Identifies an hour glass cursor.

Pascal

```
crHourGlass = TCursor(-11);
```

C++

```
crHourGlass = TCursor(-11);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -11 identifies an hour glass cursor. This is typically used to inform the user to wait until an application completes its current operation.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.112 Controls.crHSplit Constant

Identifies a horizontal split cursor.

Pascal

```
crHSplit = TCursor(-14);
```

C++

```
crHSplit = TCursor(-14);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -14 identifies a horizontal split cursor. This is used to indicate when a TSplitter control under the mouse can be dragged horizontally. It is represented as 2 horizontal lines bracketed by 2 arrows. Like a lift door open symbol.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

TSplitter (see page 13210)

32.7.113 Controls.crIBeam Constant

Identifies a text insert cursor.

Pascal

```
crIBeam = TCursor(-4);
```

C++

```
crIBeam = TCursor(-4);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -4 identifies a text insert cursor, in the shape of a thin capital I. It is used when choosing where in a passage of text where typed characters next.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.114 Controls.crMultiDrag Constant

Identifies a multiple item drag cursor.

Pascal

```
crMultiDrag = TCursor(-16);
```

C++

```
crMultiDrag = TCursor(-16);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -16 identifies a multi item drag cursor. It is used to indicate that a group of items have been selected and are being dragged.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.115 Controls.crNo Constant

Identifies a not allowed cursor.

Pascal

```
crNo = TCursor(-18);
```

C++

```
crNo = TCursor(-18);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -18 identifies an action denied cursor. It is used to indicate to the user that the cursor is hovering over an area which is not a valid target. It is represented by a black cross within a black circle.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.116 Controls.crNoDrop Constant

Identifies a not allowed to drop cursor.

Pascal

```
crNoDrop = TCursor(-13);
```

C++

```
crNoDrop = TCursor(-13);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -13 identifies a drop disallowed cursor. It is used to indicate to the user that the cursor is hovering over an area which is not a valid target for a drag and drop operation. It is represented by a white cross within a white circle.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.117 Controls.crNone Constant

Identifies an invisible cursor.

Pascal

```
crNone = TCursor(-1);
```

C++

```
crNone = TCursor(-1);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -1 identifies an invisible cursor. The cursor literally disappears when hovering over the application - except for the title bar.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.118 Controls.crSize Constant

Identifies an obsolete cursor.

Pascal

```
crSize = TCursor(-22);
```

C++

```
crSize = TCursor(-22);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -22 identifies a sizing cursor that is no longer available. It is now replaced by 5 different orientation sizing cursors.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.119 Controls.crSizeAll Constant

Identifies a size in all directions cursor.

Pascal

```
crSizeAll = TCursor(-22);
```

C++

```
crSizeAll = TCursor(-22);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -22 identifies a resizing cursor that allows for resizing in all 4 directions, up, down, left and right. It is represented as a set of 4 arrows pointing outwards in those 4 directions.

Note: crSizeAll has the same value of -22 as the obsolete crSize (see page 6367).

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.120 Controls.crSizeNESW Constant

Identifies a North-East to South-West sizing cursor.

Pascal

```
crSizeNESW = TCursor(-6);
```

C++

```
crSizeNESW = TCursor(-6);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -6 identifies a resizing cursor that allows for resizing in either up and to the right (to the North East) or down and to the left (to the South West). It is identified by a double headed arrow sloping 45 degrees to the right.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.121 Controls.crSizeNS Constant

Identifies a vertical sizing cursor.

Pascal

```
crSizeNS = TCursor(-7);
```

C++

```
crSizeNS = TCursor(-7);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -7 identifies a resizing cursor that allows for vertical resizing. It is identified by a double headed arrow aligned vertically.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.122 Controls.crSizeNWSE Constant

Identifies a North-West to South-East sizing cursor.

Pascal

```
crSizeNWSE = TCursor(-8);
```

C++

```
crSizeNWSE = TCursor(-8);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -8 identifies a resizing cursor that allows for resizing in either up and to the left (to the North West) or down and to the right (to the South East). It is identified by a double headed arrow sloping 45 degrees to the left.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.123 Controls.crSizeWE Constant

Identifies a horizontal sizing cursor.

Pascal

```
crSizeWE = TCursor(-9);
```

C++

```
crSizeWE = TCursor(-9);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -9 identifies a resizing cursor that allows for horizontal resizing. It is identified by a double headed arrow aligned horizontally.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.124 Controls.crSQLWait Constant

Identifies an SQL wait hour glass cursor.

Pascal

```
crSQLWait = TCursor(-17);
```

C++

```
crSQLWait = TCursor(-17);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -17 identifies an hour glass cursor used for SQL operations to indicate that the current SQL operation is still in progress.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.125 Controls.crUpArrow Constant

Identifies an upwards pointing arrow cursor.

Pascal

```
crUpArrow = TCursor(-10);
```

C++

```
crUpArrow = TCursor(-10);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -10 identifies an upwards pointing arrow cursor. This is a thin arrow of the type used in sizing operations, rather than the thick default cursor arrow.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

32.7.126 Controls.crVSplit Constant

Identifies a vertical split cursor.

Pascal

```
crVSplit = TCursor(-15);
```

C++

```
crVSplit = TCursor(-15);
```

File

Controls

Description

The TCursor (see page 6305) type defines a cursor ident (integer). The value -15 identifies a vertical split cursor. This is used to indicate when a TSplitter control under the mouse can be dragged vertically. It is represented as 2 horizontal lines bracketed by 2 arrows.

Use the Screen Cursor property to set the cursor type to one of the TCursor (see page 6305) values.

See Also

TCursor (see page 6305)

Cursor (see page 14209)

TSplitter (see page 13210)

32.7.127 Controls.CTL3D_ALL Constant

Pascal

```
CTL3D_ALL = $FFFF;
```

C++

```
CTL3D_ALL = 0xFFFF;
```

File

Controls

Description

This is constant Controls.CTL3D_ALL.

32.7.128 Controls.mrAbort Constant

Indicates that Abort was selected in a modal dialog.

Pascal

```
mrAbort = idAbort;
```

C++

```
mrAbort = idAbort;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrAbort is the returned TModalResult (see page 6312) value when the MsgDlgBtn mbAbort button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.129 Controls.mrAll Constant

Pascal

```
mrAll = mrNo + 1;
```

C++

```
mrAll = mrNo + 1;
```

File

Controls

Description

This is constant Controls.mrAll.

32.7.130 Controls.mrCancel Constant

Indicates that Cancel was selected in a modal dialog.

Pascal

```
mrCancel = idCancel;
```

C++

```
mrCancel = idCancel;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrCancel is the returned TModalResult (see page 6312) value when the MsgDlgBtn mbCancel button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.131 Controls.mrIgnore Constant

Indicates that Ignore was selected in a modal dialog.

Pascal

```
mrIgnore = idIgnore;
```

C++

```
mrIgnore = idIgnore;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrIgnore is returned TModalResult (see page 6312) value when the MsgDlgBtn mbIgnore button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.132 Controls.mrNo Constant

Indicates that No was selected in a modal dialog.

Pascal

```
mrNo = idNo;
```

C++

```
mrNo = idNo;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrNo is returned TModalResult (see page 6312) value when the MsgDlgBtn mbNo button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.133 Controls.mrNone Constant

The default modal dialog return value.

Pascal

```
mrNone = 0;
```

C++

```
mrNone = 0;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrNone is the default value before a user exits the dialog.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.134 Controls.mrNoToAll Constant

Indicates that 'No To All' was selected in a modal dialog.

Pascal

```
mrNoToAll = mrAll + 1;
```

C++

```
mrNoToAll = mrAll + 1;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrNoToAll is returned TModalResult (see page 6312) value when the MsgDlgBtn mbNoToAll button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.135 Controls.mrOk Constant

Pascal

```
mrOk = idOk;
```

C++

```
mrOk = idOk;
```

File

Controls

Description

This is constant Controls.mrOk.

32.7.136 Controls.mrRetry Constant

Indicates that Retry was selected in a modal dialog.

Pascal

```
mrRetry = idRetry;
```

C++

```
mrRetry = idRetry;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrRetry is returned TModalResult (see page 6312) value when the MsgDlgBtn mbRetry button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.137 Controls.mrYes Constant

Indicates that Yes was selected in a modal dialog.

Pascal

```
mrYes = idYes;
```

C++

```
mrYes = idYes;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrYes is returned TModalResult (see page 6312) value when the MsgDlgBtn mbYes button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.138 Controls.mrYesToAll Constant

Indicates that 'Yes To All' was selected in a modal dialog.

Pascal

```
mrYesToAll = mrNoToAll + 1;
```

C++

```
mrYesToAll = mrNoToAll + 1;
```

File

Controls

Description

The MessageDlg function provides a convenient mechanism for asking the user for a decision. mrYesToAll is returned TModalResult (see page 6312) value when the MsgDlgBtn mbYesToAll button was pressed.

See Also

MessageDlg (see page 11535)

MsgDlgBtn

TModalResult (see page 6312)

32.7.139 Controls.NullDockSite Constant

Pascal

```
NullDockSite = TWinControl($FFFFFFFF);
```

C++

```
NullDockSite = TWinControl($FFFFFFFF);
```

File

Controls

Description

This is constant Controls.NullDockSite.

33 ConvUtils Namespace

This is namespace ConvUtils.

Topics

Name	Description
Classes (see page 6381)	The following table lists classes in this documentation.
Functions (see page 6395)	The following table lists functions in this documentation.
Types (see page 6416)	The following table lists types in this documentation.
Variables (see page 6419)	The following table lists variables in this documentation.
Constants (see page 6420)	The following table lists constants in this documentation.

Classes

	Name	Description
	EConversionError (see page 6381)	EConversionError is the exception class for measurement conversion errors.
	TConvTypeFactor (see page 6382)	TConvTypeFactor describes a single registered conversion type (measurement unit) that differs from its family's base units by a simple conversion factor.
	TConvTypeInfo (see page 6386)	TConvTypeInfo describes a single registered conversion type (measurement unit).
	TConvTypeProcs (see page 6391)	TConvTypeProcs describes a single registered conversion type (measurement unit) that is registered by supplying conversion methods.

Constants

Name	Description
CIllegalConvFamily (see page 6420)	This is constant ConvUtils.CIllegalConvFamily.
CIllegalConvType (see page 6420)	This is constant ConvUtils.CIllegalConvType.

Functions

	Name	Description
	CompatibleConversionType (see page 6396)	Indicates whether a specified conversion type is registered with a specified conversion family.
	CompatibleConversionTypes (see page 6396)	Indicates whether the Convert (see page 6397) function can convert between two specified conversion types.
	Convert (see page 6397)	Converts a measurement from one set of units to another.
	Convert (see page 6397)	Converts a measurement from one set of units to another.
	ConvertFrom (see page 6398)	Converts a measurement from the specified units to the base units of its conversion family.
	ConvertTo (see page 6399)	Converts a measurement from the base units of a conversion family into a specified conversion type.

	ConvFamilyToDescription (see page 6399)	Returns the string description of what a conversion family measures.
	ConvTypeToDescription (see page 6400)	Returns the string description of a conversion type (measurement unit).
	ConvTypeToFamily (see page 6400)	Returns the identifier for the conversion family with which a conversion type or pair of types is registered.
	ConvTypeToFamily (see page 6400)	Returns the identifier for the conversion family with which a conversion type or pair of types is registered.
	ConvUnitAdd (see page 6401)	Adds two measurements and returns the result using a specified unit of measurement.
	ConvUnitCompareValue (see page 6402)	Indicates the relationship between two measurements.
	ConvUnitDec (see page 6402)	Decrements a specified measurement by a specified amount.
	ConvUnitDec (see page 6402)	Decrements a specified measurement by a specified amount.
	ConvUnitDiff (see page 6403)	Subtracts one measurement from another and returns the result using a specified unit of measurement.
	ConvUnitInc (see page 6404)	Increments a specified measurement by a specified amount.
	ConvUnitInc (see page 6404)	Increments a specified measurement by a specified amount.
	ConvUnitSameValue (see page 6404)	Indicates whether two measurements are equivalent.
	ConvUnitToStr (see page 6405)	Formats a measurement and its conversion unit into a human-readable string.
	ConvUnitWithinNext (see page 6406)	Indicates whether a specified measurement exceeds another measurement by at most a specified amount.
	ConvUnitWithinPrevious (see page 6406)	Indicates whether a specified measurement is at most a specified amount less than another measurement.
	DescriptionToConvFamily (see page 6407)	Retrieves the identifier for a conversion family given its name.
	DescriptionToConvType (see page 6408)	Retrieves the identifier for a conversion type given its name and family.
	DescriptionToConvType (see page 6408)	Retrieves the identifier for a conversion type given its name and family.
	GetConvFamilies (see page 6408)	Returns a list of all registered conversion families.
	GetConvTypes (see page 6409)	Returns a list of all registered conversion types in a specified conversion family.
	RaiseConversionError (see page 6409)	Raises an EConversionError (see page 6381) exception.
	RaiseConversionError (see page 6409)	Raises an EConversionError (see page 6381) exception.
	RaiseConversionRegError (see page 6410)	This is function ConvUtils.RaiseConversionRegError.
	RegisterConversionFamily (see page 6410)	Registers a new conversion family and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	StrToConvUnit (see page 6412)	Parses a string into a value and conversion type.
	TryConvTypeToFamily (see page 6413)	Retrieves the identifier for the conversion family with which a conversion type or pair of types is registered.
	TryConvTypeToFamily (see page 6413)	Retrieves the identifier for the conversion family with which a conversion type or pair of types is registered.
	TryStrToConvUnit (see page 6414)	Parses a string into a value and conversion type.
	UnregisterConversionFamily (see page 6414)	Unregisters a conversion family previously registered using RegisterConversionFamily (see page 6410).
	UnregisterConversionType (see page 6415)	Unregisters a conversion type previously registered using RegisterConversionType (see page 6411).

Types

Name	Description
TConversionProc (see page 6416)	This is type ConvUtils.TConversionProc.
TConvFamily (see page 6416)	This is type ConvUtils.TConvFamily.
TConvFamilyArray (see page 6417)	TConvFamilyArray represents a dynamic array of conversion families.
TConvType (see page 6417)	This is type ConvUtils.TConvType.
TConvTypeArray (see page 6417)	TConvTypeArray represents a dynamic array of conversion types (measurement units)
TConvTypeList (see page 6418)	This is type ConvUtils.TConvTypeList.

Variables

Name	Description
GConvUnitToStrFmt (see page 6419)	This is variable ConvUtils.GConvUnitToStrFmt.

33.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EConversionError (see page 6381)	EConversionError is the exception class for measurement conversion errors.
	TConvTypeFactor (see page 6382)	TConvTypeFactor describes a single registered conversion type (measurement unit) that differs from its family's base units by a simple conversion factor.
	TConvTypeInfo (see page 6386)	TConvTypeInfo describes a single registered conversion type (measurement unit).
	TConvTypeProcs (see page 6391)	TConvTypeProcs describes a single registered conversion type (measurement unit) that is registered by supplying conversion methods.

33.1.1 EConversionError Class

EConversionError is the exception class for measurement conversion errors.

Class Hierarchy

Pascal

```
EConversionError = class(Exception);
```

C++

```
class EConversionError : public Exception;
```

File

ConvUtils

Description

EConversionError is raised by the global Convert (see page 6397) function when

The specified units (TConvType (see page 6417) values) are not compatible with each other.

The specified units are not registered with any conversion family.

It is also thrown by the RegisterConversionType (see page 6411) function when an application tries to register a conversion type with an unregistered conversion family.

RaiseConversionError

Convert

TConvType

RegisterConversionType

33.1.2 TConvTypeFactor Class

TConvTypeFactor describes a single registered conversion type (measurement unit) that differs from its family's base units by a simple conversion factor.

Class Hierarchy

Pascal

```
TConvTypeFactor = class(TConvTypeInfo);
```

C++

```
class TConvTypeFactor : public TConvTypeInfo;
```

File

ConvUtils

Description

The global RegisterConversionType (see page 6411) function creates a TConvTypeFactor instance automatically when you register a conversion type by supplying a conversion factor. TConvTypeFactor implements the FromCommon (see page 6384) and ToCommon (see page 6385) methods to perform their conversions by using a conversion factor that is the value of the Factor (see page 6385) property.

There is no need to use TConvTypeFactor directly. To register a conversion type that uses a simple conversion factor, call RegisterConversionType (see page 6411) using the syntax that supplies a conversion factor.

You can, however, use TConvTypeFactor as a base class when implementing your own conversion type that performs addition actions beyond a conversion factor. For example, you could write a class that multiplies by a conversion factor and then shifts the zero point by adding a constant.

33.1.2.1 TConvTypeFactor Members

The following tables list the members exposed by TConvTypeFactor.

Protected Properties

	Name	Description
R	Factor (see page 6385)	Specifies the conversion factor that converts from the conversion type into the base units of the conversion family.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6383)	Creates an instance of TConvTypeFactor (see page 6382).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
V	FromCommon (see page 6384)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ToCommon (see page 6385)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Public Properties

	Name	Description
R	ConvFamily (see page 6390)	Identifies the conversion family to which the conversion type belongs.
R	ConvType (see page 6390)	Indicates the registered identifier for the conversion type.
R	Description (see page 6391)	Names the measurement unit represented by the conversion type.

33.1.2.2 TConvTypeFactor.Create Constructor

Creates an instance of TConvTypeFactor (see page 6382).

Pascal

```
constructor Create(const AConvFamily: TConvFamily; const ADescription: string; const AFactor:
Double);
```

C++

```
__fastcall TConvTypeFactor(const TConvFamily AConvFamily, const AnsiString ADescription, const
Double AFactor);
```

Description

Call Create to instantiate a TConvTypeFactor (see page 6382) descendant at runtime. This descendant can then be passed to the RegisterConversionType (see page 6411) function in order to register a new conversion type. There is no need to instantiate TConvTypeFactor (see page 6382) instances directly, because the RegisterConversionType (see page 6411) function creates a new TConvTypeFactor (see page 6382) instance when you register a conversion type by specifying a conversion factor.

Create assigns the AFactor parameter to the Factor (see page 6385) property, the AConvFamily parameter to the ConvFamily (see page 6390) property, and the ADescription parameter to the Description (see page 6391) property.

If AFactor is zero, Create raises an EZeroDivide exception. If AConvFamily is not the identifier of a registered conversion family, Create raises an EConversionError (see page 6381) exception.

See Also

RegisterConversionType (see page 6411)

ConvFamily (see page 6390)

Description (see page 6391)

EConversionError (see page 6381)

EZeroDivide (see page 22761)

33.1.2.3 TConvTypeFactor Methods

The methods of the TConvTypeFactor class are listed here.

Public Methods

	Name	Description
	FromCommon (see page 6384)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
	ToCommon (see page 6385)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

33.1.2.3.1 TConvTypeFactor.FromCommon Method

Converts measurements in the base unit for the conversion family into the units represented by this conversion type.

Pascal

```
function FromCommon(const AValue: Double): Double; override;
```

C++

```
virtual __fastcall Double FromCommon(const Double AValue);
```

Description

FromCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon (see page 6385) method of the source conversion type's TConvTypeFactor (see page 6382) instance to obtain the measurement in the base units of the conversion family, and then calls the FromCommon method of the destination conversion type's TConvTypeFactor (see page 6382) instance to obtain the measurement in the destination units.

AValue is a value expressed in the base units of the conversion family.

FromCommon divides AValue by the value of the Factor (see page 6385) property and returns the result.

See Also

ToCommon (see page 6385)

ConvFamily (see page 6390)

Convert (see page 6397)

Factor (see page 6385)

33.1.2.3.2 TConvTypeFactor.ToCommon Method

Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Pascal

```
function ToCommon(const AValue: Double): Double; override;
```

C++

```
virtual __fastcall Double ToCommon(const Double AValue);
```

Description

ToCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon method of the source conversion type's TConvTypeFactor (see page 6382) instance to obtain the measurement in the base units of the conversion family, and then calls the ToCommon method of the destination conversion type's TConvTypeFactor (see page 6382) instance to obtain the measurement in the destination units.

AValue is a value expressed in the units represented by this conversion type.

ToCommon multiplies AValue by the value of the Factor (see page 6385) property and returns the result.

See Also

FromCommon (see page 6384)

ConvFamily (see page 6390)

Convert (see page 6397)

Factor (see page 6385)

33.1.2.4 TConvTypeFactor Properties

The properties of the TConvTypeFactor class are listed here.

Protected Properties

	Name	Description
R	Factor (see page 6385)	Specifies the conversion factor that converts from the conversion type into the base units of the conversion family.

33.1.2.4.1 TConvTypeFactor.Factor Property

Specifies the conversion factor that converts from the conversion type into the base units of the conversion family.

Pascal

```
property Factor: Double;
```

C++

```
__property Double Factor;
```

Description

Factor is the conversion factor that defines the relationship between this conversion type and the base units of its conversion family. The ToCommon (see page 6385) method multiplies a measurement made using this conversion type to obtain the corresponding value that uses the base units for the conversion family. The FromCommon (see page 6384) method divides a measurement made using the base units for the conversion family to obtain the corresponding value expressed using this conversion unit.

See Also

FromCommon (see page 6384)

ToCommon (see page 6385)

33.1.3 TConvTypeInfo Class

TConvTypeInfo describes a single registered conversion type (measurement unit).

Class Hierarchy

Pascal

```
TConvTypeInfo = class(TObject);
```

C++

```
class TConvTypeInfo : public TObject;
```

File

ConvUtils

Description

TConvTypeInfo contains information about a conversion type, including

The ConvFamily (see page 6390) property, which indicates the conversion family to which the conversion type belongs.

The ConvType (see page 6390) property, which is the TConvType (see page 6417) identifier for the conversion type.

The Description (see page 6391) property, which is a human-readable description of the conversion type.

In addition, each TConvTypeInfo instance defines two methods for converting between the conversion type and the base units of its conversion family. These methods are abstract (pure virual) in TConvTypeInfo, and implemented by the descendant classes created by the RegisterConversionType (see page 6411) function.

When you call RegisterConversionType (see page 6411) to register a new conversion type (measurement unit), you can describe the new unit in one of three ways:

Specify the conversion family, a description, and supply a factor for converting from the new type to the base units of the conversion family.

Specify the conversion family, a description, and supply two methods for converting between the new type and the base units of the conversion family.

Provide a TConvTypeInfo descendant whose properties describe the conversion family and description and whose methods

convert between the new type and the base units of the conversion family.

If you choose either of the first two methods, RegisterConversionType (see page 6411) creates a special TConvTypeInfo descendant to represent the new conversion type.

By creating your own TConvTypeInfo descendant, you can make use of a common conversion scheme that relies only on a simple parameterized conversion method rather than creating many nearly identical conversion functions, one for each conversion type. Thus, for example, the TConvTypeFactor (see page 6382) class, which is created automatically when you register a conversion type by specifying a conversion factor, implements the FromCommon (see page 6389) and ToCommon (see page 6389) methods only once, using a property to specify the conversion factor.

33.1.3.1 TConvTypeInfo Members

The following tables list the members exposed by TConvTypeInfo.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6388)	Creates an instance of TConvTypeInfo (see page 6386).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FromCommon (see page 6389)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
A	ToCommon (see page 6389)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Public Properties

	Name	Description
R	ConvFamily (see page 6390)	Identifies the conversion family to which the conversion type belongs.
R	ConvType (see page 6390)	Indicates the registered identifier for the conversion type.
R	Description (see page 6391)	Names the measurement unit represented by the conversion type.

33.1.3.2 TConvTypeInfo.Create Constructor

Creates an instance of TConvTypeInfo (see page 6386).

Pascal

```
constructor Create(const AConvFamily: TConvFamily; const ADescription: string);
```

C++

```
__fastcall TConvTypeInfo(const TConvFamily AConvFamily, const AnsiString ADescription);
```

Description

Call Create to instantiate a TConvTypeInfo (see page 6386) descendant at runtime. This descendant can then be passed to the RegisterConversionType (see page 6411) function in order to register a new conversion type.

Create assigns the AConvFamily parameter to the ConvFamily (see page 6390) property and the ADescription parameter to the Description (see page 6391) property. If AConvFamily is not the identifier of a registered conversion family, Create raises an EConversionError (see page 6381) exception.

See Also

RegisterConversionType (see page 6411)

ConvFamily (see page 6390)

Description (see page 6391)

EConversionError (see page 6381)

33.1.3.3 TConvTypeInfo Methods

The methods of the TConvTypeInfo class are listed here.

Public Methods

	Name	Description
A	FromCommon (see page 6389)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
A	ToCommon (see page 6389)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

33.1.3.3.1 TConvTypeInfo.FromCommon Method

Converts measurements in the base unit for the conversion family into the units represented by this conversion type.

Pascal

```
function FromCommon(const AValue: Double): Double; virtual; abstract;
```

C++

```
virtual __fastcall Double FromCommon(const Double AValue) = 0;
```

Description

FromCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon (see page 6389) method of the source conversion type's TConvTypeInfo (see page 6386) instance to obtain the measurement in the base units of the conversion family, and then calls the FromCommon method of the destination conversion type's TConvTypeInfo (see page 6386) instance to obtain the measurement in the destination units.

TConvTypeInfo (see page 6386) introduces FromCommon as an abstract (pure virtual) method. Descendant classes implement this method to perform the conversion from the base units of a conversion family into the measurement units represented by this conversion type.

See Also

ToCommon (see page 6389)

ConvFamily (see page 6390)

Convert (see page 6397)

33.1.3.3.2 TConvTypeInfo.ToCommon Method

Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Pascal

```
function ToCommon(const AValue: Double): Double; virtual; abstract;
```

C++

```
virtual __fastcall Double ToCommon(const Double AValue) = 0;
```

Description

ToCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon method of the source conversion type's TConvTypeInfo (see page 6386) instance to obtain the measurement in the base units of the conversion family, and then calls the ToCommon method of the destination conversion type's TConvTypeInfo (see page 6386) instance to obtain the measurement in the destination units.

TConvTypeInfo (see page 6386) introduces ToCommon as an abstract (pure virtual) method. Descendant classes implement this method to perform the conversion from the units represented by this conversion type to the base units of its conversion family.

See Also

FromCommon (see page 6389)

ConvFamily (see page 6390)

Convert (see page 6397)

33.1.3.4 TConvTypeInfo Properties

The properties of the TConvTypeInfo class are listed here.

Public Properties

	Name	Description
R	ConvFamily (see page 6390)	Identifies the conversion family to which the conversion type belongs.
R	ConvType (see page 6390)	Indicates the registered identifier for the conversion type.
R	Description (see page 6391)	Names the measurement unit represented by the conversion type.

33.1.3.4.1 TConvTypeInfo.ConvFamily Property

Identifies the conversion family to which the conversion type belongs.

Pascal

```
property ConvFamily: TConvFamily;
```

C++

```
__property TConvFamily ConvFamily;
```

Description

ConvFamily is the identifier for the conversion family to which the conversion type belong. The RegisterConversionType (see page 6411) function associates each conversion type with its family.

Measurements in the units represented by the conversion type can be converted to any other conversion type in the same family.

See Also

ConvType (see page 6390)

RegisterConversionType (see page 6411)

RegisterConversionFamily (see page 6410)

33.1.3.4.2 TConvTypeInfo.ConvType Property

Indicates the registered identifier for the conversion type.

Pascal

```
property ConvType: TConvType;
```

C++

```
__property TConvType ConvType;
```

Description

ConvType is the identifier for the conversion type described by this TConvTypeInfo (see page 6386) instance. It is generated by the RegisterConversionType (see page 6411) function to uniquely identify the conversion type (measurement unit).

See Also

ConvFamily (see page 6390)

RegisterConversionType (see page 6411)

Description (see page 6391)

33.1.3.4.3 TConvTypeInfo.Description Property

Names the measurement unit represented by the conversion type.

Pascal

```
property Description: string;
```

C++

```
__property AnsiString Description;
```

Description

Description is the descriptive name supplied for the conversion type when it is registered. Typically, this is the name of a type of measurement unit. For example, the Description for the tuFortnights conversion type is 'Fortnights'.

See Also

ConvType (see page 6390)

RegisterConversionType (see page 6411)

33.1.4 TConvTypeProcs Class

TConvTypeProcs describes a single registered conversion type (measurement unit) that is registered by supplying conversion methods.

Class Hierarchy

Pascal

```
TConvTypeProcs = class(TConvTypeInfo);
```

C++

```
class TConvTypeProcs : public TConvTypeInfo;
```

File

ConvUtils

Description

The global RegisterConversionType (see page 6411) function creates a TConvTypeProcs instance automatically when you register a conversion type by supplying functions to convert between the that type and the base units in its conversion family. TConvTypeProcs implements the FromCommon (see page 6393) and ToCommon (see page 6394) methods to perform their conversions by using the functions supplied to its constructor.

There is no need to use TConvTypeProcs directly. To register a conversion type that uses custom conversion functions, call RegisterConversionType (see page 6411) using the syntax that supplies two conversion functions.

You can, however, use TConvTypeProcs as a base class when implementing your own conversion type that performs addition common actions before or after the custom conversion procedure. For example, you could write a class that always rounds the result to a specified number of decimal places after a conversion is computed using the supplied functions.

33.1.4.1 TConvTypeProcs Members

The following tables list the members exposed by TConvTypeProcs.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6393)	Creates an instance of TConvTypeProcs (see page 6391).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
V	FromCommon (see page 6393)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	ToCommon (see page 6394)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Public Properties

	Name	Description
R	ConvFamily (see page 6390)	Identifies the conversion family to which the conversion type belongs.
R	ConvType (see page 6390)	Indicates the registered identifier for the conversion type.
R	Description (see page 6391)	Names the measurement unit represented by the conversion type.

33.1.4.2 TConvTypeProcs.Create Constructor

Creates an instance of TConvTypeProcs (see page 6391).

Pascal

```
constructor Create(const AConvFamily: TConvFamily; const ADescription: string; const
AToCommonProc: TConversionProc; const AFromCommonProc: TConversionProc);
```

C++

```
__fastcall TConvTypeProcs(const TConvFamily AConvFamily, const AnsiString ADescription, const
TConversionProc AToCommonProc, const TConversionProc AFromCommonProc);
```

Description

Call Create to instantiate a TConvTypeProcs (see page 6391) descendant at runtime. This descendant can then be passed to the RegisterConversionType (see page 6411) function in order to register a new conversion type. There is no need to instantiate TConvTypeProcs (see page 6391) instances directly, because the RegisterConversionType (see page 6411) function creates a new TConvTypeProcs (see page 6391) instance when you register a conversion type by specifying two conversion functions.

Create assigns the AConvFamily parameter to the ConvFamily (see page 6390) property, and the ADescription parameter to the Description (see page 6391) property. It saves the AToCommonProc and AFromCommonProc parameters, which it then uses to implement the FromCommon (see page 6393) and ToCommon (see page 6394) methods.

If AConvFamily is not the identifier of a registered conversion family, Create raises an EConversionError (see page 6381) exception.

See Also

RegisterConversionType (see page 6411)

ConvFamily (see page 6390)

Description (see page 6391)

EConversionError (see page 6381)

33.1.4.3 TConvTypeProcs Methods

The methods of the TConvTypeProcs class are listed here.

Public Methods

	Name	Description
	FromCommon (see page 6393)	Converts measurements in the base unit for the conversion family into the units represented by this conversion type.
	ToCommon (see page 6394)	Converts measurements in the units represented by this conversion type to the base units of the conversion family.

33.1.4.3.1 TConvTypeProcs.FromCommon Method

Converts measurements in the base unit for the conversion family into the units represented by this conversion type.

Pascal

```
function FromCommon(const AValue: Double): Double; override;
```

C++

```
virtual __fastcall Double FromCommon(const Double AValue);
```

Description

FromCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon (see page 6394) method of the source conversion type's TConvTypeProcs (see page 6391) instance to obtain the measurement in the base units of the conversion family, and then calls the FromCommon method of the destination conversion type's TConvTypeProcs (see page 6391) instance to obtain the measurement in the destination units.

AValue is a value expressed in the base units of the conversion family.

FromCommon executes the AFromCommonProc function that was supplied to the constructor.

See Also

ToCommon (see page 6394)

ConvFamily (see page 6390)

Convert (see page 6397)

Create (see page 6393)

33.1.4.3.2 TConvTypeProcs.ToCommon Method

Converts measurements in the units represented by this conversion type to the base units of the conversion family.

Pascal

```
function ToCommon(const AValue: Double): Double; override;
```

C++

```
virtual __fastcall Double ToCommon(const Double AValue);
```

Description

ToCommon provides part of the underlying implementation of the global Convert (see page 6397) function. In order to convert a measurement from one set of units to another, Convert (see page 6397) calls the ToCommon method of the source conversion type's TConvTypeProcs (see page 6391) instance to obtain the measurement in the base units of the conversion family, and then calls the ToCommon method of the destination conversion type's TConvTypeProcs (see page 6391) instance to obtain the measurement in the destination units.

AValue is a value expressed in the units represented by this conversion type.

ToCommon executes the AToCommonProc function that was supplied to the constructor.

See Also

FromCommon (see page 6393)

ConvFamily (see page 6390)

Convert (see page 6397)

Create (see page 6393)

33.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CompatibleConversionType (see page 6396)	Indicates whether a specified conversion type is registered with a specified conversion family.
	CompatibleConversionTypes (see page 6396)	Indicates whether the Convert (see page 6397) function can convert between two specified conversion types.
	Convert (see page 6397)	Converts a measurement from one set of units to another.
	Convert (see page 6397)	Converts a measurement from one set of units to another.
	ConvertFrom (see page 6398)	Converts a measurement from the specified units to the base units of its conversion family.
	ConvertTo (see page 6399)	Converts a measurement from the base units of a conversion family into a specified conversion type.
	ConvFamilyToDescription (see page 6399)	Returns the string description of what a conversion family measures.
	ConvTypeToDescription (see page 6400)	Returns the string description of a conversion type (measurement unit).
	ConvTypeToFamily (see page 6400)	Returns the identifier for the conversion family with which a conversion type or pair of types is registered.
	ConvTypeToFamily (see page 6400)	Returns the identifier for the conversion family with which a conversion type or pair of types is registered.
	ConvUnitAdd (see page 6401)	Adds two measurements and returns the result using a specified unit of measurement.
	ConvUnitCompareValue (see page 6402)	Indicates the relationship between two measurements.
	ConvUnitDec (see page 6402)	Decrements a specified measurement by a specified amount.
	ConvUnitDec (see page 6402)	Decrements a specified measurement by a specified amount.
	ConvUnitDiff (see page 6403)	Subtracts one measurement from another and returns the result using a specified unit of measurement.
	ConvUnitInc (see page 6404)	Increments a specified measurement by a specified amount.
	ConvUnitInc (see page 6404)	Increments a specified measurement by a specified amount.
	ConvUnitSameValue (see page 6404)	Indicates whether two measurements are equivalent.
	ConvUnitToStr (see page 6405)	Formats a measurement and its conversion unit into a human-readable string.
	ConvUnitWithinNext (see page 6406)	Indicates whether a specified measurement exceeds another measurement by at most a specified amount.
	ConvUnitWithinPrevious (see page 6406)	Indicates whether a specified measurement is at most a specified amount less than another measurement.
	DescriptionToConvFamily (see page 6407)	Retrieves the identifier for a conversion family given its name.
	DescriptionToConvType (see page 6408)	Retrieves the identifier for a conversion type given its name and family.
	DescriptionToConvType (see page 6408)	Retrieves the identifier for a conversion type given its name and family.
	GetConvFamilies (see page 6408)	Returns a list of all registered conversion families.
	GetConvTypes (see page 6409)	Returns a list of all registered conversion types in a specified conversion family.
	RaiseConversionError (see page 6409)	Raises an EConversionError (see page 6381) exception.
	RaiseConversionError (see page 6409)	Raises an EConversionError (see page 6381) exception.
	RaiseConversionRegError (see page 6410)	This is function ConvUtils.RaiseConversionRegError.
	RegisterConversionFamily (see page 6410)	Registers a new conversion family and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	RegisterConversionType (see page 6411)	Registers a new conversion type and returns its identifier.
	StrToConvUnit (see page 6412)	Parses a string into a value and conversion type.
	TryConvTypeToFamily (see page 6413)	Retrieves the identifier for the conversion family with which a conversion type or pair of types is registered.
	TryConvTypeToFamily (see page 6413)	Retrieves the identifier for the conversion family with which a conversion type or pair of types is registered.

	TryStrToConvUnit (see page 6414)	Parses a string into a value and conversion type.
	UnregisterConversionFamily (see page 6414)	Unregisters a conversion family previously registered using RegisterConversionFamily (see page 6410).
	UnregisterConversionType (see page 6415)	Unregisters a conversion type previously registered using RegisterConversionType (see page 6411).

33.2.1 ConvUtils.CompatibleConversionType Function

Indicates whether a specified conversion type is registered with a specified conversion family.

Pascal

```
function CompatibleConversionType(const AType: TConvType; const AFamily: TConvFamily): Boolean;
```

C++

```
Boolean CompatibleConversionType(const TConvType AType, const TConvFamily AFamily);
```

File

ConvUtils

Description

CompatibleConversionType returns true if AType represents a member of the family specified by AFamily, false otherwise.

When a conversion type is a member of a conversion family, the Convert (see page 6397) function can convert between that type and any other type in the family.

See Also

Convert (see page 6397)

RegisterConversionType (see page 6411)

ConvTypeToFamily (see page 6400)

TryConvTypeToFamily (see page 6413)

33.2.2 ConvUtils.CompatibleConversionTypes Function

Indicates whether the Convert (see page 6397) function can convert between two specified conversion types.

Pascal

```
function CompatibleConversionTypes(const AFrom: TConvType; const ATo: TConvType): Boolean;
```

C++

```
Boolean CompatibleConversionTypes(const TConvType AFrom, const TConvType ATo);
```

File

ConvUtils

Description

CompatibleConversionTypes returns true if AFrom and ATo are in the same conversion family, false otherwise.

When two conversion types are in the same family, the Convert (see page 6397) function can convert between measurements that use them.

See Also

Convert (see page 6397)

RegisterConversionType (see page 6411)

ConvTypeToFamily (see page 6400)

GetConvTypes (see page 6409)

CompatibleConversionType (see page 6396)

TryConvTypeToFamily (see page 6413)

Performing Conversions

33.2.3 ConvUtils.Convert Function

Converts a measurement from one set of units to another.

Pascal

```
function Convert(const AValue: Double; const AFrom: TConvType; const ATo: TConvType): Double;
overload;
function Convert(const AValue: Double; const AFrom1: TConvType; const AFrom2: TConvType; const
ATo1: TConvType; const ATo2: TConvType): Double; overload;
```

C++

```
Double Convert(const Double AValue, const TConvType AFrom, const TConvType ATo);
Double Convert(const Double AValue, const TConvType AFrom1, const TConvType AFrom2, const
TConvType ATo1, const TConvType ATo2);
```

File

ConvUtils

Description

Call Convert to convert the value AValue from one set of measurement units to another.

Using the first syntax, the AFrom parameter specifies the current units of the measurement AValue. Convert returns the corresponding measurement in the units specified by ATo. For example, the following line converts a temperature measurement from degrees Fahrenheit to degrees Kelvin:

Note: TempInKelvin := Convert(StrToFloat(Edit1.Text), tuFahrenheit, tuKelvin);

Note: TempInKelvin = Convert(StrToFloat(Edit1->Text), tuFahrenheit, tuKelvin);

Using the second syntax, the AFrom1 parameter and AFrom2 parameter specify the current units of AValue, where the units for AValue are AFrom1 per AFrom2. Convert returns the corresponding measurement in the units ATo1 per ATo2. For example, the following call converts miles per gallon to kilometers per liter:

Note: nKPL := Convert(StrToFloat(Edit1.Text), duMiles, vuGallons, duKilometers, vuLiter);

Note: double nKPL = Convert(StrToFloat(Edit1.Text), duMiles, vuGallons, duKilometers, vuLiter);

The units specified by AFrom and ATo, AFrom1 and ATo1, and AFrom2 and ATo2 must be in the same conversion family (they must measure the same thing). You can check whether two TConvType (see page 6417) values are in the same conversion

family by calling CompatibleConversionTypes (see page 6396). If the units are not compatible, Convert raises an EConversionError (see page 6381) exception.

Note: The StdConvs (see page 20827) unit defines several families of TConvType (see page 6417) values. See conversion family variables for a list of the predefined families of measurement units and the measurement units in each family. In addition, you can register your own conversion families and units using the RegisterConversionType (see page 6411) and RegisterConversionFamily (see page 6410) functions.

Note: Convert performs its conversion by converting AValue from the AFrom units to the base units of its conversion family, and then from the base units to the ATo units. If the AFrom units and the ATo units differ greatly from the base units of the conversion family, this can lead to problems such as overflow. You can ameliorate these problems by registering your own conversion families that are narrower subsets of a broad conversion family.

See Also

RegisterConversionType (see page 6411)

CompatibleConversionTypes (see page 6396)

TConvFamily (see page 6416)

RegisterConversionFamily (see page 6410)

EConversionError (see page 6381)

33.2.4 ConvUtils.ConvertFrom Function

Converts a measurement from the specified units to the base units of its conversion family.

Pascal

```
function ConvertFrom(const AFrom: TConvType; const AValue: Double): Double;
```

C++

```
Double ConvertFrom(const TConvType AFrom, const Double AValue);
```

File

ConvUtils

Description

Call ConvertFrom to convert the value AValue from the units specified by AFrom to the base units of the conversion family for AFrom.

If AFrom is not a registered conversion type, ConvertFrom raises an EConversionError (see page 6381) exception.

See Also

RegisterConversionType (see page 6411)

TConvFamily (see page 6416)

Convert (see page 6397)

ConvertTo (see page 6399)

33.2.5 ConvUtils.ConvertTo Function

Converts a measurement from the base units of a conversion family into a specified conversion type.

Pascal

```
function ConvertTo(const AValue: Double; const ATo: TConvType): Double;
```

C++

```
Double ConvertTo(const Double AValue, const TConvType ATo);
```

File

ConvUtils

Description

Call ConvertTo to convert the value AValue from the base units of the conversion family for ATo into the conversion units specified by ATo.

If ATo is not a registered conversion type, ConvertTo raises an EConversionError (see page 6381) exception.

See Also

RegisterConversionType (see page 6411)

TConvFamily (see page 6416)

Convert (see page 6397)

ConvertFrom (see page 6398)

33.2.6 ConvUtils.ConvFamilyToDescription Function

Returns the string description of what a conversion family measures.

Pascal

```
function ConvFamilyToDescription(const AFamily: TConvFamily): string;
```

C++

```
AnsiString ConvFamilyToDescription(const TConvFamily AFamily);
```

File

ConvUtils

Description

ConvFamilyToDescription returns the string supplied when the conversion family was registered. Typically, this string is the name of whatever it is that the conversion family measures. For example, ConvFamilyToDescription returns "Volume" when passed an argument of cbVolume.

AFamily is the TConvFamily (see page 6416) value that represents the conversion family. This is the value that is returned by RegisterConversionFamily (see page 6410) when the family is registered.

See Also

ConvTYpeToDescription

REgisterConversionFamily

DescriptionToConvFamily (see page 6407)

33.2.7 ConvUtils.ConvTypeToDescription Function

Returns the string description of a conversion type (measurement unit).

Pascal

```
function ConvTypeToDescription(const AType: TConvType): string;
```

C++

```
AnsiString ConvTypeToDescription(const TConvType AType);
```

File

ConvUtils

Description

ConvTypeToDescription returns the string supplied when the conversion type specified by AType was registered. Typically, this string is the (plural) name of a unit of measurement. For example, ConvTypeToDescription returns 'Millennia' when passed an argument of tuMillennia.

See Also

ConvFamilyToDescription (see page 6399)

RegisterConversionType (see page 6411)

DescriptionToConvType (see page 6408)

ConvTypeToFamily (see page 6400)

ConvUnitToStr (see page 6405)

33.2.8 ConvUtils.ConvTypeToFamily Function

Returns the identifier for the conversion family with which a conversion type or pair of types is registered.

Pascal

```
function ConvTypeToFamily(const AType: TConvType): TConvFamily; overload;
function ConvTypeToFamily(const AFrom: TConvType; const ATo: TConvType): TConvFamily; overload;
```

C++

```
TConvFamily ConvTypeToFamily(const TConvType AType);
TConvFamily ConvTypeToFamily(const TConvType AFrom, const TConvType ATo);
```

File

ConvUtils

Description

ConvTypeToFamily returns the conversion family identifier for the family of the specified conversion type or types. Conversion types are associated with a conversion family by the RegisterConversionType (see page 6411) function when the conversion type is registered.

AType is the identifier for a registered conversion type (unit of measurement).

AFrom and ATo are two registered conversion types that are assumed to be in the same family.

If AType is not registered, or if AFrom and ATo are not registered with the same conversion family, ConvTypeToFamily returns CIllegalConvFamily (see page 6420) (0).

See Also

DescriptionToConvFamily (see page 6407)

RegisterConversionType (see page 6411)

GetConvTypes (see page 6409)

ConvTypeToDescription (see page 6400)

CompatibleConversionType (see page 6396)

TryConvTypeToFamily (see page 6413)

33.2.9 ConvUtils.ConvUnitAdd Function

Adds two measurements and returns the result using a specified unit of measurement.

Pascal

```
function ConvUnitAdd(const AValue1: Double; const AType1: TConvType; const AValue2: Double;
const AType2: TConvType; const AResultType: TConvType): Double;
```

C++

```
Double ConvUnitAdd(const Double AValue1, const TConvType AType1, const Double AValue2, const
TConvType AType2, const TConvType AResultType);
```

File

ConvUtils

Description

Call ConvUnitAdd two add two measurements and obtain the result in a specified conversion type.

AValue1 and AValue2 are the two measurements to be added.

AType1 is the unit of measurement for AValue1.

AType2 is the unit of measurement for AValue2.

AResultType is the unit of measurement for the resulting value.

See Also

ConvUnitDec (see page 6402)

ConvUnitInc (see page 6404)

ConvUnitDiff (see page 6403)

33.2.10 ConvUtils.ConvUnitCompareValue Function

Indicates the relationship between two measurements.

Pascal

```
function ConvUnitCompareValue(const AValue1: Double; const AType1: TConvType; const AValue2:
Double; const AType2: TConvType): TValueRelationship;
```

C++

```
TValueRelationship ConvUnitCompareValue(const Double AValue1, const TConvType AType1, const
Double AValue2, const TConvType AType2);
```

File

ConvUtils

Description

Call ConvUnitCompareValue to compare the two measurements. The two measurements must measure the same thing (use the same conversion family), but do not need to use the same units of measurement.

AValue 1 and AValue2 are the two measurements to compare.

AType1 is the unit of measurement for AValue1.

AType2 is the unit of measurement for AValue2.

ConvUnitCompareValue returns

LessThanValue if AValue1 represents a smaller value than AValue2.

EqualsValue if AValue1 is equivalent to AValue2.

GreaterThanValue if AValue1 represents a larger value than AValue2.

See Also

ConvUnitSameValue (see page 6404)

CompareValue

33.2.11 ConvUtils.ConvUnitDec Function

Decrements a specified measurement by a specified amount.

Pascal

```
function ConvUnitDec(const AValue: Double; const AType: TConvType; const AAmountType:
TConvType): Double; overload;
function ConvUnitDec(const AValue: Double; const AType: TConvType; const AAmount: Double;
const AAmountType: TConvType): Double; overload;
```

C++

```
Double ConvUnitDec(const Double AValue, const TConvType AType, const TConvType AAmountType);
Double ConvUnitDec(const Double AValue, const TConvType AType, const Double AAmount, const
TConvType AAmountType);
```

File

ConvUtils

Description

Call ConvUnitDec two decrement a measurement by a specified amount. The result is returned in the same measurement units as the original amount, although the amount by which the measurement is decremented can be expressed using a different unit of measurement in the same family.

AValue is the original measurement.

AType is the unit of measurement of the starting amount and the return value.

AAmount is the amount by which to decrease AValue. If this value is omitted, it is assumed to be one.

AAmountType is the unit of measurement for AAmount.

See Also

ConvUnitAdd (see page 6401)

ConvUnitInc (see page 6404)

ConvUnitDiff (see page 6403)

Dec

33.2.12 ConvUtils.ConvUnitDiff Function

Subtracts one measurement from another and returns the result using a specified unit of measurement.

Pascal

```
function ConvUnitDiff(const AValue1: Double; const AType1: TConvType; const AValue2: Double;
const AType2: TConvType; const AResultType: TConvType): Double;
```

C++

```
Double ConvUnitDiff(const Double AValue1, const TConvType AType1, const Double AValue2, const
TConvType AType2, const TConvType AResultType);
```

File

ConvUtils

Description

Call ConvUnitDiff to find the difference between two measurements, with the result expressed in a specified conversion type.

AValue1 is the starting value.

AType1 is the unit of measurement for AValue1.

AValue2 is the value to be subtracted from AValue1.

AType2 is the unit of measurement for AValue2.

AResultType is the unit of measurement for the resulting value.

See Also

ConvUnitAdd (see page 6401)

ConvUnitInc (see page 6404)

ConvUnitDec (see page 6402)

ConvUnitWithinNext (see page 6406)

ConvUnitWithinPrevious (see page 6406)

33.2.13 ConvUtils.ConvUnitInc Function

Increments a specified measurement by a specified amount.

Pascal

```
function ConvUnitInc(const AValue: Double; const AType: TConvType; const AAmountType:
TConvType): Double; overload;
function ConvUnitInc(const AValue: Double; const AType: TConvType; const AAmount: Double;
const AAmountType: TConvType): Double; overload;
```

C++

```
Double ConvUnitInc(const Double AValue, const TConvType AType, const TConvType AAmountType);
Double ConvUnitInc(const Double AValue, const TConvType AType, const Double AAmount, const
TConvType AAmountType);
```

File

ConvUtils

Description

Call ConvUnitInc to increment a measurement by a specified amount. The result is returned in the same measurement units as the original amount, although the amount by which the measurement is incremented can be expressed using a different unit of measurement in the same family.

AValue is the original measurement.

AType is the unit of measurement of the starting amount and the return value.

AAmount is the amount by which to increase AValue. If this parameter is omitted, it is assumed to be one.

AAmountType is the unit of measurement for AAmount.

See Also

ConvUnitAdd (see page 6401)

ConvUnitDec (see page 6402)

ConvUnitDiff (see page 6403)

Inc

33.2.14 ConvUtils.ConvUnitSameValue Function

Indicates whether two measurements are equivalent.

Pascal

```
function ConvUnitSameValue(const AValue1: Double; const AType1: TConvType; const AValue2:
Double; const AType2: TConvType): Boolean;
```

C++

```
Boolean ConvUnitSameValue(const Double AValue1, const TConvType AType1, const Double AValue2,
const TConvType AType2);
```

File

ConvUtils

Description

Call ConvUnitSameValue to compare determine whether two measurements are equivalent. The two values can use different units of measurement, but the two units of measurement must be in the same conversion family.

AValue 1 and AValue2 are the two measurements to compare.

AType1 is the unit of measurement for AValue1.

AType2 is the unit of measurement for AValue2.

ConvUnitSameValue returns true if the two measurements are equivalent, false otherwise.

See Also

ConvUnitCompareValue (see page 6402)

SameValue

33.2.15 ConvUtils.ConvUnitToStr Function

Formats a measurement and its conversion unit into a human-readable string.

Pascal

```
function ConvUnitToStr(const AValue: Double; const AType: TConvType): string;
```

C++

```
AnsiString ConvUnitToStr(const Double AValue, const TConvType AType);
```

File

ConvUtils

Description

Call ConvUnitToStr to obtain a string representation of a measurement.

AValue is the number of units.

AType is the conversion type (unit of measurement).

ConvUnitToString formats the result as the string representation of AValue followed by the description that was provided when AType was registered. Thus, for example,

ConvUnitToStr(3.5, duMiles)

returns the string "3.5 Miles"

Warning: The resulting string may seem awkward, depending on the description provided when registering the conversion type. For example, ConvUnitToStr(53, duFahrenheit) produces the string "53 Fahrenheit", not "53 degrees Fahrenheit".

See Also

StrToConvUnit (see page 6412)

RegisterConversionType (see page 6411)

33.2.16 ConvUtils.ConvUnitWithinNext Function

Indicates whether a specified measurement exceeds another measurement by at most a specified amount.

Pascal

```
function ConvUnitWithinNext(const AValue: Double; const ATest: Double; const AType: TConvType;
const AAmount: Double; const AAmountType: TConvType): Boolean;
```

C++

```
Boolean ConvUnitWithinNext(const Double AValue, const Double ATest, const TConvType AType,
const Double AAmount, const TConvType AAmountType);
```

File

ConvUtils

Description

Call ConvUnitWithinNext to determine whether the value specified by ATest exceeds the value specified by AValue by at most AAmount.

AValue is the base value against which to check ATest.

ATest is a measurement to test against AValue.

AType is the unit of measurement for both AValue and ATest.

AAmount is the amount by which ATest can exceed AValue.

AAmountType is the unit of measurement for AAmount.

ConvUnitWithinNext returns true if ATest equals AValue or exceeds it by at most AAmount.

See Also

ConvUnitDiff (see page 6403)

ConvUnitWithinPrevious (see page 6406)

33.2.17 ConvUtils.ConvUnitWithinPrevious Function

Indicates whether a specified measurement is at most a specified amount less than another measurement.

Pascal

```
function ConvUnitWithinPrevious(const AValue: Double; const ATest: Double; const AType:
TConvType; const AAmount: Double; const AAmountType: TConvType): Boolean;
```

C++

```
Boolean ConvUnitWithinPrevious(const Double AValue, const Double ATest, const TConvType AType,
const Double AAmount, const TConvType AAmountType);
```

File

ConvUtils

Description

Call ConvUnitWithinPrevious to determine whether the value specified by ATest is less than the value specified by AValue by at most AAmount.

AValue is the base value against which to check ATest.

ATest is a measurement to test against AValue.

AType is the unit of measurement for both AValue and ATest.

AAmount is the amount by which ATest can be less than AValue.

AAmountType is the unit of measurement for AAmount.

ConvUnitWithinPrevious returns true if ATest equals AValue or is at most AAmount less than AValue.

ConvUnitDiff (see page 6403)

ConvUnitWithinPrevious

33.2.18 ConvUtils.DescriptionToConvFamily Function

Retrieves the identifier for a conversion family given its name.

Pascal

```
function DescriptionToConvFamily(const ADescription: string; out AFamily: TConvFamily):
Boolean;
```

C++

```
Boolean DescriptionToConvFamily(const AnsiString ADescription, TConvFamily AFamily);
```

File

ConvUtils

Description

DescriptionToConvFamily retrieves the conversion family identifier for the family with the name specified by ADescription.

ADescription is the name supplied to the RegisterConversionFamily (see page 6410) method when the family was registered. Typically, it identifies the type of thing measured by conversion types in the family. For example, the description for the cbTemperature family is 'Temperature'.

AFamily returns the identifier for the specified conversion family when DescriptionToConvFamilyt returns true.

DescriptionToConvFamily returns true if ADescription identifies a registered conversion family, false otherwise.

See Also

ConvTypeToFamily (see page 6400)

RegisterConversionFamily (see page 6410)

DescriptionToConvType (see page 6408)

ConvFamilyToDescription (see page 6399)

TryConvTypeToFamily (see page 6413)

33.2.19 ConvUtils.DescriptionToConvType Function

Retrieves the identifier for a conversion type given its name and family.

Pascal

```
function DescriptionToConvType(const ADescription: string; out AType: TConvType): Boolean;
overload;
function DescriptionToConvType(const AFamily: TConvFamily; const ADescription: string; out
AType: TConvType): Boolean; overload;
```

C++

```
Boolean DescriptionToConvType(const AnsiString ADescription, TConvType AType);
Boolean DescriptionToConvType(const TConvFamily AFamily, const AnsiString ADescription,
TConvType AType);
```

File

ConvUtils

Description

DescriptionToConvType returns the conversion type identifier for the conversion type (measurement unit) that was registered under the name specified by ADescription.

AFamily is the identifier for the conversion family supplied to the RegisterConversionType (see page 6411) function when the conversion type was registered.

ADescription is the name supplied to the RegisterConversionType (see page 6411) function when the conversion type was registered. Typically, it is the plural form of the measurement unit name. For example, the description for the auAcres conversion type is 'Acres'.

AType returns the identifier for the conversion type.

DescriptionToConvType returns true if it can successfully locate and return the specified conversion type, false otherwise.

See Also

ConvTypeToDescription (see page 6400)

RegisterConversionType (see page 6411)

DescriptionToConvFamily (see page 6407)

StrToConvUnit (see page 6412)

33.2.20 ConvUtils.GetConvFamilies Function

Returns a list of all registered conversion families.

Pascal

```
procedure GetConvFamilies(out AFamilies: TConvFamilyArray);
```

C++

```
GetConvFamilies(TConvFamilyArray AFamilies);
```

File

ConvUtils

Description

GetConvFamilies returns a dynamic array of identifiers for all currently registered conversion families. Every entry in the array represents a conversion family registered by the RegisterConversionFamily (see page 6410) function.

See Also

RegisterConversionFamily (see page 6410)

GetConvTypes (see page 6409)

33.2.21 ConvUtils.GetConvTypes Function

Returns a list of all registered conversion types in a specified conversion family.

Pascal

```
procedure GetConvTypes(const AFamily: TConvFamily; out ATypes: TConvTypeArray);
```

C++

```
GetConvTypes(const TConvFamily AFamily, TConvTypeArray ATypes);
```

File

ConvUtils

Description

GetConvTypes fills a dynamic array with all the conversion types (TConvType (see page 6417) values) that have been registered for a specified conversion family. Any measurement based on one of these conversion types can be converted into a measurement based on any other in the family.

AFamily is the identifier for the conversion family.

ATypes is the array to fill with conversion type identifiers.

See Also

RegisterConversionType (see page 6411)

GetConvFamilies (see page 6408)

33.2.22 ConvUtils.RaiseConversionError Function

Raises an EConversionError (see page 6381) exception.

Pascal

```
procedure RaiseConversionError(const AText: string); overload;
procedure RaiseConversionError(const AText: string; const AArgs: array of const); overload;
```

C++

```
RaiseConversionError(const AnsiString AText);
RaiseConversionError(const AnsiString AText, const array of const AArgs);
```

File

ConvUtils

Description

Call RaiseConversionError to raise an EConversionError (see page 6381) exception. Most applications do not need to call this method because most conversion errors are raised by the Convert (see page 6397) function.

However, you might want to raise an EConversionError (see page 6381) exception from a method you supply to the RegisterConversionType (see page 6411) function for converting between a new conversion type and the base units of a conversion family. For example, if a unit of measurement does not permit negative values, you could check for negative values and call RaiseConversionError if an attempt is made to use one in a conversion.

AText is the error message for the exception that is raised. It can contain standard string formatting specifiers.

AArgs is a list of arguments that are supplied for the format specifiers in AText.

Note: In C++, Args_Size is the index of the last argument in AArgs. (One less than the number of elements).

See Also

EConversionError (see page 6381)

Convert (see page 6397)

33.2.23 ConvUtils.RaiseConversionRegError Function

Pascal

```
procedure RaiseConversionRegError(AFamily: TConvFamily; const ADescription: string);
```

C++

```
RaiseConversionRegError(TConvFamily AFamily, const AnsiString ADescription);
```

File

ConvUtils

Description

This is function ConvUtils.RaiseConversionRegError.

33.2.24 ConvUtils.RegisterConversionFamily Function

Registers a new conversion family and returns its identifier.

Pascal

```
function RegisterConversionFamily(const ADescription: string): TConvFamily;
```

C++

```
TConvFamily RegisterConversionFamily(const AnsiString ADescription);
```

File

ConvUtils

Description

Call RegisterConversionFamily to create a new conversion family. A conversion family represents a type of thing that can be measured using different measurement units. For example, the StdConvs (see page 20827) unit defines conversion families for distance, volume, area, temperature, and so on.

Once you have registered a new conversion family, you can register units of measurement that belong to the family using the RegisterConversionType (see page 6411) function. RegisterConversionType (see page 6411) takes the conversion family identifier returned by RegisterConversionFamily as an argument. The global Convert (see page 6397) function can then convert between any two conversion types (units of measurement) that have been registered with the same conversion family.

ADescription is a string that names the conversion family. Typically, this names the thing measured, such as 'Distance', 'Volume', 'Area', 'Temperature', and so on.

RegisterConversionFamily returns an identifier for the new conversion family.

See Also

RegisterConversionType (see page 6411)

UnregisterConversionFamily (see page 6414)

GetConvFamilies (see page 6408)

Convert (see page 6397)

Adding New Measurement Types

Converting Measurements

33.2.25 ConvUtils.RegisterConversionType Function

Registers a new conversion type and returns its identifier.

Pascal

```
function RegisterConversionType(const AFamily: TConvFamily; const ADescription: string; const
AFactor: Double): TConvType; overload;
function RegisterConversionType(const AFamily: TConvFamily; const ADescription: string; const
AToCommonProc: TConversionProc; const AFromCommonProc: TConversionProc): TConvType; overload;
function RegisterConversionType(AConvTypeInfo: TConvTypeInfo; out AType: TConvType): Boolean;
overload;
```

C++

```
TConvType RegisterConversionType(const TConvFamily AFamily, const AnsiString ADescription,
const Double AFactor);
TConvType RegisterConversionType(const TConvFamily AFamily, const AnsiString ADescription,
const TConversionProc AToCommonProc, const TConversionProc AFromCommonProc);
Boolean RegisterConversionType(TConvTypeInfo AConvTypeInfo, TConvType AType);
```

File

ConvUtils

Description

Call RegisterConversionType to add a new conversion type (unit of measurement) to a registered conversion family. The global Convert (see page 6397) function can convert between any two conversion types that have been registered with the same conversion family.

AFamily is the identifier for the conversion family to which the new conversion type belongs. This can be one of the pre-defined

conversion families in the StdConvs (see page 20827) unit, or the value returned from a call to RegisterConversionFamily (see page 6410).

ADescription is a string that names the conversion type. Typically, this is the plural form of the measurement unit name. For example, the description for the duMeters conversion type is 'Meters'.

AFactor is the factor by which a measurement using the new conversion type must be multiplied to convert to the base units of the conversion family. Thus, for example, the factor for duKilometers is 1000 because the base unit for the distance family is meters.

AToCommonProc and AFromCommonProc are functions that convert between the new conversion type and the base units for the conversion family. They are used when conversions between the new conversion type and the base units can't be accomplished by a simple multiplication. For example, temperature measurements use different values for the 0 point, and so require conversion functions rather than a factor. AToCommonProc converts measurements in the new conversion type to the base units for the family, while AFromCommonProc converts measurements in the base units for the family to the new conversion type.

AConvTypeInfo is an instance of a TConvTypeInfo (see page 6386) descendant that represents the new conversion type. On entry, its ConvFamily and Description properties must be set to the conversion family that contains the new conversion type and the string that names the new type (analogous to the AFamily and ADescription parameters). In addition, its ToCommon and FromCommon methods convert between the new conversion type and the base units of the conversion family (analogous to the AToCommonProc and AFromCommonProc parameters). RegisterConversionType sets its ConvType property, which it also returns as the AType parameter. When using this syntax, RegisterConversionType returns true if the new type is successfully registered, false if the new type could not be registered (either because the family was not registered or because the description was already registered).

RegisterConversionFamily (see page 6410)

UnregisterConversionType (see page 6415)

GetConvTypes (see page 6409)

Convert (see page 6397)

Adding New Measurement Types

Converting Measurements

33.2.26 ConvUtils.StrToConvUnit Function

Parses a string into a value and conversion type.

Pascal

```
function StrToConvUnit(AText: string; out AType: TConvType): Double;
```

C++

```
Double StrToConvUnit(AnsiString AText, TConvType AType);
```

File

ConvUtils

Description

Call StrToConvUnit to reverse the conversion performed by the ConvUnitToStr (see page 6405) function.

AText is the string to parse. It should represent a numeric value followed by the name of a conversion type. For example, '2.5 hours'.

AType returns the identifier for the conversion type (unit of measurement).

StrToConvUnit returns the number of units (the numeric portion of the string).

If AText can't be parsed into a value and conversion type, StrToConvUnit raises an EConversionError (see page 6381) exception.

See Also

ConvUnitToStr (see page 6405)

RegisterConversionType (see page 6411)

DescriptionToConvType (see page 6408)

TryStrToConvUnit (see page 6414)

EConversionError (see page 6381)

33.2.27 ConvUtils.TryConvTypeToFamily Function

Retrieves the identifier for the conversion family with which a conversion type or pair of types is registered.

Pascal

```
function TryConvTypeToFamily(const AType: TConvType; out AFamily: TConvFamily): Boolean;
overload;
function TryConvTypeToFamily(const AFrom: TConvType; const ATo: TConvType; out AFamily:
TConvFamily): Boolean; overload;
```

C++

```
Boolean TryConvTypeToFamily(const TConvType AType, TConvFamily AFamily);
Boolean TryConvTypeToFamily(const TConvType AFrom, const TConvType ATo, TConvFamily AFamily);
```

File

ConvUtils

Description

TryConvTypeToFamily looks up the conversion family identifier for the family of the specified conversion type or types. Conversion types are associated with a conversion family by the RegisterConversionType (see page 6411) function when the conversion type is registered.

AType is the identifier for a registered conversion type (unit of measurement).

AFrom and ATo are two registered conversion types that are assumed to be in the same family.

AFamily returns the identifier of the conversion family.

TryConvTypeToFamily returns true if the family can be obtained (if AType is a registered conversion type or if AFrom and ATo are both registered in the same family), false otherwise.

GetConvTypes (see page 6409)

ConvTypeToDescription (see page 6400)

CompatibleConversionType (see page 6396)

ConvTypeToFamily (see page 6400)

33.2.28 ConvUtils.TryStrToConvUnit Function

Parses a string into a value and conversion type.

Pascal

```
function TryStrToConvUnit(AText: string; out AValue: Double; out AType: TConvType): Boolean;
```

C++

```
Boolean TryStrToConvUnit(AnsiString AText, Double AValue, TConvType AType);
```

File

ConvUtils

Description

Call TryStrToConvUnit to reverse the conversion performed by the ConvUnitToStr (see page 6405) function.

AText is the string to parse. It should represent a numeric value followed by the name of a conversion type. For example, '2.5 hours'.

AValue returns the number of units (the numeric value in the string).

AType returns the identifier for the conversion type (unit of measurement).

TryStrToConvUnit returns true if AText can be converted, false otherwise.

See Also

ConvUnitToStr (see page 6405)

RegisterConversionType (see page 6411)

DescriptionToConvType (see page 6408)

StrToConvUnit (see page 6412)

33.2.29 ConvUtils.UnregisterConversionFamily Function

Unregisters a conversion family previously registered using RegisterConversionFamily (see page 6410).

Pascal

```
procedure UnregisterConversionFamily(const AFamily: TConvFamily);
```

C++

```
UnregisterConversionFamily(const TConvFamily AFamily);
```

File

ConvUtils

Description

Call UnregisterConversionFamily when a conversion family becomes unavailable. Typically, this function is called from the finalization section of a unit that implements the conversion family. UnregisterConversionFamily unregisters all of the conversion types registered with the family and then unregisters the family itself.

AFamily is the conversion family identifier for the family to unregister.

After a conversion family is unregistered, it is no longer listed by the GetConvFamilies (see page 6408) procedure. Calling the Convert (see page 6397) function with conversion types from an unregistered family results in an EConversionError (see page 6381) exception.

See Also

UnregisterConversionType (see page 6415)

RegisterConversionFamily (see page 6410)

GetConvFamilies (see page 6408)

EConversionError (see page 6381)

Convert (see page 6397)

33.2.30 ConvUtils.UnregisterConversionType Function

Unregisters a conversion type previously registered using RegisterConversionType (see page 6411).

Pascal

```
procedure UnregisterConversionType(const AType: TConvType);
```

C++

```
UnregisterConversionType(const TConvType AType);
```

File

ConvUtils

Description

Call UnregisterConversionType when a conversion type becomes unavailable. Typically, this function is called from the finalization section of a unit that implements the conversion type.

AType is the conversion type identifier for the type to unregister.

After a conversion type is unregistered, it is no longer listed by the GetConvTypes (see page 6409) procedure. Calling the Convert (see page 6397) function with an unregistered conversion type results in an EConversionError (see page 6381) exception.

33.3 Types

The following table lists types in this documentation.

Types

Name	Description
TConversionProc (see page 6416)	This is type ConvUtils.TConversionProc.
TConvFamily (see page 6416)	This is type ConvUtils.TConvFamily.
TConvFamilyArray (see page 6417)	TConvFamilyArray represents a dynamic array of conversion families.
TConvType (see page 6417)	This is type ConvUtils.TConvType.
TConvTypeArray (see page 6417)	TConvTypeArray represents a dynamic array of conversion types (measurement units)
TConvTypeList (see page 6418)	This is type ConvUtils.TConvTypeList.

33.3.1 ConvUtils.TConversionProc Type

Pascal

```
TConversionProc = function (const AValue: Double): Double;
```

C++

```
(const AValue: Double): Double ( TConversionProc)();
```

File

ConvUtils

Description

This is type ConvUtils.TConversionProc.

33.3.2 ConvUtils.TConvFamily Type

Pascal

```
TConvFamily = type Word;
```

C++

```
type Word TConvFamily;
```

File

ConvUtils

Description

This is type ConvUtils.TConvFamily.

33.3.3 ConvUtils.TConvFamilyArray Type

TConvFamilyArray represents a dynamic array of conversion families.

Pascal

```
TConvFamilyArray = array of TConvFamily;
```

C++

```
array of TConvFamily TConvFamilyArray;
```

File

ConvUtils

Description

TConvFamilyArray is a dynamic array of TConvFamily (see page 6416) values. Each value in the array is the identifier for a family of TConvType (see page 6417) values. That is, each entry represents a set of registered conversion types that can be converted into each other.

See Also

IDH

33.3.4 ConvUtils.TConvType Type

Pascal

```
TConvType = type Word;
```

C++

```
type Word TConvType;
```

File

ConvUtils

Description

This is type ConvUtils.TConvType.

33.3.5 ConvUtils.TConvTypeArray Type

TConvTypeArray represents a dynamic array of conversion types (measurement units)

Pascal

```
TConvTypeArray = array of TConvType;
```

C++

```
array of TConvType TConvTypeArray;
```

File

ConvUtils

Description

TConvTypeArray is a dynamic array of TConvType (see page 6417) values. Each value in the array is the identifier for a single conversion type (measurement unit).

See Also

IDH

33.3.6 ConvUtils.TConvTypeList Type

Pascal

```
TConvTypeList = array of TConvTypeInfo;
```

C++

```
array of TConvTypeInfo TConvTypeList;
```

File

ConvUtils

Description

This is type ConvUtils.TConvTypeList.

33.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
GConvUnitToStrFmt (see page 6419)	This is variable ConvUtils.GConvUnitToStrFmt.

33.4.1 ConvUtils.GConvUnitToStrFmt Variable

Pascal

```
GConvUnitToStrFmt: string = '%f %s';
```

C++

```
AnsiString GConvUnitToStrFmt = '%f %s';
```

File

ConvUtils

Description

This is variable ConvUtils.GConvUnitToStrFmt.

33.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CIllegalConvFamily (see page 6420)	This is constant ConvUtils.CIllegalConvFamily.
CIllegalConvType (see page 6420)	This is constant ConvUtils.CIllegalConvType.

33.5.1 ConvUtils.CIllegalConvFamily Constant

Pascal

```
CIllegalConvFamily: TConvFamily = 0;
```

C++

```
TConvFamily CIllegalConvFamily = 0;
```

File

ConvUtils

Description

This is constant ConvUtils.CIllegalConvFamily.

33.5.2 ConvUtils.CIllegalConvType Constant

Pascal

```
CIllegalConvType: TConvType = 0;
```

C++

```
TConvType CIllegalConvType = 0;
```

File

ConvUtils

Description

This is constant ConvUtils.CIllegalConvType.

34 CorbaObj Namespace

This is namespace CorbaObj.

Name	Description
CorbaInterfaceIDManager (see page 6493)	This is variable CorbaObj.CorbaInterfaceIDManager.
CorbaSkeletonManager (see page 6493)	This is variable CorbaObj.CorbaSkeletonManager.
CorbaStubManager (see page 6493)	This is variable CorbaObj.CorbaStubManager.

34.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ECorbaDispatch (see page 6423)	This is class CorbaObj.ECorbaDispatch.
	ECorbaException (see page 6423)	This is class CorbaObj.ECorbaException.
	ECorbaUserException (see page 6426)	This is class CorbaObj.ECorbaUserException.
	TBOA (see page 6431)	This is class CorbaObj.TBOA.
	TCorbaDispatchStub (see page 6433)	This is class CorbaObj.TCorbaDispatchStub.
	TCorbaFactory (see page 6436)	This is class CorbaObj.TCorbaFactory.
	TCorbaFactoryManager (see page 6442)	This is class CorbaObj.TCorbaFactoryManager.
	TCorbaImplementation (see page 6444)	This is class CorbaObj.TCorbaImplementation.
	TCorbaInterfaceIDManager (see page 6449)	This is class CorbaObj.TCorbaInterfaceIDManager.
	TCorbaListManager (see page 6451)	This is class CorbaObj.TCorbaListManager.
	TCorbaObjectFactory (see page 6453)	This is class CorbaObj.TCorbaObjectFactory.
	TCorbaSkeleton (see page 6456)	This is class CorbaObj.TCorbaSkeleton.
	TCorbaSkeletonManager (see page 6460)	This is class CorbaObj.TCorbaSkeletonManager.
	TCorbaStub (see page 6462)	This is class CorbaObj.TCorbaStub.
	TCorbaStubManager (see page 6466)	This is class CorbaObj.TCorbaStubManager.
	TORB (see page 6467)	This is class CorbaObj.TORB.

34.1.1 ECorbaDispatch Class

Class Hierarchy

Pascal

```
ECorbaDispatch = class(Exception);
```

C++

```
class ECorbaDispatch : public Exception;
```

File

CorbaObj

Description

This is class CorbaObj.ECorbaDispatch.

34.1.2 ECorbaException Class

Class Hierarchy

Pascal

```
ECorbaException = class(Exception);
```

C++

```
class ECorbaException : public Exception;
```

File

CorbaObj

Description

This is class CorbaObj.ECorbaException.

34.1.2.1 ECorbaException Members

The following tables list the members exposed by ECorbaException.

Protected Methods

	Name	Description
	GetMessage (see page 6425)	This is GetMessage, a member of class ECorbaException.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.

	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	Name (see page 6425)	This is Name, a member of class ECorbaException.

34.1.2.2 ECorbaException Methods

The methods of the ECorbaException class are listed here.

Protected Methods

	Name	Description
	GetMessage (see page 6425)	This is GetMessage, a member of class ECorbaException.

34.1.2.2.1 ECorbaException.GetMessage Method

Pascal

```
function GetMessage: string;
```

C++

```
__fastcall AnsiString GetMessage();
```

Description

This is GetMessage, a member of class ECorbaException.

34.1.2.3 ECorbaException Properties

The properties of the ECorbaException class are listed here.

Public Properties

	Name	Description
R	Name (see page 6425)	This is Name, a member of class ECorbaException.

34.1.2.3.1 ECorbaException.Name Property

Pascal

```
property Name: string;
```

C++

```
__property AnsiString Name;
```

Description

This is Name, a member of class ECorbaException.

34.1.3 ECorbaUserException Class

Class Hierarchy

System::TObject → SysUtils.Exception → CorbaObj.ECorbaException → CorbaObj.ECorbaUserException

Pascal

```
ECorbaUserException = class(ECorbaException);
```

C++

```
class ECorbaUserException : public ECorbaException;
```

File

CorbaObj

Description

This is class CorbaObj.ECorbaUserException.

34.1.3.1 ECorbaUserException Members

The following tables list the members exposed by ECorbaUserException.

Protected Methods

	Name	Description
	GetMessage (see page 6425)	This is GetMessage, a member of class ECorbaException.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Copy (see page 6430)	This is Copy, a member of class ECorbaUserException.
	Create (see page 6427)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.

	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Throw (see page 6430)	This is Throw, a member of class ECorbaUserException.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	Name (see page 6425)	This is Name, a member of class ECorbaException.
R	Proxy (see page 6430)	This is Proxy, a member of class ECorbaUserException.

34.1.3.2 ECorbaUserException.Create Constructor

Instantiates an instance of an exception with a simple message string.

Pascal

```
constructor Create(const Name: string);
```

C++

```
__fastcall ECorbaUserException(const AnsiString Name);
```

Description

Call Create to construct an exception object with a simple message string.

Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("The c:\\temp directory already exists.");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
```

```
            FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
            GetMem(Buffer, StringLen); { allocate the buffer }
            cellString := StringGrid1.Cells[X,Y];
            for I := 1 to StringLen do
               Buffer[I - 1] := cellString[I];
            FileWrite(FileHandle, Buffer^, StringLen);
          finally
            FreeMem(Buffer, StringLen);
          end;
        end;
      end;
      FileClose(FileHandle);
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    with StringGrid1 do
    begin
      Cells[1,0] := 'Column 1';
      Cells[2,0] := 'Column 2';
      Cells[3,0] := 'Column 3';
      Cells[4,0] := 'Column 4';
      Cells[0,1] := 'Row 1';
      Cells[1,1] := 'Object';
      Cells[2,1] := 'Pascal';
      Cells[3,1] := 'is';
      Cells[4,1] := 'excellent';
      Cells[0,2] := 'Row 2';
      Cells[1,2] := 'Delphi';
      Cells[2,2] := 'is';
      Cells[4,2] := 'RAD';
    end;
  end;
  {
  In addition to displaying the exception message, which
  happens by default, the following code shuts down the
  application when an exception is not caught and handled.
  AppException should be declared a method of TForm1.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnException := AppException;
  end;
  procedure TForm1.AppException(Sender: TObject; E: Exception);
  begin
    Application.ShowException(E);
    Application.Terminate;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    raise EPasswordInvalid.Create('Incorrect password entered');
  end;
```

34.1.3.3 ECorbaUserException Methods

The methods of the ECorbaUserException class are listed here.

Public Methods

	Name	Description
	Copy (see page 6430)	This is Copy, a member of class ECorbaUserException.
	Throw (see page 6430)	This is Throw, a member of class ECorbaUserException.

34.1.3.3.1 ECorbaUserException.Copy Method

Pascal

```
procedure Copy(const InBuf: IMarshalInBuffer); virtual; abstract;
```

C++

```
virtual __fastcall Copy(const IMarshalInBuffer InBuf) = 0;
```

Description

This is Copy, a member of class ECorbaUserException.

34.1.3.3.2 ECorbaUserException.Throw Method

Pascal

```
procedure Throw;
```

C++

```
__fastcall Throw();
```

Description

This is Throw, a member of class ECorbaUserException.

34.1.3.4 ECorbaUserException Properties

The properties of the ECorbaUserException class are listed here.

Public Properties

	Name	Description
	Proxy (see page 6430)	This is Proxy, a member of class ECorbaUserException.

34.1.3.4.1 ECorbaUserException.Proxy Property

Pascal

```
property Proxy: PUserExceptionProxy;
```

C++

```
__property PUserExceptionProxy Proxy;
```

Description

This is Proxy, a member of class ECorbaUserException.

34.1.4 TBOA Class

Class Hierarchy

CorbaObj.TBOA

Pascal

```
TBOA = class;
```

C++

```
class TBOA;
```

File

CorbaObj

Description

This is class CorbaObj.TBOA.

34.1.4.1 TBOA Members

The following tables list the members exposed by TBOA.

Public Methods

	Name	Description
	Deactivate (see page 6431)	This is Deactivate, a member of class TBOA.
	GetPrincipal (see page 6432)	This is GetPrincipal, a member of class TBOA.
	ImplIsReady (see page 6432)	This is ImplIsReady, a member of class TBOA.
	Initialize (see page 6432)	This is Initialize, a member of class TBOA.
	ObjIsReady (see page 6432)	This is ObjIsReady, a member of class TBOA.

34.1.4.2 TBOA Methods

The methods of the TBOA class are listed here.

Public Methods

	Name	Description
	Deactivate (see page 6431)	This is Deactivate, a member of class TBOA.
	GetPrincipal (see page 6432)	This is GetPrincipal, a member of class TBOA.
	ImplIsReady (see page 6432)	This is ImplIsReady, a member of class TBOA.
	Initialize (see page 6432)	This is Initialize, a member of class TBOA.
	ObjIsReady (see page 6432)	This is ObjIsReady, a member of class TBOA.

34.1.4.2.1 TBOA.Deactivate Method

Pascal

```
procedure Deactivate(const Obj: IObject);
```

C++

```
__fastcall Deactivate(const IObject Obj);
```

Description

This is Deactivate, a member of class TBOA.

34.1.4.2.2 TBOA.GetPrincipal Method

Pascal

```
function GetPrincipal(const Obj: IObject): TCorbaPrincipal;
```

C++

```
__fastcall TCorbaPrincipal GetPrincipal(const IObject Obj);
```

Description

This is GetPrincipal, a member of class TBOA.

34.1.4.2.3 TBOA.ImplIsReady Method

Pascal

```
procedure ImplIsReady;
```

C++

```
__fastcall ImplIsReady();
```

Description

This is ImplIsReady, a member of class TBOA.

34.1.4.2.4 TBOA.Initialize Method

Pascal

```
class procedure Initialize(const CommandLine: TCommandLine);
```

C++

```
__fastcall Initialize(const TCommandLine CommandLine);
```

Description

This is Initialize, a member of class TBOA.

34.1.4.2.5 TBOA.ObjIsReady Method

Pascal

```
procedure ObjIsReady(const Obj: IObject);
```

C++

```
__fastcall ObjIsReady(const IObject Obj);
```

Description

This is ObjIsReady, a member of class TBOA.

34.1.5 TCorbaDispatchStub Class

Class Hierarchy

Pascal

```
TCorbaDispatchStub = class(TCorbaStub, IDispatch);
```

C++

```
class TCorbaDispatchStub : public TCorbaStub, public IDispatch;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaDispatchStub.

34.1.5.1 TCorbaDispatchStub Members

The following tables list the members exposed by TCorbaDispatchStub.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Fields

	Name	Description
	FStub (see page 6464)	This is FStub, a member of class TCorbaStub.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
V	GetIDsOfNames (see page 6435)	This is GetIDsOfNames, a member of class TCorbaDispatchStub.
	GetStub (see page 6465)	This is GetStub, a member of class TCorbaStub.
V	GetTypeInfo (see page 6435)	This is GetTypeInfo, a member of class TCorbaDispatchStub.
V	GetTypeInfoCount (see page 6435)	This is GetTypeInfoCount, a member of class TCorbaDispatchStub.
	Hash (see page 6465)	This is Hash, a member of class TCorbaStub.
V	Invoke (see page 6435)	This is Invoke, a member of class TCorbaDispatchStub.
	IsA (see page 6465)	This is IsA, a member of class TCorbaStub.
	NonExistent (see page 6465)	This is NonExistent, a member of class TCorbaStub.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

	SetPrincipal (see page 6466)	This is SetPrincipal, a member of class TCorbaStub.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6463)	This is Create, a member of class TCorbaStub.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6464)	Disposes of an object instance.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetStub (see page 18212)	This is GetStub, a member of class IStubObject.
	Hash (see page 6476)	This is Hash, a member of class ICorbaObject.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsA (see page 6476)	This is IsA, a member of class ICorbaObject.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NonExistent (see page 6476)	This is NonExistent, a member of class ICorbaObject.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetPrincipal (see page 6476)	This is SetPrincipal, a member of class ICorbaObject.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

34.1.5.2 TCorbaDispatchStub Methods

The methods of the TCorbaDispatchStub class are listed here.

Protected Methods

	Name	Description
	GetIDsOfNames (see page 6435)	This is GetIDsOfNames, a member of class TCorbaDispatchStub.
	GetTypeInfo (see page 6435)	This is GetTypeInfo, a member of class TCorbaDispatchStub.
	GetTypeInfoCount (see page 6435)	This is GetTypeInfoCount, a member of class TCorbaDispatchStub.
	Invoke (see page 6435)	This is Invoke, a member of class TCorbaDispatchStub.

34.1.5.2.1 TCorbaDispatchStub.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int
NameCount, int LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TCorbaDispatchStub.

34.1.5.2.2 TCorbaDispatchStub.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; virtual;
stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TCorbaDispatchStub.

34.1.5.2.3 TCorbaDispatchStub.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TCorbaDispatchStub.

34.1.5.2.4 TCorbaDispatchStub.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
```

```
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word
Flags,  Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TCorbaDispatchStub.

34.1.6 TCorbaFactory Class

Class Hierarchy

Pascal

```
TCorbaFactory = class(TInterfacedObject, ISkeletonObject);
```

C++

```
class TCorbaFactory : public TInterfacedObject, public ISkeletonObject;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaFactory.

34.1.6.1 TCorbaFactory Members

The following tables list the members exposed by TCorbaFactory.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
V	CreateInstance (see page 6439)	This is CreateInstance, a member of class TCorbaFactory.
V	CreateInterface (see page 6439)	This is CreateInterface, a member of class TCorbaFactory.
	Execute (see page 6439)	This is Execute, a member of class TCorbaFactory.
	GetImplementation (see page 6439)	This is GetImplementation, a member of class TCorbaFactory.
	GetSkeleton (see page 6440)	This is GetSkeleton, a member of class TCorbaFactory.
	GetTypeInfo (see page 6440)	This is GetTypeInfo, a member of class TCorbaFactory.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.
	RegisterFactory (see page 6440)	This is RegisterFactory, a member of class TCorbaFactory.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6437)	This is Create, a member of class TCorbaFactory.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6438)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	InstanceName (see page 6440)	This is InstanceName, a member of class TCorbaFactory.
R	Instancing (see page 6441)	This is Instancing, a member of class TCorbaFactory.
R	InterfaceName (see page 6441)	This is InterfaceName, a member of class TCorbaFactory.
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.
R	RepositoryID (see page 6441)	This is RepositoryID, a member of class TCorbaFactory.
R	ThreadModel (see page 6441)	This is ThreadModel, a member of class TCorbaFactory.

34.1.6.2 TCorbaFactory.Create Constructor

Pascal

```
constructor Create(const InterfaceName: string; const InstanceName: string; const
```

```
RepositoryId: string; const ImplGUID: TGUID; Instancing: TCorbaInstancing = iMultiInstance;
ThreadModel: TCorbaThreadModel = tmSingleThread);
```

C++

```
__fastcall TCorbaFactory(const AnsiString InterfaceName, const AnsiString InstanceName, const
AnsiString RepositoryId, const TGUID ImplGUID, TCorbaInstancing Instancing = iMultiInstance,
TCorbaThreadModel ThreadModel = tmSingleThread);
```

Description

This is Create, a member of class TCorbaFactory.

34.1.6.3 TCorbaFactory.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCorbaFactory();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

34.1.6.4 TCorbaFactory Methods

The methods of the TCorbaFactory class are listed here.

Protected Methods

	Name	Description
V	CreateInstance (see page 6439)	This is CreateInstance, a member of class TCorbaFactory.
V	CreateInterface (see page 6439)	This is CreateInterface, a member of class TCorbaFactory.
	Execute (see page 6439)	This is Execute, a member of class TCorbaFactory.
	GetImplementation (see page 6439)	This is GetImplementation, a member of class TCorbaFactory.
	GetSkeleton (see page 6440)	This is GetSkeleton, a member of class TCorbaFactory.

	GetTypeInfo (see page 6440)	This is GetTypeInfo, a member of class TCorbaFactory.
	RegisterFactory (see page 6440)	This is RegisterFactory, a member of class TCorbaFactory.

34.1.6.4.1 TCorbaFactory.CreateInstance Method

Pascal

```
function CreateInstance(const InstanceName: string): ISkeletonObject; virtual;
```

C++

```
virtual __fastcall ISkeletonObject CreateInstance(const AnsiString InstanceName);
```

Description

This is CreateInstance, a member of class TCorbaFactory.

34.1.6.4.2 TCorbaFactory.CreateInterface Method

Pascal

```
function CreateInterface(const InstanceName: string): IObject; virtual;
```

C++

```
virtual __fastcall IObject CreateInterface(const AnsiString InstanceName);
```

Description

This is CreateInterface, a member of class TCorbaFactory.

34.1.6.4.3 TCorbaFactory.Execute Method

Pascal

```
function Execute(Operation: PChar; const Strm: IMarshalInBuffer; Cookie: Pointer):
CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean Execute(const char * Operation, const IMarshalInBuffer Strm,
void * Cookie);
```

Description

This is Execute, a member of class TCorbaFactory.

34.1.6.4.4 TCorbaFactory.GetImplementation Method

Pascal

```
procedure GetImplementation(out Impl: IObject); stdcall;
```

C++

```
__fastcall __stdcall GetImplementation(IObject Impl);
```

Description

This is GetImplementation, a member of class TCorbaFactory.

34.1.6.4.5 TCorbaFactory.GetSkeleton Method

Pascal

```
procedure GetSkeleton(out Skeleton: ISkeleton); stdcall;
```

C++

```
__fastcall __stdcall GetSkeleton(ISkeleton Skeleton);
```

Description

This is GetSkeleton, a member of class TCorbaFactory.

34.1.6.4.6 TCorbaFactory.GetTypeInfo Method

Pascal

```
function GetTypeInfo(out TypeInfo): HRESULT;
```

C++

```
__fastcall HRESULT GetTypeInfo( TypeInfo);
```

Description

This is GetTypeInfo, a member of class TCorbaFactory.

34.1.6.4.7 TCorbaFactory.RegisterFactory Method

Pascal

```
procedure RegisterFactory;
```

C++

```
__fastcall RegisterFactory();
```

Description

This is RegisterFactory, a member of class TCorbaFactory.

34.1.6.5 TCorbaFactory Properties

The properties of the TCorbaFactory class are listed here.

Public Properties

	Name	Description
R	InstanceName (see page 6440)	This is InstanceName, a member of class TCorbaFactory.
R	Instancing (see page 6441)	This is Instancing, a member of class TCorbaFactory.
R	InterfaceName (see page 6441)	This is InterfaceName, a member of class TCorbaFactory.
R	RepositoryID (see page 6441)	This is RepositoryID, a member of class TCorbaFactory.
R	ThreadModel (see page 6441)	This is ThreadModel, a member of class TCorbaFactory.

34.1.6.5.1 TCorbaFactory.InstanceName Property

Pascal

```
property InstanceName: string;
```

C++

```
__property AnsiString InstanceName;
```

Description

This is InstanceName, a member of class TCorbaFactory.

34.1.6.5.2 TCorbaFactory.Instancing Property

Pascal

```
property Instancing: TCorbaInstancing;
```

C++

```
__property TCorbaInstancing Instancing;
```

Description

This is Instancing, a member of class TCorbaFactory.

34.1.6.5.3 TCorbaFactory.InterfaceName Property

Pascal

```
property InterfaceName: string;
```

C++

```
__property AnsiString InterfaceName;
```

Description

This is InterfaceName, a member of class TCorbaFactory.

34.1.6.5.4 TCorbaFactory.RepositoryID Property

Pascal

```
property RepositoryID: string;
```

C++

```
__property AnsiString RepositoryID;
```

Description

This is RepositoryID, a member of class TCorbaFactory.

34.1.6.5.5 TCorbaFactory.ThreadModel Property

Pascal

```
property ThreadModel: TCorbaThreadModel;
```

C++

```
__property TCorbaThreadModel ThreadModel;
```

Description

This is ThreadModel, a member of class TCorbaFactory.

34.1.7 TCorbaFactoryManager Class

Class Hierarchy

Pascal

```
TCorbaFactoryManager = class(TCorbaListManager);
```

C++

```
class TCorbaFactoryManager : public TCorbaListManager;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaFactoryManager.

34.1.7.1 TCorbaFactoryManager Members

The following tables list the members exposed by TCorbaFactoryManager.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.
	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

Public Methods

	Name	Description
	AddFactory (see page 6443)	This is AddFactory, a member of class TCorbaFactoryManager.
	Create (see page 6451)	This is Create, a member of class TCorbaListManager.
V	Destroy (see page 6442)	This is Destroy, a member of class TCorbaFactoryManager.
	Find (see page 6443)	This is Find, a member of class TCorbaFactoryManager.
	RegisterFactories (see page 6443)	This is RegisterFactories, a member of class TCorbaFactoryManager.

34.1.7.2 TCorbaFactoryManager.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCorbaFactoryManager();
```

Description

This is Destroy, a member of class TCorbaFactoryManager.

34.1.7.3 TCorbaFactoryManager Methods

The methods of the TCorbaFactoryManager class are listed here.

Public Methods

	Name	Description
	AddFactory (see page 6443)	This is AddFactory, a member of class TCorbaFactoryManager.
	Find (see page 6443)	This is Find, a member of class TCorbaFactoryManager.
	RegisterFactories (see page 6443)	This is RegisterFactories, a member of class TCorbaFactoryManager.

34.1.7.3.1 TCorbaFactoryManager.AddFactory Method

Pascal

```
procedure AddFactory(Factory: TCorbaFactory);
```

C++

```
__fastcall AddFactory(TCorbaFactory Factory);
```

Description

This is AddFactory, a member of class TCorbaFactoryManager.

34.1.7.3.2 TCorbaFactoryManager.Find Method

Pascal

```
function Find(const RepositoryID: string; const InterfaceName: string; const InstanceName:
string): TCorbaFactory;
```

C++

```
__fastcall TCorbaFactory Find(const AnsiString RepositoryID, const AnsiString InterfaceName,
const AnsiString InstanceName);
```

Description

This is Find, a member of class TCorbaFactoryManager.

34.1.7.3.3 TCorbaFactoryManager.RegisterFactories Method

Pascal

```
procedure RegisterFactories;
```

C++

```
__fastcall RegisterFactories();
```

Description

This is RegisterFactories, a member of class TCorbaFactoryManager.

34.1.8 TCorbaImplementation Class

Class Hierarchy

Pascal

```
TCorbaImplementation = class(TObject, IUnknown);
```

C++

```
class TCorbaImplementation : public TObject, public IUnknown;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaImplementation.

34.1.8.1 TCorbaImplementation Members

The following tables list the members exposed by TCorbaImplementation.

Protected Fields

	Name	Description
	FController (see page 6445)	This is FController, a member of class TCorbaImplementation.
	FFactory (see page 6446)	This is FFactory, a member of class TCorbaImplementation.
	FRefCount (see page 6446)	This is FRefCount, a member of class TCorbaImplementation.

Protected Methods

	Name	Description
	_AddRef (see page 6446)	This is _AddRef, a member of class TCorbaImplementation.
	_Release (see page 6447)	This is _Release, a member of class TCorbaImplementation.
	GetIDsOfNames (see page 6447)	This is GetIDsOfNames, a member of class TCorbaImplementation.
	GetTypeInfo (see page 6447)	This is GetTypeInfo, a member of class TCorbaImplementation.
	GetTypeInfoCount (see page 6447)	This is GetTypeInfoCount, a member of class TCorbaImplementation.
	Invoke (see page 6448)	This is Invoke, a member of class TCorbaImplementation.
V	ObjAddRef (see page 6448)	This is ObjAddRef, a member of class TCorbaImplementation.
V	ObjQueryInterface (see page 6448)	This is ObjQueryInterface, a member of class TCorbaImplementation.
V	ObjRelease (see page 6448)	This is ObjRelease, a member of class TCorbaImplementation.
	QueryInterface (see page 6448)	This is QueryInterface, a member of class TCorbaImplementation.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6445)	This is Create, a member of class TCorbaImplementation.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

34.1.8.2 TCorbaImplementation.Create Constructor

Pascal

```
constructor Create(Controller: IObject; AFactory: TCorbaFactory); virtual;
```

C++

```
virtual __fastcall TCorbaImplementation(IObject Controller, TCorbaFactory AFactory);
```

Description

This is Create, a member of class TCorbaImplementation.

34.1.8.3 TCorbaImplementation Fields

The fields of the TCorbaImplementation class are listed here.

Protected Fields

	Name	Description
	FController (see page 6445)	This is FController, a member of class TCorbaImplementation.
	FFactory (see page 6446)	This is FFactory, a member of class TCorbaImplementation.
	FRefCount (see page 6446)	This is FRefCount, a member of class TCorbaImplementation.

34.1.8.3.1 TCorbaImplementation.FController Field

Pascal

```
FController: Pointer;
```

C++

```
void * FController;
```

Description

This is FController, a member of class TCorbaImplementation.

34.1.8.3.2 TCorbaImplementation.FFactory Field

Pascal

```
FFactory: TCorbaFactory;
```

C++

```
TCorbaFactory FFactory;
```

Description

This is FFactory, a member of class TCorbaImplementation.

34.1.8.3.3 TCorbaImplementation.FRefCount Field

Pascal

```
FRefCount: Integer;
```

C++

```
int FRefCount;
```

Description

This is FRefCount, a member of class TCorbaImplementation.

34.1.8.4 TCorbaImplementation Methods

The methods of the TCorbaImplementation class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 6446)	This is _AddRef, a member of class TCorbaImplementation.
	_Release (see page 6447)	This is _Release, a member of class TCorbaImplementation.
	GetIDsOfNames (see page 6447)	This is GetIDsOfNames, a member of class TCorbaImplementation.
	GetTypeInfo (see page 6447)	This is GetTypeInfo, a member of class TCorbaImplementation.
	GetTypeInfoCount (see page 6447)	This is GetTypeInfoCount, a member of class TCorbaImplementation.
	Invoke (see page 6448)	This is Invoke, a member of class TCorbaImplementation.
V	ObjAddRef (see page 6448)	This is ObjAddRef, a member of class TCorbaImplementation.
V	ObjQueryInterface (see page 6448)	This is ObjQueryInterface, a member of class TCorbaImplementation.
V	ObjRelease (see page 6448)	This is ObjRelease, a member of class TCorbaImplementation.
	QueryInterface (see page 6448)	This is QueryInterface, a member of class TCorbaImplementation.

34.1.8.4.1 TCorbaImplementation._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TCorbaImplementation.

34.1.8.4.2 TCorbaImplementation._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TCorbaImplementation.

34.1.8.4.3 TCorbaImplementation.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TCorbaImplementation.

34.1.8.4.4 TCorbaImplementation.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TCorbaImplementation.

34.1.8.4.5 TCorbaImplementation.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TCorbaImplementation.

34.1.8.4.6 TCorbaImplementation.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TCorbaImplementation.

34.1.8.4.7 TCorbaImplementation.ObjAddRef Method

Pascal

```
function ObjAddRef: Integer; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall int ObjAddRef();
```

Description

This is ObjAddRef, a member of class TCorbaImplementation.

34.1.8.4.8 TCorbaImplementation.ObjQueryInterface Method

Pascal

```
function ObjQueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT ObjQueryInterface(const TGUID IID,  Obj);
```

Description

This is ObjQueryInterface, a member of class TCorbaImplementation.

34.1.8.4.9 TCorbaImplementation.ObjRelease Method

Pascal

```
function ObjRelease: Integer; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall int ObjRelease();
```

Description

This is ObjRelease, a member of class TCorbaImplementation.

34.1.8.4.10 TCorbaImplementation.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TCorbaImplementation.

34.1.9 TCorbaInterfaceIDManager Class

Class Hierarchy

Pascal

```
TCorbaInterfaceIDManager = class(TCorbaListManager);
```

C++

```
class TCorbaInterfaceIDManager : public TCorbaListManager;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaInterfaceIDManager.

34.1.9.1 TCorbaInterfaceIDManager Members

The following tables list the members exposed by TCorbaInterfaceIDManager.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.
	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

Public Methods

	Name	Description
	Create (see page 6451)	This is Create, a member of class TCorbaListManager.
V	Destroy (see page 6452)	This is Destroy, a member of class TCorbaListManager.
	FindGUID (see page 6450)	This is FindGUID, a member of class TCorbaInterfaceIDManager.
	FindID (see page 6450)	This is FindID, a member of class TCorbaInterfaceIDManager.
	RegisterInterface (see page 6450)	This is RegisterInterface, a member of class TCorbaInterfaceIDManager.
	SearchGUID (see page 6450)	This is SearchGUID, a member of class TCorbaInterfaceIDManager.
	SearchID (see page 6451)	This is SearchID, a member of class TCorbaInterfaceIDManager.

34.1.9.2 TCorbaInterfaceIDManager Methods

The methods of the TCorbaInterfaceIDManager class are listed here.

Public Methods

	Name	Description
	FindGUID (see page 6450)	This is FindGUID, a member of class TCorbaInterfaceIDManager.
	FindID (see page 6450)	This is FindID, a member of class TCorbaInterfaceIDManager.
	RegisterInterface (see page 6450)	This is RegisterInterface, a member of class TCorbaInterfaceIDManager.
	SearchGUID (see page 6450)	This is SearchGUID, a member of class TCorbaInterfaceIDManager.
	SearchID (see page 6451)	This is SearchID, a member of class TCorbaInterfaceIDManager.

34.1.9.2.1 TCorbaInterfaceIDManager.FindGUID Method

Pascal

```
function FindGUID(const RepositoryID: string): TGUID;
```

C++

```
__fastcall TGUID FindGUID(const AnsiString RepositoryID);
```

Description

This is FindGUID, a member of class TCorbaInterfaceIDManager.

34.1.9.2.2 TCorbaInterfaceIDManager.FindID Method

Pascal

```
function FindID(const IID: TGUID): string;
```

C++

```
__fastcall AnsiString FindID(const TGUID IID);
```

Description

This is FindID, a member of class TCorbaInterfaceIDManager.

34.1.9.2.3 TCorbaInterfaceIDManager.RegisterInterface Method

Pascal

```
procedure RegisterInterface(const IID: TGUID; const RepositoryID: string);
```

C++

```
__fastcall RegisterInterface(const TGUID IID, const AnsiString RepositoryID);
```

Description

This is RegisterInterface, a member of class TCorbaInterfaceIDManager.

34.1.9.2.4 TCorbaInterfaceIDManager.SearchGUID Method

Pascal

```
function SearchGUID(const RepositoryID: string; out IID: TGUID): Boolean;
```

C++

```
__fastcall Boolean SearchGUID(const AnsiString RepositoryID, TGUID IID);
```

Description

This is SearchGUID, a member of class TCorbaInterfaceIDManager.

34.1.9.2.5 TCorbaInterfaceIDManager.SearchID Method

Pascal

```
function SearchID(const IID: TGUID; out RepositoryID: string): Boolean;
```

C++

```
__fastcall Boolean SearchID(const TGUID IID, AnsiString RepositoryID);
```

Description

This is SearchID, a member of class TCorbaInterfaceIDManager.

34.1.10 TCorbaListManager Class

Class Hierarchy

Pascal

```
TCorbaListManager = class;
```

C++

```
class TCorbaListManager;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaListManager.

34.1.10.1 TCorbaListManager Members

The following tables list the members exposed by TCorbaListManager.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.
	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

Public Methods

	Name	Description
	Create (see page 6451)	This is Create, a member of class TCorbaListManager.
V	Destroy (see page 6452)	This is Destroy, a member of class TCorbaListManager.

34.1.10.2 TCorbaListManager.Create Constructor

Pascal

```
constructor Create;
```

C++

```
__fastcall TCorbaListManager();
```

Description

This is Create, a member of class TCorbaListManager.

34.1.10.3 TCorbaListManager.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCorbaListManager();
```

Description

This is Destroy, a member of class TCorbaListManager.

34.1.10.4 TCorbaListManager Methods

The methods of the TCorbaListManager class are listed here.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.
	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

34.1.10.4.1 TCorbaListManager.BeginRead Method

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

This is BeginRead, a member of class TCorbaListManager.

34.1.10.4.2 TCorbaListManager.BeginWrite Method

Pascal

```
procedure BeginWrite;
```

C++

```
__fastcall BeginWrite();
```

Description

This is BeginWrite, a member of class TCorbaListManager.

34.1.10.4.3 TCorbaListManager.EndRead Method

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

This is EndRead, a member of class TCorbaListManager.

34.1.10.4.4 TCorbaListManager.EndWrite Method

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

This is EndWrite, a member of class TCorbaListManager.

34.1.11 TCorbaObjectFactory Class

Class Hierarchy

Pascal

```
TCorbaObjectFactory = class(TCorbaFactory);
```

C++

```
class TCorbaObjectFactory : public TCorbaFactory;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaObjectFactory.

34.1.11.1 TCorbaObjectFactory Members

The following tables list the members exposed by TCorbaObjectFactory.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
V	CreateInstance (see page 6439)	This is CreateInstance, a member of class TCorbaFactory.
V	CreateInterface (see page 6455)	This is CreateInterface, a member of class TCorbaObjectFactory.
	Execute (see page 6439)	This is Execute, a member of class TCorbaFactory.
	GetImplementation (see page 6439)	This is GetImplementation, a member of class TCorbaFactory.
	GetSkeleton (see page 6440)	This is GetSkeleton, a member of class TCorbaFactory.
	GetTypeInfo (see page 6440)	This is GetTypeInfo, a member of class TCorbaFactory.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.
	RegisterFactory (see page 6440)	This is RegisterFactory, a member of class TCorbaFactory.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6455)	This is Create, a member of class TCorbaObjectFactory.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6438)	Disposes of an object instance.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 18207)	This is Execute, a member of class ISkeletonObject.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetImplementation (see page 18207)	This is GetImplementation, a member of class ISkeletonObject.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetSkeleton (see page 18207)	This is GetSkeleton, a member of class ISkeletonObject.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.

V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	ImplementationClass (see page 6456)	This is ImplementationClass, a member of class TCorbaObjectFactory.
R	InstanceName (see page 6440)	This is InstanceName, a member of class TCorbaFactory.
R	Instancing (see page 6441)	This is Instancing, a member of class TCorbaFactory.
R	InterfaceName (see page 6441)	This is InterfaceName, a member of class TCorbaFactory.
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.
R	RepositoryID (see page 6441)	This is RepositoryID, a member of class TCorbaFactory.
R	ThreadModel (see page 6441)	This is ThreadModel, a member of class TCorbaFactory.

34.1.11.2 TCorbaObjectFactory.Create Constructor

Pascal

```
constructor Create(const InterfaceName: string; const InstanceName: string; const
RepositoryId: string; const ImplGUID: TGUID; ImplementationClass: TCorbaImplementationClass;
Instancing: TCorbaInstancing = iMultiInstance; ThreadModel: TCorbaThreadModel =
tmSingleThread);
```

C++

```
__fastcall TCorbaObjectFactory(const AnsiString InterfaceName, const AnsiString InstanceName,
const AnsiString RepositoryId, const TGUID ImplGUID, TCorbaImplementationClass
ImplementationClass, TCorbaInstancing Instancing = iMultiInstance, TCorbaThreadModel
ThreadModel = tmSingleThread);
```

Description

This is Create, a member of class TCorbaObjectFactory.

34.1.11.3 TCorbaObjectFactory Methods

The methods of the TCorbaObjectFactory class are listed here.

Protected Methods

	Name	Description
V	CreateInterface (see page 6455)	This is CreateInterface, a member of class TCorbaObjectFactory.

34.1.11.3.1 TCorbaObjectFactory.CreateInterface Method

Pascal

```
function CreateInterface(const InstanceName: string): IObject; override;
```

C++

```
virtual __fastcall IObject CreateInterface(const AnsiString InstanceName);
```

Description

This is CreateInterface, a member of class TCorbaObjectFactory.

34.1.11.4 TCorbaObjectFactory Properties

The properties of the TCorbaObjectFactory class are listed here.

Public Properties

	Name	Description
R	ImplementationClass (see page 6456)	This is ImplementationClass, a member of class TCorbaObjectFactory.

34.1.11.4.1 TCorbaObjectFactory.ImplementationClass Property

Pascal

```
property ImplementationClass: TCorbaImplementationClass;
```

C++

```
__property TCorbaImplementationClass ImplementationClass;
```

Description

This is ImplementationClass, a member of class TCorbaObjectFactory.

34.1.12 TCorbaSkeleton Class

Class Hierarchy

Pascal

```
TCorbaSkeleton = class(TInterfacedObject, ISkeletonObject);
```

C++

```
class TCorbaSkeleton : public TInterfacedObject, public ISkeletonObject;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaSkeleton.

34.1.12.1 TCorbaSkeleton Members

The following tables list the members exposed by TCorbaSkeleton.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Fields

	Name	Description
	FSkeleton (see page 6459)	This is FSkeleton, a member of class TCorbaSkeleton.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	Execute (see page 6459)	This is Execute, a member of class TCorbaSkeleton.
V	GetImplementation (see page 6459)	This is GetImplementation, a member of class TCorbaSkeleton.
	GetSkeleton (see page 6460)	This is GetSkeleton, a member of class TCorbaSkeleton.
	InitSkeleton (see page 6460)	This is InitSkeleton, a member of class TCorbaSkeleton.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6458)	This is Create, a member of class TCorbaSkeleton.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6458)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.

	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

34.1.12.2 TCorbaSkeleton.Create Constructor

Pascal

```
constructor Create(const InstanceName: string; const Impl: IObject); virtual;
```

C++

```
virtual __fastcall TCorbaSkeleton(const AnsiString InstanceName, const IObject Impl);
```

Description

This is Create, a member of class TCorbaSkeleton.

34.1.12.3 TCorbaSkeleton.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCorbaSkeleton();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

34.1.12.4 TCorbaSkeleton Fields

The fields of the TCorbaSkeleton class are listed here.

Protected Fields

	Name	Description
	FSkeleton (see page 6459)	This is FSkeleton, a member of class TCorbaSkeleton.

34.1.12.4.1 TCorbaSkeleton.FSkeleton Field

Pascal

```
FSkeleton: ISkeleton;
```

C++

```
ISkeleton FSkeleton;
```

Description

This is FSkeleton, a member of class TCorbaSkeleton.

34.1.12.5 TCorbaSkeleton Methods

The methods of the TCorbaSkeleton class are listed here.

Protected Methods

	Name	Description
	Execute (see page 6459)	This is Execute, a member of class TCorbaSkeleton.
V	GetImplementation (see page 6459)	This is GetImplementation, a member of class TCorbaSkeleton.
	GetSkeleton (see page 6460)	This is GetSkeleton, a member of class TCorbaSkeleton.
	InitSkeleton (see page 6460)	This is InitSkeleton, a member of class TCorbaSkeleton.

34.1.12.5.1 TCorbaSkeleton.Execute Method

Pascal

```
function Execute(Operation: PChar; const Strm: IMarshalInBuffer; Cookie: Pointer):
CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean Execute(const char * Operation, const IMarshalInBuffer Strm,
void * Cookie);
```

Description

This is Execute, a member of class TCorbaSkeleton.

34.1.12.5.2 TCorbaSkeleton.GetImplementation Method

Pascal

```
procedure GetImplementation(out Impl: IObject); virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall GetImplementation(IObject Impl);
```

Description

This is GetImplementation, a member of class TCorbaSkeleton.

34.1.12.5.3 TCorbaSkeleton.GetSkeleton Method

Pascal

```
procedure GetSkeleton(out Skeleton: ISkeleton); stdcall;
```

C++

```
__fastcall __stdcall GetSkeleton(ISkeleton Skeleton);
```

Description

This is GetSkeleton, a member of class TCorbaSkeleton.

34.1.12.5.4 TCorbaSkeleton.InitSkeleton Method

Pascal

```
procedure InitSkeleton(const InterfaceName: string; const InstanceName: string; const
RepositoryID: string; ThreadModel: TCorbaThreadModel; ClientRefCount: Boolean);
```

C++

```
__fastcall InitSkeleton(const AnsiString InterfaceName, const AnsiString InstanceName, const
AnsiString RepositoryID, TCorbaThreadModel ThreadModel, Boolean ClientRefCount);
```

Description

This is InitSkeleton, a member of class TCorbaSkeleton.

34.1.13 TCorbaSkeletonManager Class

Class Hierarchy

Pascal

```
TCorbaSkeletonManager = class(TCorbaListManager);
```

C++

```
class TCorbaSkeletonManager : public TCorbaListManager;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaSkeletonManager.

34.1.13.1 TCorbaSkeletonManager Members

The following tables list the members exposed by TCorbaSkeletonManager.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.

	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

Public Methods

	Name	Description
	Create (see page 6451)	This is Create, a member of class TCorbaListManager.
	CreateSkeleton (see page 6461)	This is CreateSkeleton, a member of class TCorbaSkeletonManager.
	Destroy (see page 6452)	This is Destroy, a member of class TCorbaListManager.
	RegisterSkeleton (see page 6461)	This is RegisterSkeleton, a member of class TCorbaSkeletonManager.

34.1.13.2 TCorbaSkeletonManager Methods

The methods of the TCorbaSkeletonManager class are listed here.

Public Methods

	Name	Description
	CreateSkeleton (see page 6461)	This is CreateSkeleton, a member of class TCorbaSkeletonManager.
	RegisterSkeleton (see page 6461)	This is RegisterSkeleton, a member of class TCorbaSkeletonManager.

34.1.13.2.1 TCorbaSkeletonManager.CreateSkeleton Method

Pascal

```
function CreateSkeleton(IID: TGUID; const InstanceName: string; const Impl: IObject):
ISkeletonObject;
```

C++

```
__fastcall ISkeletonObject CreateSkeleton(TGUID IID, const AnsiString InstanceName, const
IObject Impl);
```

Description

This is CreateSkeleton, a member of class TCorbaSkeletonManager.

34.1.13.2.2 TCorbaSkeletonManager.RegisterSkeleton Method

Pascal

```
procedure RegisterSkeleton(IID: TGUID; Skeleton: TCorbaSkeletonClass);
```

C++

```
__fastcall RegisterSkeleton(TGUID IID, TCorbaSkeletonClass Skeleton);
```

Description

This is RegisterSkeleton, a member of class TCorbaSkeletonManager.

34.1.14 TCorbaStub Class

Class Hierarchy

Pascal

```
TCorbaStub = class(TInterfacedObject, IStubObject, ICorbaObject);
```

C++

```
class TCorbaStub : public TInterfacedObject, public IStubObject, public ICorbaObject;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaStub.

34.1.14.1 TCorbaStub Members

The following tables list the members exposed by TCorbaStub.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Fields

	Name	Description
	FStub (see page 6464)	This is FStub, a member of class TCorbaStub.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	GetStub (see page 6465)	This is GetStub, a member of class TCorbaStub.
	Hash (see page 6465)	This is Hash, a member of class TCorbaStub.
	IsA (see page 6465)	This is IsA, a member of class TCorbaStub.
	NonExistent (see page 6465)	This is NonExistent, a member of class TCorbaStub.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.
	SetPrincipal (see page 6466)	This is SetPrincipal, a member of class TCorbaStub.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.

	AfterConstruction (see page 22279)	Responds after the last constructor executes.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6463)	This is Create, a member of class TCorbaStub.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 6464)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

34.1.14.2 TCorbaStub.Create Constructor

Pascal

```
constructor Create(const Stub: IStub); virtual;
```

C++

```
virtual __fastcall TCorbaStub(const IStub Stub);
```

Description

This is Create, a member of class TCorbaStub.

34.1.14.3 TCorbaStub.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCorbaStub();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

34.1.14.4 TCorbaStub Fields

The fields of the TCorbaStub class are listed here.

Protected Fields

	Name	Description
	FStub (see page 6464)	This is FStub, a member of class TCorbaStub.

34.1.14.4.1 TCorbaStub.FStub Field

Pascal

```
FStub: IStub;
```

C++

```
IStub FStub;
```

Description

This is FStub, a member of class TCorbaStub.

34.1.14.5 TCorbaStub Methods

The methods of the TCorbaStub class are listed here.

Protected Methods

	Name	Description
	GetStub (see page 6465)	This is GetStub, a member of class TCorbaStub.
	Hash (see page 6465)	This is Hash, a member of class TCorbaStub.
	IsA (see page 6465)	This is IsA, a member of class TCorbaStub.
	NonExistent (see page 6465)	This is NonExistent, a member of class TCorbaStub.
	SetPrincipal (see page 6466)	This is SetPrincipal, a member of class TCorbaStub.

34.1.14.5.1 TCorbaStub.GetStub Method

Pascal

```
procedure GetStub(out Stub: IStub); stdcall;
```

C++

```
__fastcall __stdcall GetStub(IStub Stub);
```

Description

This is GetStub, a member of class TCorbaStub.

34.1.14.5.2 TCorbaStub.Hash Method

Pascal

```
function Hash(Maximum: Integer): Integer;
```

C++

```
__fastcall int Hash(int Maximum);
```

Description

This is Hash, a member of class TCorbaStub.

34.1.14.5.3 TCorbaStub.IsA Method

Pascal

```
function IsA(const LogicalTypeId: string): Boolean;
```

C++

```
__fastcall Boolean IsA(const AnsiString LogicalTypeId);
```

Description

This is IsA, a member of class TCorbaStub.

34.1.14.5.4 TCorbaStub.NonExistent Method

Pascal

```
function NonExistent: Boolean;
```

C++

```
__fastcall Boolean NonExistent();
```

Description

This is NonExistent, a member of class TCorbaStub.

34.1.14.5.5 TCorbaStub.SetPrincipal Method

Pascal

```
procedure SetPrincipal(const Prinicpal: TCorbaPrincipal);
```

C++

```
__fastcall SetPrincipal(const TCorbaPrincipal Prinicpal);
```

Description

This is SetPrincipal, a member of class TCorbaStub.

34.1.15 TCorbaStubManager Class

Class Hierarchy

Pascal

```
TCorbaStubManager = class(TCorbaListManager);
```

C++

```
class TCorbaStubManager : public TCorbaListManager;
```

File

CorbaObj

Description

This is class CorbaObj.TCorbaStubManager.

34.1.15.1 TCorbaStubManager Members

The following tables list the members exposed by TCorbaStubManager.

Protected Methods

	Name	Description
	BeginRead (see page 6452)	This is BeginRead, a member of class TCorbaListManager.
	BeginWrite (see page 6452)	This is BeginWrite, a member of class TCorbaListManager.
	EndRead (see page 6453)	This is EndRead, a member of class TCorbaListManager.
	EndWrite (see page 6453)	This is EndWrite, a member of class TCorbaListManager.

Public Methods

	Name	Description
	Create (see page 6451)	This is Create, a member of class TCorbaListManager.
	CreateStub (see page 6467)	This is CreateStub, a member of class TCorbaStubManager.

	Destroy (see page 6452)	This is Destroy, a member of class TCorbaListManager.
	RegisterStub (see page 6467)	This is RegisterStub, a member of class TCorbaStubManager.

34.1.15.2 TCorbaStubManager Methods

The methods of the TCorbaStubManager class are listed here.

Public Methods

	Name	Description
	CreateStub (see page 6467)	This is CreateStub, a member of class TCorbaStubManager.
	RegisterStub (see page 6467)	This is RegisterStub, a member of class TCorbaStubManager.

34.1.15.2.1 TCorbaStubManager.CreateStub Method

Pascal

```
function CreateStub(IID: TGUID; const Stub: IStub): IObject;
```

C++

```
__fastcall IObject CreateStub(TGUID IID, const IStub Stub);
```

Description

This is CreateStub, a member of class TCorbaStubManager.

34.1.15.2.2 TCorbaStubManager.RegisterStub Method

Pascal

```
procedure RegisterStub(IID: TGUID; Stub: TCorbaStubClass);
```

C++

```
__fastcall RegisterStub(TGUID IID, TCorbaStubClass Stub);
```

Description

This is RegisterStub, a member of class TCorbaStubManager.

34.1.16 TORB Class

Class Hierarchy

CorbaObj.TORB

Pascal

```
TORB = class;
```

C++

```
class TORB;
```

File

CorbaObj

Description

This is class CorbaObj.TORB.

34.1.16.1 TORB Members

The following tables list the members exposed by TORB.

Public Methods

	Name	Description
	Bind (see page 6468)	This is the overview for the Bind method overload.
	FindTypeCode (see page 6469)	This is FindTypeCode, a member of class TORB.
	Initialize (see page 6469)	This is the overview for the Initialize method overload.
	MakeAlias (see page 6470)	This is MakeAlias, a member of class TORB.
	MakeAliasTypeCode (see page 6470)	This is MakeAliasTypeCode, a member of class TORB.
	MakeArray (see page 6471)	This is the overview for the MakeArray method overload.
	MakeObjectRefTypeCode (see page 6471)	This is MakeObjectRefTypeCode, a member of class TORB.
	MakeSequence (see page 6471)	This is the overview for the MakeSequence method overload.
	MakeSequenceTypeCode (see page 6472)	This is MakeSequenceTypeCode, a member of class TORB.
	MakeStructure (see page 6472)	This is MakeStructure, a member of class TORB.
	MakeStructureTypeCode (see page 6473)	This is MakeStructureTypeCode, a member of class TORB.
	MakeTypeCode (see page 6473)	This is MakeTypeCode, a member of class TORB.
	ObjectToString (see page 6473)	This is ObjectToString, a member of class TORB.
	Shutdown (see page 6473)	This is Shutdown, a member of class TORB.
	StringToObject (see page 6473)	This is StringToObject, a member of class TORB.

34.1.16.2 TORB Methods

The methods of the TORB class are listed here.

Public Methods

	Name	Description
	Bind (see page 6468)	This is the overview for the Bind method overload.
	FindTypeCode (see page 6469)	This is FindTypeCode, a member of class TORB.
	Initialize (see page 6469)	This is the overview for the Initialize method overload.
	MakeAlias (see page 6470)	This is MakeAlias, a member of class TORB.
	MakeAliasTypeCode (see page 6470)	This is MakeAliasTypeCode, a member of class TORB.
	MakeArray (see page 6471)	This is the overview for the MakeArray method overload.
	MakeObjectRefTypeCode (see page 6471)	This is MakeObjectRefTypeCode, a member of class TORB.
	MakeSequence (see page 6471)	This is the overview for the MakeSequence method overload.
	MakeSequenceTypeCode (see page 6472)	This is MakeSequenceTypeCode, a member of class TORB.
	MakeStructure (see page 6472)	This is MakeStructure, a member of class TORB.
	MakeStructureTypeCode (see page 6473)	This is MakeStructureTypeCode, a member of class TORB.
	MakeTypeCode (see page 6473)	This is MakeTypeCode, a member of class TORB.
	ObjectToString (see page 6473)	This is ObjectToString, a member of class TORB.
	Shutdown (see page 6473)	This is Shutdown, a member of class TORB.
	StringToObject (see page 6473)	This is StringToObject, a member of class TORB.

34.1.16.2.1 Bind Method

This is the overview for the Bind method overload.

Overload List

	Name	Description
	TORB.Bind (string, string, string) (see page 6469)	This is Bind, a member of class TORB.
	TORB.Bind (TGUID, string, string) (see page 6469)	This is Bind, a member of class TORB.

34.1.16.2.1.1 TORB.Bind Method (TGUID, string, string)

Pascal

```
function Bind(const InterfaceID: TGUID; const ObjectName: string = ''; const HostName: string
= ''): IObject; overload;
```

C++

```
__fastcall IObject Bind(const TGUID InterfaceID, const AnsiString ObjectName = '', const
AnsiString HostName = '');
```

Description

This is Bind, a member of class TORB.

34.1.16.2.1.2 TORB.Bind Method (string, string, string)

Pascal

```
function Bind(const RepositoryID: string; const ObjectName: string = ''; const HostName:
string = ''): IObject; overload;
```

C++

```
__fastcall IObject Bind(const AnsiString RepositoryID, const AnsiString ObjectName = '', const
AnsiString HostName = '');
```

Description

This is Bind, a member of class TORB.

34.1.16.2.2 TORB.FindTypeCode Method

Pascal

```
function FindTypeCode(const RepositoryID: string): ITypeCode;
```

C++

```
__fastcall ITypeCode FindTypeCode(const AnsiString RepositoryID);
```

Description

This is FindTypeCode, a member of class TORB.

34.1.16.2.3 Initialize Method

This is the overview for the Initialize method overload.

Overload List

	Name	Description
	TORB.Initialize () (see page 6470)	This is Initialize, a member of class TORB.

	TORB.Initialize (TCommandLine) (see page 6470)	This is Initialize, a member of class TORB.

34.1.16.2.3.1 TORB.Initialize Method ()

Pascal

```
class procedure Initialize; overload;
```

C++

```
__fastcall Initialize();
```

Description

This is Initialize, a member of class TORB.

34.1.16.2.3.2 TORB.Initialize Method (TCommandLine)

Pascal

```
class procedure Initialize(const CommandLine: TCommandLine); overload;
```

C++

```
__fastcall Initialize(const TCommandLine CommandLine);
```

Description

This is Initialize, a member of class TORB.

34.1.16.2.4 TORB.MakeAlias Method

Pascal

```
function MakeAlias(const RepositoryID: string; const TypeName: string; Value: TAny; Test:
TAny): TAny;
```

C++

```
__fastcall TAny MakeAlias(const AnsiString RepositoryID, const AnsiString TypeName, TAny
Value, TAny Test);
```

Description

This is MakeAlias, a member of class TORB.

34.1.16.2.5 TORB.MakeAliasTypeCode Method

Pascal

```
function MakeAliasTypeCode(const RepositoryID: string; const Name: string; const TC:
ITypeCode): ITypeCode;
```

C++

```
__fastcall ITypeCode MakeAliasTypeCode(const AnsiString RepositoryID, const AnsiString Name,
const ITypeCode TC);
```

Description

This is MakeAliasTypeCode, a member of class TORB.

34.1.16.2.6 MakeArray Method

This is the overview for the MakeArray method overload.

Overload List

	Name	Description
	TORB.MakeArray (ITypeCode, array of TAny) (see page 6471)	This is MakeArray, a member of class TORB.
	TORB.MakeArray (TCKind, array of TAny) (see page 6471)	This is MakeArray, a member of class TORB.

34.1.16.2.6.1 TORB.MakeArray Method (ITypeCode, array of TAny)

Pascal

```
function MakeArray(TypeCode: ITypeCode; const Elements: array of TAny): TAny; overload;
```

C++

```
__fastcall TAny MakeArray(ITypeCode TypeCode, const array of TAny Elements);
```

Description

This is MakeArray, a member of class TORB.

34.1.16.2.6.2 TORB.MakeArray Method (TCKind, array of TAny)

Pascal

```
function MakeArray(Kind: TCKind; const Elements: array of TAny): TAny; overload;
```

C++

```
__fastcall TAny MakeArray(TCKind Kind, const array of TAny Elements);
```

Description

This is MakeArray, a member of class TORB.

34.1.16.2.7 TORB.MakeObjectRefTypeCode Method

Pascal

```
function MakeObjectRefTypeCode(const RepositoryID: string; const Name: string): ITypeCode;
```

C++

```
__fastcall ITypeCode MakeObjectRefTypeCode(const AnsiString RepositoryID, const AnsiString
Name);
```

Description

This is MakeObjectRefTypeCode, a member of class TORB.

34.1.16.2.8 MakeSequence Method

This is the overview for the MakeSequence method overload.

Overload List

	Name	Description
	TORB.MakeSequence (ITypeCode, array of TAny) (see page 6472)	This is MakeSequence, a member of class TORB.
	TORB.MakeSequence (TCKind, array of TAny) (see page 6472)	This is MakeSequence, a member of class TORB.

34.1.16.2.8.1 TORB.MakeSequence Method (ITypeCode, array of TAny)

Pascal

```
function MakeSequence(TypeCode: ITypeCode; const Elements: array of TAny): TAny; overload;
```

C++

```
__fastcall TAny MakeSequence(ITypeCode TypeCode, const array of TAny Elements);
```

Description

This is MakeSequence, a member of class TORB.

34.1.16.2.8.2 TORB.MakeSequence Method (TCKind, array of TAny)

Pascal

```
function MakeSequence(Kind: TCKind; const Elements: array of TAny): TAny; overload;
```

C++

```
__fastcall TAny MakeSequence(TCKind Kind, const array of TAny Elements);
```

Description

This is MakeSequence, a member of class TORB.

34.1.16.2.9 TORB.MakeSequenceTypeCode Method

Pascal

```
function MakeSequenceTypeCode(Bound: CorbaULong; const TC: ITypeCode): ITypeCode;
```

C++

```
__fastcall ITypeCode MakeSequenceTypeCode(CorbaULong Bound, const ITypeCode TC);
```

Description

This is MakeSequenceTypeCode, a member of class TORB.

34.1.16.2.10 TORB.MakeStructure Method

Pascal

```
function MakeStructure(TypeCode: ITypeCode; const Elements: array of TAny): TAny;
```

C++

```
__fastcall TAny MakeStructure(ITypeCode TypeCode, const array of TAny Elements);
```

Description

This is MakeStructure, a member of class TORB.

34.1.16.2.11 TORB.MakeStructureTypeCode Method

Pascal

```
function MakeStructureTypeCode(const RepositoryID: string; const Name: string; Members:
TStructMembers): ITypeCode;
```

C++

```
__fastcall ITypeCode MakeStructureTypeCode(const AnsiString RepositoryID, const AnsiString
Name, TStructMembers Members);
```

Description

This is MakeStructureTypeCode, a member of class TORB.

34.1.16.2.12 TORB.MakeTypeCode Method

Pascal

```
function MakeTypeCode(Kind: TCKind): ITypeCode;
```

C++

```
__fastcall ITypeCode MakeTypeCode(TCKind Kind);
```

Description

This is MakeTypeCode, a member of class TORB.

34.1.16.2.13 TORB.ObjectToString Method

Pascal

```
function ObjectToString(const Obj: IObject): string;
```

C++

```
__fastcall AnsiString ObjectToString(const IObject Obj);
```

Description

This is ObjectToString, a member of class TORB.

34.1.16.2.14 TORB.Shutdown Method

Pascal

```
procedure Shutdown;
```

C++

```
__fastcall Shutdown();
```

Description

This is Shutdown, a member of class TORB.

34.1.16.2.15 TORB.StringToObject Method

Pascal

```
function StringToObject(const ObjectString: string): IObject;
```

C++

```
__fastcall IObject StringToObject(const AnsiString ObjectString);
```

Description

This is StringToObject, a member of class TORB.

34.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	ICorbaObject (see page 6475)	This is class CorbaObj.ICorbaObject.

34.2.1 ICorbaObject Interface

Class Hierarchy

CorbaObj.ICorbaObject

Pascal

```
ICorbaObject = interface;
```

C++

```
__interface ICorbaObject;
```

File

CorbaObj

Description

This is class CorbaObj.ICorbaObject.

34.2.1.1 ICorbaObject Members

The following tables list the members exposed by ICorbaObject.

Public Methods

	Name	Description
	Hash (see page 6476)	This is Hash, a member of class ICorbaObject.
	IsA (see page 6476)	This is IsA, a member of class ICorbaObject.
	NonExistent (see page 6476)	This is NonExistent, a member of class ICorbaObject.
	SetPrincipal (see page 6476)	This is SetPrincipal, a member of class ICorbaObject.

34.2.1.2 ICorbaObject Methods

The methods of the ICorbaObject class are listed here.

Public Methods

	Name	Description
	Hash (see page 6476)	This is Hash, a member of class ICorbaObject.
	IsA (see page 6476)	This is IsA, a member of class ICorbaObject.
	NonExistent (see page 6476)	This is NonExistent, a member of class ICorbaObject.

	SetPrincipal (see page 6476)	This is SetPrincipal, a member of class ICorbaObject.

34.2.1.2.1 ICorbaObject.Hash Method

Pascal

```
function Hash(Maximum: Integer): Integer;
```

C++

```
__fastcall int Hash(int Maximum);
```

Description

This is Hash, a member of class ICorbaObject.

34.2.1.2.2 ICorbaObject.IsA Method

Pascal

```
function IsA(const LogicalTypeId: string): Boolean;
```

C++

```
__fastcall Boolean IsA(const AnsiString LogicalTypeId);
```

Description

This is IsA, a member of class ICorbaObject.

34.2.1.2.3 ICorbaObject.NonExistent Method

Pascal

```
function NonExistent: Boolean;
```

C++

```
__fastcall Boolean NonExistent();
```

Description

This is NonExistent, a member of class ICorbaObject.

34.2.1.2.4 ICorbaObject.SetPrincipal Method

Pascal

```
procedure SetPrincipal(const Prinicpal: TCorbaPrincipal);
```

C++

```
__fastcall SetPrincipal(const TCorbaPrincipal Prinicpal);
```

Description

This is SetPrincipal, a member of class ICorbaObject.

34.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnyToObject (see page 6477)	This is function CorbaObj.AnyToObject.
	BOA (see page 6477)	This is function CorbaObj.BOA.
	CorbaBind (see page 6478)	This is function CorbaObj.CorbaBind.
	CorbaBind (see page 6478)	This is function CorbaObj.CorbaBind.
	CorbaFactoryCreateStub (see page 6478)	This is function CorbaObj.CorbaFactoryCreateStub.
	CorbaInitialize (see page 6479)	This is function CorbaObj.CorbaInitialize.
	MakePrincipal (see page 6479)	This is function CorbaObj.MakePrincipal.
	MarshalAny (see page 6479)	This is function CorbaObj.MarshalAny.
	MarshalObject (see page 6480)	This is function CorbaObj.MarshalObject.
	MarshalWordBool (see page 6480)	This is function CorbaObj.MarshalWordBool.
	ORB (see page 6480)	This is function CorbaObj.ORB.
	SequenceToVariantArray (see page 6481)	This is function CorbaObj.SequenceToVariantArray.
	UnmarshalAny (see page 6481)	This is function CorbaObj.UnmarshalAny.
	UnmarshalObject (see page 6481)	This is function CorbaObj.UnmarshalObject.
	UnmarshalText (see page 6482)	This is function CorbaObj.UnmarshalText.
	UnmarshalWideText (see page 6482)	This is function CorbaObj.UnmarshalWideText.
	UnmarshalWordBool (see page 6482)	This is function CorbaObj.UnmarshalWordBool.
	VariantArrayToSequence (see page 6483)	This is function CorbaObj.VariantArrayToSequence.

34.3.1 CorbaObj.AnyToObject Function

Pascal

```
function AnyToObject(Any: TAny; IID: TGUID): IObject;
```

C++

```
IObject AnyToObject(TAny Any, TGUID IID);
```

File

CorbaObj

Description

This is function CorbaObj.AnyToObject.

34.3.2 CorbaObj.BOA Function

Pascal

```
function BOA: TBOA;
```

C++

```
TBOA BOA();
```

File

CorbaObj

Description

This is function CorbaObj.BOA.

34.3.3 CorbaObj.CorbaBind Function

Pascal

```
function CorbaBind(const InterfaceID: TGUID; const ObjectName: string = ''; const HostName:
string = ''): IObject; overload;
```

C++

```
IObject CorbaBind(const TGUID InterfaceID, const AnsiString ObjectName = '', const AnsiString
HostName = '');
```

File

CorbaObj

Description

This is function CorbaObj.CorbaBind.

34.3.4 CorbaObj.CorbaBind Function

Pascal

```
function CorbaBind(const RepositoryID: string; const ObjectName: string = ''; const HostName:
string = ''): IObject; overload;
```

C++

```
IObject CorbaBind(const AnsiString RepositoryID, const AnsiString ObjectName = '', const
AnsiString HostName = '');
```

File

CorbaObj

Description

This is function CorbaObj.CorbaBind.

34.3.5 CorbaObj.CorbaFactoryCreateStub Function

Pascal

```
function CorbaFactoryCreateStub(const RepId: string; const FactoryId: string; const
InstanceName: string; const HostName: string; IID: TGUID): IObject;
```

C++

```
IObject CorbaFactoryCreateStub(const AnsiString RepId, const AnsiString FactoryId, const
AnsiString InstanceName, const AnsiString HostName, TGUID IID);
```

File

CorbaObj

Description

This is function CorbaObj.CorbaFactoryCreateStub.

34.3.6 CorbaObj.CorbaInitialize Function

Pascal

```
procedure CorbaInitialize;
```

C++

```
CorbaInitialize();
```

File

CorbaObj

Description

This is function CorbaObj.CorbaInitialize.

34.3.7 CorbaObj.MakePrincipal Function

Pascal

```
function MakePrincipal(const Bytes: array of Byte): TCorbaPrincipal;
```

C++

```
TCorbaPrincipal MakePrincipal(const array of Byte Bytes);
```

File

CorbaObj

Description

This is function CorbaObj.MakePrincipal.

34.3.8 CorbaObj.MarshalAny Function

Pascal

```
procedure MarshalAny(const OutBuf: IMarshalOutBuffer; const OV: Variant);
```

C++

```
MarshalAny(const IMarshalOutBuffer OutBuf, const Variant OV);
```

File

CorbaObj

Description

This is function CorbaObj.MarshalAny.

34.3.9 CorbaObj.MarshalObject Function

Pascal

```
procedure MarshalObject(const OutBuf: IMarshalOutBuffer; IID: TGUID; const Intf: IObject);
```

C++

```
MarshalObject(const IMarshalOutBuffer OutBuf, TGUID IID, const IObject Intf);
```

File

CorbaObj

Description

This is function CorbaObj.MarshalObject.

34.3.10 CorbaObj.MarshalWordBool Function

Pascal

```
procedure MarshalWordBool(const OutBuf: IMarshalOutBuffer; Value: WordBool);
```

C++

```
MarshalWordBool(const IMarshalOutBuffer OutBuf, WordBool Value);
```

File

CorbaObj

Description

This is function CorbaObj.MarshalWordBool.

34.3.11 CorbaObj.ORB Function

Pascal

```
function ORB: TORB;
```

C++

```
TORB ORB();
```

File

CorbaObj

Description

This is function CorbaObj.ORB.

34.3.12 CorbaObj.SequenceToVariantArray Function

Pascal

```
function SequenceToVariantArray(Sequence: TAny): Variant;
```

C++

```
Variant SequenceToVariantArray(TAny Sequence);
```

File

CorbaObj

Description

This is function CorbaObj.SequenceToVariantArray.

34.3.13 CorbaObj.UnmarshalAny Function

Pascal

```
function UnmarshalAny(const InBuf: IMarshalInBuffer): Variant;
```

C++

```
Variant UnmarshalAny(const IMarshalInBuffer InBuf);
```

File

CorbaObj

Description

This is function CorbaObj.UnmarshalAny.

34.3.14 CorbaObj.UnmarshalObject Function

Pascal

```
function UnmarshalObject(const InBuf: IMarshalInBuffer; IID: TGUID): IObject;
```

C++

```
IObject UnmarshalObject(const IMarshalInBuffer InBuf, TGUID IID);
```

File

CorbaObj

Description

This is function CorbaObj.UnmarshalObject.

34.3.15 CorbaObj.UnmarshalText Function

Pascal

```
function UnmarshalText(const InBuf: IMarshalInBuffer): string;
```

C++

```
AnsiString UnmarshalText(const IMarshalInBuffer InBuf);
```

File

CorbaObj

Description

This is function CorbaObj.UnmarshalText.

34.3.16 CorbaObj.UnmarshalWideText Function

Pascal

```
function UnmarshalWideText(const InBuf: IMarshalInBuffer): WideString;
```

C++

```
BSTR UnmarshalWideText(const IMarshalInBuffer InBuf);
```

File

CorbaObj

Description

This is function CorbaObj.UnmarshalWideText.

34.3.17 CorbaObj.UnmarshalWordBool Function

Pascal

```
function UnmarshalWordBool(const InBuf: IMarshalInBuffer): WordBool;
```

C++

```
WordBool UnmarshalWordBool(const IMarshalInBuffer InBuf);
```

File

CorbaObj

Description

This is function CorbaObj.UnmarshalWordBool.

34.3.18 CorbaObj.VariantArrayToSequence Function

Pascal

```
function VariantArrayToSequence(TypeCode: ITypeCode; const VariantArray: Variant): TAny;
```

C++

```
TAny VariantArrayToSequence(ITypeCode TypeCode, const Variant VariantArray);
```

File

CorbaObj

Description

This is function CorbaObj.VariantArrayToSequence.

34.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCorbaInstancing (see page 6484)	This is record CorbaObj.TCorbaInstancing.
	TCorbaThreadModel (see page 6484)	This is record CorbaObj.TCorbaThreadModel.

Records

	Name	Description
	TInterfaceIDEntryDesc (see page 6485)	This is record CorbaObj.TInterfaceIDEntryDesc.
	TSkeletonEntryDesc (see page 6485)	This is record CorbaObj.TSkeletonEntryDesc.
	TStubEntryDesc (see page 6486)	This is record CorbaObj.TStubEntryDesc.

34.4.1 CorbaObj.TCorbaInstancing Enumeration

Pascal

```
TCorbaInstancing = (
  iSingleInstance,
  iMultiInstance
);
```

C++

```
enum TCorbaInstancing {
  iSingleInstance,
  iMultiInstance
};
```

File

CorbaObj

Description

This is record CorbaObj.TCorbaInstancing.

34.4.2 CorbaObj.TCorbaThreadModel Enumeration

Pascal

```
TCorbaThreadModel = (
  tmMultiThreaded,
  tmSingleThread
);
```

C++

```
enum TCorbaThreadModel {
  tmMultiThreaded,
  tmSingleThread
```

```
};
```

File

CorbaObj

Description

This is record CorbaObj.TCorbaThreadModel.

34.4.3 CorbaObj.TInterfaceIDEntryDesc Record

Pascal

```
TInterfaceIDEntryDesc = record
  RepositoryID: string;
  IID: TGUID;
end;
```

C++

```
struct TInterfaceIDEntryDesc {
  AnsiString RepositoryID;
  TGUID IID;
};
```

File

CorbaObj

Description

This is record CorbaObj.TInterfaceIDEntryDesc.

34.4.4 CorbaObj.TSkeletonEntryDesc Record

Pascal

```
TSkeletonEntryDesc = record
  IID: TGUID;
  SkeletonClass: TCorbaSkeletonClass;
end;
```

C++

```
struct TSkeletonEntryDesc {
  TGUID IID;
  TCorbaSkeletonClass SkeletonClass;
};
```

File

CorbaObj

Description

This is record CorbaObj.TSkeletonEntryDesc.

34.4.5 CorbaObj.TStubEntryDesc Record

Pascal

```
TStubEntryDesc = record
  IID: TGUID;
  StubClass: TCorbaStubClass;
end;
```

C++

```
struct TStubEntryDesc {
  TGUID IID;
  TCorbaStubClass StubClass;
};
```

File

CorbaObj

Description

This is record CorbaObj.TStubEntryDesc.

34.5 Types

The following table lists types in this documentation.

Types

Name	Description
CorbaBoolean (see page 6487)	This is type CorbaObj.CorbaBoolean.
CorbaULong (see page 6487)	This is type CorbaObj.CorbaULong.
IObject (see page 6488)	This is type CorbaObj.IObject.
ITypeCode (see page 6488)	This is type CorbaObj.ITypeCode.
TAny (see page 6488)	This is type CorbaObj.TAny.
TCKind (see page 6489)	This is type CorbaObj.TCKind.
TCommandLine (see page 6489)	This is type CorbaObj.TCommandLine.
TCorbaImplementationClass (see page 6489)	This is type CorbaObj.TCorbaImplementationClass.
TCorbaPrincipal (see page 6490)	This is type CorbaObj.TCorbaPrincipal.
TCorbaSkeletonClass (see page 6490)	This is type CorbaObj.TCorbaSkeletonClass.
TCorbaStubClass (see page 6490)	This is type CorbaObj.TCorbaStubClass.
TFactoryList (see page 6491)	This is type CorbaObj.TFactoryList.
TInterfaceIDList (see page 6491)	This is type CorbaObj.TInterfaceIDList.
TSkeletonList (see page 6491)	This is type CorbaObj.TSkeletonList.
TStubList (see page 6492)	This is type CorbaObj.TStubList.

34.5.1 CorbaObj.CorbaBoolean Type

Pascal

```
CorbaBoolean = ORBPAS.CorbaBoolean;
```

C++

```
ORBPAS.CorbaBoolean CorbaBoolean;
```

File

CorbaObj

Description

This is type CorbaObj.CorbaBoolean.

34.5.2 CorbaObj.CorbaULong Type

Pascal

```
CorbaULong = ORBPAS.CorbaULong;
```

C++

```
ORBPAS.CorbaULong CorbaULong;
```

File

CorbaObj

Description

This is type CorbaObj.CorbaULong.

34.5.3 CorbaObj.IObject Type

Pascal

```
IObject = System.IUnknown;
```

C++

```
System.IUnknown IObject;
```

File

CorbaObj

Description

This is type CorbaObj.IObject.

34.5.4 CorbaObj.ITypeCode Type

Pascal

```
ITypeCode = ORBPAS.ITypeCode;
```

C++

```
ORBPAS.ITypeCode ITypeCode;
```

File

CorbaObj

Description

This is type CorbaObj.ITypeCode.

34.5.5 CorbaObj.TAny Type

Pascal

```
TAny = Variant;
```

C++

```
Variant TAny;
```

File

CorbaObj

Description

This is type CorbaObj.TAny.

34.5.6 CorbaObj.TCKind Type

Pascal

```
TCKind = ORBPAS.TCKind;
```

C++

```
ORBPAS.TCKind TCKind;
```

File

CorbaObj

Description

This is type CorbaObj.TCKind.

34.5.7 CorbaObj.TCommandLine Type

Pascal

```
TCommandLine = ORBPAS.TArgv;
```

C++

```
ORBPAS.TArgv TCommandLine;
```

File

CorbaObj

Description

This is type CorbaObj.TCommandLine.

34.5.8 CorbaObj.TCorbaImplementationClass Type

Pascal

```
TCorbaImplementationClass = class of TCorbaImplementation;
```

C++

```
TCorbaImplementation TCorbaImplementationClass;
```

File

CorbaObj

Description

This is type CorbaObj.TCorbaImplementationClass.

34.5.9 CorbaObj.TCorbaPrincipal Type

Pascal

```
TCorbaPrincipal = array of Byte;
```

C++

```
array of Byte TCorbaPrincipal;
```

File

CorbaObj

Description

This is type CorbaObj.TCorbaPrincipal.

34.5.10 CorbaObj.TCorbaSkeletonClass Type

Pascal

```
TCorbaSkeletonClass = class of TCorbaSkeleton;
```

C++

```
TCorbaSkeleton TCorbaSkeletonClass;
```

File

CorbaObj

Description

This is type CorbaObj.TCorbaSkeletonClass.

34.5.11 CorbaObj.TCorbaStubClass Type

Pascal

```
TCorbaStubClass = class of TCorbaStub;
```

C++

```
TCorbaStub TCorbaStubClass;
```

File

CorbaObj

Description

This is type CorbaObj.TCorbaStubClass.

34.5.12 CorbaObj.TFactoryList Type

Pascal

```
TFactoryList = array of TCorbaFactory;
```

C++

```
array of TCorbaFactory TFactoryList;
```

File

CorbaObj

Description

This is type CorbaObj.TFactoryList.

34.5.13 CorbaObj.TInterfaceIDList Type

Pascal

```
TInterfaceIDList = array of TInterfaceIDEntryDesc;
```

C++

```
array of TInterfaceIDEntryDesc TInterfaceIDList;
```

File

CorbaObj

Description

This is type CorbaObj.TInterfaceIDList.

34.5.14 CorbaObj.TSkeletonList Type

Pascal

```
TSkeletonList = array of TSkeletonEntryDesc;
```

C++

```
array of TSkeletonEntryDesc TSkeletonList;
```

File

CorbaObj

Description

This is type CorbaObj.TSkeletonList.

34.5.15 CorbaObj.TStubList Type

Pascal

```
TStubList = array of TStubEntryDesc;
```

C++

```
array of TStubEntryDesc TStubList;
```

File

CorbaObj

Description

This is type CorbaObj.TStubList.

34.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CorbaInterfaceIDManager (see page 6493)	This is variable CorbaObj.CorbaInterfaceIDManager.
CorbaSkeletonManager (see page 6493)	This is variable CorbaObj.CorbaSkeletonManager.
CorbaStubManager (see page 6493)	This is variable CorbaObj.CorbaStubManager.

34.6.1 CorbaObj.CorbaInterfaceIDManager Variable

Pascal

```
CorbaInterfaceIDManager: TCorbaInterfaceIDManager;
```

C++

```
TCorbaInterfaceIDManager CorbaInterfaceIDManager;
```

File

CorbaObj

Description

This is variable CorbaObj.CorbaInterfaceIDManager.

34.6.2 CorbaObj.CorbaSkeletonManager Variable

Pascal

```
CorbaSkeletonManager: TCorbaSkeletonManager;
```

C++

```
TCorbaSkeletonManager CorbaSkeletonManager;
```

File

CorbaObj

Description

This is variable CorbaObj.CorbaSkeletonManager.

34.6.3 CorbaObj.CorbaStubManager Variable

Pascal

```
CorbaStubManager: TCorbaStubManager;
```

C++

```
TCorbaStubManager CorbaStubManager;
```

File

CorbaObj

Description

This is variable CorbaObj.CorbaStubManager.

35 CtlPanel Namespace

This is namespace CtlPanel.

Topics

Name	Description
Classes (see page 6497)	The following table lists classes in this documentation.
Functions (see page 6519)	The following table lists functions in this documentation.
Types (see page 6520)	The following table lists types in this documentation.
Variables (see page 6526)	The following table lists variables in this documentation.

Classes

	Name	Description
	EAppletException (see page 6497)	EAppletException is the exception class for errors that occur in a Control Panel Application (see page 6526).
	TAppletApplication (see page 6497)	TAppletApplication represents a Windows control panel application.
	TAppletModule (see page 6507)	TAppletModule represents a single Control Panel Applet in a control panel applet application.

Functions

	Name	Description
	CPlApplet (see page 6519)	This is function CtlPanel.CPlApplet.

Types

Name	Description
TActivateEvent (see page 6520)	TActivateEvent is the type of the OnActivate event handler.
TAppletModuleClass (see page 6520)	This is type CtlPanel.TAppletModuleClass.
TCountEvent (see page 6521)	TCountEvent is the type of the OnCount event handler.
TCPLAppletClass (see page 6521)	This is type CtlPanel.TCPLAppletClass.
TDataModuleClass (see page 6522)	This is type CtlPanel.TDataModuleClass.
TExitEvent (see page 6522)	TExitEvent is the type for event handlers that respond when a control panel application is about to shut down.
TInitEvent (see page 6522)	TInitEvent is the type of the OnInit event handler.
TInquireEvent (see page 6523)	TInquireEvent is the type of the OnInquire event handler.
TNewInquireEvent (see page 6523)	TNewInquireEvent is the type of the OnNewInquire event handler.
TOnAppletExceptionEvent (see page 6524)	TOnAppletExceptionEvent is the type for event handlers that respond when a control panel applet encounters an exception.

TSetupEvent (see page 6524)	TSetupEvent is the type for event handlers that respond when a control panel applet is invoked from the command line during system installation.
TStartWParmsEvent (see page 6524)	TStartWParmsEvent is the type of the OnStartWParms event handler.
TStopEvent (see page 6525)	TStopEvent is the type of the OnStop event handler.

Variables

Name	Description
Application (see page 6526)	Represents the application for a control panel applet project.

35.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EAppletException (see page 6497)	EAppletException is the exception class for errors that occur in a Control Panel Application (see page 6526).
	TAppletApplication (see page 6497)	TAppletApplication represents a Windows control panel application.
	TAppletModule (see page 6507)	TAppletModule represents a single Control Panel Applet in a control panel applet application.

35.1.1 EAppletException Class

EAppletException is the exception class for errors that occur in a Control Panel Application (see page 6526).

Class Hierarchy

Pascal

```
EAppletException = class(Exception);
```

C++

```
class EAppletException : public Exception;
```

File

CtlPanel

Description

EAppletException is the exception for errors specific to applications created by the control panel wizard.

See Also

TAppletApplication (see page 6497)

TAppletModule (see page 6507)

35.1.2 TAppletApplication Class

TAppletApplication represents a Windows control panel application.

Class Hierarchy

Pascal

```
TAppletApplication = class(TComponent);
```

C++

```
class TAppletApplication : public TComponent;
```

File

CtlPanel

Description

TAppletApplication represents an application that implements one or more applets, each of which appear in the Windows control panel. Each applet that the application implements is built using an AppletModule, which is a special data module that holds the nonvisual components in the applet and which responds when users execute the applet from the control panel. TAppletApplication contains a set of AppletModules. It lets you respond to a number of events that are called by the Windows control panel for starting up or shutting down the application.

A global Application (see page 6526) variable of type TAppletApplication is declared in the CtlPanel (see page 6495) unit.

See Also

TAppletModule (see page 6507)

EAppletException (see page 6497)

35.1.2.1 TAppletApplication Members

The following tables list the members exposed by TAppletApplication.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DoCount (see page 6502)	This is DoCount, a member of class TAppletApplication.
	DoExit (see page 6503)	This is DoExit, a member of class TAppletApplication.
	DoHandleException (see page 6503)	This is DoHandleException, a member of class TAppletApplication.
	DoInit (see page 6503)	This is DoInit, a member of class TAppletApplication.
	DoSetup (see page 6503)	This is DoSetup, a member of class TAppletApplication.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Events

	Name	Description
	OnCount (see page 6506)	Occurs when the control panel requests a count of the AppletModules.
	OnException (see page 6507)	Occurs when an exception raised by the application is not handled.
	OnInit (see page 6507)	Occurs when the Application (see page 6526) is first initialized.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6501)	Instantiates a TAppletApplication (see page 6497) object.
V	CreateForm (see page 6502)	Creates the Applet object or objects for the applet application.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6501)	Disposes of an instance of a TAppletApplication (see page 6497) object.

	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HandleException (see page 6503)	Responds to exceptions that are not caught by a try block in the application.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	Initialize (see page 6504)	Sets the initial state of the application and hides any associated MainForm.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Run (see page 6504)	Sets the Applications Exception handler.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.

R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlPanelHandle (see page 6505)	Indicates the window handle for the controlling application.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	ModuleCount (see page 6505)	Indicates the number of AppletModules available.
	Modules (see page 6505)	Lists the available modules in the Applet application.
	OnExit (see page 6506)	Occurs when the Application (see page 6526) should unload.
	OnSetup (see page 6506)	Occurs when the applet is invoked from the command line during system installation.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

35.1.2.2 TAppletApplication.Create Constructor

Instantiates a TAppletApplication (see page 6497) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAppletApplication(TComponent * AOwner);
```

Description

Applications do not need to call the constructor directly. TAppletApplication (see page 6497) is instantiated by selecting File | New | Other from the menu of the IDE main window and selecting Applet Application (see page 6526) in the New Items dialog. An Application (see page 6526) variable of type TAppletApplication (see page 6497) is declared and initialized as the instance of the application.

35.1.2.3 TAppletApplication.Destroy Destructor

Disposes of an instance of a TAppletApplication (see page 6497) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAppletApplication();
```

Description

Do not call the destructor directly. TAppletApplication (see page 6497) is destroyed when your application closes.

The destructor frees the memory associated with sub-objects.

See Also

Free (see page 22300)

35.1.2.4 TAppletApplication Methods

The methods of the TAppletApplication class are listed here.

Protected Methods

	Name	Description
	DoCount (see page 6502)	This is DoCount, a member of class TAppletApplication.
	DoExit (see page 6503)	This is DoExit, a member of class TAppletApplication.
	DoHandleException (see page 6503)	This is DoHandleException, a member of class TAppletApplication.
	DoInit (see page 6503)	This is DoInit, a member of class TAppletApplication.
	DoSetup (see page 6503)	This is DoSetup, a member of class TAppletApplication.

Public Methods

	Name	Description
V	CreateForm (see page 6502)	Creates the Applet object or objects for the applet application.
	HandleException (see page 6503)	Responds to exceptions that are not caught by a try block in the application.
V	Initialize (see page 6504)	Sets the initial state of the application and hides any associated MainForm.
V	Run (see page 6504)	Sets the Applications Exception handler.

35.1.2.4.1 TAppletApplication.CreateForm Method

Creates the Applet object or objects for the applet application.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference); virtual;
```

C++

```
virtual __fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Do not call CreateForm in an application.The module manager calls CreateForm internally to register the applet objects with the applet application.

CreateForm instantiates a TApplet object for each applet contained in the applet application. CreateForm is called automatically, for the first applet module, when the applet application is first created. Subsequently, CreateForm is called for each new applet module added to the application. To add a new applet module, select File | New | Other from the menu of the IDE main window and choose Applet Module in the New Items dialog.

35.1.2.4.2 TAppletApplication.DoCount Method

Pascal

```
procedure DoCount(var AppCount: Integer); dynamic;
```

C++

```
__fastcall DoCount(int AppCount);
```

Description

This is DoCount, a member of class TAppletApplication.

35.1.2.4.3 TAppletApplication.DoExit Method

Pascal

```
procedure DoExit; dynamic;
```

C++

```
__fastcall DoExit();
```

Description

This is DoExit, a member of class TAppletApplication.

35.1.2.4.4 TAppletApplication.DoHandleException Method

Pascal

```
procedure DoHandleException(Sender: TObject; E: Exception); dynamic;
```

C++

```
__fastcall DoHandleException(TObject * Sender, Exception E);
```

Description

This is DoHandleException, a member of class TAppletApplication.

35.1.2.4.5 TAppletApplication.DoInit Method

Pascal

```
procedure DoInit(var AppInitOK: Boolean); dynamic;
```

C++

```
__fastcall DoInit(Boolean AppInitOK);
```

Description

This is DoInit, a member of class TAppletApplication.

35.1.2.4.6 TAppletApplication.DoSetup Method

Pascal

```
procedure DoSetup; dynamic;
```

C++

```
__fastcall DoSetup();
```

Description

This is DoSetup, a member of class TAppletApplication.

35.1.2.4.7 TAppletApplication.HandleException Method

Responds to exceptions that are not caught by a try block in the application.

Pascal

```
procedure HandleException(Sender: TObject);
```

C++

```
__fastcall HandleException(TObject * Sender);
```

Description

HandleException is called automatically when an exception is not caught by any of the try blocks in the application code. It calls the global ExceptObject function to obtain the exception object.

If ExceptObject is Exception or one of its descendants, HandleException generates an OnException (see page 6507) event.

If ExceptObject is not an Exception descendant, or if there is no OnException (see page 6507) event handler, HandleException calls the global ShowException method to display a message box that indicates what exception occurred.

Sender is the object that raised the exception.

See Also

OnException (see page 6507)

ExceptObject (see page 22452)

ShowException (see page 22941)

35.1.2.4.8 TAppletApplication.Initialize Method

Sets the initial state of the application and hides any associated MainForm.

Pascal

```
procedure Initialize; virtual;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize follows the standard (default) VCL application initialization process.

35.1.2.4.9 TAppletApplication.Run Method

Sets the Applications Exception handler.

Pascal

```
procedure Run; virtual;
```

C++

```
virtual __fastcall Run();
```

Description

Run sets the Application (see page 6526)'s Exception handler.

35.1.2.5 TAppletApplication Properties

The properties of the TAppletApplication class are listed here.

Public Properties

	Name	Description
R	ControlPanelHandle (see page 6505)	Indicates the window handle for the controlling application.

	ModuleCount (see page 6505)	Indicates the number of AppletModules available.
	Modules (see page 6505)	Lists the available modules in the Applet application.
	OnExit (see page 6506)	Occurs when the Application (see page 6526) should unload.
	OnSetup (see page 6506)	Occurs when the applet is invoked from the command line during system installation.

35.1.2.5.1 TAppletApplication.ControlPanelHandle Property

Indicates the window handle for the controlling application.

Pascal

```
property ControlPanelHandle: THandle;
```

C++

```
__property THandle ControlPanelHandle;
```

Description

ControlPanelHandle is the handle to the Control Panel or the controlling application (the application which invoked the CplApplet function).

35.1.2.5.2 TAppletApplication.ModuleCount Property

Indicates the number of AppletModules available.

Pascal

```
property ModuleCount: Integer;
```

C++

```
__property int ModuleCount;
```

Description

ModuleCount is the number of AppletModules that are available to the controlling application from this AppletApplication.

See Also

Modules (see page 6505)

35.1.2.5.3 TAppletApplication.Modules Property

Lists the available modules in the Applet application.

Pascal

```
property Modules [Index: Integer]: TAppletModule;
```

C++

```
__property TAppletModule Modules[int Index];
```

Description

Modules is a list of the TAppletModule (see page 6507) objects that are available to the AppletApplication.

See Also

ModuleCount (see page 6505)

35.1.2.5.4 TAppletApplication.OnExit Property

Occurs when the Application (see page 6526) should unload.

Pascal

```
property OnExit: TExitEvent;
```

C++

```
__property TExitEvent OnExit;
```

Description

The OnExit event occurs when the Application (see page 6526) receives a CPL_EXIT message from the controlling application. This is a recommended spot to do non-applet specific clean-up.

35.1.2.5.5 TAppletApplication.OnSetup Property

Occurs when the applet is invoked from the command line during system installation.

Pascal

```
property OnSetup: TSetupEvent;
```

C++

```
__property TSetupEvent OnSetup;
```

Description

This event occurs when the CPL_SETUP message is received from the controlling application. This message is only sent when an applet is invoked from the Command line during system installation.

35.1.2.6 TAppletApplication Events

The events of the TAppletApplication class are listed here.

Public Events

	Name	Description
	OnCount (see page 6506)	Occurs when the control panel requests a count of the AppletModules.
	OnException (see page 6507)	Occurs when an exception raised by the application is not handled.
	OnInit (see page 6507)	Occurs when the Application (see page 6526) is first initialized.

35.1.2.6.1 TAppletApplication.OnCount Event

Occurs when the control panel requests a count of the AppletModules.

Pascal

```
property OnCount: TCountEvent;
```

C++

```
__property TCountEvent OnCount;
```

Description

The OnCount event occurs when the Application (see page 6526) receives a CPL_GETCOUNT message from the controlling application. It must return the number of AppletModules that are available. The default is to return ModuleCount (see page 6505), but it may be overridden by changing the value of the AppCount parameter of the event handler.

35.1.2.6.2 TAppletApplication.OnException Event

Occurs when an exception raised by the application is not handled.

Pascal

```
property OnException: TOnAppletExceptionEvent;
```

C++

```
__property TOnAppletExceptionEvent OnException;
```

Description

Use OnException to change the default behavior that occurs when an exception is not handled by application code. If an exception passes through the try blocks in the application code, the application automatically calls the HandleException (see page 6503) method. The HandleException (see page 6503) method generates an OnException event when it encounters an exception that descends from Exception. If there is no OnException event handler, or if the Exception object does not descend from Exception, the applet displays a message box indicating an error occurred.

See Also

HandleException (see page 6503)

35.1.2.6.3 TAppletApplication.OnInit Event

Occurs when the Application (see page 6526) is first initialized.

Pascal

```
property OnInit: TInitEvent;
```

C++

```
__property TInitEvent OnInit;
```

Description

The OnInit event occurs when the Application (see page 6526) receives a CPL_INIT message from the controlling application. The application must return either true or false to determine whether the controlling application should attempt to continue loading this module. The default is to return true, but this value may be overridden by assigning a value to the AppInitOK parameter of the event handler.

35.1.3 TAppletModule Class

TAppletModule represents a single Control Panel Applet in a control panel applet application.

Class Hierarchy

Pascal

```
TAppletModule = class(TDataModule);
```

C++

```
class TAppletModule : public TDataModule;
```

File

CtlPanel

Description

TAppletModule encapsulates the functionality of a Control Panel Applet. Its properties specify how the icon for the applet appears in the control panel, including the help that appears when users press F1. The events of TAppletModule let you specify what the applet does when users start or stop it, either by double-clicking in the control panel or by launching the applet programmatically.

See Also

TAppletApplication (see page 6497)

EAppletException (see page 6497)

35.1.3.1 TAppletModule Members

The following tables list the members exposed by TAppletModule.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DoActivate (see page 6512)	This is DoActivate, a member of class TAppletModule.
V	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
V	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
	DoInquire (see page 6512)	This is DoInquire, a member of class TAppletModule.
	DoNewInquire (see page 6512)	This is DoNewInquire, a member of class TAppletModule.
	DoStartWParms (see page 6513)	This is DoStartWParms, a member of class TAppletModule.
	DoStop (see page 6513)	This is DoStop, a member of class TAppletModule.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.

	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6511)	Instantiates a TAppletModule (see page 6507) object.
V	CreateNew (see page 2828)	Creates an instance of a data module and registers with the global screen object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6511)	Disposes of an instance of a TAppletModule (see page 6507) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Data (see page 6514)	Specifies user-defined data.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnActivate (see page 6516)	Occurs when the applet's icon is double clicked.
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.
	OnInquire (see page 6516)	Occurs when the AppletModule is queried for its information.
	OnNewInquire (see page 6517)	Occurs when the AppletModule is queried for its information.
	OnStartWParms (see page 6517)	Occurs when the AppletModule is invoked from RunDLL.
	OnStop (see page 6517)	Occurs when the AppletModule receives a request to shutdown.

Published Properties

	Name	Description
	AppletIcon (see page 6513)	Indicates the icon for the AppletModule.
	Caption (see page 6514)	Indicates the caption of the applet module.
	Help (see page 6514)	Indicates a help string that appears in the control panel for this applet.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.
	ResidIcon (see page 6515)	Indicates the resource ID of the icon associated with the applet module.
	ResidInfo (see page 6515)	Indicates the resource ID of the help string.
	ResidName (see page 6515)	Indicates the resource ID of the caption string.
	Tag (see page 2808)	Stores an integer value as part of a component.

35.1.3.2 TAppletModule.Create Constructor

Instantiates a TAppletModule (see page 6507) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAppletModule(TComponent * AOwner);
```

Description

Create constructs a TAppletModule (see page 6507) instance and adds itself to the list of Modules in the TAppletApplication (see page 6497) specified as the value of AOwner.

35.1.3.3 TAppletModule.Destroy Destructor

Disposes of an instance of a TAppletModule (see page 6507) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAppletModule();
```

Description

The destructor destroys the specified instance of a TAppletModule (see page 6507) and removes it from the list of applet modules in the owning TAppletApplication (see page 6497).

Typically, applications do not call Destroy, because the owning TAppletApplication (see page 6497) is responsible for freeing them. However, if an Owner is not specified, do not call Destroy directly. Rather, call the Free method.

See Also

Free (see page 22300)

35.1.3.4 TAppletModule Methods

The methods of the TAppletModule class are listed here.

Protected Methods

	Name	Description
	DoActivate (see page 6512)	This is DoActivate, a member of class TAppletModule.
	DoInquire (see page 6512)	This is DoInquire, a member of class TAppletModule.
	DoNewInquire (see page 6512)	This is DoNewInquire, a member of class TAppletModule.
	DoStartWParms (see page 6513)	This is DoStartWParms, a member of class TAppletModule.
	DoStop (see page 6513)	This is DoStop, a member of class TAppletModule.

35.1.3.4.1 TAppletModule.DoActivate Method

Pascal

```
procedure DoActivate(Data: LongInt); dynamic;
```

C++

```
__fastcall DoActivate(LongInt Data);
```

Description

This is DoActivate, a member of class TAppletModule.

35.1.3.4.2 TAppletModule.DoInquire Method

Pascal

```
procedure DoInquire(var ACPLInfo: TCPLInfo); dynamic;
```

C++

```
__fastcall DoInquire(TCPLInfo ACPLInfo);
```

Description

This is DoInquire, a member of class TAppletModule.

35.1.3.4.3 TAppletModule.DoNewInquire Method

Pascal

```
procedure DoNewInquire(var ANewCPLInfo: TNewCPLInfo); dynamic;
```

C++

```
__fastcall DoNewInquire(TNewCPLInfo ANewCPLInfo);
```

Description

This is DoNewInquire, a member of class TAppletModule.

35.1.3.4.4 TAppletModule.DoStartWParms Method

Pascal

```
procedure DoStartWParms(Params: string); dynamic;
```

C++

```
__fastcall DoStartWParms(AnsiString Params);
```

Description

This is DoStartWParms, a member of class TAppletModule.

35.1.3.4.5 TAppletModule.DoStop Method

Pascal

```
procedure DoStop(Data: LongInt); dynamic;
```

C++

```
__fastcall DoStop(LongInt Data);
```

Description

This is DoStop, a member of class TAppletModule.

35.1.3.5 TAppletModule Properties

The properties of the TAppletModule class are listed here.

Public Properties

	Name	Description
	Data (see page 6514)	Specifies user-defined data.

Published Properties

	Name	Description
	AppletIcon (see page 6513)	Indicates the icon for the AppletModule.
	Caption (see page 6514)	Indicates the caption of the applet module.
	Help (see page 6514)	Indicates a help string that appears in the control panel for this applet.
	ResidIcon (see page 6515)	Indicates the resource ID of the icon associated with the applet module.
	ResidInfo (see page 6515)	Indicates the resource ID of the help string.
	ResidName (see page 6515)	Indicates the resource ID of the caption string.

35.1.3.5.1 TAppletModule.AppletIcon Property

Indicates the icon for the AppletModule.

Pascal

```
property AppletIcon: TIcon;
```

C++

```
__property TIcon AppletIcon;
```

Description

AppletIcon contains the icon that is associated with this Applet Module.

See Also

Caption (see page 6514)

ResidIcon (see page 6515)

35.1.3.5.2 TAppletModule.Caption Property

Indicates the caption of the applet module.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

Description

Caption is the string that shows in the Control Panel under the icon of the Applet.

See Also

AppletIcon (see page 6513)

Help (see page 6514)

ResidName (see page 6515)

35.1.3.5.3 TAppletModule.Data Property

Specifies user-defined data.

Pascal

```
property Data: LongInt;
```

C++

```
__property LongInt Data;
```

Description

Data is a user-defined value that is passed to the controlling application on the OnInquire (see page 6516)/OnNewInquire (see page 6517) events.

See Also

OnInquire (see page 6516)

OnNewInquire (see page 6517)

35.1.3.5.4 TAppletModule.Help Property

Indicates a help string that appears in the control panel for this applet.

Pascal

```
property Help: string;
```

C++

```
__property AnsiString Help;
```

Description

Help is the string that is visible in the status bar of the Control Panel when a particular Applet is selected.

See Also

Caption (see page 6514)

ResidInfo (see page 6515)

35.1.3.5.5 TAppletModule.ResidIcon Property

Indicates the resource ID of the icon associated with the applet module.

Pascal

```
property ResidIcon: Integer;
```

C++

```
__property int ResidIcon;
```

Description

ResidIcon is the resource ID of the icon associated with the applet module. This property is mutually exclusive with the AppletIcon (see page 6513) property.

See Also

AppletIcon (see page 6513)

35.1.3.5.6 TAppletModule.ResidInfo Property

Indicates the resource ID of the help string.

Pascal

```
property ResidInfo: Integer;
```

C++

```
__property int ResidInfo;
```

Description

ResidInfo is the resource ID of the help string associated with the applet module. This property is mutually exclusive with the Help (see page 6514) property.

See Also

Help (see page 6514)

35.1.3.5.7 TAppletModule.ResidName Property

Indicates the resource ID of the caption string.

Pascal

```
property ResidName: Integer;
```

C++

```
__property int ResidName;
```

Description

ResidName is the resource ID of the caption string associated with the applet module. This property is mutually exclusive with the Caption (see page 6514) property.

See Also

Caption (see page 6514)

35.1.3.6 TAppletModule Events

The events of the TAppletModule class are listed here.

Published Events

	Name	Description
	OnActivate (see page 6516)	Occurs when the applet's icon is double clicked.
	OnInquire (see page 6516)	Occurs when the AppletModule is queried for its information.
	OnNewInquire (see page 6517)	Occurs when the AppletModule is queried for its information.
	OnStartWParms (see page 6517)	Occurs when the AppletModule is invoked from RunDLL.
	OnStop (see page 6517)	Occurs when the AppletModule receives a request to shutdown.

35.1.3.6.1 TAppletModule.OnActivate Event

Occurs when the applet's icon is double clicked.

Pascal

```
property OnActivate: TActivateEvent;
```

C++

```
__property TActivateEvent OnActivate;
```

Description

OnActivate is invoked when the Applet icon is double clicked in the Control Panel.

See Also

OnInquire (see page 6516)

OnNewInquire (see page 6517)

OnStartWParms (see page 6517)

35.1.3.6.2 TAppletModule.OnInquire Event

Occurs when the AppletModule is queried for its information.

Pascal

```
property OnInquire: TInquireEvent;
```

C++

```
__property TInquireEvent OnInquire;
```

Description

OnInquire occurs when the controlling application requests each applet's information such as its icon, caption, Help (see page 6514) and Data (see page 6514) values. This event populates a structure with the resource ID's which are changed in this event (such as idIcon, idName, idInfo and lData). These values default to the corresponding module properties.

See Also

Data (see page 6514)

OnNewInquire (see page 6517)

35.1.3.6.3 TAppletModule.OnNewInquire Event

Occurs when the AppletModule is queried for its information.

Pascal

```
property OnNewInquire: TNewInquireEvent;
```

C++

```
__property TNewInquireEvent OnNewInquire;
```

Description

OnNewInquire occurs when the controlling application requests each applet's information such as its Icon, Caption (see page 6514), Help (see page 6514), and Data (see page 6514) Values. This event populates a structure with the values that are changed in this event (such as hIcon, AppletName, AppletInfo, and lData). HIcon defaults to the handle of the AppletIcon (see page 6513) property. AppletName defaults to Caption (see page 6514), AppletInfo defaults to Help (see page 6514), and lData defaults to the Data (see page 6514) property of the AppletModule.

See Also

Data (see page 6514)

OnInquire (see page 6516)

35.1.3.6.4 TAppletModule.OnStartWParms Event

Occurs when the AppletModule is invoked from RunDLL.

Pascal

```
property OnStartWParms: TStartWParmsEvent;
```

C++

```
__property TStartWParmsEvent OnStartWParms;
```

Description

OnStartWParms parallels the OnActivate (see page 6516) event. Where it differs is that the invocation is coming from RunDLL. Params may contain extra directions for execution.

See Also

OnActivate (see page 6516)

35.1.3.6.5 TAppletModule.OnStop Event

Occurs when the AppletModule receives a request to shutdown.

Pascal

```
property OnStop: TStopEvent;
```

C++

```
__property TStopEvent OnStop;
```

Description

Write an OnStop event handler to perform Applet-specific clean-up. OnStop occurs when the applet module receives a request to shutdown.

See Also

OnStartWParms (see page 6517)

OnActivate (see page 6516)

OnInquire (see page 6516)

OnNewInquire (see page 6517)

35.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CPlApplet (see page 6519)	This is function CtlPanel.CPlApplet.

35.2.1 CtlPanel.CPlApplet Function

Pascal

```
function CPlApplet(hwndCPl: THandle; uMsg: DWORD; lParam1: Longint; lParam2: Longint):
Longint; stdcall;
```

C++

```
__stdcall Longint CPlApplet(THandle hwndCPl, DWORD uMsg, Longint lParam1, Longint lParam2);
```

File

CtlPanel

Description

This is function CtlPanel.CPlApplet.

35.3 Types

The following table lists types in this documentation.

Types

Name	Description
TActivateEvent (see page 6520)	TActivateEvent is the type of the OnActivate event handler.
TAppletModuleClass (see page 6520)	This is type CtlPanel.TAppletModuleClass.
TCountEvent (see page 6521)	TCountEvent is the type of the OnCount event handler.
TCPLAppletClass (see page 6521)	This is type CtlPanel.TCPLAppletClass.
TDataModuleClass (see page 6522)	This is type CtlPanel.TDataModuleClass.
TExitEvent (see page 6522)	TExitEvent is the type for event handlers that respond when a control panel application is about to shut down.
TInitEvent (see page 6522)	TInitEvent is the type of the OnInit event handler.
TInquireEvent (see page 6523)	TInquireEvent is the type of the OnInquire event handler.
TNewInquireEvent (see page 6523)	TNewInquireEvent is the type of the OnNewInquire event handler.
TOnAppletExceptionEvent (see page 6524)	TOnAppletExceptionEvent is the type for event handlers that respond when a control panel applet encounters an exception.
TSetupEvent (see page 6524)	TSetupEvent is the type for event handlers that respond when a control panel applet is invoked from the command line during system installation.
TStartWParmsEvent (see page 6524)	TStartWParmsEvent is the type of the OnStartWParms event handler.
TStopEvent (see page 6525)	TStopEvent is the type of the OnStop event handler.

35.3.1 CtlPanel.TActivateEvent Type

TActivateEvent is the type of the OnActivate event handler.

Pascal

```
TActivateEvent = procedure (Sender: TObject; Data: LongInt) of object;
```

C++

```
(Sender: TObject; Data: LongInt) ( TActivateEvent)();
```

File

CtlPanel

Description

TActivateEvent lets you respond when the user first activates a control panel applet.

Sender is the Applet Module which was clicked.

Data is the value that was set in the Inquire events (OnInquire or OnNewInquire).

35.3.2 CtlPanel.TAppletModuleClass Type

Pascal

```
TAppletModuleClass = class of TAppletModule;
```

C++

```
TAppletModule TAppletModuleClass;
```

File

CtlPanel

Description

This is type CtlPanel.TAppletModuleClass.

35.3.3 CtlPanel.TCountEvent Type

TCountEvent is the type of the OnCount event handler.

Pascal

```
TCountEvent = procedure (Sender: TObject; var AppCount: Integer) of object;
```

C++

```
(Sender: TObject; var AppCount: Integer) ( TCountEvent)();
```

File

CtlPanel

Description

TCountEvent lets you override the indication a control panel application gives for number of applets it makes available.

Sender is the control panel application object.

AppCount returns the number of modules. On entry, this is the number of TAppletModule (see page 6507) instances in the application. The event handler can change this amount.

35.3.4 CtlPanel.TCPLAppletClass Type

Pascal

```
TCPLAppletClass = class of TAppletModule;
```

C++

```
TAppletModule TCPLAppletClass;
```

File

CtlPanel

Description

This is type CtlPanel.TCPLAppletClass.

35.3.5 CtlPanel.TDataModuleClass Type

Pascal

```
TDataModuleClass = class of TDataModule;
```

C++

```
TDataModule TDataModuleClass;
```

File

CtlPanel

Description

This is type CtlPanel.TDataModuleClass.

35.3.6 CtlPanel.TExitEvent Type

TExitEvent is the type for event handlers that respond when a control panel application is about to shut down.

Pascal

```
TExitEvent = TNotifyEvent;
```

C++

```
TNotifyEvent TExitEvent;
```

File

CtlPanel

Description

TExitEvent maps to the TNotifyEvent type. It has a single parameter, Sender, which is the TAppletApplication (see page 6497) instance.

35.3.7 CtlPanel.TInitEvent Type

TInitEvent is the type of the OnInit event handler.

Pascal

```
TInitEvent = procedure (Sender: TObject; var AppInitOK: Boolean) of object;
```

C++

```
(Sender: TObject; var AppInitOK: Boolean) ( TInitEvent)();
```

File

CtlPanel

Description

TInitEvent lets you indicate whether the controlling application should finish loading a control panel application.

Sender is the control panel application object.

AppInitOK returns true if the controlling application should continue loading the application, false if the controlling application should abort this application.

35.3.8 CtlPanel.TInquireEvent Type

TInquireEvent is the type of the OnInquire event handler.

Pascal

```
TInquireEvent = procedure (Sender: TObject; var idIcon: Integer; var idName: Integer; var
idInfo: Integer; var lData: Integer) of object;
```

C++

```
(Sender: TObject; var idIcon: Integer; var idName: Integer; var idInfo: Integer; var lData:
Integer) ( TInquireEvent)();
```

File

CtlPanel

Description

TInquireEvent lets you provide information about a control panel applet.

Sender is the Applet Module about which you are providing information.

idIcon is the resource ID for the icon of the applet.

idName is the resource ID for the applet's name as it appears in the control panel.

lData is a user-defined value that you want to have passed to the applet's OnActivate event handler.

35.3.9 CtlPanel.TNewInquireEvent Type

TNewInquireEvent is the type of the OnNewInquire event handler.

Pascal

```
TNewInquireEvent = procedure (Sender: TObject; var lData: Integer; var hIcon: HICON; var
AppletName: string; var AppletInfo: string) of object;
```

C++

```
(Sender: TObject; var lData: Integer; var hIcon: HICON; var AppletName: string; var
AppletInfo: string) ( TNewInquireEvent)();
```

File

CtlPanel

Description

TNewInquireEvent lets you provide information about a control panel applet.

Sender is the Applet Module about which you are providing information.

lData is a user-defined value that you want to have passed to the applet's OnActivate event handler.

hIcon is the handle to the icon for the applet.

AppletName is the applet's name as it appears in the control panel.

AppletInfo is the help string that describes the applet in the control panel.

35.3.10 CtlPanel.TOnAppletExceptionEvent Type

TOnAppletExceptionEvent is the type for event handlers that respond when a control panel applet encounters an exception.

Pascal

```
TOnAppletExceptionEvent = procedure (Sender: TObject; E: Exception) of object;
```

C++

```
(Sender: TObject; E: Exception) ( TOnAppletExceptionEvent)();
```

File

CtlPanel

Description

TOnAppletExceptionEvent lets you customize the response to exceptions that occur in a control panel application.

Sender is the object that raised the exception.

E is the exception object that describes the exception.

35.3.11 CtlPanel.TSetupEvent Type

TSetupEvent is the type for event handlers that respond when a control panel applet is invoked from the command line during system installation.

Pascal

```
TSetupEvent = TNotifyEvent;
```

C++

```
TNotifyEvent TSetupEvent;
```

File

CtlPanel

Description

TSetupEvent maps to the TNotifyEvent type. It has a single parameter, Sender, which is the TAppletApplication (see page 6497) instance.

35.3.12 CtlPanel.TStartWParmsEvent Type

TStartWParmsEvent is the type of the OnStartWParms event handler.

Pascal

```
TStartWParmsEvent = procedure (Sender: TObject; Params: string) of object;
```

C++

```
(Sender: TObject; Params: string) ( TStartWParmsEvent)();
```

File

CtlPanel

Description

TStartWParmsEvent lets you respond when a control panel applet first starts up.

Sender is the Applet Module that is starting up.

Params is the parameter string that is passed to RunDLL.

35.3.13 CtlPanel.TStopEvent Type

TStopEvent is the type of the OnStop event handler.

Pascal

```
TStopEvent = procedure (Sender: TObject; Data: LongInt) of object;
```

C++

```
(Sender: TObject; Data: LongInt) ( TStopEvent)();
```

File

CtlPanel

Description

TStopEvent lets you respond when a control panel applet receives a shutdown request.

Sender is the Applet Module that received the request to shut down.

Data is the value that was set in the Inquire events (OnInquire or OnNewInquire).

35.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Application (see page 6526)	Represents the application for a control panel applet project.

35.4.1 CtlPanel.Application Variable

Represents the application for a control panel applet project.

Pascal

```
Application: TAppletApplication = nil;
```

C++

```
TAppletApplication Application = nil;
```

File

CtlPanel

Description

When a new control panel project is created, the IDE constructs an application object and assigns it to Application. If the project represents a control panel applet, Application is initialized to a TAppletApplication (see page 6497) object.

See Also

,

36 CustomizeDlg Namespace

This is namespace CustomizeDlg.

Topics

Name	Description
Classes (see page 6528)	The following table lists classes in this documentation.

Classes

	Name	Description
	TCustomizeDlg (see page 6528)	TCustomizeDlg is the customization dialog for action bands.
	TCustomizeFrm (see page 6535)	This is class CustomizeDlg.TCustomizeFrm.

36.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCustomizeDlg (see page 6528)	TCustomizeDlg is the customization dialog for action bands.
	TCustomizeFrm (see page 6535)	This is class CustomizeDlg.TCustomizeFrm.

36.1.1 TCustomizeDlg Class

TCustomizeDlg is the customization dialog for action bands.

Class Hierarchy

Pascal

```
TCustomizeDlg = class(TComponent);
```

C++

```
class TCustomizeDlg : public TComponent;
```

File

CustomizeDlg

Description

TCustomizeDlg is the customization dialog for action bands. This dialog appears when a user indicates a wish to customize user interface elements using a control provided by the application developer. The dialog is also used in the IDE when action bands for an application are first being created.

See Also

Creating Customizable Toolbars and Menus

36.1.1.1 TCustomizeDlg Members

The following tables list the members exposed by TCustomizeDlg.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.

	_Release (see page 2769)	Called when an application releases a component interface.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 6531)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetupDlg (see page 6532)	This is SetupDlg, a member of class TCustomizeDlg.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	Show (see page 6532)	Displays the customization dialog.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CustomizeForm (see page 6533)	Provides access to the form that implements the customize dialog.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnClose (see page 6534)	Occurs when the dialog closes.
	OnShow (see page 6534)	Occurs when the dialog opens.

Published Properties

	Name	Description
	ActionManager (see page 6533)	Indicates the action manager associated with the customization dialog.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	StayOnTop (see page 6533)	Specifies whether the customization dialog can be placed behind other windows.
	Tag (see page 2808)	Stores an integer value as part of a component.

36.1.1.2 TCustomizeDlg Methods

The methods of the TCustomizeDlg class are listed here.

Protected Methods

	Name	Description
V	Notification (see page 6531)	Forwards notification messages to all owned components.
V	SetupDlg (see page 6532)	This is SetupDlg, a member of class TCustomizeDlg.

Public Methods

	Name	Description
	Show (see page 6532)	Displays the customization dialog.

36.1.1.2.1 TCustomizeDlg.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification

to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

36.1.1.2.2 TCustomizeDlg.SetupDlg Method

Pascal

```
procedure SetupDlg; virtual;
```

C++

```
virtual __fastcall SetupDlg();
```

Description

This is SetupDlg, a member of class TCustomizeDlg.

36.1.1.2.3 TCustomizeDlg.Show Method

Displays the customization dialog.

Pascal

```
procedure Show;
```

C++

```
__fastcall Show();
```

Description

Call Show to display the customization dialog. Show causes the form that the CustomizeForm (see page 6533) property specifies to become visible. Immediately before the dialog appears to the user, TCustomizeDlg (see page 6528) receives an OnShow (see page 6534) event.

See Also

OnShow (see page 6534)

CustomizeForm (see page 6533)

36.1.1.3 TCustomizeDlg Properties

The properties of the TCustomizeDlg class are listed here.

Public Properties

	Name	Description
R	CustomizeForm (see page 6533)	Provides access to the form that implements the customize dialog.

Published Properties

	Name	Description
	ActionManager (see page 6533)	Indicates the action manager associated with the customization dialog.
	StayOnTop (see page 6533)	Specifies whether the customization dialog can be placed behind other windows.

36.1.1.3.1 TCustomizeDlg.ActionManager Property

Indicates the action manager associated with the customization dialog.

Pascal

```
property ActionManager: TCustomActionManager;
```

C++

```
__property TCustomActionManager ActionManager;
```

Description

At design time, set ActionManager to refer to your application's action manager object. The action manager maintains a logical description of the user interface elements as a hierarchy of action clients. The customization dialog operates on this hierarchy to change how user interface elements are organized or to hide and show individual elements.

See Also

TActionManager (see page 432)

ActionBars (see page 553)

36.1.1.3.2 TCustomizeDlg.CustomizeForm Property

Provides access to the form that implements the customize dialog.

Pascal

```
property CustomizeForm: TCustomizeFrm;
```

C++

```
__property TCustomizeFrm CustomizeForm;
```

Description

Read CustomizeForm to access the form that TCustomizeDlg (see page 6528) displays when you call the Show (see page 6532) method.

See Also

Show (see page 6532)

36.1.1.3.3 TCustomizeDlg.StayOnTop Property

Specifies whether the customization dialog can be placed behind other windows.

Pascal

```
property StayOnTop: Boolean;
```

C++

```
__property Boolean StayOnTop;
```

Description

If you want the customization dialog to stay on top of all windows while it is visible, set StayOnTop to true. Otherwise, it should be set to false.

36.1.1.4 TCustomizeDlg Events

The events of the TCustomizeDlg class are listed here.

Published Events

	Name	Description
	OnClose (see page 6534)	Occurs when the dialog closes.
	OnShow (see page 6534)	Occurs when the dialog opens.

36.1.1.4.1 TCustomizeDlg.OnClose Event

Occurs when the dialog closes.

Pascal

```
property OnClose: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClose;
```

Description

Write an OnClose event handler if you want special actions taken when the customization dialog closes.

See Also

OnShow (see page 6534)

36.1.1.4.2 TCustomizeDlg.OnShow Event

Occurs when the dialog opens.

Pascal

```
property OnShow: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnShow;
```

Description

Write an OnShow event handler if you want special actions taken immediately before the customization dialog opens.

See Also

OnClose (see page 6534)

Show (see page 6532)

36.1.2 TCustomizeFrm Class

Class Hierarchy

Pascal

```
TCustomizeFrm = class(TForm);
```

C++

```
class TCustomizeFrm : public TForm;
```

File

CustomizeDlg

Description

This is class CustomizeDlg.TCustomizeFrm.

36.1.2.1 TCustomizeFrm Members

The following tables list the members exposed by TCustomizeFrm.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.

	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.

	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddAction (see page 6567)	This is AddAction, a member of class TCustomizeFrm.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
V	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
V	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
V	ClearCatList (see page 6568)	This is ClearCatList, a member of class TCustomizeFrm.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	CMVisiblechanged (see page 6568)	This is CMVisiblechanged, a member of class TCustomizeFrm.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.

	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
V	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CreateWnd (see page 13869)	Creates the form window.
V	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
V	DoCreate (see page 13873)	Form creation event dispatcher.
V	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
V	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindActionBars (see page 6568)	This is FindActionBars, a member of class TCustomizeFrm.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event

	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsDupShortCut (see page 6569)	This is IsDupShortCut, a member of class TCustomizeFrm.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 6570)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
V	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
V	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.

	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetActiveActionList (see page 6572)	This is SetActiveActionList, a member of class TCustomizeFrm.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
V	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParent (see page 13887)	Sets the Parent property.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
V	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateDialog (see page 6573)	This is UpdateDialog, a member of class TCustomizeFrm.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.

V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.

	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Fields

	Name	Description
	ActionBarList (see page 6554)	This is ActionBarList, a member of class TCustomizeFrm.
	ActionImages (see page 6554)	This is ActionImages, a member of class TCustomizeFrm.
	ActionList1 (see page 6554)	This is ActionList1, a member of class TCustomizeFrm.
	ActionsActionsLbl (see page 6554)	This is ActionsActionsLbl, a member of class TCustomizeFrm.
	ActionsCatLbl (see page 6554)	This is ActionsCatLbl, a member of class TCustomizeFrm.

	ActionsList (see page 6555)	This is ActionsList, a member of class TCustomizeFrm.
	ActionsTab (see page 6555)	This is ActionsTab, a member of class TCustomizeFrm.
	ApplyToAllActn (see page 6555)	This is ApplyToAllActn, a member of class TCustomizeFrm.
	ApplyToAllChk (see page 6555)	This is ApplyToAllChk, a member of class TCustomizeFrm.
	CaptionOptionsCombo (see page 6556)	This is CaptionOptionsCombo, a member of class TCustomizeFrm.
	CaptionOptionsGrp (see page 6556)	This is CaptionOptionsGrp, a member of class TCustomizeFrm.
	CatList (see page 6556)	This is CatList, a member of class TCustomizeFrm.
	CloseActn (see page 6556)	This is CloseActn, a member of class TCustomizeFrm.
	CloseBtn (see page 6556)	This is CloseBtn, a member of class TCustomizeFrm.
	CloseItem (see page 6557)	This is CloseItem, a member of class TCustomizeFrm.
	CloseMenu (see page 6557)	This is CloseMenu, a member of class TCustomizeFrm.
	ComboPanel (see page 6557)	This is ComboPanel, a member of class TCustomizeFrm.
	DescGroupBox (see page 6557)	This is DescGroupBox, a member of class TCustomizeFrm.
	FullMenusActn (see page 6558)	This is FullMenusActn, a member of class TCustomizeFrm.
	HintLbl (see page 6558)	This is HintLbl, a member of class TCustomizeFrm.
	InfoLbl (see page 6558)	This is InfoLbl, a member of class TCustomizeFrm.
	Label1 (see page 6558)	This is Label1, a member of class TCustomizeFrm.
	Label2 (see page 6558)	This is Label2, a member of class TCustomizeFrm.
	Label4 (see page 6559)	This is Label4, a member of class TCustomizeFrm.
	LargeIconsActn (see page 6559)	This is LargeIconsActn, a member of class TCustomizeFrm.
	LargeIconsChk (see page 6559)	This is LargeIconsChk, a member of class TCustomizeFrm.
	ListCombo (see page 6559)	This is ListCombo, a member of class TCustomizeFrm.
	ListPanel (see page 6560)	This is ListPanel, a member of class TCustomizeFrm.
	MenuAnimationStyles (see page 6560)	This is MenuAnimationStyles, a member of class TCustomizeFrm.
	OptionsBevel1 (see page 6560)	This is OptionsBevel1, a member of class TCustomizeFrm.
	OptionsBevel2 (see page 6560)	This is OptionsBevel2, a member of class TCustomizeFrm.
	OptionsTab (see page 6560)	This is OptionsTab, a member of class TCustomizeFrm.
	OtherLbl (see page 6561)	This is OtherLbl, a member of class TCustomizeFrm.
	PersonalizeLbl (see page 6561)	This is PersonalizeLbl, a member of class TCustomizeFrm.
	RecentlyUsedActn (see page 6561)	This is RecentlyUsedActn, a member of class TCustomizeFrm.
	RecentlyUsedChk (see page 6561)	This is RecentlyUsedChk, a member of class TCustomizeFrm.
	ResetActn (see page 6562)	This is ResetActn, a member of class TCustomizeFrm.
	ResetBtn (see page 6562)	This is ResetBtn, a member of class TCustomizeFrm.
	ResetUsageBtn (see page 6562)	This is ResetUsageBtn, a member of class TCustomizeFrm.
	ResetUsageDataActn (see page 6562)	This is ResetUsageDataActn, a member of class TCustomizeFrm.
	SeparatorBtn (see page 6562)	This is SeparatorBtn, a member of class TCustomizeFrm.
	ShortCutTipsChk (see page 6563)	This is ShortCutTipsChk, a member of class TCustomizeFrm.
	ShowHintsActn (see page 6563)	This is ShowHintsActn, a member of class TCustomizeFrm.
	ShowShortCutsInTipsActn (see page 6563)	This is ShowShortCutsInTipsActn, a member of class TCustomizeFrm.
	ShowTipsChk (see page 6563)	This is ShowTipsChk, a member of class TCustomizeFrm.
	Tabs (see page 6564)	This is Tabs, a member of class TCustomizeFrm.
	ToolbarsLbl (see page 6564)	This is ToolbarsLbl, a member of class TCustomizeFrm.
	ToolbarsTab (see page 6564)	This is ToolbarsTab, a member of class TCustomizeFrm.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActionBarListClick (see page 6565)	This is ActionBarListClick, a member of class TCustomizeFrm.
	ActionBarListClickCheck (see page 6565)	This is ActionBarListClickCheck, a member of class TCustomizeFrm.
	ActionsListClick (see page 6566)	This is ActionsListClick, a member of class TCustomizeFrm.
	ActionsListData (see page 6566)	This is ActionsListData, a member of class TCustomizeFrm.
	ActionsListDrawItem (see page 6566)	This is ActionsListDrawItem, a member of class TCustomizeFrm.
	ActionsListMeasureItem (see page 6566)	This is ActionsListMeasureItem, a member of class TCustomizeFrm.

	ActionsListStartDrag (see page 6566)	This is ActionsListStartDrag, a member of class TCustomizeFrm.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	ApplyToAllActnUpdate (see page 6567)	This is ApplyToAllActnUpdate, a member of class TCustomizeFrm.
	ArrangeIcons (see page 14006)	Arranges the icons of minimized MDI child forms.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	CaptionOptionsComboChange (see page 6567)	This is CaptionOptionsComboChange, a member of class TCustomizeFrm.
	Cascade (see page 14007)	Arranges MDI child forms so they overlap.
	CatListClick (see page 6567)	This is CatListClick, a member of class TCustomizeFrm.
	CatListStartDrag (see page 6568)	This is CatListStartDrag, a member of class TCustomizeFrm.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
	CloseBtnClick (see page 6568)	This is CloseBtnClick, a member of class TCustomizeFrm.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 13861)	Creates and initializes a new TForm (see page 13992) object.
V	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	FormClose (see page 6569)	This is FormClose, a member of class TCustomizeFrm.
	FormCreate (see page 6569)	This is FormCreate, a member of class TCustomizeFrm.
	FormResize (see page 6569)	This is FormResize, a member of class TCustomizeFrm.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.

	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	LargeIconsActnExecute (see page 6570)	This is LargeIconsActnExecute, a member of class TCustomizeFrm.
	LargeIconsActnUpdate (see page 6570)	This is LargeIconsActnUpdate, a member of class TCustomizeFrm.
	ListComboSelect (see page 6570)	This is ListComboSelect, a member of class TCustomizeFrm.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MenuAnimationStylesChange (see page 6570)	This is MenuAnimationStylesChange, a member of class TCustomizeFrm.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 14008)	Activates the next child form in the form sequence.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Previous (see page 14009)	Activates the previous MDI child form in the form sequence.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecentlyUsedActnExecute (see page 6571)	This is RecentlyUsedActnExecute, a member of class TCustomizeFrm.
	RecentlyUsedActnUpdate (see page 6571)	This is RecentlyUsedActnUpdate, a member of class TCustomizeFrm.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	ResetActnExecute (see page 6571)	This is ResetActnExecute, a member of class TCustomizeFrm.
	ResetActnUpdate (see page 6572)	This is ResetActnUpdate, a member of class TCustomizeFrm.
	ResetUsageDataActnExecute (see page 6572)	This is ResetUsageDataActnExecute, a member of class TCustomizeFrm.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.

	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SeparatorBtnStartDrag (see page 6572)	This is SeparatorBtnStartDrag, a member of class TCustomizeFrm.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
	ShowHintsActnExecute (see page 6572)	This is ShowHintsActnExecute, a member of class TCustomizeFrm.
	ShowHintsActnUpdate (see page 6573)	This is ShowHintsActnUpdate, a member of class TCustomizeFrm.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
	ShowShortCutsInTipsActnExecute (see page 6573)	This is ShowShortCutsInTipsActnExecute, a member of class TCustomizeFrm.
	Tile (see page 14009)	Arranges MDI child forms so that they are all the same size.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
	ActionManager (see page 6573)	This is ActionManager, a member of class TCustomizeFrm.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveActionList (see page 6574)	This is ActiveActionList, a member of class TCustomizeFrm.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveMDIChild (see page 14013)	Specifies the MDI child that has focus.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	ClientHandle (see page 14024)	Provides access to the handle of the form's internal MDI client window.

	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockManager (see page 14029)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	MDIChildCount (see page 14044)	Specifies the number of open MDI child forms.
	MDIChildren (see page 14044)	Provides indexed access to all MDI child forms.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.

	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TileMode (see page 14059)	Represents how MDI child forms are arranged when the Tile method is called.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnActivate (see page 14065)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.
	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.

	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.
	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.
	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.

	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Menu (see page 14045)	Specifies the form's main menu.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.
	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.
	WindowState (see page 14063)	Represents how the form appears on the screen.

36.1.2.2 TCustomizeFrm Fields

The fields of the TCustomizeFrm class are listed here.

Public Fields

	Name	Description
	ActionBarList (see page 6554)	This is ActionBarList, a member of class TCustomizeFrm.
	ActionImages (see page 6554)	This is ActionImages, a member of class TCustomizeFrm.
	ActionList1 (see page 6554)	This is ActionList1, a member of class TCustomizeFrm.
	ActionsActionsLbl (see page 6554)	This is ActionsActionsLbl, a member of class TCustomizeFrm.
	ActionsCatLbl (see page 6554)	This is ActionsCatLbl, a member of class TCustomizeFrm.
	ActionsList (see page 6555)	This is ActionsList, a member of class TCustomizeFrm.
	ActionsTab (see page 6555)	This is ActionsTab, a member of class TCustomizeFrm.
	ApplyToAllActn (see page 6555)	This is ApplyToAllActn, a member of class TCustomizeFrm.
	ApplyToAllChk (see page 6555)	This is ApplyToAllChk, a member of class TCustomizeFrm.
	CaptionOptionsCombo (see page 6556)	This is CaptionOptionsCombo, a member of class TCustomizeFrm.
	CaptionOptionsGrp (see page 6556)	This is CaptionOptionsGrp, a member of class TCustomizeFrm.
	CatList (see page 6556)	This is CatList, a member of class TCustomizeFrm.
	CloseActn (see page 6556)	This is CloseActn, a member of class TCustomizeFrm.
	CloseBtn (see page 6556)	This is CloseBtn, a member of class TCustomizeFrm.
	CloseItem (see page 6557)	This is CloseItem, a member of class TCustomizeFrm.
	CloseMenu (see page 6557)	This is CloseMenu, a member of class TCustomizeFrm.
	ComboPanel (see page 6557)	This is ComboPanel, a member of class TCustomizeFrm.
	DescGroupBox (see page 6557)	This is DescGroupBox, a member of class TCustomizeFrm.
	FullMenusActn (see page 6558)	This is FullMenusActn, a member of class TCustomizeFrm.
	HintLbl (see page 6558)	This is HintLbl, a member of class TCustomizeFrm.
	InfoLbl (see page 6558)	This is InfoLbl, a member of class TCustomizeFrm.
	Label1 (see page 6558)	This is Label1, a member of class TCustomizeFrm.
	Label2 (see page 6558)	This is Label2, a member of class TCustomizeFrm.
	Label4 (see page 6559)	This is Label4, a member of class TCustomizeFrm.
	LargeIconsActn (see page 6559)	This is LargeIconsActn, a member of class TCustomizeFrm.
	LargeIconsChk (see page 6559)	This is LargeIconsChk, a member of class TCustomizeFrm.
	ListCombo (see page 6559)	This is ListCombo, a member of class TCustomizeFrm.
	ListPanel (see page 6560)	This is ListPanel, a member of class TCustomizeFrm.
	MenuAnimationStyles (see page 6560)	This is MenuAnimationStyles, a member of class TCustomizeFrm.
	OptionsBevel1 (see page 6560)	This is OptionsBevel1, a member of class TCustomizeFrm.
	OptionsBevel2 (see page 6560)	This is OptionsBevel2, a member of class TCustomizeFrm.
	OptionsTab (see page 6560)	This is OptionsTab, a member of class TCustomizeFrm.
	OtherLbl (see page 6561)	This is OtherLbl, a member of class TCustomizeFrm.
	PersonalizeLbl (see page 6561)	This is PersonalizeLbl, a member of class TCustomizeFrm.
	RecentlyUsedActn (see page 6561)	This is RecentlyUsedActn, a member of class TCustomizeFrm.
	RecentlyUsedChk (see page 6561)	This is RecentlyUsedChk, a member of class TCustomizeFrm.
	ResetActn (see page 6562)	This is ResetActn, a member of class TCustomizeFrm.
	ResetBtn (see page 6562)	This is ResetBtn, a member of class TCustomizeFrm.
	ResetUsageBtn (see page 6562)	This is ResetUsageBtn, a member of class TCustomizeFrm.
	ResetUsageDataActn (see page 6562)	This is ResetUsageDataActn, a member of class TCustomizeFrm.
	SeparatorBtn (see page 6562)	This is SeparatorBtn, a member of class TCustomizeFrm.
	ShortCutTipsChk (see page 6563)	This is ShortCutTipsChk, a member of class TCustomizeFrm.
	ShowHintsActn (see page 6563)	This is ShowHintsActn, a member of class TCustomizeFrm.
	ShowShortCutsInTipsActn (see page 6563)	This is ShowShortCutsInTipsActn, a member of class TCustomizeFrm.
	ShowTipsChk (see page 6563)	This is ShowTipsChk, a member of class TCustomizeFrm.
	Tabs (see page 6564)	This is Tabs, a member of class TCustomizeFrm.
	ToolbarsLbl (see page 6564)	This is ToolbarsLbl, a member of class TCustomizeFrm.

	ToolbarsTab (see page 6564)	This is ToolbarsTab, a member of class TCustomizeFrm.

36.1.2.2.1 TCustomizeFrm.ActionBarList Field

Pascal

```
ActionBarList: TCheckListBox;
```

C++

```
TCheckListBox ActionBarList;
```

Description

This is ActionBarList, a member of class TCustomizeFrm.

36.1.2.2.2 TCustomizeFrm.ActionImages Field

Pascal

```
ActionImages: TImageList;
```

C++

```
TImageList ActionImages;
```

Description

This is ActionImages, a member of class TCustomizeFrm.

36.1.2.2.3 TCustomizeFrm.ActionList1 Field

Pascal

```
ActionList1: TActionList;
```

C++

```
TActionList ActionList1;
```

Description

This is ActionList1, a member of class TCustomizeFrm.

36.1.2.2.4 TCustomizeFrm.ActionsActionsLbl Field

Pascal

```
ActionsActionsLbl: TLabel;
```

C++

```
TLabel ActionsActionsLbl;
```

Description

This is ActionsActionsLbl, a member of class TCustomizeFrm.

36.1.2.2.5 TCustomizeFrm.ActionsCatLbl Field

Pascal

```
ActionsCatLbl: TLabel;
```

C++

```
TLabel ActionsCatLbl;
```

Description

This is ActionsCatLbl, a member of class TCustomizeFrm.

36.1.2.2.6 TCustomizeFrm.ActionsList Field

Pascal

```
ActionsList: TListBox;
```

C++

```
TListBox ActionsList;
```

Description

This is ActionsList, a member of class TCustomizeFrm.

36.1.2.2.7 TCustomizeFrm.ActionsTab Field

Pascal

```
ActionsTab: TTabSheet;
```

C++

```
TTabSheet ActionsTab;
```

Description

This is ActionsTab, a member of class TCustomizeFrm.

36.1.2.2.8 TCustomizeFrm.ApplyToAllActn Field

Pascal

```
ApplyToAllActn: TAction;
```

C++

```
TAction ApplyToAllActn;
```

Description

This is ApplyToAllActn, a member of class TCustomizeFrm.

36.1.2.2.9 TCustomizeFrm.ApplyToAllChk Field

Pascal

```
ApplyToAllChk: TCheckBox;
```

C++

```
TCheckBox ApplyToAllChk;
```

Description

This is ApplyToAllChk, a member of class TCustomizeFrm.

36.1.2.2.10 TCustomizeFrm.CaptionOptionsCombo Field

Pascal

```
CaptionOptionsCombo: TComboBox;
```

C++

```
TComboBox CaptionOptionsCombo;
```

Description

This is CaptionOptionsCombo, a member of class TCustomizeFrm.

36.1.2.2.11 TCustomizeFrm.CaptionOptionsGrp Field

Pascal

```
CaptionOptionsGrp: TGroupBox;
```

C++

```
TGroupBox CaptionOptionsGrp;
```

Description

This is CaptionOptionsGrp, a member of class TCustomizeFrm.

36.1.2.2.12 TCustomizeFrm.CatList Field

Pascal

```
CatList: TListBox;
```

C++

```
TListBox CatList;
```

Description

This is CatList, a member of class TCustomizeFrm.

36.1.2.2.13 TCustomizeFrm.CloseActn Field

Pascal

```
CloseActn: TAction;
```

C++

```
TAction CloseActn;
```

Description

This is CloseActn, a member of class TCustomizeFrm.

36.1.2.2.14 TCustomizeFrm.CloseBtn Field

Pascal

```
CloseBtn: TButton;
```

C++

```
TButton CloseBtn;
```

Description

This is CloseBtn, a member of class TCustomizeFrm.

36.1.2.2.15 TCustomizeFrm.CloseItem Field

Pascal

```
CloseItem: TMenuItem;
```

C++

```
TMenuItem CloseItem;
```

Description

This is CloseItem, a member of class TCustomizeFrm.

36.1.2.2.16 TCustomizeFrm.CloseMenu Field

Pascal

```
CloseMenu: TPopupMenu;
```

C++

```
TPopupMenu CloseMenu;
```

Description

This is CloseMenu, a member of class TCustomizeFrm.

36.1.2.2.17 TCustomizeFrm.ComboPanel Field

Pascal

```
ComboPanel: TPanel;
```

C++

```
TPanel ComboPanel;
```

Description

This is ComboPanel, a member of class TCustomizeFrm.

36.1.2.2.18 TCustomizeFrm.DescGroupBox Field

Pascal

```
DescGroupBox: TGroupBox;
```

C++

```
TGroupBox DescGroupBox;
```

Description

This is DescGroupBox, a member of class TCustomizeFrm.

36.1.2.2.19 TCustomizeFrm.FullMenusActn Field

Pascal

```
FullMenusActn: TAction;
```

C++

```
TAction FullMenusActn;
```

Description

This is FullMenusActn, a member of class TCustomizeFrm.

36.1.2.2.20 TCustomizeFrm.HintLbl Field

Pascal

```
HintLbl: TLabel;
```

C++

```
TLabel HintLbl;
```

Description

This is HintLbl, a member of class TCustomizeFrm.

36.1.2.2.21 TCustomizeFrm.InfoLbl Field

Pascal

```
InfoLbl: TLabel;
```

C++

```
TLabel InfoLbl;
```

Description

This is InfoLbl, a member of class TCustomizeFrm.

36.1.2.2.22 TCustomizeFrm.Label1 Field

Pascal

```
Label1: TLabel;
```

C++

```
TLabel Label1;
```

Description

This is Label1, a member of class TCustomizeFrm.

36.1.2.2.23 TCustomizeFrm.Label2 Field

Pascal

```
Label2: TLabel;
```

C++

```
TLabel Label2;
```

Description

This is Label2, a member of class TCustomizeFrm.

36.1.2.2.24 TCustomizeFrm.Label4 Field

Pascal

```
Label4: TLabel;
```

C++

```
TLabel Label4;
```

Description

This is Label4, a member of class TCustomizeFrm.

36.1.2.2.25 TCustomizeFrm.LargeIconsActn Field

Pascal

```
LargeIconsActn: TAction;
```

C++

```
TAction LargeIconsActn;
```

Description

This is LargeIconsActn, a member of class TCustomizeFrm.

36.1.2.2.26 TCustomizeFrm.LargeIconsChk Field

Pascal

```
LargeIconsChk: TCheckBox;
```

C++

```
TCheckBox LargeIconsChk;
```

Description

This is LargeIconsChk, a member of class TCustomizeFrm.

36.1.2.2.27 TCustomizeFrm.ListCombo Field

Pascal

```
ListCombo: TComboBox;
```

C++

```
TComboBox ListCombo;
```

Description

This is ListCombo, a member of class TCustomizeFrm.

36.1.2.2.28 TCustomizeFrm.ListPanel Field

Pascal

```
ListPanel: TPanel;
```

C++

```
TPanel ListPanel;
```

Description

This is ListPanel, a member of class TCustomizeFrm.

36.1.2.2.29 TCustomizeFrm.MenuAnimationStyles Field

Pascal

```
MenuAnimationStyles: TComboBox;
```

C++

```
TComboBox MenuAnimationStyles;
```

Description

This is MenuAnimationStyles, a member of class TCustomizeFrm.

36.1.2.2.30 TCustomizeFrm.OptionsBevel1 Field

Pascal

```
OptionsBevel1: TBevel;
```

C++

```
TBevel OptionsBevel1;
```

Description

This is OptionsBevel1, a member of class TCustomizeFrm.

36.1.2.2.31 TCustomizeFrm.OptionsBevel2 Field

Pascal

```
OptionsBevel2: TBevel;
```

C++

```
TBevel OptionsBevel2;
```

Description

This is OptionsBevel2, a member of class TCustomizeFrm.

36.1.2.2.32 TCustomizeFrm.OptionsTab Field

Pascal

```
OptionsTab: TTabSheet;
```

C++

```
TTabSheet OptionsTab;
```

Description

This is OptionsTab, a member of class TCustomizeFrm.

36.1.2.2.33 TCustomizeFrm.OtherLbl Field

Pascal

```
OtherLbl: TLabel;
```

C++

```
TLabel OtherLbl;
```

Description

This is OtherLbl, a member of class TCustomizeFrm.

36.1.2.2.34 TCustomizeFrm.PersonalizeLbl Field

Pascal

```
PersonalizeLbl: TLabel;
```

C++

```
TLabel PersonalizeLbl;
```

Description

This is PersonalizeLbl, a member of class TCustomizeFrm.

36.1.2.2.35 TCustomizeFrm.RecentlyUsedActn Field

Pascal

```
RecentlyUsedActn: TAction;
```

C++

```
TAction RecentlyUsedActn;
```

Description

This is RecentlyUsedActn, a member of class TCustomizeFrm.

36.1.2.2.36 TCustomizeFrm.RecentlyUsedChk Field

Pascal

```
RecentlyUsedChk: TCheckBox;
```

C++

```
TCheckBox RecentlyUsedChk;
```

Description

This is RecentlyUsedChk, a member of class TCustomizeFrm.

36.1.2.2.37 TCustomizeFrm.ResetActn Field

Pascal

```
ResetActn: TAction;
```

C++

```
TAction ResetActn;
```

Description

This is ResetActn, a member of class TCustomizeFrm.

36.1.2.2.38 TCustomizeFrm.ResetBtn Field

Pascal

```
ResetBtn: TButton;
```

C++

```
TButton ResetBtn;
```

Description

This is ResetBtn, a member of class TCustomizeFrm.

36.1.2.2.39 TCustomizeFrm.ResetUsageBtn Field

Pascal

```
ResetUsageBtn: TButton;
```

C++

```
TButton ResetUsageBtn;
```

Description

This is ResetUsageBtn, a member of class TCustomizeFrm.

36.1.2.2.40 TCustomizeFrm.ResetUsageDataActn Field

Pascal

```
ResetUsageDataActn: TAction;
```

C++

```
TAction ResetUsageDataActn;
```

Description

This is ResetUsageDataActn, a member of class TCustomizeFrm.

36.1.2.2.41 TCustomizeFrm.SeparatorBtn Field

Pascal

```
SeparatorBtn: TButton;
```

C++

```
TButton SeparatorBtn;
```

Description

This is SeparatorBtn, a member of class TCustomizeFrm.

36.1.2.2.42 TCustomizeFrm.ShortCutTipsChk Field

Pascal

```
ShortCutTipsChk: TCheckBox;
```

C++

```
TCheckBox ShortCutTipsChk;
```

Description

This is ShortCutTipsChk, a member of class TCustomizeFrm.

36.1.2.2.43 TCustomizeFrm.ShowHintsActn Field

Pascal

```
ShowHintsActn: TAction;
```

C++

```
TAction ShowHintsActn;
```

Description

This is ShowHintsActn, a member of class TCustomizeFrm.

36.1.2.2.44 TCustomizeFrm.ShowShortCutsInTipsActn Field

Pascal

```
ShowShortCutsInTipsActn: TAction;
```

C++

```
TAction ShowShortCutsInTipsActn;
```

Description

This is ShowShortCutsInTipsActn, a member of class TCustomizeFrm.

36.1.2.2.45 TCustomizeFrm.ShowTipsChk Field

Pascal

```
ShowTipsChk: TCheckBox;
```

C++

```
TCheckBox ShowTipsChk;
```

Description

This is ShowTipsChk, a member of class TCustomizeFrm.

36.1.2.2.46 TCustomizeFrm.Tabs Field

Pascal

```
Tabs: TPageControl;
```

C++

```
TPageControl Tabs;
```

Description

This is Tabs, a member of class TCustomizeFrm.

36.1.2.2.47 TCustomizeFrm.ToolbarsLbl Field

Pascal

```
ToolbarsLbl: TLabel;
```

C++

```
TLabel ToolbarsLbl;
```

Description

This is ToolbarsLbl, a member of class TCustomizeFrm.

36.1.2.2.48 TCustomizeFrm.ToolbarsTab Field

Pascal

```
ToolbarsTab: TTabSheet;
```

C++

```
TTabSheet ToolbarsTab;
```

Description

This is ToolbarsTab, a member of class TCustomizeFrm.

36.1.2.3 TCustomizeFrm Methods

The methods of the TCustomizeFrm class are listed here.

Protected Methods

	Name	Description
	AddAction (see page 6567)	This is AddAction, a member of class TCustomizeFrm.
V	ClearCatList (see page 6568)	This is ClearCatList, a member of class TCustomizeFrm.
	CMVisiblechanged (see page 6568)	This is CMVisiblechanged, a member of class TCustomizeFrm.
	FindActionBars (see page 6568)	This is FindActionBars, a member of class TCustomizeFrm.
	IsDupShortCut (see page 6569)	This is IsDupShortCut, a member of class TCustomizeFrm.
V	Notification (see page 6570)	Responds to notifications that objects are about to be inserted or removed.
	SetActiveActionList (see page 6572)	This is SetActiveActionList, a member of class TCustomizeFrm.
V	UpdateDialog (see page 6573)	This is UpdateDialog, a member of class TCustomizeFrm.

Public Methods

	Name	Description
	ActionBarListClick (see page 6565)	This is ActionBarListClick, a member of class TCustomizeFrm.

	ActionBarListClickCheck (see page 6565)	This is ActionBarListClickCheck, a member of class TCustomizeFrm.
	ActionsListClick (see page 6566)	This is ActionsListClick, a member of class TCustomizeFrm.
	ActionsListData (see page 6566)	This is ActionsListData, a member of class TCustomizeFrm.
	ActionsListDrawItem (see page 6566)	This is ActionsListDrawItem, a member of class TCustomizeFrm.
	ActionsListMeasureItem (see page 6566)	This is ActionsListMeasureItem, a member of class TCustomizeFrm.
	ActionsListStartDrag (see page 6566)	This is ActionsListStartDrag, a member of class TCustomizeFrm.
	ApplyToAllActnUpdate (see page 6567)	This is ApplyToAllActnUpdate, a member of class TCustomizeFrm.
	CaptionOptionsComboChange (see page 6567)	This is CaptionOptionsComboChange, a member of class TCustomizeFrm.
	CatListClick (see page 6567)	This is CatListClick, a member of class TCustomizeFrm.
	CatListStartDrag (see page 6568)	This is CatListStartDrag, a member of class TCustomizeFrm.
	CloseBtnClick (see page 6568)	This is CloseBtnClick, a member of class TCustomizeFrm.
	FormClose (see page 6569)	This is FormClose, a member of class TCustomizeFrm.
	FormCreate (see page 6569)	This is FormCreate, a member of class TCustomizeFrm.
	FormResize (see page 6569)	This is FormResize, a member of class TCustomizeFrm.
	LargeIconsActnExecute (see page 6570)	This is LargeIconsActnExecute, a member of class TCustomizeFrm.
	LargeIconsActnUpdate (see page 6570)	This is LargeIconsActnUpdate, a member of class TCustomizeFrm.
	ListComboSelect (see page 6570)	This is ListComboSelect, a member of class TCustomizeFrm.
	MenuAnimationStylesChange (see page 6570)	This is MenuAnimationStylesChange, a member of class TCustomizeFrm.
	RecentlyUsedActnExecute (see page 6571)	This is RecentlyUsedActnExecute, a member of class TCustomizeFrm.
	RecentlyUsedActnUpdate (see page 6571)	This is RecentlyUsedActnUpdate, a member of class TCustomizeFrm.
	ResetActnExecute (see page 6571)	This is ResetActnExecute, a member of class TCustomizeFrm.
	ResetActnUpdate (see page 6572)	This is ResetActnUpdate, a member of class TCustomizeFrm.
	ResetUsageDataActnExecute (see page 6572)	This is ResetUsageDataActnExecute, a member of class TCustomizeFrm.
	SeparatorBtnStartDrag (see page 6572)	This is SeparatorBtnStartDrag, a member of class TCustomizeFrm.
	ShowHintsActnExecute (see page 6572)	This is ShowHintsActnExecute, a member of class TCustomizeFrm.
	ShowHintsActnUpdate (see page 6573)	This is ShowHintsActnUpdate, a member of class TCustomizeFrm.
	ShowShortCutsInTipsActnExecute (see page 6573)	This is ShowShortCutsInTipsActnExecute, a member of class TCustomizeFrm.

36.1.2.3.1 TCustomizeFrm.ActionBarListClick Method

Pascal

```
procedure ActionBarListClick(Sender: TObject);
```

C++

```
__fastcall ActionBarListClick(TObject * Sender);
```

Description

This is ActionBarListClick, a member of class TCustomizeFrm.

36.1.2.3.2 TCustomizeFrm.ActionBarListClickCheck Method

Pascal

```
procedure ActionBarListClickCheck(Sender: TObject);
```

C++

```
__fastcall ActionBarListClickCheck(TObject * Sender);
```

Description

This is ActionBarListClickCheck, a member of class TCustomizeFrm.

36.1.2.3.3 TCustomizeFrm.ActionsListClick Method

Pascal

```
procedure ActionsListClick(Sender: TObject);
```

C++

```
__fastcall ActionsListClick(TObject * Sender);
```

Description

This is ActionsListClick, a member of class TCustomizeFrm.

36.1.2.3.4 TCustomizeFrm.ActionsListData Method

Pascal

```
procedure ActionsListData(Control: TWinControl; Index: Integer; var Data: string);
```

C++

```
__fastcall ActionsListData(TWinControl * Control, int Index, AnsiString Data);
```

Description

This is ActionsListData, a member of class TCustomizeFrm.

36.1.2.3.5 TCustomizeFrm.ActionsListDrawItem Method

Pascal

```
procedure ActionsListDrawItem(Control: TWinControl; Index: Integer; Rect: TRect; State:
TOwnerDrawState);
```

C++

```
__fastcall ActionsListDrawItem(TWinControl * Control, int Index, TRect Rect, TOwnerDrawState
State);
```

Description

This is ActionsListDrawItem, a member of class TCustomizeFrm.

36.1.2.3.6 TCustomizeFrm.ActionsListMeasureItem Method

Pascal

```
procedure ActionsListMeasureItem(Control: TWinControl; Index: Integer; var Height: Integer);
```

C++

```
__fastcall ActionsListMeasureItem(TWinControl * Control, int Index, int Height);
```

Description

This is ActionsListMeasureItem, a member of class TCustomizeFrm.

36.1.2.3.7 TCustomizeFrm.ActionsListStartDrag Method

Pascal

```
procedure ActionsListStartDrag(Sender: TObject; var DragObject: TDragObject);
```

C++

```
__fastcall ActionsListStartDrag(TObject * Sender, TDragObject DragObject);
```

Description

This is ActionsListStartDrag, a member of class TCustomizeFrm.

36.1.2.3.8 TCustomizeFrm.AddAction Method

Pascal

```
function AddAction(AnAction: TContainedAction): string;
```

C++

```
__fastcall AnsiString AddAction(TContainedAction AnAction);
```

Description

This is AddAction, a member of class TCustomizeFrm.

36.1.2.3.9 TCustomizeFrm.ApplyToAllActnUpdate Method

Pascal

```
procedure ApplyToAllActnUpdate(Sender: TObject);
```

C++

```
__fastcall ApplyToAllActnUpdate(TObject * Sender);
```

Description

This is ApplyToAllActnUpdate, a member of class TCustomizeFrm.

36.1.2.3.10 TCustomizeFrm.CaptionOptionsComboChange Method

Pascal

```
procedure CaptionOptionsComboChange(Sender: TObject);
```

C++

```
__fastcall CaptionOptionsComboChange(TObject * Sender);
```

Description

This is CaptionOptionsComboChange, a member of class TCustomizeFrm.

36.1.2.3.11 TCustomizeFrm.CatListClick Method

Pascal

```
procedure CatListClick(Sender: TObject);
```

C++

```
__fastcall CatListClick(TObject * Sender);
```

Description

This is CatListClick, a member of class TCustomizeFrm.

36.1.2.3.12 TCustomizeFrm.CatListStartDrag Method

Pascal

```
procedure CatListStartDrag(Sender: TObject; var DragObject: TDragObject);
```

C++

```
__fastcall CatListStartDrag(TObject * Sender, TDragObject DragObject);
```

Description

This is CatListStartDrag, a member of class TCustomizeFrm.

36.1.2.3.13 TCustomizeFrm.ClearCatList Method

Pascal

```
procedure ClearCatList; virtual;
```

C++

```
virtual __fastcall ClearCatList();
```

Description

This is ClearCatList, a member of class TCustomizeFrm.

36.1.2.3.14 TCustomizeFrm.CloseBtnClick Method

Pascal

```
procedure CloseBtnClick(Sender: TObject);
```

C++

```
__fastcall CloseBtnClick(TObject * Sender);
```

Description

This is CloseBtnClick, a member of class TCustomizeFrm.

36.1.2.3.15 TCustomizeFrm.CMVisiblechanged Method

Pascal

```
procedure CMVisiblechanged(var Message: TMessage); message CM_VISIBLECHANGED;
```

C++

```
__fastcall CMVisiblechanged(TMessage Message);
```

Description

This is CMVisiblechanged, a member of class TCustomizeFrm.

36.1.2.3.16 TCustomizeFrm.FindActionBars Method

Pascal

```
procedure FindActionBars;
```

C++

```
__fastcall FindActionBars();
```

Description

This is FindActionBars, a member of class TCustomizeFrm.

36.1.2.3.17 TCustomizeFrm.FormClose Method

Pascal

```
procedure FormClose(Sender: TObject; var Action: TCloseAction);
```

C++

```
__fastcall FormClose(TObject * Sender, TCloseAction Action);
```

Description

This is FormClose, a member of class TCustomizeFrm.

36.1.2.3.18 TCustomizeFrm.FormCreate Method

Pascal

```
procedure FormCreate(Sender: TObject);
```

C++

```
__fastcall FormCreate(TObject * Sender);
```

Description

This is FormCreate, a member of class TCustomizeFrm.

36.1.2.3.19 TCustomizeFrm.FormResize Method

Pascal

```
procedure FormResize(Sender: TObject);
```

C++

```
__fastcall FormResize(TObject * Sender);
```

Description

This is FormResize, a member of class TCustomizeFrm.

36.1.2.3.20 TCustomizeFrm.IsDupShortCut Method

Pascal

```
function IsDupShortCut(AShortCut: TShortCut; var Action: TContainedAction): Boolean;
```

C++

```
__fastcall Boolean IsDupShortCut(TShortCut AShortCut, TContainedAction Action);
```

Description

This is IsDupShortCut, a member of class TCustomizeFrm.

36.1.2.3.21 TCustomizeFrm.LargeIconsActnExecute Method

Pascal

```
procedure LargeIconsActnExecute(Sender: TObject);
```

C++

```
__fastcall LargeIconsActnExecute(TObject * Sender);
```

Description

This is LargeIconsActnExecute, a member of class TCustomizeFrm.

36.1.2.3.22 TCustomizeFrm.LargeIconsActnUpdate Method

Pascal

```
procedure LargeIconsActnUpdate(Sender: TObject);
```

C++

```
__fastcall LargeIconsActnUpdate(TObject * Sender);
```

Description

This is LargeIconsActnUpdate, a member of class TCustomizeFrm.

36.1.2.3.23 TCustomizeFrm.ListComboSelect Method

Pascal

```
procedure ListComboSelect(Sender: TObject);
```

C++

```
__fastcall ListComboSelect(TObject * Sender);
```

Description

This is ListComboSelect, a member of class TCustomizeFrm.

36.1.2.3.24 TCustomizeFrm.MenuAnimationStylesChange Method

Pascal

```
procedure MenuAnimationStylesChange(Sender: TObject);
```

C++

```
__fastcall MenuAnimationStylesChange(TObject * Sender);
```

Description

This is MenuAnimationStylesChange, a member of class TCustomizeFrm.

36.1.2.3.25 TCustomizeFrm.Notification Method

Responds to notifications that objects are about to be inserted or removed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification is called when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, forms pass along the notification to their owned components, if any. In addition, Notification makes internal adjustments if the main menu is added or deleted.

A form can, if needed, override Notification to make other adjustments when components are inserted or removed. In particular, if a form has object fields or properties that contains references to other components, it might check the notifications of component removals and invalidate those references as needed.

See Also

InsertComponent (see page 2780)

36.1.2.3.26 TCustomizeFrm.RecentlyUsedActnExecute Method

Pascal

```
procedure RecentlyUsedActnExecute(Sender: TObject);
```

C++

```
__fastcall RecentlyUsedActnExecute(TObject * Sender);
```

Description

This is RecentlyUsedActnExecute, a member of class TCustomizeFrm.

36.1.2.3.27 TCustomizeFrm.RecentlyUsedActnUpdate Method

Pascal

```
procedure RecentlyUsedActnUpdate(Sender: TObject);
```

C++

```
__fastcall RecentlyUsedActnUpdate(TObject * Sender);
```

Description

This is RecentlyUsedActnUpdate, a member of class TCustomizeFrm.

36.1.2.3.28 TCustomizeFrm.ResetActnExecute Method

Pascal

```
procedure ResetActnExecute(Sender: TObject);
```

C++

```
__fastcall ResetActnExecute(TObject * Sender);
```

Description

This is ResetActnExecute, a member of class TCustomizeFrm.

36.1.2.3.29 TCustomizeFrm.ResetActnUpdate Method

Pascal

```
procedure ResetActnUpdate(Sender: TObject);
```

C++

```
__fastcall ResetActnUpdate(TObject * Sender);
```

Description

This is ResetActnUpdate, a member of class TCustomizeFrm.

36.1.2.3.30 TCustomizeFrm.ResetUsageDataActnExecute Method

Pascal

```
procedure ResetUsageDataActnExecute(Sender: TObject);
```

C++

```
__fastcall ResetUsageDataActnExecute(TObject * Sender);
```

Description

This is ResetUsageDataActnExecute, a member of class TCustomizeFrm.

36.1.2.3.31 TCustomizeFrm.SeparatorBtnStartDrag Method

Pascal

```
procedure SeparatorBtnStartDrag(Sender: TObject; var DragObject: TDragObject);
```

C++

```
__fastcall SeparatorBtnStartDrag(TObject * Sender, TDragObject DragObject);
```

Description

This is SeparatorBtnStartDrag, a member of class TCustomizeFrm.

36.1.2.3.32 TCustomizeFrm.SetActiveActionList Method

Pascal

```
procedure SetActiveActionList(const Value: TCustomActionList);
```

C++

```
__fastcall SetActiveActionList(const TCustomActionList Value);
```

Description

This is SetActiveActionList, a member of class TCustomizeFrm.

36.1.2.3.33 TCustomizeFrm.ShowHintsActnExecute Method

Pascal

```
procedure ShowHintsActnExecute(Sender: TObject);
```

C++

```
__fastcall ShowHintsActnExecute(TObject * Sender);
```

Description

This is ShowHintsActnExecute, a member of class TCustomizeFrm.

36.1.2.3.34 TCustomizeFrm.ShowHintsActnUpdate Method

Pascal

```
procedure ShowHintsActnUpdate(Sender: TObject);
```

C++

```
__fastcall ShowHintsActnUpdate(TObject * Sender);
```

Description

This is ShowHintsActnUpdate, a member of class TCustomizeFrm.

36.1.2.3.35 TCustomizeFrm.ShowShortCutsInTipsActnExecute Method

Pascal

```
procedure ShowShortCutsInTipsActnExecute(Sender: TObject);
```

C++

```
__fastcall ShowShortCutsInTipsActnExecute(TObject * Sender);
```

Description

This is ShowShortCutsInTipsActnExecute, a member of class TCustomizeFrm.

36.1.2.3.36 TCustomizeFrm.UpdateDialog Method

Pascal

```
procedure UpdateDialog; virtual;
```

C++

```
virtual __fastcall UpdateDialog();
```

Description

This is UpdateDialog, a member of class TCustomizeFrm.

36.1.2.4 TCustomizeFrm Properties

The properties of the TCustomizeFrm class are listed here.

Public Properties

	Name	Description
	ActionManager (see page 6573)	This is ActionManager, a member of class TCustomizeFrm.
	ActiveActionList (see page 6574)	This is ActiveActionList, a member of class TCustomizeFrm.

36.1.2.4.1 TCustomizeFrm.ActionManager Property

Pascal

```
property ActionManager: TCustomActionManager;
```

C++

```
__property TCustomActionManager ActionManager;
```

Description

This is ActionManager, a member of class TCustomizeFrm.

36.1.2.4.2 TCustomizeFrm.ActiveActionList Property

Pascal

```
property ActiveActionList: TCustomActionList;
```

C++

```
__property TCustomActionList ActiveActionList;
```

Description

This is ActiveActionList, a member of class TCustomizeFrm.

37 DataBkr Namespace

This is namespace DataBkr.

Topics

Name	Description
Classes (see page 6576)	The following table lists classes in this documentation.
Functions (see page 6600)	The following table lists functions in this documentation.

Classes

	Name	Description
	TCRemoteDataModule (see page 6576)	TCRemoteDataModule maintains a list of available providers in an application server.
	TRemoteDataModule (see page 6585)	TRemoteDataModule encapsulates the objects and interfaces of an application server in a multi-tiered database application.

Functions

	Name	Description
	DisableSocketTransport (see page 6600)	Unregisters a remote data module so clients can't access it using a Socket connection.
	DisableWebTransport (see page 6601)	Unregisters a remote data module so clients can't access it using a Web connection.
	EnableSocketTransport (see page 6601)	Registers a remote data module so clients can access it using a Socket connection.
	EnableWebTransport (see page 6602)	Registers a remote data module so clients can access it using a Web connection.
	RegisterPooled (see page 6602)	Registers a remote data module so that instances are pooled.
	UnregisterPooled (see page 6603)	Removes the object pooling registry entries for a remote data module.

37.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCRemoteDataModule (see page 6576)	TCRemoteDataModule maintains a list of available providers in an application server.
	TRemoteDataModule (see page 6585)	TRemoteDataModule encapsulates the objects and interfaces of an application server in a multi-tiered database application.

37.1.1 TCRemoteDataModule Class

TCRemoteDataModule maintains a list of available providers in an application server.

Class Hierarchy

Pascal

```
TCRemoteDataModule = class(TDataModule);
```

C++

```
class TCRemoteDataModule : public TDataModule;
```

File

DataBkr

Description

TCRemoteDataModule is the base class for remote data modules that appear in the application servers of multi-tiered database applications that are written in C++. It manages a list of provider components, which handle providing data to client applications and applying updates received from those clients.

Remote data modules act as the central repository for all objects in the application server. They can contain any nonvisual components. Typically these are data access components, such as datasets and the provider components that handle communication between these datasets and client applications. Remote data modules can also contain other nonvisual components, such as TTimer, or TImageList.

At design time a remote data module provides a visual container into which a developer can place nonvisual components, set their properties, and write event handlers for them. In the unit file for the remote data module a developer can also code any business rules that are to be centralized in the middle tier of a multi-tiered application.

To create a remote data module at design time, choose File|New, and select Remote Data Module from the multi-tiered page of the new items dialog. The Remote Data Module Wizard then creates a new descendant of TCRemoteDataModule that supports an interface that descends from IAppServer.

The interface itself is handled by a companion implementation object. This object descends from REMOTEDATAMODULE_IMPL(), which is a macro defined in Atlvcl.h. The implementation object uses the ATL to provide

Automation support for the IAppServer interface, which client applications use to communicate with the providers in the remote data module.

Note: TCRemoteDataModule does not provide support for the IAppServer interface. This support is introduced by the TRemoteDataModule (see page 6585) class, a descendant of TCRemoteDataModule.

See Also

IAppServer (see page 16450)

TDataSetProvider (see page 18508)

RemoteDataModule

37.1.1.1 TCRemoteDataModule Members

The following tables list the members exposed by TCRemoteDataModule.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
V	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.

	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CRDMGetProviderNames (see page 6581)	Returns a list of all the available providers on the remote data module.
	Create (see page 6580)	The Create method creates a remote data module instance.
	CreateNew (see page 2828)	Creates an instance of a data module and registers with the global screen object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 6580)	Frees a remote data module instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.

	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetProvider (see page 6581)	Returns a registered provider component given its name.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	Lock (see page 6582)	Locks the remote data module so that it can't be locked by other threads.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
V	RegisterProvider (see page 6582)	Adds a provider to the list returned by CRDMGetProviderNames (see page 6581).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	UnLock (see page 6583)	This is UnLock, a member of class TCRemoteDataModule.
V	UnRegisterProvider (see page 6583)	Removes a provider from the list returned by AS_GetProviderNames.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ProviderCount (see page 6584)	Indicates the number of providers registered with the remote data module.
R	Providers (see page 6584)	Lists the provider components that are contained in the remote data module.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.
	Tag (see page 2808)	Stores an integer value as part of a component.

37.1.1.2 TCRemoteDataModule.Create Constructor

The Create method creates a remote data module instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCRemoteDataModule(TComponent * AOwner);
```

Description

Do not use the contstructor to instantiate TCRemoteDataModule (see page 6576). Instead, add a remote data module to a server application using the remote data module wizard on the multi-tier page of the new items dialog.

AOwner specifies the component that is responsible for freeing the remote data module (typically the application).

See Also

Create (see page 2827)

37.1.1.3 TCRemoteDataModule.Destroy Destructor

Frees a remote data module instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCRemoteDataModule();
```

Description

Most applications do not need to call the destructor for TCRemoteDataModule (see page 6576). The remote data module is freed by its owner when the application shuts down.

If you must destroy a remote data module at runtime,

37.1.1.4 TCRemoteDataModule Methods

The methods of the TCRemoteDataModule class are listed here.

Public Methods

	Name	Description
	CRDMGetProviderNames (see page 6581)	Returns a list of all the available providers on the remote data module.
V	GetProvider (see page 6581)	Returns a registered provider component given its name.
V	Lock (see page 6582)	Locks the remote data module so that it can't be locked by other threads.
V	RegisterProvider (see page 6582)	Adds a provider to the list returned by CRDMGetProviderNames (see page 6581).
V	UnLock (see page 6583)	This is UnLock, a member of class TCRemoteDataModule.
V	UnRegisterProvider (see page 6583)	Removes a provider from the list returned by AS_GetProviderNames.

37.1.1.4.1 TCRemoteDataModule.CRDMGetProviderNames Method

Returns a list of all the available providers on the remote data module.

Pascal

```
function CRDMGetProviderNames: OleVariant;
```

C++

```
__fastcall OleVariant CRDMGetProviderNames();
```

Description

Call CRDMGetProviderNames for a list of all providers available from a remote data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the remote data module. When calling any of the remote data modules through the IAppServer interface, pass one of these names to indicate the provider that is the target of the method call.

CRDMGetProviderNames returns the names of the providers in a Variant array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

CRDMGetProviderNames provides the underlying implementation for the IAppServer method AS_GetProviderNames.

Warning: CRDMGetProviderNames returns a list that can include providers that are not exported. If a provider in the list has its Exported property set to false, trying to use that provider over an IAppServer interface results in an exception.

See Also

ProviderName (see page 8492)

GetProvider (see page 6581)

IAppServer (see page 16450)

Exported (see page 18474)

RegisterProvider (see page 6582)

37.1.1.4.2 TCRemoteDataModule.GetProvider Method

Returns a registered provider component given its name.

Pascal

```
function GetProvider(const ProviderName: string): TCustomProvider; virtual;
```

C++

```
virtual __fastcall TCustomProvider GetProvider(const AnsiString ProviderName);
```

Description

GetProvider returns the reference to a provider given its name. ProviderName specifies the name of a provider that is returned. If ProviderName is not one of the names returned by CRDMGetProviderNames (see page 6581), or if the provider's Exported property is false, GetProvider raises an exception.

See Also

Providers (see page 6584)

Exported (see page 18474)

CRDMGetProviderNames (see page 6581)

RegisterProvider (see page 6582)

37.1.1.4.3 TCRemoteDataModule.Lock Method

Locks the remote data module so that it can't be locked by other threads.

Pascal

```
procedure Lock; virtual;
```

C++

```
virtual __fastcall Lock();
```

Description

TCRemoteDataModule (see page 6576) descendants use Lock internally to ensure that all IAppServer calls are thread-safe. When implementing a remote data module that supports the free-threading model, call Lock before accessing any instance data, including the providers contained in the data module. When finished with the block of code that must be protected from thread conflicts, call the Unlock method to release the lock.

Lock uses a critical section to guard against thread conflicts. This means that any code which accesses the remote data module's properties or contained objects must call Lock or it will introduce thread conflicts.

See Also

Providers (see page 6584)

Unlock (see page 6583)

IAppServer (see page 16450)

TCriticalSection (see page 22058)

37.1.1.4.4 TCRemoteDataModule.RegisterProvider Method

Adds a provider to the list returned by CRDMGetProviderNames (see page 6581).

Pascal

```
procedure RegisterProvider(Value: TCustomProvider); virtual;
```

C++

```
virtual __fastcall RegisterProvider(TCustomProvider Value);
```

Description

Call RegisterProvider to make a provider available through a remote data module's IAppServer interface. Pass a reference to the provider as the Value parameter. Once a provider is registered, its availability to client applications can be turned on or off using its Exported property. However, even the names of unexported providers are returned by CRDMGetProviderNames (see page

6581).

There is no need to call RegisterProvider for providers that are added at design time or when the remote data module is assigned as an Owner in the provider's constructor. These are registered automatically.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider (see page 6583) method. Providers (see page 6584) that have the remote data module as an Owner are unregistered automatically from their destructors.

See Also

UnRegisterProvider (see page 6583)

CRDMGetProviderNames (see page 6581)

IAppServer (see page 16450)

Create (see page 18454)

Exported (see page 18474)

37.1.1.4.5 TCRemoteDataModule.UnLock Method

Pascal

```
procedure UnLock; virtual;
```

C++

```
virtual __fastcall UnLock();
```

Description

This is UnLock, a member of class TCRemoteDataModule.

37.1.1.4.6 TCRemoteDataModule.UnRegisterProvider Method

Removes a provider from the list returned by AS_GetProviderNames.

Pascal

```
procedure UnRegisterProvider(Value: TCustomProvider); virtual;
```

C++

```
virtual __fastcall UnRegisterProvider(TCustomProvider Value);
```

Description

Call UnRegisterProvider to remove a provider from the remote data module's list of available providers. Pass a reference to the provider that should be removed as the Value parameter. When a provider is not registered, it is not returned by the CRDMGetProviderNames (see page 6581) method, which can be accessed through the IAppServer interface.

To temporarily disable a provider, use the provider's Exported property. Unexported providers are listed by CRDMGetProviderNames (see page 6581) but can't be accessed through any IAppServer method calls.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider method. Providers (see page 6584) that have the remote data module as an Owner are unregistered automatically from their destructors.

See Also

RegisterProvider (see page 6582)

CRDMGetProviderNames (see page 6581)

IAppServer (see page 16450)

Destroy (see page 18454)

Exported (see page 18474)

37.1.1.5 TCRemoteDataModule Properties

The properties of the TCRemoteDataModule class are listed here.

Public Properties

	Name	Description
R	ProviderCount (see page 6584)	Indicates the number of providers registered with the remote data module.
R	Providers (see page 6584)	Lists the provider components that are contained in the remote data module.

37.1.1.5.1 TCRemoteDataModule.ProviderCount Property

Indicates the number of providers registered with the remote data module.

Pascal

```
property ProviderCount: integer;
```

C++

```
__property int ProviderCount;
```

Description

ProviderCount is the number of providers listed by the Providers (see page 6584) property.

See Also

Providers (see page 6584)

RegisterProvider (see page 6582)

37.1.1.5.2 TCRemoteDataModule.Providers Property

Lists the provider components that are contained in the remote data module.

Pascal

```
property Providers [const ProviderName:string]: TCustomProvider;
```

C++

```
__property TCustomProvider Providers[AnsiString const ProviderName];
```

Description

Use Providers to access a provider component from the remote data module given its name. The remote data module uses Providers to locate the target of method calls made using the IAppServer interface.

If the value passed as is not one of the names returned by AS_GetProviderNames, or if the provider's Exported property is false, reading Providers raises an exception.

See Also

AS_GetProviderNames (see page 16454)

Exported (see page 18474)

ProviderCount (see page 6584)

37.1.2 TRemoteDataModule Class

TRemoteDataModule encapsulates the objects and interfaces of an application server in a multi-tiered database application.

Class Hierarchy

Pascal

```
TRemoteDataModule = class(TDataModule, IAppServer);
```

C++

```
class TRemoteDataModule : public TDataModule, public IAppServer;
```

File

DataBkr

Description

Use a TRemoteDataModule object as the central repository for all objects in an application server that is written in Delphi. Remote data modules can contain any nonvisual components. Typically these are data access components, such as datasets and the provider components that handle communication between these datasets and client applications. Remote data modules can also contain other nonvisual components, such as TTimer, or TImageList.

At design time a TRemoteDataModule object provides a visual container into which a developer can place nonvisual components, set their properties, and write event handlers for them. In the unit file for the remote data module a developer can also code any business rules that are to be centralized in the middle tier of a multi-tiered application.

Remote data modules are dual-interface Automation servers that implement the IAppServer interface.Connection components on client applications are designed to look for this interface.

To create a remote data module at design time, choose File|New|Other, and select Remote Data Module from the multi-tiered page of the new items dialog. If you are using Delphi, the Remote Data Module Wizard then creates a new descendant of TRemoteDataModule that supports an interface that descends from IAppServer.

See Also

IAppServer (see page 16450)

37.1.2.1 TRemoteDataModule Members

The following tables list the members exposed by TRemoteDataModule.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AS_ApplyUpdates (see page 6590)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 6591)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 6591)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 6592)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 6593)	Returns a list of all the available providers on the remote data module.
	AS_GetRecords (see page 6593)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 6594)	Returns information from a specified record of the provider's dataset.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
V	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetProvider (see page 6595)	This is GetProvider, a member of class TRemoteDataModule.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 6597)	Registers the remote data module in the system registry as an automation server.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.

	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 6589)	Creates a remote data module instance.
V	CreateNew (see page 2828)	Creates an instance of a data module and registers with the global screen object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6589)	Frees a remote data module instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetIDsOfNames (see page 22395)	This is GetIDsOfNames, a member of class IDispatch.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetTypeInfo (see page 22395)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 22395)	This is GetTypeInfoCount, a member of class IDispatch.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invoke (see page 22395)	This is Invoke, a member of class IDispatch.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	Lock (see page 6595)	Locks the remote data module so that it can't be locked by other threads.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
V	RegisterProvider (see page 6596)	Adds a provider to the list returned by AS_GetProviderNames (see page 6593).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Unlock (see page 6596)	Unlocks the remote data module after it was locked by a call to the Lock (see page 6595) method.
V	UnRegisterProvider (see page 6597)	Removes a provider from the list returned by AS_GetProviderNames (see page 6593).
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ProviderCount (see page 6599)	Indicates the number of providers registered with the remote data module.
R	Providers (see page 6599)	This is Providers, a member of class TRemoteDataModule.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.

	Tag (see page 2808)	Stores an integer value as part of a component.

37.1.2.2 TRemoteDataModule.Create Constructor

Creates a remote data module instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRemoteDataModule(TComponent * AOwner);
```

Description

Most applications do not need to call the constructor for TRemoteDataModule (see page 6585). Instead, add a remote data module to a server application using the remote data module wizard on the multi-tier page of the new items dialog.

AOwner specifies the component that is responsible for freeing the remote data module (typically the application).

See Also

Create (see page 2827)

37.1.2.3 TRemoteDataModule.Destroy Destructor

Frees a remote data module instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TRemoteDataModule();
```

Description

Most applications do not need to call the destructor for TRemoteDataModule (see page 6585). The remote data module is freed by its owner when the application shuts down.

If you must destroy a remote data module at runtime, call the Free method instead.

See Also

Free (see page 22300)

37.1.2.4 TRemoteDataModule Methods

The methods of the TRemoteDataModule class are listed here.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 6590)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 6591)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 6591)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 6592)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 6593)	Returns a list of all the available providers on the remote data module.
	AS_GetRecords (see page 6593)	Returns a data packet that contains the specified data.

	AS_RowRequest (see page 6594)	Returns information from a specified record of the provider's dataset.
	GetProvider (see page 6595)	This is GetProvider, a member of class TRemoteDataModule.
	UpdateRegistry (see page 6597)	Registers the remote data module in the system registry as an automation server.

Public Methods

	Name	Description
	Lock (see page 6595)	Locks the remote data module so that it can't be locked by other threads.
	RegisterProvider (see page 6596)	Adds a provider to the list returned by AS_GetProviderNames (see page 6593).
	Unlock (see page 6596)	Unlocks the remote data module after it was locked by a call to the Lock (see page 6595) method.
	UnRegisterProvider (see page 6597)	Removes a provider from the list returned by AS_GetProviderNames (see page 6593).

37.1.2.4.1 TRemoteDataModule.AS_ApplyUpdates Method

Applies updates received from a client dataset using a specified provider.

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

AS_AS_ApplyUpdates writes client updates to a dataset or database server. ProviderName specifies the name of the provider component that manages the update operation. Delta is a Variant containing the updated, inserted, and deleted records to write to the database. MaxErrors indicates the maximum number of errors to permit before rolling back the update operation; ErrorCount returns the actual number of errors encountered during the update operation. OwnerData is information supplied by the client application in a BeforeAS_ApplyUpdates event handler and returned to the client application in an AfterAS_ApplyUpdates event handler. It is passed to the provider's BeforeAS_ApplyUpdates event handler and returned from the provider's AfterAS_ApplyUpdates event handler.

AS_AS_ApplyUpdates The AS_ApplyUpdates_result parameter returns a Variant that is a data packet containing all records that could not be applied.

Note: Applications can only call the protected AS_AS_ApplyUpdates method using the IAppServer interface. To apply updates directly in code from the application server, use the provider component's AS_ApplyUpdates method.

See Also

ApplyUpdates (see page 8394)

applyupdates (see page 18459)

BeforeApplyUpdates (see page 18479)

AfterApplyUpdates (see page 18475)

BeforeApplyUpdates (see page 8511)

AfterApplyUpdates (see page 8497)

providers (see page 6599)

IAppServer (see page 16450)

37.1.2.4.2 TRemoteDataModule.AS_DataRequest Method

Generates an OnAS_DataRequest event on the specified provider component.

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use AS_AS_DataRequest to invoke an OnAS_DataRequest event handler of the provider named by ProviderName. This method is provided to allow application developers to customize the communication between a client application and a provider component. There is no predefined meaning for the Data parameter or the return value AS_DataRequest_result parameter, which is returned to the caller.

Note: Applications can only call the protected AS_AS_DataRequest method using the IAppServer interface.

See Also

OnDataRequest (see page 18482)

providers (see page 6599)

DataRequest (see page 8404)

IAppServer (see page 16450)

37.1.2.4.3 TRemoteDataModule.AS_Execute Method

AS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Use AS_AS_Execute to pass an execute command to a remote provider, using a specified set of parameters. AS_AS_Execute calls the AS_Execute method of the specified provider after assigning any parameters. Output parameters that result from executing a query or stored procedure are returned in the Params parameter.

The provider's AS_Execute method generates a BeforeAS_Execute event, passes the command on to its associated dataset, and generates an AfterAS_Execute event. The dataset must represent a query or stored procedure that does not return a cursor.

The ProviderName parameter specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the query, or the name of a stored procedure that replaces the dataset's stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

The Params parameter encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams routine. To decode Params into a TParams object, use the Unpackparams routine.

The OwnerData parameter contains custom information that appears as an argument to the provider's BeforeAS_Execute and AfterAS_Execute event handlers. This information originates in a client dataset's BeforeAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterAS_Execute event handler.

Options (see page 18440)

PackageParams (see page 8534)

UnpackParams (see page 8534)

Communicating with the Client Dataset

37.1.2.4.4 TRemoteDataModule.AS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use AS_AS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

The ProviderName parameter specifies the name of the provider component whose dataset has the parameters.

The OwnerData represents custom information that originates in a client dataset's BeforeAS_GetParams event handler and returns information that is passed to the client dataset's AfterAS_GetParams event handler.

AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns the parameters, encoded as a Variant array, where each element is a 2-element Variant array containing a parameter name and a parameter value. These parameters can be converted to a TParams object using the UnpackParams procedure. If the dataset has no parameters, or if the provider does not support parameter fetching, AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns a Null Variant.

Note: AS_AS_GetParams should not be used to retrieve output parameters from stateless application servers, because parameter values may be changed by other applications. When writing a stateless application server, retrieve parameter values using the AS_Execute method instead.

See Also

DataSet (see page 18529)

AS_Execute (see page 16453)

UnpackParams (see page 8534)

Communicating with the Client Dataset

37.1.2.4.5 TRemoteDataModule.AS_GetProviderNames Method

Returns a list of all the available providers on the remote data module.

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

Call AS_AS_GetProviderNames for a list of all registered providers available from a remote data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the remote data module. When calling any of the remote data modules through the IAppServer interface, pass one of these names to indicate the provider that is the target of the method call.

AS_AS_GetProviderNames returns the names of the providers in a Variant array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

Note: Applications can only call the protected AS_AS_GetProviderNames method using the IAppServer interface.

See Also

ProviderName (see page 8492)

providers (see page 6599)

IAppServer (see page 16450)

Exported (see page 18474)

37.1.2.4.6 TRemoteDataModule.AS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call AS_AS_GetRecords to retrieve a specified number of records. AS_AS_GetRecords returns the requested records, starting

with the current record of the provider's dataset. When working with a stateless remote data module, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeAS_GetRecords event handler.

ProviderName gives the name of the provider component that provides the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params is a Variant containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_GetRecords event handler. This information is passed to the provider's BeforeAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterAS_GetRecords event handler.

Records are returned as a data packet in a Variant parameter, AS_GetRecords_result.

Note: Applications can only call the protected AS_AS_GetRecords method using the IAppServer interface. To fetch records directly in code from the application server, use the provider component's AS_GetRecords method.

providers (see page 6599)

IAppServer (see page 16450)

37.1.2.4.7 TRemoteDataModule.AS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

Client datasets call AS_AS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

The ProviderName parameter indicates the provider associated with the dataset from which information should be fetched.

The Row parameter is an OleVariant that describes the current record on the client dataset.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_RowRequest event handler. This information is passed to the provider's BeforeAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterAS_RowRequest event handler.

The requested data is returned as a delta packet.

Note: Applications can only call the protected AS_AS_RowRequest method using the IAppServer interface.

RowRequest (see page 18472)

BeforeRowRequest (see page 18482)

AfterRowRequest (see page 18478)

FetchBlobs (see page 8414)

FetchDetails (see page 8414)

RefreshRecord (see page 8442)

providers (see page 6599)

IAppServer (see page 16450)

37.1.2.4.8 TRemoteDataModule.GetProvider Method

Pascal

```
function GetProvider(const ProviderName: string): TCustomProvider; virtual;
```

C++

```
virtual __fastcall TCustomProvider GetProvider(const AnsiString ProviderName);
```

Description

This is GetProvider, a member of class TRemoteDataModule.

37.1.2.4.9 TRemoteDataModule.Lock Method

Locks the remote data module so that it can't be locked by other threads.

Pascal

```
procedure Lock; virtual;
```

C++

```
virtual __fastcall Lock();
```

Description

Remote data modules use Lock internally to ensure that all IAppServer calls are thread-safe. When implementing a remote data module descendant that supports the free-threading model, call Lock before accessing any instance data, including the providers contained in the data module. When finished with the block of code that must be protected from thread conflicts, call the Unlock (see page 6596) method to release the lock.

Lock uses a critical section to guard against thread conflicts. This means that any code which accesses the remote data module's properties or contained objects must call Lock or it will introduce thread conflicts.

See Also

providers (see page 6599)

Unlock (see page 6596)

IAppServer (see page 16450)

TCriticalSection (see page 22058)

37.1.2.4.10 TRemoteDataModule.RegisterProvider Method

Adds a provider to the list returned by AS_GetProviderNames (see page 6593).

Pascal

```
procedure RegisterProvider(Value: TCustomProvider); virtual;
```

C++

```
virtual __fastcall RegisterProvider(TCustomProvider Value);
```

Description

Call RegisterProvider to make a provider available through the remote data module's IAppServer interface. Pass a reference to the provider as the Value parameter. Once a provider is registered, its availability to client applications can be turned on or off using its Exported property.

There is no need to call RegisterProvider for providers that are added at design time or when the remote data module is assigned as an Owner in the provider's constructor. These are registered automatically.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider (see page 6597) method. Providers (see page 6599) that have the remote data module as an Owner are unregistered automatically from their destructors.

See Also

UnRegisterProvider (see page 6597)

AS_GetProviderNames (see page 6593)

IAppServer (see page 16450)

Create (see page 18454)

Exported (see page 18474)

37.1.2.4.11 TRemoteDataModule.Unlock Method

Unlocks the remote data module after it was locked by a call to the Lock (see page 6595) method.

Pascal

```
procedure Unlock; virtual;
```

C++

```
virtual __fastcall Unlock();
```

Description

Use Unlock to release the critical section that was entered by a call to the Lock (see page 6595) method. Every call to the Lock (see page 6595) method must be paired with a corresponding call to Unlock.

See Also

Lock (see page 6595)

37.1.2.4.12 TRemoteDataModule.UnRegisterProvider Method

Removes a provider from the list returned by AS_GetProviderNames (see page 6593).

Pascal

```
procedure UnRegisterProvider(Value: TCustomProvider); virtual;
```

C++

```
virtual __fastcall UnRegisterProvider(TCustomProvider Value);
```

Description

Call UnRegisterProvider to remove a provider from the remote data module's list of available providers. Pass a reference to the provider that should be removed as the Value parameter. When a provider is not registered, it is not returned by the AS_GetProviderNames (see page 6593) method, which can be accessed through the IAppServer interface.

To temporarily disable a provider, use the provider's Exported property. Unexported providers can't be accessed through any IAppServer method calls.

Before a registered provider is destroyed, it must be unregistered using the UnRegisterProvider method. Providers (see page 6599) that have the remote data module as an Owner are unregistered automatically from their destructors.

See Also

RegisterProvider (see page 6596)

AS_GetProviderNames (see page 6593)

IAppServer (see page 16450)

Destroy (see page 18454)

Exported (see page 18474)

37.1.2.4.13 TRemoteDataModule.UpdateRegistry Method

Registers the remote data module in the system registry as an automation server.

Pascal

```
class procedure UpdateRegistry(Register: Boolean; const ClassID: string; const ProgID:
string); override;
```

C++

```
virtual __fastcall UpdateRegistry(Boolean Register, const AnsiString ClassID, const AnsiString
ProgID);
```

Description

The protected UpdateRegistry is called automatically when you register or unregister the application server as an automation server.

The Register parameter is true when registering an application server, false when unregistering.

The ClassID and ProgID parameters specify the server's ClassID and ProgID respectively.

Note: If your application server pools remote data modules, you must override this method to call the global RegisterPooled (see page 6602) procedure when the Register parameter is true and UnregisterPooled (see page 6603) when the Register parameter is false.

Delphi Examples:

```
{
The following UpdateRegistry method adjusts a pooled remote
data module accessed from a
TWebConnection component. This allows the resources of the
data module to be freed when it is not in use, while
optimizing the use of existing remote data modules by letting
clients share them.  The UpdateRegistry method also comments
out the calls to DisableSocketTransport and EnableSocket
transport that are added by the Remote Data Module Wizard.
This prevents socket-based connections, which do not provide
for a secure connection, from using the remote data module.
}
class procedure TPooledRDM.UpdateRegistry(Register: Boolean; const ClassID, ProgID: string);
begin
  if Register then
  begin
    inherited UpdateRegistry(Register, ClassID, ProgID);
    EnableSocketTransport(ClassID);
    EnableWebTransport(ClassID);
  end else
  begin
    DisableSocketTransport(ClassID);
    DisableWebTransport(ClassID);
    inherited UpdateRegistry(Register, ClassID, ProgID);
  end;
end;
```

See Also

RegisterPooled (see page 6602)

UnregisterPooled (see page 6603)

Pooling Remote Data Modules

37.1.2.5 TRemoteDataModule Properties

The properties of the TRemoteDataModule class are listed here.

Public Properties

	Name	Description
R	ProviderCount (see page 6599)	Indicates the number of providers registered with the remote data module.
R	Providers (see page 6599)	This is Providers, a member of class TRemoteDataModule.

37.1.2.5.1 TRemoteDataModule.ProviderCount Property

Indicates the number of providers registered with the remote data module.

Pascal

```
property ProviderCount: integer;
```

C++

```
__property int ProviderCount;
```

Description

ProviderCount is the number of providers that can be accessed using the Providers (see page 6599) property.

See Also

providers (see page 6599)

RegisterProvider (see page 6596)

37.1.2.5.2 TRemoteDataModule.Providers Property

Pascal

```
property Providers [const ProviderName: string]: TCustomProvider;
```

C++

```
__property TCustomProvider Providers[AnsiString const ProviderName];
```

Description

This is Providers, a member of class TRemoteDataModule.

37.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DisableSocketTransport (see page 6600)	Unregisters a remote data module so clients can't access it using a Socket connection.
	DisableWebTransport (see page 6601)	Unregisters a remote data module so clients can't access it using a Web connection.
	EnableSocketTransport (see page 6601)	Registers a remote data module so clients can access it using a Socket connection.
	EnableWebTransport (see page 6602)	Registers a remote data module so clients can access it using a Web connection.
	RegisterPooled (see page 6602)	Registers a remote data module so that instances are pooled.
	UnregisterPooled (see page 6603)	Removes the object pooling registry entries for a remote data module.

37.2.1 DataBkr.DisableSocketTransport Function

Unregisters a remote data module so clients can't access it using a Socket connection.

Pascal

```
procedure DisableSocketTransport(const ClassID: string);
```

C++

```
DisableSocketTransport(const AnsiString ClassID);
```

File

DataBkr

Description

When working in Delphi, the remote data module Wizard automatically adds a call to DisableSocketTransport to the overridden UpdateRegistry method of the new remote data module class. This removes the registry entries that Scktsrvr.exe uses to check whether clients can access the application server. The registry entries are added by a call to EnableSocketTransport (see page 6601) (also added to UpdateRegistry).

To make an application server unavailable to Socket-based connections, remove these two calls from UpdateRegistry. The application server can still receive requests over connections formed using other protocols.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls DisableSocketTransport.

See Also

EnableSocketTransport (see page 6601)

TRemoteDataModule (see page 6585)

37.2.2 DataBkr.DisableWebTransport Function

Unregisters a remote data module so clients can't access it using a Web connection.

Pascal

```
procedure DisableWebTransport(const ClassID: string);
```

C++

```
DisableWebTransport(const AnsiString ClassID);
```

File

DataBkr

Description

When working in Delphi, the remote data module Wizard automatically adds a call to DisableWebTransport to the overridden UpdateRegistry method of the new remote data module class. This removes the registry entries that httpsrvr.dll uses to check whether clients can access the application server. The registry entries are added by a call to EnableWebTransport (see page 6602) (also added to UpdateRegistry).

To make an application server unavailable to HTTP-based connections, remove these two calls from UpdateRegistry. The application server can still receive requests over connections formed using other protocols.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls DisableSocketTransport (see page 6600).

See Also

EnableWebTransport (see page 6602)

TRemoteDataModule (see page 6585)

37.2.3 DataBkr.EnableSocketTransport Function

Registers a remote data module so clients can access it using a Socket connection.

Pascal

```
procedure EnableSocketTransport(const ClassID: string);
```

C++

```
EnableSocketTransport(const AnsiString ClassID);
```

File

DataBkr

Description

When working in Delphi, the remote data module Wizard automatically adds a call to EnableSocketTransport to the overridden UpdateRegistry method of the new remote data module class. This adds the registry entries that Scktsrvr.exe uses to check whether clients can access the application server. The registry entries are removed by a call to DisableSocketTransport (see page 6600) (also added to UpdateRegistry).

To make an application server unavailable to Socket-based connections, remove these two calls from UpdateRegistry. The

application server can still receive requests over connections formed using other protocols.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls EnableSocketTransport.

Using Socket Connections

37.2.4 DataBkr.EnableWebTransport Function

Registers a remote data module so clients can access it using a Web connection.

Pascal

```
procedure EnableWebTransport(const ClassID: string);
```

C++

```
EnableWebTransport(const AnsiString ClassID);
```

File

DataBkr

Description

When working in Delphi, the remote data module Wizard automatically adds a call to EnableWebTransport to the overridden UpdateRegistry method of the new remote data module class. This adds the registry entries that httpsrvr.dll uses to check whether clients can access the application server. The registry entries are removed by a call to DisableWebTransport (see page 6601) (also added to UpdateRegistry).

To make an application server unavailable to HTTP-based connections, remove these two calls from UpdateRegistry. The application server can still receive requests over connections formed using other protocols.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls DisableSocketTransport (see page 6600).

Using Web Connections

37.2.5 DataBkr.RegisterPooled Function

Registers a remote data module so that instances are pooled.

Pascal

```
procedure RegisterPooled(const ClassID: string; Max: Integer; Timeout: Integer; Singleton:
Boolean = False);
```

C++

```
RegisterPooled(const AnsiString ClassID, int Max, int Timeout, Boolean Singleton = False);
```

File

DataBkr

Description

In Delphi applications, to enable remote data module instances to be pooled, call RegisterPooled from the UpdateRegistry method of a remote data module class. When data module instances are pooled, the server maintains a cache of remote data module instances. Each client request is serviced by the first available instance from that cache. Because instances are shared, the remote data module can't rely on persistent state information.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls RegisterPooled.

Max indicates the maximum number of instances in the pool. If client applications request more than this maximum number, the application server raises a "Server too busy" exception.

Timeout indicates the number of minutes a remote data module instance can sit idle in the object pool. If an instance receives no client requests for more than Timeout minutes, it is automatically freed. The server checks every 6 minutes, so an object may persist in an idle state up to 6 minutes longer than Timeout. Setting Timeout to 0 indicates an infinite timeout period (that is, unused objects are not freed until the application server shuts down).

Singleton indicates that all client calls go to the same remote data module instance. There is only a single instance rather than a pool of available instances. Only set Singleton to true if the remote data module is free-threaded.

Note: When Singleton is true, the values of Max and Timeout are ignored because there is only one instance with no timeout period.

UnregisterPooled (see page 6603)

TRemoteDataModule (see page 6585)

Pooling Remote Data Modules

37.2.6 DataBkr.UnregisterPooled Function

Removes the object pooling registry entries for a remote data module.

Pascal

```
procedure UnregisterPooled(const ClassID: string);
```

C++

```
UnregisterPooled(const AnsiString ClassID);
```

File

DataBkr

Description

When remote data module instances are pooled in a Delphi application, call UnregisterPooled from the UpdateRegistry method of a remote data module class. This unregisters the object pooling at the same time the remote data module is unregistered as an automation server.

ClassID is the class ID of the remote data module. This value is passed as a parameter to the UpdateRegistry method that calls UnregisterPooled.

Constants

Name	Description
DayFriday (see page 6718)	This is constant DateUtils.DayFriday.
DayMonday (see page 6718)	This is constant DateUtils.DayMonday.
DaySaturday (see page 6719)	This is constant DateUtils.DaySaturday.
DaysPerWeek (see page 6719)	This is constant DateUtils.DaysPerWeek.
DaysPerYear (see page 6719)	This is constant DateUtils.DaysPerYear.
DaySunday (see page 6720)	This is constant DateUtils.DaySunday.
DayThursday (see page 6720)	This is constant DateUtils.DayThursday.
DayTuesday (see page 6720)	This is constant DateUtils.DayTuesday.
DayWednesday (see page 6721)	This is constant DateUtils.DayWednesday.
MonthsPerYear (see page 6721)	This is constant DateUtils.MonthsPerYear.
OneHour (see page 6721)	Delphi inverse time unit constants.
OneMillisecond (see page 6722)	This is constant DateUtils.OneMillisecond.
OneMinute (see page 6722)	This is constant DateUtils.OneMinute.
OneSecond (see page 6722)	This is constant DateUtils.OneSecond.
RecodeLeaveFieldAsIs (see page 6723)	This is constant DateUtils.RecodeLeaveFieldAsIs.
WeeksPerFortnight (see page 6723)	This is constant DateUtils.WeeksPerFortnight.
YearsPerCentury (see page 6723)	This is constant DateUtils.YearsPerCentury.
YearsPerDecade (see page 6724)	This is constant DateUtils.YearsPerDecade.
YearsPerMillennium (see page 6724)	This is constant DateUtils.YearsPerMillennium.

Functions

	Name	Description
	CompareDate (see page 6614)	Indicates the relationship between the date portions of two TDateTime values.
	CompareDateTime (see page 6614)	Indicates the relationship between two TDateTime values.
	CompareTime (see page 6615)	Indicates the relationship between the time portions of two TDateTime values.

	DateOf (see page 6616)	Strips the time portion from a TDateTime value.
	DateTimeToJulianDate (see page 6616)	Converts a TDateTime value into a Julian date.
	DateTimeToModifiedJulianDate (see page 6617)	Converts a TDateTime value into a modified Julian date.
	DateTimeToUnix (see page 6617)	Converts a TDateTime value into a Unix/Linux-style date-and-time value.
	DayOf (see page 6618)	Returns the day of the month represented by a TDateTime value.
	DayOfTheMonth (see page 6618)	Returns the day of the month represented by a TDateTime value.
	DayOfTheWeek (see page 6619)	Returns the day of the week represented by a TDateTime value.
	DayOfTheYear (see page 6620)	Returns the number of days between a specified TDateTime value and December 31 of the previous year.
	DaysBetween (see page 6621)	Returns the number of whole days between two specified TDateTime values.
	DaysInAMonth (see page 6622)	Returns the number of days in a specified month of a specified year.
	DaysInAYear (see page 6622)	Returns the number of days in a specified year.
	DaysInMonth (see page 6623)	Returns the number of days in the month of a specified TDateTime value.
	DaysInYear (see page 6623)	Returns the number of days in the year of a specified TDateTime value.
	DaySpan (see page 6624)	Returns the number of days (including fractional days) between two specified TDateTime values.
	DecodeDateDay (see page 6624)	Returns the year and day of the year for a specified TDateTime.
	DecodeDateMonthWeek (see page 6625)	Returns the year, month, week of the month, and day of the week for a specified TDateTime.
	DecodeDateTime (see page 6626)	Returns Year, Month, Day, Hour, Minute, Second, and Millisecond values for a TDateTime.
	DecodeDateWeek (see page 6627)	Returns the year, week of the year, and day of the week for a specified TDateTime value object.
	DecodeDayOfWeekInMonth (see page 6628)	For a given TDateTime value, returns the year, month, day of the week, and the count of that day of the week in the month.
	EncodeDateDay (see page 6629)	Returns a TDateTime that represents a specified day of the year for a specified year.
	EncodeDateMonthWeek (see page 6629)	Returns a TDateTime that represents a specified day of a specified week in a specified month and year.
	EncodeDateTime (see page 6630)	Returns a TDateTime that represents a specified year, month, day, hour, minute, second, and millisecond.
	EncodeDateWeek (see page 6631)	Returns a TDateTime that represents a specified day of a specified week in a specified year.
	EncodeDayOfWeekInMonth (see page 6632)	Returns a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.
	EndOfADay (see page 6633)	Returns a TDateTime that represents the last millisecond of a specified day.
	EndOfADay (see page 6633)	Returns a TDateTime that represents the last millisecond of a specified day.
	EndOfAMonth (see page 6634)	Returns a TDateTime that represents the last millisecond of the last day of a specified month.
	EndOfAWeek (see page 6635)	Returns a TDateTime object value that represents the last millisecond of a specified day of a specified week.
	EndOfAYear (see page 6636)	Returns a TDateTime that represents the last millisecond of a specified year.
	EndOfTheDay (see page 6636)	Returns a TDateTime that represents the last millisecond of the day identified by a specified TDateTime.
	EndOfTheMonth (see page 6637)	Returns a TDateTime that represents the last millisecond of the last day of the month identified by a specified TDateTime.
	EndOfTheWeek (see page 6637)	Returns a TDateTime that represents the last millisecond of the last day of the week identified by a specified TDateTime.
	EndOfTheYear (see page 6638)	Returns a TDateTime that represents the last millisecond of the last day of the year identified by a specified TDateTime.
	HourOf (see page 6638)	Returns the hour of the day represented by a TDateTime value.
	HourOfTheDay (see page 6639)	Returns the hour of the day represented by a TDateTime value.
	HourOfTheMonth (see page 6640)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the month.
	HourOfTheWeek (see page 6641)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the week.
	HourOfTheYear (see page 6641)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the year.
	HoursBetween (see page 6642)	Returns the number of whole hours between two specified TDateTime values.
	HourSpan (see page 6643)	Returns the number of Hours (including fractional Hours) between two specified TDateTime values.

	IncDay (see page 6643)	Returns a date shifted by a specified number of days.
	IncHour (see page 6644)	Returns a date/time value shifted by a specified number of hours.
	IncMilliSecond (see page 6645)	Returns a date/time value shifted by a specified number of milliseconds.
	IncMinute (see page 6645)	Returns a date/time value shifted by a specified number of minutes.
	IncSecond (see page 6646)	Returns a date/time value shifted by a specified number of seconds.
	IncWeek (see page 6647)	Returns a date shifted by a specified number of weeks.
	IncYear (see page 6647)	Returns a date shifted by a specified number of years.
	InvalidDateDayError (see page 6648)	This is function DateUtils.InvalidDateDayError.
	InvalidDateMonthWeekError (see page 6648)	This is function DateUtils.InvalidDateMonthWeekError.
	InvalidDateTimeError (see page 6649)	This is function DateUtils.InvalidDateTimeError.
	InvalidDateWeekError (see page 6649)	This is function DateUtils.InvalidDateWeekError.
	InvalidDayOfWeekInMonthError (see page 6650)	This is function DateUtils.InvalidDayOfWeekInMonthError.
	IsInLeapYear (see page 6650)	Indicates whether a specified TDateTime value occurs in a leap year.
	IsPM (see page 6650)	Indicates whether the time portion of a specified TDateTime value occurs after noon.
	IsSameDay (see page 6651)	Indicates whether a specified TDateTime value occurs on a the same day as a criterion date.
	IsToday (see page 6651)	Indicates whether a specified TDateTime value occurs on the current date.
	IsValidDate (see page 6652)	Indicates whether a specified year, month, and day represent a valid date.
	IsValidDateDay (see page 6652)	Indicates whether a specified year and day of the year represent a valid date.
	IsValidDateMonthWeek (see page 6653)	Indicates whether a specified year, month, week of the month, and day of the week represent a valid date.
	IsValidDateTime (see page 6654)	Indicates whether a specified year, month, day, hour, minute, second, and millisecond represent a valid date and time.
	IsValidDateWeek (see page 6654)	Indicates whether a specified year, week of the year, and day of the week represent a valid date.
	IsValidTime (see page 6655)	Indicates whether a specified hour, minute, second, and millisecond represent a valid date and time.
	JulianDateToDateTime (see page 6656)	Converts a Julian date to a TDateTime value.
	MilliSecondOf (see page 6656)	Returns the millisecond of the second represented by a TDateTime value.
	MilliSecondOfTheDay (see page 6657)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same day.
	MilliSecondOfTheHour (see page 6658)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same hour.
	MilliSecondOfTheMinute (see page 6659)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same minute.
	MilliSecondOfTheMonth (see page 6659)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the month.
	MilliSecondOfTheSecond (see page 6660)	Returns the millisecond of the second represented by a TDateTime value.
	MilliSecondOfTheWeek (see page 6661)	Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the week.
	MilliSecondOfTheYear (see page 6661)	Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the year.
	MilliSecondsBetween (see page 6662)	Returns the number of milliseconds between two specified TDateTime values.
	MilliSecondSpan (see page 6663)	Returns the number of milliseconds between two specified TDateTime values.
	MinuteOf (see page 6663)	Returns the minute of the hour represented by a TDateTime value.
	MinuteOfTheDay (see page 6664)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the same day.
	MinuteOfTheHour (see page 6665)	Returns the number of minutes between a specified TDateTime value and the beginning of the same hour.
	MinuteOfTheMonth (see page 6666)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the month.
	MinuteOfTheWeek (see page 6666)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the week.
	MinuteOfTheYear (see page 6667)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the year.
	MinutesBetween (see page 6668)	Returns the number of minutes between two specified TDateTime values.
	MinuteSpan (see page 6668)	Returns the number of minutes, including fractions thereof, between two specified TDateTime values.
	ModifiedJulianDateToDateTime (see page 6669)	Converts a modified Julian date to a TDateTime value.

	MonthOf (see page 6670)	Returns the month of the year represented by a TDateTime value.
	MonthOfTheYear (see page 6670)	Returns the month of the year represented by a TDateTime value.
	MonthsBetween (see page 6671)	Returns the approximate number of months between two specified TDateTime values.
	MonthSpan (see page 6672)	Returns the approximate number of months, including fractions, between two specified TDateTime values.
	NthDayOfWeek (see page 6672)	Returns which occurrence of its weekday a specified TDateTime value represents.
	RecodeDate (see page 6673)	Replaces the date portion of a specified TDateTime value.
	RecodeDateTime (see page 6674)	Selectively replaces parts of a specified TDateTime value.
	RecodeDay (see page 6675)	Replaces the day of the month for a specified TDateTime value.
	RecodeHour (see page 6675)	Replaces the hour of the day for a specified TDateTime value.
	RecodeMilliSecond (see page 6676)	Replaces the millisecond of the second for a specified TDateTime value.
	RecodeMinute (see page 6677)	Replaces the minute of the hour for a specified TDateTime value.
	RecodeMonth (see page 6678)	Replaces the month of the year for a specified TDateTime value.
	RecodeSecond (see page 6678)	Replaces the second of the minute for a specified TDateTime value.
	RecodeTime (see page 6679)	Replaces the time portion of a specified TDateTime value.
	RecodeYear (see page 6680)	Replaces the year for a specified TDateTime value.
	SameDate (see page 6681)	Indicates whether two TDateTime values represent the same year, month, and day.
	SameDateTime (see page 6681)	Indicates whether two TDateTime values represent the same year, month, day, hour, minute, second, and millisecond.
	SameTime (see page 6682)	Indicates whether two TDateTime values represent the same time of day, ignoring the date portion.
	SecondOf (see page 6682)	Returns the second of the minute represented by a TDateTime value.
	SecondOfTheDay (see page 6683)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the same day.
	SecondOfTheHour (see page 6684)	Returns the number of seconds between a specified TDateTime value and the beginning of the same hour.
	SecondOfTheMinute (see page 6685)	Returns the number of seconds between a specified TDateTime value and the beginning of the same minute.
	SecondOfTheMonth (see page 6685)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the month.
	SecondOfTheWeek (see page 6686)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the first day of the week.
	SecondOfTheYear (see page 6687)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the year.
	SecondsBetween (see page 6687)	Returns the number of seconds between two specified TDateTime values.
	SecondSpan (see page 6688)	Returns the number of seconds (including fractions thereof) between two specified TDateTime values.
	StartOfADay (see page 6689)	Returns a TDateTime that represents 12:00:00:00 AM on a specified day.
	StartOfADay (see page 6689)	Returns a TDateTime that represents 12:00:00:00 AM on a specified day.
	StartOfAMonth (see page 6690)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of a specified month.
	StartOfAWeek (see page 6690)	Returns a TDateTime that represents 1the first moment on a specified day of a specified week.
	StartOfAYear (see page 6691)	Returns a TDateTime that represents the first moment on the first day of a specified year.
	StartOfTheDay (see page 6692)	Returns a TDateTime that represents 12:00:00:00 AM on the day identified by a specified TDateTime.
	StartOfTheMonth (see page 6692)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the month identified by a specified TDateTime.
	StartOfTheWeek (see page 6693)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the week identified by a specified TDateTime.
	StartOfTheYear (see page 6693)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the year identified by a specified TDateTime.
	TimeOf (see page 6694)	Strips the date portion from a TDateTime value.
	Today (see page 6694)	Returns a TDateTime value that represents the current date.
	Tomorrow (see page 6695)	Returns a TDateTime value that represents the following day.
	TryEncodeDateDay (see page 6695)	Calculates the TDateTime value that represents a specified day of the year for a specified year.

	TryEncodeDateMonthWeek (see page 6696)	Calculates the TDateTime value that represents a specified day of a specified week in a specified month and year.
	TryEncodeDateTime (see page 6697)	Calculates the TDateTime value that represents a specified year, month, day, hour, minute, second, and millisecond.
	TryEncodeDateWeek (see page 6698)	Calculates the TDateTime value that represents a specified day of a specified week in a specified year.
	TryEncodeDayOfWeekInMonth (see page 6699)	Calculates a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.
	TryJulianDateToDateTime (see page 6700)	Converts a Julian date to a TDateTime value.
	TryModifiedJulianDateToDateTime (see page 6701)	Converts a modified Julian date to a TDateTime value.
	TryRecodeDateTime (see page 6702)	Selectively replaces parts of a specified TDateTime value.
	UnixToDateTime (see page 6703)	Converts a Unix/Linux style date-and-time value to a TDateTime value.
	WeekOf (see page 6703)	Returns the week of the year represented by a TDateTime value.
	WeekOfTheMonth (see page 6704)	Returns the week of the month represented by a TDateTime value.
	WeekOfTheMonth (see page 6704)	Returns the week of the month represented by a TDateTime value.
	WeekOfTheYear (see page 6705)	Returns the week of the year represented by a TDateTime value.
	WeekOfTheYear (see page 6705)	Returns the week of the year represented by a TDateTime value.
	WeeksBetween (see page 6706)	Returns the number of whole weeks between two specified TDateTime values.
	WeeksInAYear (see page 6706)	Returns the number of weeks in a specified year.
	WeeksInYear (see page 6707)	Returns the number of weeks in the year of a specified TDateTime value.
	WeekSpan (see page 6708)	Returns the number of weeks (including fractional weeks) between two specified TDateTime values.
	WithinPastDays (see page 6708)	Indicates whether two dates are within a specified number of days of each other.
	WithinPastHours (see page 6709)	Indicates whether two date/time values are within a specified number of hours of each other.
	WithinPastMilliSeconds (see page 6710)	Indicates whether two date/time values are within a specified number of milliseconds of each other.
	WithinPastMinutes (see page 6710)	Indicates whether two date/time values are within a specified number of minutes of each other.
	WithinPastMonths (see page 6711)	Indicates whether two date/time values are within a specified number of months of each other.
	WithinPastSeconds (see page 6712)	Indicates whether two date/time values are within a specified number of seconds of each other.
	WithinPastWeeks (see page 6712)	Indicates whether two date/time values are within a specified number of weeks of each other.
	WithinPastYears (see page 6713)	Indicates whether two date/time values are within a specified number of years of each other.
	YearOf (see page 6714)	Returns the year represented by a TDateTime value.
	YearsBetween (see page 6714)	Returns the approximate number of years between two specified TDateTime values.
	YearSpan (see page 6715)	Returns the approximate number of years (including fractions thereof) between two specified TDateTime values.
	Yesterday (see page 6716)	Returns a TDateTime value that represents the preceding day.

Variables

Name	Description
ApproxDaysPerMonth (see page 6717)	This is variable DateUtils.ApproxDaysPerMonth.
ApproxDaysPerYear (see page 6717)	This is variable DateUtils.ApproxDaysPerYear.

38.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CompareDate (see page 6614)	Indicates the relationship between the date portions of two TDateTime values.
	CompareDateTime (see page 6614)	Indicates the relationship between two TDateTime values.
	CompareTime (see page 6615)	Indicates the relationship between the time portions of two TDateTime values.
	DateOf (see page 6616)	Strips the time portion from a TDateTime value.
	DateTimeToJulianDate (see page 6616)	Converts a TDateTime value into a Julian date.
	DateTimeToModifiedJulianDate (see page 6617)	Converts a TDateTime value into a modified Julian date.
	DateTimeToUnix (see page 6617)	Converts a TDateTime value into a Unix/Linux-style date-and-time value.
	DayOf (see page 6618)	Returns the day of the month represented by a TDateTime value.
	DayOfTheMonth (see page 6618)	Returns the day of the month represented by a TDateTime value.
	DayOfTheWeek (see page 6619)	Returns the day of the week represented by a TDateTime value.
	DayOfTheYear (see page 6620)	Returns the number of days between a specified TDateTime value and December 31 of the previous year.
	DaysBetween (see page 6621)	Returns the number of whole days between two specified TDateTime values.
	DaysInAMonth (see page 6622)	Returns the number of days in a specified month of a specified year.
	DaysInAYear (see page 6622)	Returns the number of days in a specified year.
	DaysInMonth (see page 6623)	Returns the number of days in the month of a specified TDateTime value.
	DaysInYear (see page 6623)	Returns the number of days in the year of a specified TDateTime value.
	DaySpan (see page 6624)	Returns the number of days (including fractional days) between two specified TDateTime values.
	DecodeDateDay (see page 6624)	Returns the year and day of the year for a specified TDateTime.
	DecodeDateMonthWeek (see page 6625)	Returns the year, month, week of the month, and day of the week for a specified TDateTime.
	DecodeDateTime (see page 6626)	Returns Year, Month, Day, Hour, Minute, Second, and Millisecond values for a TDateTime.
	DecodeDateWeek (see page 6627)	Returns the year, week of the year, and day of the week for a specified TDateTime value object.
	DecodeDayOfWeekInMonth (see page 6628)	For a given TDateTime value, returns the year, month, day of the week, and the count of that day of the week in the month.
	EncodeDateDay (see page 6629)	Returns a TDateTime that represents a specified day of the year for a specified year.
	EncodeDateMonthWeek (see page 6629)	Returns a TDateTime that represents a specified day of a specified week in a specified month and year.
	EncodeDateTime (see page 6630)	Returns a TDateTime that represents a specified year, month, day, hour, minute, second, and millisecond.
	EncodeDateWeek (see page 6631)	Returns a TDateTime that represents a specified day of a specified week in a specified year.
	EncodeDayOfWeekInMonth (see page 6632)	Returns a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.
	EndOfADay (see page 6633)	Returns a TDateTime that represents the last millisecond of a specified day.
	EndOfADay (see page 6633)	Returns a TDateTime that represents the last millisecond of a specified day.
	EndOfAMonth (see page 6634)	Returns a TDateTime that represents the last millisecond of the last day of a specified month.
	EndOfAWeek (see page 6635)	Returns a TDateTime object value that represents the last millisecond of a specified day of a specified week.
	EndOfAYear (see page 6636)	Returns a TDateTime that represents the last millisecond of a specified year.
	EndOfTheDay (see page 6636)	Returns a TDateTime that represents the last millisecond of the day identified by a specified TDateTime.
	EndOfTheMonth (see page 6637)	Returns a TDateTime that represents the last millisecond of the last day of the month identified by a specified TDateTime.

	EndOfTheWeek (see page 6637)	Returns a TDateTime that represents the last millisecond of the last day of the week identified by a specified TDateTime.
	EndOfTheYear (see page 6638)	Returns a TDateTime that represents the last millisecond of the last day of the year identified by a specified TDateTime.
	HourOf (see page 6638)	Returns the hour of the day represented by a TDateTime value.
	HourOfTheDay (see page 6639)	Returns the hour of the day represented by a TDateTime value.
	HourOfTheMonth (see page 6640)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the month.
	HourOfTheWeek (see page 6641)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the week.
	HourOfTheYear (see page 6641)	Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the year.
	HoursBetween (see page 6642)	Returns the number of whole hours between two specified TDateTime values.
	HourSpan (see page 6643)	Returns the number of Hours (including fractional Hours) between two specified TDateTime values.
	IncDay (see page 6643)	Returns a date shifted by a specified number of days.
	IncHour (see page 6644)	Returns a date/time value shifted by a specified number of hours.
	IncMilliSecond (see page 6645)	Returns a date/time value shifted by a specified number of milliseconds.
	IncMinute (see page 6645)	Returns a date/time value shifted by a specified number of minutes.
	IncSecond (see page 6646)	Returns a date/time value shifted by a specified number of seconds.
	IncWeek (see page 6647)	Returns a date shifted by a specified number of weeks.
	IncYear (see page 6647)	Returns a date shifted by a specified number of years.
	InvalidDateDayError (see page 6648)	This is function DateUtils.InvalidDateDayError.
	InvalidDateMonthWeekError (see page 6648)	This is function DateUtils.InvalidDateMonthWeekError.
	InvalidDateTimeError (see page 6649)	This is function DateUtils.InvalidDateTimeError.
	InvalidDateWeekError (see page 6649)	This is function DateUtils.InvalidDateWeekError.
	InvalidDayOfWeekInMonthError (see page 6650)	This is function DateUtils.InvalidDayOfWeekInMonthError.
	IsInLeapYear (see page 6650)	Indicates whether a specified TDateTime value occurs in a leap year.
	IsPM (see page 6650)	Indicates whether the time portion of a specified TDateTime value occurs after noon.
	IsSameDay (see page 6651)	Indicates whether a specified TDateTime value occurs on a the same day as a criterion date.
	IsToday (see page 6651)	Indicates whether a specified TDateTime value occurs on the current date.
	IsValidDate (see page 6652)	Indicates whether a specified year, month, and day represent a valid date.
	IsValidDateDay (see page 6652)	Indicates whether a specified year and day of the year represent a valid date.
	IsValidDateMonthWeek (see page 6653)	Indicates whether a specified year, month, week of the month, and day of the week represent a valid date.
	IsValidDateTime (see page 6654)	Indicates whether a specified year, month, day, hour, minute, second, and millisecond represent a valid date and time.
	IsValidDateWeek (see page 6654)	Indicates whether a specified year, week of the year, and day of the week represent a valid date.
	IsValidTime (see page 6655)	Indicates whether a specified hour, minute, second, and millisecond represent a valid date and time.
	JulianDateToDateTime (see page 6656)	Converts a Julian date to a TDateTime value.
	MilliSecondOf (see page 6656)	Returns the millisecond of the second represented by a TDateTime value.
	MilliSecondOfTheDay (see page 6657)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same day.
	MilliSecondOfTheHour (see page 6658)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same hour.
	MilliSecondOfTheMinute (see page 6659)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the same minute.
	MilliSecondOfTheMonth (see page 6659)	Returns the number of milliseconds between a specified TDateTime value and the beginning of the month.
	MilliSecondOfTheSecond (see page 6660)	Returns the millisecond of the second represented by a TDateTime value.
	MilliSecondOfTheWeek (see page 6661)	Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the week.
	MilliSecondOfTheYear (see page 6661)	Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the year.
	MilliSecondsBetween (see page 6662)	Returns the number of milliseconds between two specified TDateTime values.
	MilliSecondSpan (see page 6663)	Returns the number of milliseconds between two specified TDateTime values.

	MinuteOf (see page 6663)	Returns the minute of the hour represented by a TDateTime value.
	MinuteOfTheDay (see page 6664)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the same day.
	MinuteOfTheHour (see page 6665)	Returns the number of minutes between a specified TDateTime value and the beginning of the same hour.
	MinuteOfTheMonth (see page 6666)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the month.
	MinuteOfTheWeek (see page 6666)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the week.
	MinuteOfTheYear (see page 6667)	Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the year.
	MinutesBetween (see page 6668)	Returns the number of minutes between two specified TDateTime values.
	MinuteSpan (see page 6668)	Returns the number of minutes, including fractions thereof, between two specified TDateTime values.
	ModifiedJulianDateToDateTime (see page 6669)	Converts a modified Julian date to a TDateTime value.
	MonthOf (see page 6670)	Returns the month of the year represented by a TDateTime value.
	MonthOfTheYear (see page 6670)	Returns the month of the year represented by a TDateTime value.
	MonthsBetween (see page 6671)	Returns the approximate number of months between two specified TDateTime values.
	MonthSpan (see page 6672)	Returns the approximate number of months, including fractions, between two specified TDateTime values.
	NthDayOfWeek (see page 6672)	Returns which occurrence of its weekday a specified TDateTime value represents.
	RecodeDate (see page 6673)	Replaces the date portion of a specified TDateTime value.
	RecodeDateTime (see page 6674)	Selectively replaces parts of a specified TDateTime value.
	RecodeDay (see page 6675)	Replaces the day of the month for a specified TDateTime value.
	RecodeHour (see page 6675)	Replaces the hour of the day for a specified TDateTime value.
	RecodeMilliSecond (see page 6676)	Replaces the millisecond of the second for a specified TDateTime value.
	RecodeMinute (see page 6677)	Replaces the minute of the hour for a specified TDateTime value.
	RecodeMonth (see page 6678)	Replaces the month of the year for a specified TDateTime value.
	RecodeSecond (see page 6678)	Replaces the second of the minute for a specified TDateTime value.
	RecodeTime (see page 6679)	Replaces the time portion of a specified TDateTime value.
	RecodeYear (see page 6680)	Replaces the year for a specified TDateTime value.
	SameDate (see page 6681)	Indicates whether two TDateTime values represent the same year, month, and day.
	SameDateTime (see page 6681)	Indicates whether two TDateTime values represent the same year, month, day, hour, minute, second, and millisecond.
	SameTime (see page 6682)	Indicates whether two TDateTime values represent the same time of day, ignoring the date portion.
	SecondOf (see page 6682)	Returns the second of the minute represented by a TDateTime value.
	SecondOfTheDay (see page 6683)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the same day.
	SecondOfTheHour (see page 6684)	Returns the number of seconds between a specified TDateTime value and the beginning of the same hour.
	SecondOfTheMinute (see page 6685)	Returns the number of seconds between a specified TDateTime value and the beginning of the same minute.
	SecondOfTheMonth (see page 6685)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the month.
	SecondOfTheWeek (see page 6686)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the first day of the week.
	SecondOfTheYear (see page 6687)	Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the year.
	SecondsBetween (see page 6687)	Returns the number of seconds between two specified TDateTime values.
	SecondSpan (see page 6688)	Returns the number of seconds (including fractions thereof) between two specified TDateTime values.
	StartOfADay (see page 6689)	Returns a TDateTime that represents 12:00:00:00 AM on a specified day.
	StartOfADay (see page 6689)	Returns a TDateTime that represents 12:00:00:00 AM on a specified day.
	StartOfAMonth (see page 6690)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of a specified month.
	StartOfAWeek (see page 6690)	Returns a TDateTime that represents 1the first moment on a specified day of a specified week.

	StartOfAYear (see page 6691)	Returns a TDateTime that represents the first moment on the first day of a specified year.
	StartOfTheDay (see page 6692)	Returns a TDateTime that represents 12:00:00:00 AM on the day identified by a specified TDateTime.
	StartOfTheMonth (see page 6692)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the month identified by a specified TDateTime.
	StartOfTheWeek (see page 6693)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the week identified by a specified TDateTime.
	StartOfTheYear (see page 6693)	Returns a TDateTime that represents 12:00:00:00 AM on the first day of the year identified by a specified TDateTime.
	TimeOf (see page 6694)	Strips the date portion from a TDateTime value.
	Today (see page 6694)	Returns a TDateTime value that represents the current date.
	Tomorrow (see page 6695)	Returns a TDateTime value that represents the following day.
	TryEncodeDateDay (see page 6695)	Calculates the TDateTime value that represents a specified day of the year for a specified year.
	TryEncodeDateMonthWeek (see page 6696)	Calculates the TDateTime value that represents a specified day of a specified week in a specified month and year.
	TryEncodeDateTime (see page 6697)	Calculates the TDateTime value that represents a specified year, month, day, hour, minute, second, and millisecond.
	TryEncodeDateWeek (see page 6698)	Calculates the TDateTime value that represents a specified day of a specified week in a specified year.
	TryEncodeDayOfWeekInMonth (see page 6699)	Calculates a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.
	TryJulianDateToDateTime (see page 6700)	Converts a Julian date to a TDateTime value.
	TryModifiedJulianDateToDateTime (see page 6701)	Converts a modified Julian date to a TDateTime value.
	TryRecodeDateTime (see page 6702)	Selectively replaces parts of a specified TDateTime value.
	UnixToDateTime (see page 6703)	Converts a Unix/Linux style date-and-time value to a TDateTime value.
	WeekOf (see page 6703)	Returns the week of the year represented by a TDateTime value.
	WeekOfTheMonth (see page 6704)	Returns the week of the month represented by a TDateTime value.
	WeekOfTheMonth (see page 6704)	Returns the week of the month represented by a TDateTime value.
	WeekOfTheYear (see page 6705)	Returns the week of the year represented by a TDateTime value.
	WeekOfTheYear (see page 6705)	Returns the week of the year represented by a TDateTime value.
	WeeksBetween (see page 6706)	Returns the number of whole weeks between two specified TDateTime values.
	WeeksInAYear (see page 6706)	Returns the number of weeks in a specified year.
	WeeksInYear (see page 6707)	Returns the number of weeks in the year of a specified TDateTime value.
	WeekSpan (see page 6708)	Returns the number of weeks (including fractional weeks) between two specified TDateTime values.
	WithinPastDays (see page 6708)	Indicates whether two dates are within a specified number of days of each other.
	WithinPastHours (see page 6709)	Indicates whether two date/time values are within a specified number of hours of each other.
	WithinPastMilliSeconds (see page 6710)	Indicates whether two date/time values are within a specified number of milliseconds of each other.
	WithinPastMinutes (see page 6710)	Indicates whether two date/time values are within a specified number of minutes of each other.
	WithinPastMonths (see page 6711)	Indicates whether two date/time values are within a specified number of months of each other.
	WithinPastSeconds (see page 6712)	Indicates whether two date/time values are within a specified number of seconds of each other.
	WithinPastWeeks (see page 6712)	Indicates whether two date/time values are within a specified number of weeks of each other.
	WithinPastYears (see page 6713)	Indicates whether two date/time values are within a specified number of years of each other.
	YearOf (see page 6714)	Returns the year represented by a TDateTime value.
	YearsBetween (see page 6714)	Returns the approximate number of years between two specified TDateTime values.
	YearSpan (see page 6715)	Returns the approximate number of years (including fractions thereof) between two specified TDateTime values.
	Yesterday (see page 6716)	Returns a TDateTime value that represents the preceding day.

38.1.1 DateUtils.CompareDate Function

Indicates the relationship between the date portions of two TDateTime values.

Pascal

```
function CompareDate(const A: TDateTime; const B: TDateTime): TValueRelationship;
```

C++

```
TValueRelationship CompareDate(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call CompareDate to compare the two TDateTime values specified by A and B. CompareDate returns

LessThanValue if A occurs on a day prior to the day specified by B.

EqualsValue if A occurs on the same day as B, ignoring the time of day.

GreaterThanValue if A occurs on a day that follows the day specified by B.

See Also

SameDate (see page 6681)

ConvUnitCompareValue

CompareValue

CompareDateTime (see page 6614)

CompareTime (see page 6615)

IsSameDay (see page 6651)

38.1.2 DateUtils.CompareDateTime Function

Indicates the relationship between two TDateTime values.

Pascal

```
function CompareDateTime(const A: TDateTime; const B: TDateTime): TValueRelationship;
```

C++

```
TValueRelationship CompareDateTime(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call CompareDateTime to compare the two TDateTime values specified by A and B. CompareDateTime returns

LessThanValue if A is earlier than B.

EqualsValue if A is the same as B.

GreaterThanValue if A is later than B.

Note: CompareDateTime differs from a direct comparison of the corresponding double precision values in that two TDateTime values are considered the same if they have the same value down to the millisecond. It is possible to create two TDateTime values that differ numerically when viewed as doubles, but which represent the same year, month, day, hour, minute, second, and millisecond.

See Also

SameDateTime (see page 6681)

ConvUnitCompareValue

CompareValue

CompareDate (see page 6614)

CompareTime (see page 6615)

IsSameDay (see page 6651)

38.1.3 DateUtils.CompareTime Function

Indicates the relationship between the time portions of two TDateTime values.

Pascal

```
function CompareTime(const A: TDateTime; const B: TDateTime): TValueRelationship;
```

C++

```
TValueRelationship CompareTime(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call CompareTime to compare the two TDateTime values specified by A and B. CompareTime returns

LessThanValue if A occurs earlier in the day than B (even if A occurs on a later day than B).

EqualsValue if A occurs at the same time of day as B, ignoring of the date portion of the two values.

GreaterThanValue if A occurs later in the day than B (even if A occurs on an earlier day than B).

See Also

SameTime (see page 6682)

ConvUnitCompareValue

CompareValue

CompareDateTime (see page 6614)

CompareDate (see page 6614)

38.1.4 DateUtils.DateOf Function

Strips the time portion from a TDateTime value.

Pascal

```
function DateOf(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime DateOf(const TDateTime AValue);
```

File

DateUtils

Description

Call DateOf to convert a TDateTime value to a TDateTime value that includes only the date information (sets the time portion to 0, which means midnight).

See Also

DecodeDate

ReplaceTime

TimeOf (see page 6694)

38.1.5 DateUtils.DateTimeToJulianDate Function

Converts a TDateTime value into a Julian date.

Pascal

```
function DateTimeToJulianDate(const AValue: TDateTime): Double;
```

C++

```
Double DateTimeToJulianDate(const TDateTime AValue);
```

File

DateUtils

Description

Call DateTimeToJulianDate to convert a TDateTime value the corresponding Julian date.

The Julian date is the number of days, including fractional days, since 4713 BC January 1, Greenwich noon. Julian dates are used by astronomers, geophysicist, and others who need an unambiguous dating system based on continuing day counts.

See Also

DateTimeToModifiedJulianDate (see page 6617)

JulianDateToDateTime (see page 6656)

ModifiedJulianDateToDateTime (see page 6669)

Convert

TryJulianDateToDateTime (see page 6700)

TryModifiedJulianDateToDateTime (see page 6701)

38.1.6 DateUtils.DateTimeToModifiedJulianDate Function

Converts a TDateTime value into a modified Julian date.

Pascal

```
function DateTimeToModifiedJulianDate(const AValue: TDateTime): Double;
```

C++

```
Double DateTimeToModifiedJulianDate(const TDateTime AValue);
```

File

DateUtils

Description

Call DateTimeToModifiedJulianDate to convert a TDateTime value the corresponding modified Julian date.

The modified Julian date is the number of days, including fractional days, since Greenwich midnight on November 17, 1858. Modified Julian dates are based on Julian dates, but adjusted to use midnight rather than noon as a starting point and to use a more recent date as a starting point.

See Also

DateTimeToJulianDate (see page 6616)

JulianDateToDateTime (see page 6656)

ModifiedJulianDateToDateTime (see page 6669)

Convert

TryJulianDateToDateTime (see page 6700)

TryModifiedJulianDateToDateTime (see page 6701)

38.1.7 DateUtils.DateTimeToUnix Function

Converts a TDateTime value into a Unix/Linux-style date-and-time value.

Pascal

```
function DateTimeToUnix(const AValue: TDateTime): Int64;
```

C++

```
Int64 DateTimeToUnix(const TDateTime AValue);
```

File

DateUtils

Description

Call DateTimeToUnix to convert a TDateTime value the corresponding Unix/Linux encoding of the same date and time.

Unix/Linux date-and-time values are encoded as the number of seconds since midnight at the start of January 1, 1970.

See Also

UnixToDateTime (see page 6703)

Convert

38.1.8 DateUtils.DayOf Function

Returns the day of the month represented by a TDateTime value.

Pascal

```
function DayOf(const AValue: TDateTime): Word;
```

C++

```
Word DayOf(const TDateTime AValue);
```

File

DateUtils

Description

Call DayOf to obtain the day of the month represented by a specified TDateTime value. DayOf returns a value between 1 and 31.

Note: DayOf returns the same value as the DayOfTheMonth (see page 6618) function.

See Also

DecodeDate

DayOfTheYear (see page 6620)

DayOfTheMonth (see page 6618)

HourOf (see page 6638)

MilliSecondOf (see page 6656)

MinuteOf (see page 6663)

MonthOf (see page 6670)

RecodeDateDay

SecondOf (see page 6682)

WeekOf (see page 6703)

YearOf (see page 6714)

38.1.9 DateUtils.DayOfTheMonth Function

Returns the day of the month represented by a TDateTime value.

Pascal

```
function DayOfTheMonth(const AValue: TDateTime): Word;
```

C++

```
Word DayOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call DayOfTheMonth to obtain the day of the month represented by a specified TDateTime value. DayOfTheMonth returns a value between 1 and 31.

Note: DayOfTheMonth returns the same value as the DayOf (see page 6618) function.

See Also

DecodeDate

DayOfTheYear (see page 6620)

DayOfTheWeek (see page 6619)

DayOf (see page 6618)

DaysInAMonth (see page 6622)

HourOfTheMonth (see page 6640)

MilliSecondOfTheMonth (see page 6659)

MinuteOfTheMonth (see page 6666)

SecondOfTheMonth (see page 6685)

WeekOfTheMonth (see page 6704)

StartOfTheMonth (see page 6692)

DaysBetween (see page 6621)

38.1.10 DateUtils.DayOfTheWeek Function

Returns the day of the week represented by a TDateTime value.

Pascal

```
function DayOfTheWeek(const AValue: TDateTime): Word;
```

C++

```
Word DayOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

Call DayOfTheWeek to obtain the day of the week represented by a specified TDateTime value. DayOfTheWeek returns a value between 1 and 7, where 1 indicates Monday and 7 indicates Sunday.

Note: DayOfTheWeek is ISO 8601 compliant (where Monday is considered the first day of the week). To obtain the day of the week where Sunday is considered the first day of the week, use the DayOfWeek function instead.

Tip: To make the return value more readable, use the Day of week constants.

See Also

DecodeDate

DayOfTheYear (see page 6620)

DayOfTheMonth (see page 6618)

DayOfWeek

HourOfTheWeek (see page 6641)

MilliSecondOfTheWeek (see page 6661)

DaysBetween (see page 6621)

DecodeDateWeek (see page 6627)

DecodeDayOfWeekInMonth (see page 6628)

38.1.11 DateUtils.DayOfTheYear Function

Returns the number of days between a specified TDateTime value and December 31 of the previous year.

Pascal

```
function DayOfTheYear(const AValue: TDateTime): Word;
```

C++

```
Word DayOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call DayOfTheYear to obtain the ordinal position of a TDateTime value's day within its year. Thus, a TDateTime value that refers to January 1 generates a result of 1, dates on January 2 return 2, dates on February 1 return 32, and so on.

StartOfTheYear (see page 6693)

DaysBetween (see page 6621)

DecodeDateDay (see page 6624)

38.1.12 DateUtils.DaysBetween Function

Returns the number of whole days between two specified TDateTime values.

Pascal

```
function DaysBetween(const ANow: TDateTime; const AThen: TDateTime): Integer;
```

C++

```
int DaysBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call DaysBetween to obtain the difference, in days, between two TDateTime values.

DaysBetween counts only whole days. Thus, DaysBetween reports the difference between Dec 31, 1999 11:59 PM and Jan 1, 2000 11:58 PM as 0 because the difference is one minute short of an entire day.

See Also

WeeksBetween (see page 6706)

YearsBetween (see page 6714)

WithinPastDays (see page 6708)

38.1.13 DateUtils.DaysInAMonth Function

Returns the number of days in a specified month of a specified year.

Pascal

```
function DaysInAMonth(const AYear: Word; const AMonth: Word): Word;
```

C++

```
Word DaysInAMonth(const Word AYear, const Word AMonth);
```

File

DateUtils

Description

Call DaysInAMonth to obtain the number of days in the specified month of the specified year.

AYear is a year between 1 and 9999 (inclusive).

AMonth is a month between 1 and 12 (inclusive).

See Also

DaysInAYear (see page 6622)

DaysInMonth (see page 6623)

DaysBetween (see page 6621)

DayOfTheMonth (see page 6618)

IsLeapYear

38.1.14 DateUtils.DaysInAYear Function

Returns the number of days in a specified year.

Pascal

```
function DaysInAYear(const AYear: Word): Word;
```

C++

```
Word DaysInAYear(const Word AYear);
```

File

DateUtils

Description

Call DaysInAYear to obtain the number of days in the year specified by AYear. AYear is a year between 1 and 9999 (inclusive).

See Also

DaysInYear (see page 6623)

DaysInAMonth (see page 6622)

DaysBetween (see page 6621)

DayOfTheYear (see page 6620)

WeeksInAYear (see page 6706)

38.1.15 DateUtils.DaysInMonth Function

Returns the number of days in the month of a specified TDateTime value.

Pascal

```
function DaysInMonth(const AValue: TDateTime): Word;
```

C++

```
Word DaysInMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call DaysInMonth to obtain the number of days in the month of the TDateTime value specified by AValue.

See Also

DaysInYear (see page 6623)

DaysInAMonth (see page 6622)

DaysBetween (see page 6621)

DayOfTheMonth (see page 6618)

IsInLeapYear (see page 6650)

StartOfTheMonth (see page 6692)

EndOfTheMonth (see page 6637)

38.1.16 DateUtils.DaysInYear Function

Returns the number of days in the year of a specified TDateTime value.

Pascal

```
function DaysInYear(const AValue: TDateTime): Word;
```

C++

```
Word DaysInYear(const TDateTime AValue);
```

File

DateUtils

Description

Call DaysInYear to obtain the number of days in the year of the TDateTime value specified by AValue.

See Also

DaysInAYear (see page 6622)

DaysInMonth (see page 6623)

DaysBetween (see page 6621)

DayOfTheYear (see page 6620)

IsInLeapYear (see page 6650)

StartOfTheYear (see page 6693)

EndOfTheYear (see page 6638)

WeeksInYear (see page 6707)

38.1.17 DateUtils.DaySpan Function

Returns the number of days (including fractional days) between two specified TDateTime values.

Pascal

```
function DaySpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double DaySpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call DaySpan to obtain the difference, in days, between two TDateTime values. Unlike the DaysBetween (see page 6621) function, which only counts whole days, DaySpan reports incomplete days as a fraction of an entire day.

See Also

DaysBetween (see page 6621)

HourSpan (see page 6643)

MillisecondSpan

MinuteSpan (see page 6668)

MonthSpan (see page 6672)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.18 DateUtils.DecodeDateDay Function

Returns the year and day of the year for a specified TDateTime.

Pascal

```
procedure DecodeDateDay(const AValue: TDateTime; out AYear: Word; out ADayOfYear: Word);
```

C++

```
DecodeDateDay(const TDateTime AValue, Word AYear, Word ADayOfYear);
```

File

DateUtils

Description

DecodeDateDay returns the day of the year for a specified date/time value, along with the year in which that day occurs.

AValue is the date/time value about which you want information.

AYear returns the year that AValue represents.

ADayOfYear returns the day within AYear that AValue represents, where 1 is January 1.

See Also

DecodeDateTime (see page 6626)

YearOf (see page 6714)

DecodeDate

DayOfTheYear (see page 6620)

DecodeDateWeek (see page 6627)

EncodeDateDay (see page 6629)

DecodeDateMonthWeek (see page 6625)

DecodeDayOfWeekInMonth (see page 6628)

38.1.19 DateUtils.DecodeDateMonthWeek Function

Returns the year, month, week of the month, and day of the week for a specified TDateTime.

Pascal

```
procedure DecodeDateMonthWeek(const AValue: TDateTime; out AYear: Word; out AMonth: Word; out
AWeekOfMonth: Word; out ADayOfWeek: Word);
```

C++

```
DecodeDateMonthWeek(const TDateTime AValue, Word AYear, Word AMonth, Word AWeekOfMonth, Word
ADayOfWeek);
```

File

DateUtils

Description

DecodeDateMonthWeek returns the day of the week and week of the month for a specified date/time value, along with the month and year in which that day and week occur.

AValue is the date/time value about which you want information.

AYear returns the year that AValue represents.

AMonth returns the month that AValue represents, where 1 is January and 12 is December.

AWeekOfMonth returns the week within AMonth that AValue represents, where 1 is the first week with four or more days.

ADayOfWeek returns the day within AWeekOfMonth that AValue represents, where 1 Monday and 7 is Sunday.

Note: The definitions for AWeekOfMonth and ADayOfWeek reflect the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

NthDayOfWeek (see page 6672)

38.1.20 DateUtils.DecodeDateTime Function

Returns Year, Month, Day, Hour, Minute, Second, and Millisecond values for a TDateTime.

Pascal

```
procedure DecodeDateTime(const AValue: TDateTime; out AYear: Word; out AMonth: Word; out ADay:
Word; out AHour: Word; out AMinute: Word; out ASecond: Word; out AMilliSecond: Word);
```

C++

```
DecodeDateTime(const TDateTime AValue, Word AYear, Word AMonth, Word ADay, Word AHour, Word
AMinute, Word ASecond, Word AMilliSecond);
```

File

DateUtils

Description

The DecodeDateTime procedure breaks the value specified as the AValue parameter into Year, Month, Day of the month, Hour, Minute, Second, and MilliSecond values and returns these as the AYear, AMonth, ADay, AHour, AMinute, ASecond, and AMilliSecond parameters.

EncodeDateTime (see page 6630)

38.1.21 DateUtils.DecodeDateWeek Function

Returns the year, week of the year, and day of the week for a specified TDateTime value object.

Pascal

```
procedure DecodeDateWeek(const AValue: TDateTime; out AYear: Word; out AWeekOfYear: Word; out
ADayOfWeek: Word);
```

C++

```
DecodeDateWeek(const TDateTime AValue, Word AYear, Word AWeekOfYear, Word ADayOfWeek);
```

File

DateUtils

Description

DecodeDateWeek returns the day of the week and week of the year for a specified date/time value, along with the year in which that day and week occur.

AValue is the date/time value about which you want information.

AYear returns the year that AValue represents.

AWeekOfYear returns the week within AYear that AValue represents, where 1 is the first week with four or more days.

ADayOfWeek returns the day within AWeekOfYear that AValue represents, where 1 Monday and 7 is Sunday.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

38.1.22 DateUtils.DecodeDayOfWeekInMonth Function

For a given TDateTime value, returns the year, month, day of the week, and the count of that day of the week in the month.

Pascal

```
procedure DecodeDayOfWeekInMonth(const AValue: TDateTime; out AYear: Word; out AMonth: Word;
out ANthDayOfWeek: Word; out ADayOfWeek: Word);
```

C++

```
DecodeDayOfWeekInMonth(const TDateTime AValue, Word AYear, Word AMonth, Word ANthDayOfWeek,
Word ADayOfWeek);
```

File

DateUtils

Description

For a given TDateTime value, DecodeDayOfWeekInMonth returns the day of the week and, for that day of the week, which occurrence it is within the month.

AValue is the date/time value about which you want information.

AYear returns the year that AValue represents.

AMonth returns the month in which AValue occurs. This value can be from 1 to 12, inclusive.

ANthDayOfWeek indicates the count for the day of the week represented by AValue. For example, if AValue represents the 2nd Tuesday of the month, ANthDayOfWeek returns 2. Note that this value may differ from the value that the WeekOfTheMonth (see page 6704) function returns, because DecodeDayOfWeekInMonth counts every occurrence of the given weekday, while WeekOfTheMonth (see page 6704) only counts a week if it includes 4 or more days in the month. Thus, for example, if AValue represents a Saturday that is the first day of a month, DecodeDayOfWeekInMonth returns 1 as the value of ANthDayOfWeek, while WeekOfTheMonth (see page 6704) returns 5 (or maybe 4), indicating the last week of the previous month.

ADayOfWeek returns the day of the week that AValue represents, where 1 Monday and 7 is Sunday.

Note: The definition for ADayOfWeek follows the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

DecodeDayOfWeekInMonth

38.1.23 DateUtils.EncodeDateDay Function

Returns a TDateTime that represents a specified day of the year for a specified year.

Pascal

```
function EncodeDateDay(const AYear: Word; const ADayOfYear: Word): TDateTime;
```

C++

```
TDateTime EncodeDateDay(const Word AYear, const Word ADayOfYear);
```

File

DateUtils

Description

EncodeDateDay returns a TDateTime for the date specified by the AYear and ADayOfYear parameters. The time portion of the return value is 0 (Midnight at the start of the specified day).

AYear is the year. It can be any value between 1 and 9999 (inclusive).

ADayOfYear is the day of the year, where 1 is January , 2 is January 2, 32 is February 1, and so on.

If AYear is not within range, or if ADayOfYear is less than 1 or greater than the number of days in AYear, EncodeDateDay raises an EConvertError exception.

EncodeDateMonthWeek (see page 6629)

38.1.24 DateUtils.EncodeDateMonthWeek Function

Returns a TDateTime that represents a specified day of a specified week in a specified month and year.

Pascal

```
function EncodeDateMonthWeek(const AYear: Word; const AMonth: Word; const AWeekOfMonth: Word;
const ADayOfWeek: Word): TDateTime;
```

C++

```
TDateTime EncodeDateMonthWeek(const Word AYear, const Word AMonth, const Word AWeekOfMonth,
const Word ADayOfWeek);
```

File

DateUtils

Description

EncodeDateMonthWeek returns a TDateTime for the date specified by the AYear, AMonth, AWeekOfMonth, and ADayOfWeek parameters. The time portion of the return value is 0 (Midnight at the start of the specified day).

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AMonth is the month. It can be any value between 1 and 12 (inclusive).

AWeekOfMonth is the week within that month, where 1 is the first week that includes four or more days. Note that if the first calendar day of the month is a Friday, Saturday, or Sunday, then those three days must be expressed using AMonth set to the previous month and AWeekOfMonth set to the number of weeks in the previous month. Similarly, if the last calendar day of the month is a Monday, Tuesday, or Wednesday, then those three days are expressed with AMonth set to the following month and AWeekOfMonth set to 1.

ADayOfWeek is the day of the week, where 1 Monday, 2 is Tuesday, and so on.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

If any of the parameters are not in range, EncodeDateMonthWeek raises an EConvertError exception.

Note: The definitions for AWeekOfMonth and ADayOfWeek reflect the ISO 8601 standard.

38.1.25 DateUtils.EncodeDateTime Function

Returns a TDateTime that represents a specified year, month, day, hour, minute, second, and millisecond.

Pascal

```
function EncodeDateTime(const AYear: Word; const AMonth: Word; const ADay: Word; const AHour:
```

```
Word; const AMinute: Word; const ASecond: Word; const AMilliSecond: Word): TDateTime;
```

C++

```
TDateTime EncodeDateTime(const Word AYear, const Word AMonth, const Word ADay, const Word
AHour, const Word AMinute, const Word ASecond, const Word AMilliSecond);
```

File

DateUtils

Description

EncodeDateTime returns a TDateTime from the values specified as the AYear, AMonth, ADay, AHour, AMinute, ASecond, and AMilliSecond parameters.

The year must be between 1 and 9999.

Valid month values are 1 through 12.

Valid day values are 1 through 28, 29, 30, or 31, depending on the month value. For example, the possible day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the year value specifies a leap year.

Valid hour values are 0 through 24. (If the specified hour is 24, the minute, second, and millisecond values should all be 0, and the resulting TDateTime value represents midnight at the end of the specified day and the beginning of the next day).

Valid minute values are 0 through 59.

Valid second values are 0 through 59.

Valid millisecond values are 0 through 999.

If the specified values are not within range, EncodeDateTime raises an EConvertError exception.

38.1.26 DateUtils.EncodeDateWeek Function

Returns a TDateTime that represents a specified day of a specified week in a specified year.

Pascal

```
function EncodeDateWeek(const AYear: Word; const AWeekOfYear: Word; const ADayOfWeek: Word =
1): TDateTime;
```

C++

```
TDateTime EncodeDateWeek(const Word AYear, const Word AWeekOfYear, const Word ADayOfWeek = 1);
```

File

DateUtils

Description

EncodeDateWeek returns a TDateTime for the date specified by the AYear, AWeekOfYear, and ADayOfWeek parameters. The time portion of the return value is 0 (Midnight at the start of the specified day).

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AWeekOfYear is the week within that year, where 1 is the first week that includes four or more days. Note that if the first calendar day of the year is a Friday, Saturday, or Sunday, then those three days must be expressed using AYear set to the previous year and AWeekOfYear set to the number of weeks in the previous year. Similarly, if the last calendar day of the year is a Monday, Tuesday, or Wednesday, then those three days are expressed with AYear set to the following year and AWeekOfYear set to 1.

ADayOfWeek is the day of the week, where 1 Monday, 2 is Tuesday, and so on.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

If AYear is not within range, AWeekOfYear is less than 1 or greater than the number of weeks in AYear, or ADayOfWeek is less than 1 or greater than 7, EncodeDateWeek raises an EConvertError exception.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

38.1.27 DateUtils.EncodeDayOfWeekInMonth Function

Returns a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.

Pascal

```
function EncodeDayOfWeekInMonth(const AYear: Word; const AMonth: Word; const ANthDayOfWeek:
Word; const ADayOfWeek: Word): TDateTime;
```

C++

```
TDateTime EncodeDayOfWeekInMonth(const Word AYear, const Word AMonth, const Word
ANthDayOfWeek, const Word ADayOfWeek);
```

File

DateUtils

Description

EncodeDayOfWeekInMonth returns a TDateTime for the date specified by the AYear, AMonth, ANthDayOfWeek, and ADayOfWeek parameters. The time portion of the return value is 0 (Midnight at the start of the specified day).

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AMonth is the month. It can be any value between 1 and 12 (inclusive).

ANthDayOfWeek indicates the occurrence for the day of the week represented by ADayOfWeek. It can be any value between 1 and 5 (inclusive), as long as this value specifies a valid date. For example, if a month does not include 5 Mondays, setting ANthDayOfWeek to 5 and ADayOfWeek to 1 causes EncodeDayOfWeekInMonth to raise an exception.

ADayOfWeek is the day of the week, where 1 Monday and 7 is Sunday.

Note: The definition for ADayOfWeek follows the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

38.1.28 DateUtils.EndOfADay Function

Returns a TDateTime that represents the last millisecond of a specified day.

Pascal

```
function EndOfADay(const AYear: Word; const AMonth: Word; const ADay: Word): TDateTime;
overload;
function EndOfADay(const AYear: Word; const ADayOfYear: Word): TDateTime; overload;
```

C++

```
TDateTime EndOfADay(const Word AYear, const Word AMonth, const Word ADay);
TDateTime EndOfADay(const Word AYear, const Word ADayOfYear);
```

File

DateUtils

Description

EndOfADay returns the last expressible moment (11:59:59.999 PM) of a specified day.

The AYear parameter specifies the year of the desired day.

The ADayOfYear parameter specifies the desired day as a day of the year, where 1 is January 1, 2 is January 2, 32 is February 1, and so on.

The AMonth and ADay parameters specify the desired day as a month of the year and day of the month. AMonth can range from 1 to 12. ADay can range from 1 to 28, 29, 30, or 31, depending on the values of AYear and AMonth.

If the parameters do not specify a valid date, EndOfADay raises an EConvertError exception.

EncodeDate

38.1.29 DateUtils.EndOfAMonth Function

Returns a TDateTime that represents the last millisecond of the last day of a specified month.

Pascal

```
function EndOfAMonth(const AYear: Word; const AMonth: Word): TDateTime;
```

C++

```
TDateTime EndOfAMonth(const Word AYear, const Word AMonth);
```

File

DateUtils

Description

EndOfAMonth returns the last expressible moment (11:59:59.999 PM) of the last day of a specified month.

The AYear parameter specifies the year of the desired month.

The AMonth parameter specifies the month. It can range from 1 to 12.

If the parameters do not specify a valid month, EndOfAMonth raises an EConvertError exception.

See Also

EncodeDate

38.1.30 DateUtils.EndOfAWeek Function

Returns a TDateTime object value that represents the last millisecond of a specified day of a specified week.

Pascal

```
function EndOfAWeek(const AYear: Word; const AWeekOfYear: Word; const ADayOfWeek: Word = 7):
TDateTime;
```

C++

```
TDateTime EndOfAWeek(const Word AYear, const Word AWeekOfYear, const Word ADayOfWeek = 7);
```

File

DateUtils

Description

EndOfAWeek returns the last expressible moment (11:59:59.999 PM) of the specified day of the specified week.

The AYear parameter specifies the year of the desired day.

The AWeekOfYear parameter specifies the week of the year, where 1 is the first week in AYear that includes four or more days.

The ADayOfWeek parameter indicates the desired day in the specified week, where 1 is Monday, 2 is Tuesday, and so on.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

If the parameters do not specify a valid date, EndOfAWeek raises an EConvertError exception.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

38.1.31 DateUtils.EndOfAYear Function

Returns a TDateTime that represents the last millisecond of a specified year.

Pascal

```
function EndOfAYear(const AYear: Word): TDateTime;
```

C++

```
TDateTime EndOfAYear(const Word AYear);
```

File

DateUtils

Description

EndOfAYear returns the last expressible moment (December 31 at 11:59:59.999 PM) of the year specified by the AYear parameter.

See Also

EndOfTheYear (see page 6638)

EndOfADay (see page 6633)

StartOfAYear (see page 6691)

38.1.32 DateUtils.EndOfTheDay Function

Returns a TDateTime that represents the last millisecond of the day identified by a specified TDateTime.

Pascal

```
function EndOfTheDay(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime EndOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

EndOfTheDay returns the last expressible moment of the same day as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 11:59:59.999 PM and returns the result.

See Also

StartOfTheDay (see page 6692)

EndOfTheMonth (see page 6637)

EndOfTheYear (see page 6638)

EndOfTheWeek (see page 6637)

ReplaceTime

EndOfADay (see page 6633)

38.1.33 DateUtils.EndOfTheMonth Function

Returns a TDateTime that represents the last millisecond of the last day of the month identified by a specified TDateTime.

Pascal

```
function EndOfTheMonth(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime EndOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

EndOfTheMonth returns the last expressible moment of the same month as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 11:59:59.999 PM, changes the day to the last day of the month, and returns the result.

See Also

StartOfTheMonth (see page 6692)

EndOfTheDay (see page 6636)

EndOfTheYear (see page 6638)

EndOfTheWeek (see page 6637)

EndOfAMonth (see page 6634)

38.1.34 DateUtils.EndOfTheWeek Function

Returns a TDateTime that represents the last millisecond of the last day of the week identified by a specified TDateTime.

Pascal

```
function EndOfTheWeek(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime EndOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

EndOfTheWeek returns the last expressible moment of the same week as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 11:59:59.999 PM, changes the day to the last day of the week, and returns the result.

Note: EndOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

StartOfTheWeek (see page 6693)

EndOfTheDay (see page 6636)

EndOfTheYear (see page 6638)

EndOfAWeek (see page 6635)

EndOfTheMonth (see page 6637)

38.1.35 DateUtils.EndOfTheYear Function

Returns a TDateTime that represents the last millisecond of the last day of the year identified by a specified TDateTime.

Pascal

```
function EndOfTheYear(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime EndOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

EndOfTheYear returns the last expressible moment of the same year as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 11:59:59.999 PM, changes the day to December 31, and returns the result.

See Also

StartOfTheYear (see page 6693)

38.1.36 DateUtils.HourOf Function

Returns the hour of the day represented by a TDateTime value.

Pascal

```
function HourOf(const AValue: TDateTime): Word;
```

C++

```
Word HourOf(const TDateTime AValue);
```

File

DateUtils

Description

Call HourOf to obtain the hour of the day represented by a specified TDateTime value. HourOf returns a value between 0 and 23.

Note: HourOf returns the same value as the HourOfTheDay (see page 6639) function.

See Also

38.1.37 DateUtils.HourOfTheDay Function

Returns the hour of the day represented by a TDateTime value.

Pascal

```
function HourOfTheDay(const AValue: TDateTime): Word;
```

C++

```
Word HourOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

Call HourOfTheDay to obtain the hour of the day represented by a specified TDateTime value. HourOf (see page 6638) returns a value between 0 and 23.

Note: HourOfTheDay returns the same value as the HourOf (see page 6638) function.

See Also

HourOf (see page 6638)

HourOfTheYear (see page 6641)

HourOfTheMonth (see page 6640)

HourOfTheWeek (see page 6641)

HourOfTheDay

MilliSecondOfTheDay (see page 6657)

MinuteOfTheDay (see page 6664)

SecondOfTheDay (see page 6683)

HoursBetween (see page 6642)

38.1.38 DateUtils.HourOfTheMonth Function

Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the month.

Pascal

```
function HourOfTheMonth(const AValue: TDateTime): Word;
```

C++

```
Word HourOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call HourOfTheMonth to obtain the number of complete hours between AValue and 12:00 AM on the first day of the month that includes AValue.

See Also

HourOfTheDay (see page 6639)

HourOfTheWeek (see page 6641)

HourOfTheYear (see page 6641)

DayOfTheMonth (see page 6618)

MilliSecondOfTheMonth (see page 6659)

MinuteOfTheMonth (see page 6666)

SecondOfTheMonth (see page 6685)

WeekOfTheMonth (see page 6704)

StartOfTheMonth (see page 6692)

HoursBetween (see page 6642)

38.1.39 DateUtils.HourOfTheWeek Function

Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the week.

Pascal

```
function HourOfTheWeek(const AValue: TDateTime): Word;
```

C++

```
Word HourOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

Call HourOfTheWeek to obtain the number of complete hours between AValue and 12:00 AM on Monday of the week that includes AValue.

Note: HourOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

HourOfTheDay (see page 6639)

HourOfTheMonth (see page 6640)

HourOfTheYear (see page 6641)

DayOfWeek

MilliSecondOfTheWeek (see page 6661)

MinuteOfTheWeek (see page 6666)

SecondOfTheWeek (see page 6686)

StartOfTheWeek (see page 6693)

HoursBetween (see page 6642)

38.1.40 DateUtils.HourOfTheYear Function

Returns the number of hours between a specified TDateTime value and 12:00 AM of the first day of the year.

Pascal

```
function HourOfTheYear(const AValue: TDateTime): Word;
```

C++

```
Word HourOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call HourOfTheYear to obtain the number of complete hours between AValue and 12:00 AM on Jan 1 of the year that includes AValue.

See Also

HourOfTheDay (see page 6639)

HourOfTheWeek (see page 6641)

HourOfTheMonth (see page 6640)

DayOfTheYear (see page 6620)

MilliSecondOfTheYear (see page 6661)

MinuteOfTheYear (see page 6667)

MonthOfTheYear (see page 6670)

SecondOfTheYear (see page 6687)

WeekOfTheYear (see page 6705)

StartOfTheYear (see page 6693)

HoursBetween (see page 6642)

38.1.41 DateUtils.HoursBetween Function

Returns the number of whole hours between two specified TDateTime values.

Pascal

```
function HoursBetween(const ANow: TDateTime; const AThen: TDateTime): Int64;
```

C++

```
Int64 HoursBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call HoursBetween to obtain the difference, in hours, between two TDateTime values. HoursBetween counts only entire hours. Thus, HoursBetween reports the difference between 9:00 AM and 9:59:59 AM as 0 because the difference is one second short of an entire hour.

See Also

HourSpan (see page 6643)

DaysBetween (see page 6621)

MillisecondsBetween

MinutesBetween (see page 6668)

MonthsBetween (see page 6671)

SecondsBetween (see page 6687)

WeeksBetween (see page 6706)

YearsBetween (see page 6714)

WithinPastHours (see page 6709)

38.1.42 DateUtils.HourSpan Function

Returns the number of Hours (including fractional Hours) between two specified TDateTime values.

Pascal

```
function HourSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double HourSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call HourSpan to obtain the difference, in hours, between two TDateTime values. Unlike the HoursBetween (see page 6642) function, which only counts entire hours, HourSpan reports incomplete hours as a fraction of an entire hour.

See Also

HoursBetween (see page 6642)

DaySpan (see page 6624)

MillisecondSpan

MinuteSpan (see page 6668)

MonthSpan (see page 6672)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.43 DateUtils.IncDay Function

Returns a date shifted by a specified number of days.

Pascal

```
function IncDay(const AValue: TDateTime; const ANumberOfDays: Integer = 1): TDateTime;
```

C++

```
TDateTime IncDay(const TDateTime AValue, const int ANumberOfDays = 1);
```

File

DateUtils

Description

IncDay returns the value of the AValue parameter, incremented by ANumberOfDays days. ANumberOfDays can be negative, to return a date N days previous.

The time of day specified by the AValue parameter is copied to the result.

IncSecond (see page 6646)

IncWeek (see page 6647)

IncYear (see page 6647)

38.1.44 DateUtils.IncHour Function

Returns a date/time value shifted by a specified number of hours.

Pascal

```
function IncHour(const AValue: TDateTime; const ANumberOfHours: Int64 = 1): TDateTime;
```

C++

```
TDateTime IncHour(const TDateTime AValue, const Int64 ANumberOfHours = 1);
```

File

DateUtils

Description

IncHour returns the value of the AValue parameter, incremented by ANumberOfHours hours. ANumberOfHours can be negative, to return a date and time N hours prior to AValue.

See Also

DecodeDate

EncodeDate

ReplaceDate

IncMonth

IncDay (see page 6643)

IncMilliSecond (see page 6645)

IncWeek (see page 6647)

IncYear (see page 6647)

38.1.45 DateUtils.IncMilliSecond Function

Returns a date/time value shifted by a specified number of milliseconds.

Pascal

```
function IncMilliSecond(const AValue: TDateTime; const ANumberOfMilliSeconds: Int64 = 1):
TDateTime;
```

C++

```
TDateTime IncMilliSecond(const TDateTime AValue, const Int64 ANumberOfMilliSeconds = 1);
```

File

DateUtils

Description

IncMilliSecond returns the value of the AValue parameter, incremented by ANumberOfMilliSeconds milliseconds. ANumberOfMilliSeconds can be negative, to return a date and time N milliseconds prior to AValue.

See Also

DecodeDate

EncodeDate

ReplaceDate

IncMonth

IncDay (see page 6643)

IncHour (see page 6644)

IncMinute (see page 6645)

IncSecond (see page 6646)

IncYear (see page 6647)

38.1.46 DateUtils.IncMinute Function

Returns a date/time value shifted by a specified number of minutes.

Pascal

```
function IncMinute(const AValue: TDateTime; const ANumberOfMinutes: Int64 = 1): TDateTime;
```

C++

```
TDateTime IncMinute(const TDateTime AValue, const Int64 ANumberOfMinutes = 1);
```

File

DateUtils

Description

IncMinute returns the value of the AValue parameter, incremented by ANumberOfMinutes minutes. ANumberOfMinutes can be negative, to return a date and time N minutes prior to AValue.

See Also

IncWeek (see page 6647)

IncYear (see page 6647)

38.1.47 DateUtils.IncSecond Function

Returns a date/time value shifted by a specified number of seconds.

Pascal

```
function IncSecond(const AValue: TDateTime; const ANumberOfSeconds: Int64 = 1): TDateTime;
```

C++

```
TDateTime IncSecond(const TDateTime AValue, const Int64 ANumberOfSeconds = 1);
```

File

DateUtils

Description

IncSecond returns the value of the AValue parameter, incremented by ANumberOfSeconds seconds. ANumberOfSeconds can be negative, to return a date and time N seconds prior to AValue.

See Also

DecodeDate

EncodeDate

ReplaceDate

IncMonth

IncDay (see page 6643)

IncHour (see page 6644)

IncMilliSecond (see page 6645)

IncMinute (see page 6645)

IncWeek (see page 6647)

IncYear (see page 6647)

38.1.48 DateUtils.IncWeek Function

Returns a date shifted by a specified number of weeks.

Pascal

```
function IncWeek(const AValue: TDateTime; const ANumberOfWeeks: Integer = 1): TDateTime;
```

C++

```
TDateTime IncWeek(const TDateTime AValue, const int ANumberOfWeeks = 1);
```

File

DateUtils

Description

IncWeek returns the value of the AValue parameter, incremented by ANumberOfWeeks weeks. ANumberOfWeeks can be negative, to return a date N weeks previous.

The time of day specified by the AValue parameter is copied to the result.

See Also

DecodeDate

EncodeDate

ReplaceDate

IncMonth

IncHour (see page 6644)

IncMilliSecond (see page 6645)

IncMinute (see page 6645)

IncSecond (see page 6646)

IncDay (see page 6643)

IncYear (see page 6647)

38.1.49 DateUtils.IncYear Function

Returns a date shifted by a specified number of years.

Pascal

```
function IncYear(const AValue: TDateTime; const ANumberOfYears: Integer = 1): TDateTime;
```

C++

```
TDateTime IncYear(const TDateTime AValue, const int ANumberOfYears = 1);
```

File

DateUtils

Description

IncYear returns the value of the AValue parameter, incremented by ANumberOfYears years. ANumberOfYears can be negative, to return a date N years previous.

The time of day specified by the AValue parameter is copied to the result.

See Also

IncDay (see page 6643)

IncWeek (see page 6647)

38.1.50 DateUtils.InvalidDateDayError Function

Pascal

```
procedure InvalidDateDayError(const AYear: Word; const ADayOfYear: Word);
```

C++

```
InvalidDateDayError(const Word AYear, const Word ADayOfYear);
```

File

DateUtils

Description

This is function DateUtils.InvalidDateDayError.

38.1.51 DateUtils.InvalidDateMonthWeekError Function

Pascal

```
procedure InvalidDateMonthWeekError(const AYear: Word; const AMonth: Word; const AWeekOfMonth:
Word; const ADayOfWeek: Word);
```

C++

```
InvalidDateMonthWeekError(const Word AYear, const Word AMonth, const Word AWeekOfMonth, const
Word ADayOfWeek);
```

File

DateUtils

Description

This is function DateUtils.InvalidDateMonthWeekError.

38.1.52 DateUtils.InvalidDateTimeError Function

Pascal

```
procedure InvalidDateTimeError(const AYear: Word; const AMonth: Word; const ADay: Word; const
AHour: Word; const AMinute: Word; const ASecond: Word; const AMilliSecond: Word; const
ABaseDate: TDateTime = 0);
```

C++

```
InvalidDateTimeError(const Word AYear, const Word AMonth, const Word ADay, const Word AHour,
const Word AMinute, const Word ASecond, const Word AMilliSecond, const TDateTime ABaseDate =
0);
```

File

DateUtils

Description

This is function DateUtils.InvalidDateTimeError.

38.1.53 DateUtils.InvalidDateWeekError Function

Pascal

```
procedure InvalidDateWeekError(const AYear: Word; const AWeekOfYear: Word; const ADayOfWeek:
Word);
```

C++

```
InvalidDateWeekError(const Word AYear, const Word AWeekOfYear, const Word ADayOfWeek);
```

File

DateUtils

Description

This is function DateUtils.InvalidDateWeekError.

38.1.54 DateUtils.InvalidDayOfWeekInMonthError Function

Pascal

```
procedure InvalidDayOfWeekInMonthError(const AYear: Word; const AMonth: Word; const
ANthDayOfWeek: Word; const ADayOfWeek: Word);
```

C++

```
InvalidDayOfWeekInMonthError(const Word AYear, const Word AMonth, const Word ANthDayOfWeek,
const Word ADayOfWeek);
```

File

DateUtils

Description

This is function DateUtils.InvalidDayOfWeekInMonthError.

38.1.55 DateUtils.IsInLeapYear Function

Indicates whether a specified TDateTime value occurs in a leap year.

Pascal

```
function IsInLeapYear(const AValue: TDateTime): Boolean;
```

C++

```
Boolean IsInLeapYear(const TDateTime AValue);
```

File

DateUtils

Description

Call IsInLeapYear to determine whether the year of the date specified by AValue occurs in a leap year.

See Also

Date

IsLeapYear

38.1.56 DateUtils.IsPM Function

Indicates whether the time portion of a specified TDateTime value occurs after noon.

Pascal

```
function IsPM(const AValue: TDateTime): Boolean;
```

C++

```
Boolean IsPM(const TDateTime AValue);
```

File

DateUtils

Description

IsPM returns true if the time portion of AValue occurs on or after 12:00 noon and before 12:00 midnight.

See Also

HourOf (see page 6638)

38.1.57 DateUtils.IsSameDay Function

Indicates whether a specified TDateTime value occurs on a the same day as a criterion date.

Pascal

```
function IsSameDay(const AValue: TDateTime; const ABasis: TDateTime): Boolean;
```

C++

```
Boolean IsSameDay(const TDateTime AValue, const TDateTime ABasis);
```

File

DateUtils

Description

IsSameDay returns true if AValue occurs on the same day as ABasis. The time portions of AValue and ABasis can differ.

IsSameDay returns false if the date portions of AValue and ABasis differ.

See Also

IsToday (see page 6651)

CompareDate (see page 6614)

CompareDateTime (see page 6614)

SameDate (see page 6681)

SameDateTime (see page 6681)

38.1.58 DateUtils.IsToday Function

Indicates whether a specified TDateTime value occurs on the current date.

Pascal

```
function IsToday(const AValue: TDateTime): Boolean;
```

C++

```
Boolean IsToday(const TDateTime AValue);
```

File

DateUtils

Description

IsToday returns true if AValue occurs on the current day.

IsToday returns false if AValue represents a time on any other day.

See Also

IsSameDay (see page 6651)

Today (see page 6694)

Date

38.1.59 DateUtils.IsValidDate Function

Indicates whether a specified year, month, and day represent a valid date.

Pascal

```
function IsValidDate(const AYear: Word; const AMonth: Word; const ADay: Word): Boolean;
```

C++

```
Boolean IsValidDate(const Word AYear, const Word AMonth, const Word ADay);
```

File

DateUtils

Description

IsValidDate returns true if

AYear falls in the range from 1 to 9999 inclusive.

AMonth falls in the range from 1 to 12 inclusive.

ADay falls in the range from1 to the number of days in the specified month.

Otherwise, IsValidDate returns false.

See Also

IsValidDateDay (see page 6652)

IsValidDateTime (see page 6654)

IsValidDateWeek (see page 6654)

IsValidTime (see page 6655)

38.1.60 DateUtils.IsValidDateDay Function

Indicates whether a specified year and day of the year represent a valid date.

Pascal

```
function IsValidDateDay(const AYear: Word; const ADayOfYear: Word): Boolean;
```

C++

```
Boolean IsValidDateDay(const Word AYear, const Word ADayOfYear);
```

File

DateUtils

Description

IsValidDateDay returns true if

AYear falls in the range from 1 to 9999 inclusive.

ADay falls in the range from1 to the number of days in the specified year.

Otherwise, IsValidDateDay returns false.

See Also

IsValidDate (see page 6652)

IsValidDateTime (see page 6654)

IsValidDateWeek (see page 6654)

IsValidTime (see page 6655)

38.1.61 DateUtils.IsValidDateMonthWeek Function

Indicates whether a specified year, month, week of the month, and day of the week represent a valid date.

Pascal

```
function IsValidDateMonthWeek(const AYear: Word; const AMonth: Word; const AWeekOfMonth: Word;
const ADayOfWeek: Word): Boolean;
```

C++

```
Boolean IsValidDateMonthWeek(const Word AYear, const Word AMonth, const Word AWeekOfMonth,
const Word ADayOfWeek);
```

File

DateUtils

Description

IsValidDateMonthWeek returns true if

AYear falls in the range from 1 to 9999 inclusive.

AMonth falls in the range from 1 to 12 inclusive.

AWeekOfMonth falls in the range from1 to the number of weeks in the specified month.

ADayOfWeek falls in the range from 1 to 7.

Otherwise, IsValidDateMonthWeek returns false.

See Also

IsValidDate (see page 6652)

IsValidDateTime (see page 6654)

IsValidDateDay (see page 6652)

IsValidTime (see page 6655)

38.1.62 DateUtils.IsValidDateTime Function

Indicates whether a specified year, month, day, hour, minute, second, and millisecond represent a valid date and time.

Pascal

```
function IsValidDateTime(const AYear: Word; const AMonth: Word; const ADay: Word; const AHour:
Word; const AMinute: Word; const ASecond: Word; const AMilliSecond: Word): Boolean;
```

C++

```
Boolean IsValidDateTime(const Word AYear, const Word AMonth, const Word ADay, const Word
AHour, const Word AMinute, const Word ASecond, const Word AMilliSecond);
```

File

DateUtils

Description

IsValidDateTime returns true if

AYear falls in the range from 1 to 9999 inclusive.

AMonth falls in the range from 1 to 12 inclusive.

ADay falls in the range from1 to the number of days in the specified month.

AHour falls in the range from 0 to 24, and if AHour is 24, then AMinute, ASecond, and AMilliSecond must all be 0.

AMinute falls in the range from 0 to 59 inclusive.

ASecond falls in the range from 0 to 59 inclusive.

AMilliSecond falls in the range from 0 to 999 inclusive.

Otherwise, IsValidDateTime returns false.

See Also

IsValidDate (see page 6652)

IsValidDateDay (see page 6652)

IsValidDateWeek (see page 6654)

IsValidTime (see page 6655)

38.1.63 DateUtils.IsValidDateWeek Function

Indicates whether a specified year, week of the year, and day of the week represent a valid date.

Pascal

```
function IsValidDateWeek(const AYear: Word; const AWeekOfYear: Word; const ADayOfWeek: Word):
Boolean;
```

C++

```
Boolean IsValidDateWeek(const Word AYear, const Word AWeekOfYear, const Word ADayOfWeek);
```

File

DateUtils

Description

IsValidDateWeek returns true if

AYear falls in the range from 1 to 9999 inclusive.

AWeekOfYear falls in the range from1 to the number of weeks in the specified year.

ADayOfWeek falls in the range from 1 to 7.

Otherwise, IsValidDateWeek returns false.

See Also

IsValidDate (see page 6652)

IsValidDateTime (see page 6654)

IsValidDateDay (see page 6652)

IsValidTime (see page 6655)

38.1.64 DateUtils.IsValidTime Function

Indicates whether a specified hour, minute, second, and millisecond represent a valid date and time.

Pascal

```
function IsValidTime(const AHour: Word; const AMinute: Word; const ASecond: Word; const
AMilliSecond: Word): Boolean;
```

C++

```
Boolean IsValidTime(const Word AHour, const Word AMinute, const Word ASecond, const Word
AMilliSecond);
```

File

DateUtils

Description

IsValidTime returns true if

AHour falls in the range from 0 to 24, and if AHour is 24, then AMinute, ASecond, and AMilliSecond must all be 0.

AMinute falls in the range from 0 to 59 inclusive.

ASecond falls in the range from 0 to 59 inclusive.

AMilliSecond falls in the range from 0 to 999 inclusive.

Otherwise, IsValidTime returns false.

See Also

IsValidDate (see page 6652)

IsValidDateDay (see page 6652)

IsValidDateWeek (see page 6654)

IsValidDateTime (see page 6654)

38.1.65 DateUtils.JulianDateToDateTime Function

Converts a Julian date to a TDateTime value.

Pascal

```
function JulianDateToDateTime(const AValue: Double): TDateTime;
```

C++

```
TDateTime JulianDateToDateTime(const Double AValue);
```

File

DateUtils

Description

Call JulianDateToDateTime to convert a Julian date to the corresponding TDateTime value.

The Julian date is the number of days, including fractional days, since 4713 BC January 1, Greenwich noon. Julian dates are used by astronomers and others who need an unambiguous dating system based on continuing day counts.

Note: If JulianDateToDateTime can't convert the date specified by AValue, it raises an EConvertError exception.

See Also

ModifiedJulianDateToDateTime (see page 6669)

Convert

TryJulianDateToDateTime (see page 6700)

TryModifiedJulianDateToDateTime (see page 6701)

EConvertError

38.1.66 DateUtils.MilliSecondOf Function

Returns the millisecond of the second represented by a TDateTime value.

Pascal

```
function MilliSecondOf(const AValue: TDateTime): Word;
```

C++

```
Word MilliSecondOf(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOf to obtain the millisecond of the second represented by a specified TDateTime value. MilliSecondOf returns a value between 0 and 999.

Note: MilliSecondOf returns the same value as the MilliSecondOfTheSecond (see page 6660) function.

See Also

DecodeTime

YearOf (see page 6714)

38.1.67 DateUtils.MilliSecondOfTheDay Function

Returns the number of milliseconds between a specified TDateTime value and the beginning of the same day.

Pascal

```
function MilliSecondOfTheDay(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MilliSecondOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheDay to obtain the number of milliseconds between AValue and the beginning (midnight) on the same day.

See Also

MilliSecondOfTheSecond (see page 6660)

MilliSecondOfTheHour (see page 6658)

MilliSecondOfTheMinute (see page 6659)

SecondOfTheDay (see page 6683)

MilliSecondsBetween (see page 6662)

StartOfTheDay (see page 6692)

38.1.68 DateUtils.MilliSecondOfTheHour Function

Returns the number of milliseconds between a specified TDateTime value and the beginning of the same hour.

Pascal

```
function MilliSecondOfTheHour(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MilliSecondOfTheHour(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheHour to obtain the number of milliseconds between AValue and the start of the same hour on the same day.

See Also

MilliSecondOfTheSecond (see page 6660)

MilliSecondOfTheDay (see page 6657)

MilliSecondOfTheMinute (see page 6659)

MinuteOfTheHour (see page 6665)

SecondOfTheHour (see page 6684)

MilliSecondsBetween (see page 6662)

38.1.69 DateUtils.MilliSecondOfTheMinute Function

Returns the number of milliseconds between a specified TDateTime value and the beginning of the same minute.

Pascal

```
function MilliSecondOfTheMinute(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MilliSecondOfTheMinute(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheMinute to obtain the number of milliseconds between AValue and the start of the same minute on the same day.

See Also

MilliSecondOfTheSecond (see page 6660)

MilliSecondOfTheDay (see page 6657)

MilliSecondOfTheHour (see page 6658)

MilliSecondOfTheYear (see page 6661)

MilliSecondOfTheWeek (see page 6661)

SecondOfTheMinute (see page 6685)

MilliSecondsBetween (see page 6662)

38.1.70 DateUtils.MilliSecondOfTheMonth Function

Returns the number of milliseconds between a specified TDateTime value and the beginning of the month.

Pascal

```
function MilliSecondOfTheMonth(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MilliSecondOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheMonth to obtain the number of milliseconds between the beginning (Midnight on the first day) of the month that contains AValue and AValue itself.

See Also

MilliSecondOfTheDay (see page 6657)

MilliSecondOfTheWeek (see page 6661)

MilliSecondOfTheYear (see page 6661)

StartOfTheMonth (see page 6692)

MilliSecondsBetween (see page 6662)

38.1.71 DateUtils.MilliSecondOfTheSecond Function

Returns the millisecond of the second represented by a TDateTime value.

Pascal

```
function MilliSecondOfTheSecond(const AValue: TDateTime): Word;
```

C++

```
Word MilliSecondOfTheSecond(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheSecond to obtain the millisecond of the second represented by a specified TDateTime value. MilliSecondOfTheSecond returns a value between 0 and 999.

Note: MilliSecondOfTheSecond returns the same value as the MilliSecondOf (see page 6656) function.

See Also

MilliSecondOf (see page 6656)

MilliSecondOfTheDay (see page 6657)

MilliSecondOfTheHour (see page 6658)

MilliSecondOfTheMinute (see page 6659)

MilliSecondOfTheYear (see page 6661)

MilliSecondOfTheMonth (see page 6659)

MilliSecondOfTheWeek (see page 6661)

MilliSecondsBetween (see page 6662)

38.1.72 DateUtils.MilliSecondOfTheWeek Function

Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the week.

Pascal

```
function MilliSecondOfTheWeek(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MilliSecondOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheWeek to obtain the number of milliseconds between AValue and 12:00:00:00 AM on Monday of the week that includes AValue.

Note: MilliSecondOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

MilliSecondOfTheDay (see page 6657)

MilliSecondOfTheMonth (see page 6659)

MilliSecondOfTheYear (see page 6661)

HourOfTheWeek (see page 6641)

MinuteOfTheWeek (see page 6666)

SecondOfTheWeek (see page 6686)

StartOfTheWeek (see page 6693)

MilliSecondsBetween (see page 6662)

38.1.73 DateUtils.MilliSecondOfTheYear Function

Returns the number of milliseconds between a specified TDateTime value and 12:00:00:00 AM of the first day of the year.

Pascal

```
function MilliSecondOfTheYear(const AValue: TDateTime): Int64;
```

C++

```
Int64 MilliSecondOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call MilliSecondOfTheYear to obtain the number of milliseconds between AValue and 12:00:00:00 AM on Jan 1 of the year that includes AValue.

See Also

MilliSecondOfTheSecond (see page 6660)

MilliSecondOfTheMinute (see page 6659)

MilliSecondOfTheHour (see page 6658)

MilliSecondOfTheDay (see page 6657)

HourOfTheYear (see page 6641)

MinuteOfTheYear (see page 6667)

MonthOfTheYear (see page 6670)

SecondOfTheYear (see page 6687)

WeekOfTheYear (see page 6705)

StartOfTheYear (see page 6693)

MilliSecondsBetween (see page 6662)

38.1.74 DateUtils.MilliSecondsBetween Function

Returns the number of milliseconds between two specified TDateTime values.

Pascal

```
function MilliSecondsBetween(const ANow: TDateTime; const AThen: TDateTime): Int64;
```

C++

```
Int64 MilliSecondsBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MilliSecondsBetween to obtain the difference, in milliseconds, between two TDateTime values.

See Also

MilliSecondSpan (see page 6663)

DaysBetween (see page 6621)

HoursBetween (see page 6642)

MinutesBetween (see page 6668)

MonthsBetween (see page 6671)

SecondsBetween (see page 6687)

WeeksBetween (see page 6706)

YearsBetween (see page 6714)

WithinPastMilliSeconds (see page 6710)

38.1.75 DateUtils.MilliSecondSpan Function

Returns the number of milliseconds between two specified TDateTime values.

Pascal

```
function MilliSecondSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double MilliSecondSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MilliSecondSpan to obtain the difference, in milliseconds, between two TDateTime values. MilliSecondSpan returns the same value as MilliSecondsBetween (see page 6662), but as a floating point type instead of an integer.

See Also

MilliSecondsBetween (see page 6662)

DaySpan (see page 6624)

HourSpan (see page 6643)

MinuteSpan (see page 6668)

MonthSpan (see page 6672)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.76 DateUtils.MinuteOf Function

Returns the minute of the hour represented by a TDateTime value.

Pascal

```
function MinuteOf(const AValue: TDateTime): Word;
```

C++

```
Word MinuteOf(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOf to obtain the minute of the hour represented by a specified TDateTime value. MinuteOf returns a value between 0 and 59.

Note: MinuteOf returns the same value as the MinuteOfTheHour (see page 6665) function.

See Also

DecodeTime

MinuteOfTheDay (see page 6664)

MinuteOfTheHour (see page 6665)

MinuteOfTheYear (see page 6667)

MinuteOfTheMonth (see page 6666)

RecodeDateMinute

SecondOf (see page 6682)

WeekOf (see page 6703)

YearOf (see page 6714)

38.1.77 DateUtils.MinuteOfTheDay Function

Returns the number of minutes between a specified TDateTime value and 12:00 AM of the same day.

Pascal

```
function MinuteOfTheDay(const AValue: TDateTime): Word;
```

C++

```
Word MinuteOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOfTheDay to obtain the number of minutes between AValue and 12:00 AM on the same day.

See Also

MinuteOfTheHour (see page 6665)

MinuteOfTheYear (see page 6667)

MinuteOfTheMonth (see page 6666)

MinuteOfTheWeek (see page 6666)

HourOfTheDay (see page 6639)

MilliSecondOfTheDay (see page 6657)

SecondOfTheDay (see page 6683)

MinutesBetween (see page 6668)

StartOfTheDay (see page 6692)

38.1.78 DateUtils.MinuteOfTheHour Function

Returns the number of minutes between a specified TDateTime value and the beginning of the same hour.

Pascal

```
function MinuteOfTheHour(const AValue: TDateTime): Word;
```

C++

```
Word MinuteOfTheHour(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOfTheHour to obtain the number of minutes between AValue and the start of the same hour on the same day.

Note: MinuteOfTheHour returns the same value as the MinuteOf (see page 6663) function.

See Also

MinuteOfTheDay (see page 6664)

MinuteOfTheYear (see page 6667)

MinuteOfTheMonth (see page 6666)

MinuteOfTheWeek (see page 6666)

MinuteOfTheHour

SecondOfTheHour (see page 6684)

MinutesBetween (see page 6668)

38.1.79 DateUtils.MinuteOfTheMonth Function

Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the month.

Pascal

```
function MinuteOfTheMonth(const AValue: TDateTime): Word;
```

C++

```
Word MinuteOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOfTheMonth to obtain the number of minutes between AValue and 12:00 AM on the first day of the month that includes AValue.

See Also

MinuteOfTheDay (see page 6664)

MinuteOfTheWeek (see page 6666)

MinuteOfTheYear (see page 6667)

MinuteOfTheHour (see page 6665)

DayOfTheMonth (see page 6618)

HourOfTheMonth (see page 6640)

MilliSecondOfTheMonth (see page 6659)

SecondOfTheMonth (see page 6685)

WeekOfTheMonth (see page 6704)

StartOfTheMonth (see page 6692)

MinutesBetween (see page 6668)

38.1.80 DateUtils.MinuteOfTheWeek Function

Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the week.

Pascal

```
function MinuteOfTheWeek(const AValue: TDateTime): Word;
```

C++

```
Word MinuteOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOfTheWeek to obtain the number of minutes between AValue and 12:00 AM on Monday of the week that includes AValue.

Note: MinuteOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

MinuteOfTheDay (see page 6664)

MinuteOfTheMonth (see page 6666)

MinuteOfTheYear (see page 6667)

MinuteOfTheHour (see page 6665)

MilliSecondOfTheWeek (see page 6661)

SecondOfTheWeek (see page 6686)

HourOfTheWeek (see page 6641)

StartOfTheWeek (see page 6693)

MinutesBetween (see page 6668)

38.1.81 DateUtils.MinuteOfTheYear Function

Returns the number of minutes between a specified TDateTime value and 12:00 AM of the first day of the year.

Pascal

```
function MinuteOfTheYear(const AValue: TDateTime): LongWord;
```

C++

```
LongWord MinuteOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call MinuteOfTheYear to obtain the number of minutes between AValue and 12:00 AM on Jan 1 of the year that includes AValue.

See Also

MinuteOfTheHour (see page 6665)

MinuteOfTheDay (see page 6664)

MinuteOfTheWeek (see page 6666)

MinuteOfTheMonth (see page 6666)

HourOfTheYear (see page 6641)

MilliSecondOfTheYear (see page 6661)

MonthOfTheYear (see page 6670)

SecondOfTheYear (see page 6687)

WeekOfTheYear (see page 6705)

StartOfTheYear (see page 6693)

MinutesBetween (see page 6668)

38.1.82 DateUtils.MinutesBetween Function

Returns the number of minutes between two specified TDateTime values.

Pascal

```
function MinutesBetween(const ANow: TDateTime; const AThen: TDateTime): Int64;
```

C++

```
Int64 MinutesBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MinutesBetween to obtain the difference, in minutes, between two TDateTime values. MinutesBetween counts only entire minutes. Thus, MinutesBetween reports the difference between 9:00:00 AM and 9:00:59:999 AM as 0 because the difference is one millisecond short of an entire minute.

See Also

MinuteSpan (see page 6668)

DaysBetween (see page 6621)

HoursBetween (see page 6642)

MilliSecondsBetween (see page 6662)

MonthsBetween (see page 6671)

SecondsBetween (see page 6687)

WeeksBetween (see page 6706)

YearsBetween (see page 6714)

WithinPastMinutes (see page 6710)

38.1.83 DateUtils.MinuteSpan Function

Returns the number of minutes, including fractions thereof, between two specified TDateTime values.

Pascal

```
function MinuteSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double MinuteSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MinuteSpan to obtain the difference, in minutes, between two TDateTime values. Unlike the MinutesBetween (see page 6668) function, which only counts entire minutes, MinuteSpan reports incomplete minutes as a fraction of an entire minute.

See Also

MinutesBetween (see page 6668)

DaySpan (see page 6624)

HourSpan (see page 6643)

MilliSecondSpan (see page 6663)

MonthSpan (see page 6672)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.84 DateUtils.ModifiedJulianDateToDateTime Function

Converts a modified Julian date to a TDateTime value.

Pascal

```
function ModifiedJulianDateToDateTime(const AValue: Double): TDateTime;
```

C++

```
TDateTime ModifiedJulianDateToDateTime(const Double AValue);
```

File

DateUtils

Description

Call ModifiedJulianDateToDateTime to convert a modified Julian date to the corresponding TDateTime value.

The modified Julian date is the number of days, including fractional days, since Greenwich midnight on November 17, 1858. Modified Julian dates are based on Julian dates, but adjusted to use midnight rather than noon as a starting point and to use a more recent date as a starting point.

Note: If ModifiedJulianDateToDateTime can't convert the date specified by AValue, it raises an EConvertError exception.

See Also

DateTimeToModifiedJulianDate (see page 6617)

DateTimeToJulianDate (see page 6616)

JulianDateToDateTime (see page 6656)

Convert

TryJulianDateToDateTime (see page 6700)

TryModifiedJulianDateToDateTime (see page 6701)

EConvertError

38.1.85 DateUtils.MonthOf Function

Returns the month of the year represented by a TDateTime value.

Pascal

```
function MonthOf(const AValue: TDateTime): Word;
```

C++

```
Word MonthOf(const TDateTime AValue);
```

File

DateUtils

Description

Call MonthOf to obtain the month of the year represented by a specified TDateTime value. MonthOf returns a value between 1 and 12.

Note: MonthOf returns the same value as the MonthOfTheYear (see page 6670) function.

See Also

DecodeDate

MonthOfTheYear (see page 6670)

DayOf (see page 6618)

MilliSecondOf (see page 6656)

MinuteOf (see page 6663)

HourOf (see page 6638)

RecodeDateMonth

SecondOf (see page 6682)

WeekOf (see page 6703)

YearOf (see page 6714)

38.1.86 DateUtils.MonthOfTheYear Function

Returns the month of the year represented by a TDateTime value.

Pascal

```
function MonthOfTheYear(const AValue: TDateTime): Word;
```

C++

```
Word MonthOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call MonthOfTheYear to obtain the month of the year represented by a specified TDateTime value. MonthOfTheYear returns a value between 1 and 12.

Note: MonthOfTheYear returns the same value as the MonthOf (see page 6670) function.

See Also

MonthOf (see page 6670)

DayOfTheYear (see page 6620)

MilliSecondOfTheYear (see page 6661)

MinuteOfTheYear (see page 6667)

HourOfTheYear (see page 6641)

SecondOfTheYear (see page 6687)

WeekOfTheYear (see page 6705)

38.1.87 DateUtils.MonthsBetween Function

Returns the approximate number of months between two specified TDateTime values.

Pascal

```
function MonthsBetween(const ANow: TDateTime; const AThen: TDateTime): Integer;
```

C++

```
int MonthsBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MonthsBetween to obtain the difference, in months, between two TDateTime values. Because months are not all the same length, MonthsBetween returns an approximation based on an assumption of 30.4375 days per month. Fractional months are not counted. Thus, for example, MonthsBetween reports the difference between Feb 1 and Mar 1 as 0.

See Also

MonthSpan (see page 6672)

DaysBetween (see page 6621)

MillisecondsBetween

MinutesBetween (see page 6668)

HoursBetween (see page 6642)

SecondsBetween (see page 6687)

WeeksBetween (see page 6706)

YearsBetween (see page 6714)

WithinPastMonths (see page 6711)

38.1.88 DateUtils.MonthSpan Function

Returns the approximate number of months, including fractions, between two specified TDateTime values.

Pascal

```
function MonthSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double MonthSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call MonthSpan to obtain the difference, in months, between two TDateTime values. Because months are not all the same length, MonthsBetween (see page 6671) returns an approximation based on an assumption of 30.4375 days per month. Unlike the MonthsBetween (see page 6671) function, which does not report fractional "months", MonthSpan reports incomplete months as a fraction of an entire month.

See Also

MonthsBetween (see page 6671)

DaySpan (see page 6624)

MillisecondSpan

MinuteSpan (see page 6668)

HourSpan (see page 6643)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.89 DateUtils.NthDayOfWeek Function

Returns which occurrence of its weekday a specified TDateTime value represents.

Pascal

```
function NthDayOfWeek(const AValue: TDateTime): Word;
```

C++

```
Word NthDayOfWeek(const TDateTime AValue);
```

File

DateUtils

Description

NthDayOfWeek indicates which occurrence of a weekday within a month the date and time specified by AValue represents. For example, if AValue represents the 2nd Tuesday of the month, NthDayOfWeek returns 2.

Note that this value may differ from the value that the WeekOfTheMonth (see page 6704) function returns, because NthDayOfWeek counts every occurrence of the given weekday, while WeekOfTheMonth (see page 6704) only counts a week if it includes 4 or more days in the month. Thus, for example, if AValue represents a Saturday that is the first day of a month, NthDayOfWeek returns 1, while WeekOfTheMonth (see page 6704) returns 5 (or maybe 4), indicating the last week of the previous month.

Note: To obtain the year, month, and day of the week, as well as which occurrence of that day of the week the specified TDateTime represents, use the DecodeDayOfWeekInMonth (see page 6628) function.

See Also

WeekOfTheMonth (see page 6704)

DecodeDayOfWeekInMonth (see page 6628)

38.1.90 DateUtils.RecodeDate Function

Replaces the date portion of a specified TDateTime value.

Pascal

```
function RecodeDate(const AValue: TDateTime; const AYear: Word; const AMonth: Word; const
ADay: Word): TDateTime;
```

C++

```
TDateTime RecodeDate(const TDateTime AValue, const Word AYear, const Word AMonth, const Word
ADay);
```

File

DateUtils

Description

Call RecodeDate to convert the date/time value specified by AValue with the value obtained by changing the year to AYear, the month to AMonth, and the day of the month to ADay.

AYear must fall between 1 and 9999 (inclusive).

AMonth can range from 1 to 12.

Legal values for ADay depend on the month represented by AMonth. (For example, if AMonth is 1, ADay can range from 1 to 31; if AMonth is 2, ADay can range from 1 to 28 or 1 to 29, depending on the year; and so on.)

If the values provided for AYear, AMonth, and ADay do not represent a valid date, RecodeDate raises an EConvertError exception.

RecodeTime (see page 6679)

38.1.91 DateUtils.RecodeDateTime Function

Selectively replaces parts of a specified TDateTime value.

Pascal

```
function RecodeDateTime(const AValue: TDateTime; const AYear: Word; const AMonth: Word; const
ADay: Word; const AHour: Word; const AMinute: Word; const ASecond: Word; const AMilliSecond:
Word): TDateTime;
```

C++

```
TDateTime RecodeDateTime(const TDateTime AValue, const Word AYear, const Word AMonth, const
Word ADay, const Word AHour, const Word AMinute, const Word ASecond, const Word AMilliSecond);
```

File

DateUtils

Description

Call RecodeDateTime to convert the date/time value specified by AValue with the value obtained by changing the year to AYear, the month to AMonth, the day of the month to ADay, the hour to AHour, the minute to AMinute, the second to ASecond, and the millisecond to AMilliSecond. Any one of these parameters can be set to RecodeLeaveFieldAsIs (see page 6723) which tells RecodeDateTime not change the existing portion of the TDateTime value.

AYear can range from 1 to 9999 (or be RecodeLeaveFieldAsIs (see page 6723)).

AMonth can range from 1 to 12 (or be RecodeLeaveFieldAsIs (see page 6723)).

Legal values for ADay depend on the month represented by AMonth. (For example, if AMonth is 1, ADay can range from 1 to 31; if AMonth is 2, ADay can range from 1 to 28 or 1 to 29, depending on the year; and so on.) ADay can also be RecodeLeaveFieldAsIs (see page 6723).

AHour can range from 0 to 24 (or be RecodeLeaveFieldAsIs (see page 6723)). If AHour is 24, AMinute, ASecond, and AMilliSecond must all be 0.

AMinute can range from 0 to 59 (or be RecodeLeaveFieldAsIs (see page 6723)).

ASecond can range from 0 to 59 (or be RecodeLeaveFieldAsIs (see page 6723)).

AMilliSecond can range from 0 to 999 (or be RecodeLeaveFieldAsIs (see page 6723)).

If the values do not result in a valid date and time, RecodeDateTime raises an EConvertError exception.

TryRecodeDateTime (see page 6702)

38.1.92 DateUtils.RecodeDay Function

Replaces the day of the month for a specified TDateTime value.

Pascal

```
function RecodeDay(const AValue: TDateTime; const ADay: Word): TDateTime;
```

C++

```
TDateTime RecodeDay(const TDateTime AValue, const Word ADay);
```

File

DateUtils

Description

Call RecodeDay to convert the date/time value specified by AValue with the value obtained by changing the day of the month to ADay. Legal values for ADay depend on the month represented by AValue. (For example, if AValue is in January, ADay can range from 1 to 31; if AValue is in February, ADay can range from 1 to 28 or 1 to 29, depending on the year; and so on.)

If the value provided for ADay does not represent a valid day in the month identified by AValue, RecodeDay raises an EConvertError exception.

38.1.93 DateUtils.RecodeHour Function

Replaces the hour of the day for a specified TDateTime value.

Pascal

```
function RecodeHour(const AValue: TDateTime; const AHour: Word): TDateTime;
```

C++

```
TDateTime RecodeHour(const TDateTime AValue, const Word AHour);
```

File

DateUtils

Description

Call RecodeHour to convert the date/time value specified by AValue with the value obtained by changing the hour of the day to AHour. Legal values for AHour range from 0 to 24. If AHour is 24, the minutes, seconds, and milliseconds of AValue must all be 0.

If the value provided for AHour is not in the legal range, RecodeHour raises an EConvertError exception.

Replaces the millisecond of the second for a specified TDateTime value.

Pascal

```
function RecodeMilliSecond(const AValue: TDateTime; const AMilliSecond: Word): TDateTime;
```

C++

```
TDateTime RecodeMilliSecond(const TDateTime AValue, const Word AMilliSecond);
```

File

DateUtils

Description

Call RecodeDateMilliSecond to convert the date/time value specified by AValue with the value obtained by changing the milliseconds of the second to AMilliSecond. Legal values for AMilliSecond range from 0 to 999.

If the value provided for AMilliSecond is not in the legal range, RecodeDateMilliSecond raises an EConvertError exception.

38.1.97 DateUtils.RecodeSecond Function

Replaces the second of the minute for a specified TDateTime value.

Pascal

```
function RecodeSecond(const AValue: TDateTime; const ASecond: Word): TDateTime;
```

C++

```
TDateTime RecodeSecond(const TDateTime AValue, const Word ASecond);
```

File

DateUtils

Description

Call RecodeSecond to convert the date/time value specified by AValue with the value obtained by changing the second of the minute to ASecond. Legal values for ASecond range from 0 to 59.

If the value provided for ASecond is not in the legal range, RecodeSecond raises an EConvertError exception.

EConvertError

38.1.98 DateUtils.RecodeTime Function

Replaces the time portion of a specified TDateTime value.

Pascal

```
function RecodeTime(const AValue: TDateTime; const AHour: Word; const AMinute: Word; const
ASecond: Word; const AMilliSecond: Word): TDateTime;
```

C++

```
TDateTime RecodeTime(const TDateTime AValue, const Word AHour, const Word AMinute, const Word
ASecond, const Word AMilliSecond);
```

File

DateUtils

Description

Call RecodeTime to convert the date/time value specified by AValue with the value obtained by changing the hour to AHour, the minute to AMinute, the second to ASecond, and the milliseconds to AMilliSecond.

AHour can range from 0 to 24. If AHour is 24, AMinute, ASecond, and AMilliSecond must all be 0.

AMinute can range from 0 to 59.

ASecond can range from 0 to 59.

AMilliSecond can range from 0 to 999.

If the values provided for AHour, AMinute, ASecond, and AMilliSecond do not fall in the valid range, RecodeTime raises an EConvertError exception.

RecodeDate (see page 6673)

38.1.99 DateUtils.RecodeYear Function

Replaces the year for a specified TDateTime value.

Pascal

```
function RecodeYear(const AValue: TDateTime; const AYear: Word): TDateTime;
```

C++

```
TDateTime RecodeYear(const TDateTime AValue, const Word AYear);
```

File

DateUtils

Description

Call RecodeYear to convert the date/time value specified by AValue with the value obtained by changing the year to AYear. Legal values for AYear range from 1 to 9999.

If the value provided for AYear is not in the legal range, or if the change results in an invalid day of the month (changing Feb 29 on a leap year to a non-leap year), RecodeYear raises an EConvertError exception.

EConvertError

38.1.100 DateUtils.SameDate Function

Indicates whether two TDateTime values represent the same year, month, and day.

Pascal

```
function SameDate(const A: TDateTime; const B: TDateTime): Boolean;
```

C++

```
Boolean SameDate(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call SameDate to determine whether the two TDateTime values specified by A and B represent the same date, ignoring the time portion. SameDate returns true if the two specified values occur on the same day, false otherwise.

See Also

CompareDate (see page 6614)

ConvUnitSameValue

SameValue

SameDateTime (see page 6681)

SameTime (see page 6682)

IsSameDay (see page 6651)

38.1.101 DateUtils.SameDateTime Function

Indicates whether two TDateTime values represent the same year, month, day, hour, minute, second, and millisecond.

Pascal

```
function SameDateTime(const A: TDateTime; const B: TDateTime): Boolean;
```

C++

```
Boolean SameDateTime(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call SameDateTime to determine whether the two TDateTime values specified by A and B represent the same time, down to the millisecond. SameDateTime returns true if the two specified values represent the same time, false otherwise.

Note: It is possible to create two TDateTime values that differ numerically when viewed as floating point types, but which represent the same year, month, day, hour, minute, second, and millisecond. SameDateTime allows applications to determine when two TDateTime values are the same even when their numeric values differ.

38.1.102 DateUtils.SameTime Function

Indicates whether two TDateTime values represent the same time of day, ignoring the date portion.

Pascal

```
function SameTime(const A: TDateTime; const B: TDateTime): Boolean;
```

C++

```
Boolean SameTime(const TDateTime A, const TDateTime B);
```

File

DateUtils

Description

Call SameTime to determine whether the two TDateTime values specified by A and B represent the same time of day, ignoring the date portion. SameTime returns true if the two specified values occur on the same hour, minute, second, and millisecond, false otherwise.

Note: It is possible to create two TDateTime values whose time portions differ numerically when viewed as floating point types, but which represent the same hour, minute, second, and millisecond. SameTime allows applications to determine when two TDateTime values represent the same time, even when the fractional parts of the values differ.

SameDateTime (see page 6681)

Date

38.1.103 DateUtils.SecondOf Function

Returns the second of the minute represented by a TDateTime value.

Pascal

```
function SecondOf(const AValue: TDateTime): Word;
```

C++

```
Word SecondOf(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOf to obtain the second of the minute represented by a specified TDateTime value. SecondOf returns a value between 0 and 59.

Note: SecondOf returns the same value as the SecondOfTheMinute (see page 6685) function.

See Also

38.1.104 DateUtils.SecondOfTheDay Function

Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the same day.

Pascal

```
function SecondOfTheDay(const AValue: TDateTime): LongWord;
```

C++

```
LongWord SecondOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheDay to obtain the number of seconds between AValue and 12:00:00 AM on the same day.

See Also

SecondOfTheHour (see page 6684)

SecondOfTheMinute (see page 6685)

SecondOfTheYear (see page 6687)

StartOfTheDay (see page 6692)

38.1.105 DateUtils.SecondOfTheHour Function

Returns the number of seconds between a specified TDateTime value and the beginning of the same hour.

Pascal

```
function SecondOfTheHour(const AValue: TDateTime): Word;
```

C++

```
Word SecondOfTheHour(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheHour to obtain the number of seconds between AValue and the start of the same hour on the same day.

See Also

SecondOfTheDay (see page 6683)

SecondOfTheMinute (see page 6685)

SecondOfTheYear (see page 6687)

SecondsBetween (see page 6687)

38.1.106 DateUtils.SecondOfTheMinute Function

Returns the number of seconds between a specified TDateTime value and the beginning of the same minute.

Pascal

```
function SecondOfTheMinute(const AValue: TDateTime): Word;
```

C++

```
Word SecondOfTheMinute(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheMinute to obtain the number of seconds between AValue and the start of the same minute on the same day.

Note: SecondOfTheMinute returns the same value as the SecondOf (see page 6682) function.

See Also

SecondOfTheDay (see page 6683)

SecondOfTheHour (see page 6684)

SecondOfTheYear (see page 6687)

MilliSecondOfTheMinute (see page 6659)

SecondsBetween (see page 6687)

38.1.107 DateUtils.SecondOfTheMonth Function

Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the month.

Pascal

```
function SecondOfTheMonth(const AValue: TDateTime): LongWord;
```

C++

```
LongWord SecondOfTheMonth(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheMonth to obtain the number of seconds between AValue and 12:00:00 AM on the first day of the month that includes AValue.

See Also

SecondOfTheDay (see page 6683)

SecondOfTheWeek (see page 6686)

WeekOfTheMonth (see page 6704)

StartOfTheMonth (see page 6692)

SecondsBetween (see page 6687)

38.1.108 DateUtils.SecondOfTheWeek Function

Returns the number of seconds between a specified TDateTime value and 12:00:00 AM of the first day of the week.

Pascal

```
function SecondOfTheWeek(const AValue: TDateTime): LongWord;
```

C++

```
LongWord SecondOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheWeek to obtain the number of seconds between AValue and 12:00:00 AM on Monday of the week that includes AValue.

Note: SecondOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

SecondOfTheDay (see page 6683)

38.1.109 DateUtils.SecondOfTheYear Function

Returns the number of seconds between a specified TDateTime value and 12:00:00 AM on the first day of the year.

Pascal

```
function SecondOfTheYear(const AValue: TDateTime): LongWord;
```

C++

```
LongWord SecondOfTheYear(const TDateTime AValue);
```

File

DateUtils

Description

Call SecondOfTheYear to obtain the number of seconds between AValue and 12:00:00 AM on Jan 1 of the year that includes AValue.

See Also

SecondOfTheMinute (see page 6685)

SecondOfTheHour (see page 6684)

SecondOfTheDay (see page 6683)

StartOfTheYear (see page 6693)

SecondsBetween (see page 6687)

38.1.110 DateUtils.SecondsBetween Function

Returns the number of seconds between two specified TDateTime values.

Pascal

```
function SecondsBetween(const ANow: TDateTime; const AThen: TDateTime): Int64;
```

C++

```
Int64 SecondsBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call SecondsBetween to obtain the difference, in seconds, between two TDateTime values. SecondsBetween counts only entire seconds. Thus, SecondsBetween reports the difference between 9:00:00 AM and 9:00:00:999 AM as 0 because the difference is one millisecond short of an entire second.

See Also

SecondSpan (see page 6688)

DaysBetween (see page 6621)

YearsBetween (see page 6714)

WithinPastSeconds (see page 6712)

38.1.111 DateUtils.SecondSpan Function

Returns the number of seconds (including fractions thereof) between two specified TDateTime values.

Pascal

```
function SecondSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double SecondSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call SecondSpan to obtain the difference, in seconds, between two TDateTime values. Unlike the SecondsBetween (see page 6687) function, which only counts entire seconds, SecondSpan reports incomplete seconds as a fraction of an entire second.

See Also

SecondsBetween (see page 6687)

DaySpan (see page 6624)

MillisecondSpan

MinuteSpan (see page 6668)

HourSpan (see page 6643)

MonthSpan (see page 6672)

WeekSpan (see page 6708)

YearSpan (see page 6715)

38.1.112 DateUtils.StartOfADay Function

Returns a TDateTime that represents 12:00:00:00 AM on a specified day.

Pascal

```
function StartOfADay(const AYear: Word; const AMonth: Word; const ADay: Word): TDateTime;
overload;
function StartOfADay(const AYear: Word; const ADayOfYear: Word): TDateTime; overload;
```

C++

```
TDateTime StartOfADay(const Word AYear, const Word AMonth, const Word ADay);
TDateTime StartOfADay(const Word AYear, const Word ADayOfYear);
```

File

DateUtils

Description

StartOfADay returns the first expressible moment (12:00:000 AM) of a specified day.

The AYear parameter specifies the year of the desired day.

The ADayOfYear parameter specifies the desired day as a day of the year, where 1 is January 1, 2 is January 2, 32 is February 1, and so on.

The AMonth and ADay parameters specify the desired day as a month of the year and day of the month. AMonth can range from 1 to 12. ADay can range from 1 to 28, 29, 30, or 31, depending on the values of AYear and AMonth.

If the parameters do not specify a valid date, StartOfADay raises throws an EConvertError exception.

EncodeDate

38.1.113 DateUtils.StartOfAMonth Function

Returns a TDateTime that represents 12:00:00:00 AM on the first day of a specified month.

Pascal

```
function StartOfAMonth(const AYear: Word; const AMonth: Word): TDateTime;
```

C++

```
TDateTime StartOfAMonth(const Word AYear, const Word AMonth);
```

File

DateUtils

Description

StartOfAMonth returns the first expressible moment (12:00:000 AM) of the first day of a specified month.

The AYear parameter specifies the year of the desired month.

The AMonth parameter specifies the month. It can range from 1 to 12.

If the parameters do not specify a valid month, StartOfAMonth raises an EConvertError exception.

38.1.114 DateUtils.StartOfAWeek Function

Returns a TDateTime that represents 1the first moment on a specified day of a specified week.

Pascal

```
function StartOfAWeek(const AYear: Word; const AWeekOfYear: Word; const ADayOfWeek: Word = 1):
TDateTime;
```

C++

```
TDateTime StartOfAWeek(const Word AYear, const Word AWeekOfYear, const Word ADayOfWeek = 1);
```

File

DateUtils

Description

StartOfAWeek returns the first expressible moment (12:00:00.000 AM) of the specified day of the specified week.

The AYear parameter specifies the year of the desired day.

The AWeekOfYear parameter specifies the week of the year, where 1 is the first week in AYear that includes four or more days.

The ADayOfWeek parameter indicates the desired day in the specified week, where 1 is Monday, 2 is Tuesday, and so on.

If the parameters do not specify a valid date, StartOfAWeek raises an EConvertError exception.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

See Also

38.1.115 DateUtils.StartOfAYear Function

Returns a TDateTime that represents the first moment on the first day of a specified year.

Pascal

```
function StartOfAYear(const AYear: Word): TDateTime;
```

C++

```
TDateTime StartOfAYear(const Word AYear);
```

File

DateUtils

Description

StartOfAYear returns the first expressible moment (January 1 at 12:00:00.000 AM) of the year specified by the AYear parameter.

See Also

StartOfTheYear (see page 6693)

StartOfADay (see page 6689)

38.1.116 DateUtils.StartOfTheDay Function

Returns a TDateTime that represents 12:00:00:00 AM on the day identified by a specified TDateTime.

Pascal

```
function StartOfTheDay(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime StartOfTheDay(const TDateTime AValue);
```

File

DateUtils

Description

StartOfTheDay returns the first expressible moment of the same day as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 0 and returns the result.

See Also

EndOfTheDay (see page 6636)

StartOfTheMonth (see page 6692)

StartOfTheYear (see page 6693)

StartOfTheWeek (see page 6693)

StartOfAMonth (see page 6690)

38.1.118 DateUtils.StartOfTheWeek Function

Returns a TDateTime that represents 12:00:00:00 AM on the first day of the week identified by a specified TDateTime.

Pascal

```
function StartOfTheWeek(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime StartOfTheWeek(const TDateTime AValue);
```

File

DateUtils

Description

StartOfTheWeek returns the first expressible moment of the same week as the TDateTime specified by AValue. That is, it replaces the time portion of AValue with 0, changes the day to Monday, and returns the result.

Note: StartOfTheWeek defines the week of AValue according to the ISO 8601 standard. That is, the week starts on Monday and ends on Sunday.

See Also

StartOfAYear (see page 6691)

38.1.120 DateUtils.TimeOf Function

Strips the date portion from a TDateTime value.

Pascal

```
function TimeOf(const AValue: TDateTime): TDateTime;
```

C++

```
TDateTime TimeOf(const TDateTime AValue);
```

File

DateUtils

Description

Call TimeOf to convert a TDateTime value to a TDateTime value that includes only the time information (sets the date portion to 0, which means 12/30/1899).

See Also

DecodeTime

ReplaceDate

DateOf (see page 6616)

38.1.121 DateUtils.Today Function

Returns a TDateTime value that represents the current date.

Pascal

```
function Today: TDateTime;
```

C++

```
TDateTime Today();
```

File

DateUtils

Description

Today returns a TDateTime value with the date portion set to the current date and the time portion set to 0.

See Also

IsToday (see page 6651)

Today

Date

Yesterday (see page 6716)

Tomorrow (see page 6695)

38.1.122 DateUtils.Tomorrow Function

Returns a TDateTime value that represents the following day.

Pascal

```
function Tomorrow: TDateTime;
```

C++

```
TDateTime Tomorrow();
```

File

DateUtils

Description

Tomorrow returns a TDateTime value with the date portion set to the day following the current date and the time portion set to 0.

See Also

Today (see page 6694)

Date

Yesterday (see page 6716)

38.1.123 DateUtils.TryEncodeDateDay Function

Calculates the TDateTime value that represents a specified day of the year for a specified year.

Pascal

```
function TryEncodeDateDay(const AYear: Word; const ADayOfYear: Word; out AValue: TDateTime):
Boolean;
```

C++

```
Boolean TryEncodeDateDay(const Word AYear, const Word ADayOfYear, TDateTime AValue);
```

File

DateUtils

Description

TryEncodeDateDay calculates the TDateTime value for the date specified by the AYear and ADayOfYear parameters.

AYear is the year. It can be any value between 1 and 9999 (inclusive).

ADayOfYear is the day of the year, where 1 is January , 2 is January 2, 32 is February 1, and so on.

AValue returns the specified date as a TDateTime value. The time portion of AValue is 0 (Midnight at the start of the specified day).

TryEncodeDateDay returns T true if AYear and ADayOfYear represent a valid date, and F false if ADayOfYear is less than 1 or greater than the number of days in AYear.

See Also

TryEncodeDateMonthWeek (see page 6696)

38.1.124 DateUtils.TryEncodeDateMonthWeek Function

Calculates the TDateTime value that represents a specified day of a specified week in a specified month and year.

Pascal

```
function TryEncodeDateMonthWeek(const AYear: Word; const AMonth: Word; const AWeekOfMonth:
Word; const ADayOfWeek: Word; var AValue: TDateTime): Boolean;
```

C++

```
Boolean TryEncodeDateMonthWeek(const Word AYear, const Word AMonth, const Word AWeekOfMonth,
const Word ADayOfWeek, TDateTime AValue);
```

File

DateUtils

Description

TryEncodeDateMonthWeek calculates the TDateTime value for the date specified by the AYear, AMonth, AWeekOfMonth, and ADayOfWeek parameters.

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AMonth is the year. It can be any value between 1 and 12 (inclusive).

AWeekOfMonth is the week within that month, where 1 is the first week that includes four or more days. Note that if the first calendar day of the month is a Friday, Saturday, or Sunday, then those three days must be expressed using AMonth set to the previous month and AWeekOfMonth set to the number of weeks in the previous month. Similarly, if the last calendar day of the month is a Monday, Tuesday, or Wednesday, then those three days are expressed with AMonth set to the following month and AWeekOfMonth set to 1.

ADayOfWeek is the day of the week, where 1 Monday, 2 is Tuesday, and so on.

AValue returns the specified date as a TDateTime value. The time portion of AValue is 0 (Midnight at the start of the specified day).

TryEncodeDateMonthWeek returns true if AYear, AMonth, AWeekOfMonth, and ADayOfWeek represent a valid date, and false if any of these parameters are not in the valid range.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

TryEncodeDateWeek (see page 6698)

38.1.125 DateUtils.TryEncodeDateTime Function

Calculates the TDateTime value that represents a specified year, month, day, hour, minute, second, and millisecond.

Pascal

```
function TryEncodeDateTime(const AYear: Word; const AMonth: Word; const ADay: Word; const
AHour: Word; const AMinute: Word; const ASecond: Word; const AMilliSecond: Word; out AValue:
TDateTime): Boolean;
```

C++

```
Boolean TryEncodeDateTime(const Word AYear, const Word AMonth, const Word ADay, const Word
AHour, const Word AMinute, const Word ASecond, const Word AMilliSecond, TDateTime AValue);
```

File

DateUtils

Description

TryEncodeDateTime calculates the TDateTime value for the values specified as the AYear, AMonth, ADay, AHour, AMinute, ASecond, and AMilliSecond parameters.

The year must be between 1 and 9999.

Valid month values are 1 through 12.

Valid day values are 1 through 28, 29, 30, or 31, depending on the month value. For example, the possible day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the year value specifies a leap year.

Valid hour values are 0 through 24. (If the specified hour is 24, the minute, second, and millisecond values should all be 0, and the resulting TDateTime value represents midnight at the end of the specified day and the beginning of the next day).

Valid minute values are 0 through 59.

Valid second values are 0 through 59.

Valid millisecond values are 0 through 999.

AValue returns the specified date and time as a TDateTime value.

TryEncodeDateDay (see page 6695) returns true if the parameters are all within range, and false otherwise.

38.1.126 DateUtils.TryEncodeDateWeek Function

Calculates the TDateTime value that represents a specified day of a specified week in a specified year.

Pascal

```
function TryEncodeDateWeek(const AYear: Word; const AWeekOfYear: Word; out AValue: TDateTime;
const ADayOfWeek: Word = 1): Boolean;
```

C++

```
Boolean TryEncodeDateWeek(const Word AYear, const Word AWeekOfYear, TDateTime AValue, const
Word ADayOfWeek = 1);
```

File

DateUtils

Description

TryEncodeDateWeek calculates the TDateTime value for the date specified by the AYear, AWeekOfYear, and ADayOfWeek parameters.

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AWeekOfYear is the week within that year, where 1 is the first week that includes four or more days. Note that if the first calendar day of the year is a Friday, Saturday, or Sunday, then those three days must be expressed using AYear set to the previous year and AWeekOfYear set to the number of weeks in the previous year. Similarly, if the last calendar day of the year is a Monday, Tuesday, or Wednesday, then those three days are expressed with AYear set to the following year and AWeekOfYear set to 1.

ADayOfWeek is the day of the week, where 1 Monday, 2 is Tuesday, and so on.

AValue returns the specified date as a TDateTime value. The time portion of AValue is 0 (Midnight at the start of the specified day).

TryEncodeDateWeek returns true if AYear, AWeekOfYear, and ADayOfWeek represent a valid date, and false if any of these parameters are not in the valid range.

Note: The definitions for AWeekOfYear and ADayOfWeek follow the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

TryEncodeDateMonthWeek (see page 6696)

38.1.127 DateUtils.TryEncodeDayOfWeekInMonth Function

Calculates a TDateTime that represents a specified occurrence of a day of the week within a specified month and year.

Pascal

```
function TryEncodeDayOfWeekInMonth(const AYear: Word; const AMonth: Word; const ANthDayOfWeek:
Word; const ADayOfWeek: Word; out AValue: TDateTime): Boolean;
```

C++

```
Boolean TryEncodeDayOfWeekInMonth(const Word AYear, const Word AMonth, const Word
ANthDayOfWeek, const Word ADayOfWeek, TDateTime AValue);
```

File

DateUtils

Description

TryEncodeDayOfWeekInMonth returns a TDateTime for the date specified by the AYear, AMonth, ANthDayOfWeek, and

ADayOfWeek parameters. The time portion of the return value is 0 (Midnight at the start of the specified day).

AYear is the year. It can be any value between 1 and 9999 (inclusive).

AMonth is the month. It can be any value between 1 and 12 (inclusive).

ANthDayOfWeek indicates the occurrence for the day of the week represented by ADayOfWeek. It can be any value between 1 and 5 (inclusive), as long as this value specifies a valid date. For example, if a month does not include 5 Mondays, setting ANthDayOfWeek to 5 and ADayOfWeek to 1 causes TryEncodeDayOfWeekInMonth to return F false.

ADayOfWeek is the day of the week, where 1 Monday and 7 is Sunday.

TryEncodeDayOfWeekInMonth returns true if AYear, AMonth, ANthDayOfWeek, and ADayOfWeek represent a valid date, and false if this combination does not correspond to a valid date.

Note: The definition for ADayOfWeek follows the ISO 8601 standard.

Tip: To make the ADayOfWeek value more readable, use the Day of week constants.

38.1.128 DateUtils.TryJulianDateToDateTime Function

Converts a Julian date to a TDateTime value.

Pascal

```
function TryJulianDateToDateTime(const AValue: Double; out ADateTime: TDateTime): Boolean;
```

C++

```
Boolean TryJulianDateToDateTime(const Double AValue, TDateTime ADateTime);
```

File

DateUtils

Description

Call TryJulianDateToDateTime to convert a Julian date to the corresponding TDateTime value.

AValue is the Julian date to convert. The Julian date is the number of days, including fractional days, since 4713 BC January 1, Greenwich noon. Julian dates are used by astronomers, geophysicist, and others who need an unambiguous dating system based on continuing day counts.

ADateTime returns the corresponding TDateTime value.

TryJulianDateToDateTime returns true if it can successfully convert AValue to a TDateTime value. It returns false if it can't convert AValue into a TDateTime value.

Convert

JulianDateToDateTime (see page 6656)

ModifiedJulianDateToDateTime (see page 6669)

38.1.129 DateUtils.TryModifiedJulianDateToDateTime Function

Converts a modified Julian date to a TDateTime value.

Pascal

```
function TryModifiedJulianDateToDateTime(const AValue: Double; out ADateTime: TDateTime):
Boolean;
```

C++

```
Boolean TryModifiedJulianDateToDateTime(const Double AValue, TDateTime ADateTime);
```

File

DateUtils

Description

Call TryModifiedJulianDateToDateTime to convert a modified Julian date to the corresponding TDateTime value.

AValue is the modified Julian date to convert. The modified Julian date is the number of days, including fractional days, since Greenwich midnight on November 17, 1858. Modified Julian dates are based on Julian dates, but adjusted to use midnight rather than noon as a starting point and to use a more recent date as a starting point.

ADateTime returns the corresponding TDateTime value.

TryModifiedJulianDateToDateTime returns true if it can successfully convert AValue to a TDateTime value. It returns false if it can't convert AValue into a TDateTime value.

See Also

DateTimeToModifiedJulianDate (see page 6617)

DateTimeToJulianDate (see page 6616)

JulianDateToDateTime (see page 6656)

Convert

TryJulianDateToDateTime (see page 6700)

ModifiedJulianDateToDateTime (see page 6669)

38.1.130 DateUtils.TryRecodeDateTime Function

Selectively replaces parts of a specified TDateTime value.

Pascal

```
function TryRecodeDateTime(const AValue: TDateTime; const AYear: Word; const AMonth: Word;
const ADay: Word; const AHour: Word; const AMinute: Word; const ASecond: Word; const
AMilliSecond: Word; out AResult: TDateTime): Boolean;
```

C++

```
Boolean TryRecodeDateTime(const TDateTime AValue, const Word AYear, const Word AMonth, const
Word ADay, const Word AHour, const Word AMinute, const Word ASecond, const Word AMilliSecond,
TDateTime AResult);
```

File

DateUtils

Description

Call TryRecodeDateTime to convert the date/time value specified by AValue with the value obtained by changing the year to AYear, the month to AMonth, the day of the month to ADay, the hour to AHour, the minute to AMinute, the second to ASecond, and the millisecond to AMilliSecond. Any one of these parameters can be set to RecodeLeaveFieldAsIs (see page 6723), which tells TryRecodeDateTime not change the existing portion of the TDateTime value.

AYear can range from 1 to 9999 (or be RecodeLeaveFieldAsIs (see page 6723)).

AMonth can range from 1 to 12 (or be RecodeLeaveFieldAsIs (see page 6723)).

Legal values for ADay depend on the month represented by AMonth. (For example, if AMonth is 1, ADay can range from 1 to 31; if AMonth is 2, ADay can range from 1 to 28 or 1 to 29, depending on the year; and so on.) ADay can also be RecodeLeaveFieldAsIs (see page 6723).

AHour can range from 0 to 24 (or be RecodeLeaveFieldAsIs (see page 6723)). If AHour is 24, AMinute, ASecond, and AMilliSecond must all be 0.

AMinute can range from 0 to 59 (or be RecodeLeaveFieldAsIs (see page 6723)).

ASecond can range from 0 to 59 (or be RecodeLeaveFieldAsIs (see page 6723)).

AMilliSecond can range from 0 to 999 (or be RecodeLeaveFieldAsIs (see page 6723)).

AResult returns the results of making the specified changes to AValue.

TryRecodeDateTime returns true if the parameters are all in the valid range, false otherwise.

TryEncodeDateTime (see page 6697)

RecodeDateTime (see page 6674)

38.1.131 DateUtils.UnixToDateTime Function

Converts a Unix/Linux style date-and-time value to a TDateTime value.

Pascal

```
function UnixToDateTime(const AValue: Int64): TDateTime;
```

C++

```
TDateTime UnixToDateTime(const Int64 AValue);
```

File

DateUtils

Description

Call UnixToDateTime to convert the Unix/Linux encoding of a date and time value into the corresponding TDateTime.

Unix date-and-time values are encoded as the number of seconds since midnight at the start of January 1, 1970.

See Also

DateTimeToUnix (see page 6617)

Convert

38.1.132 DateUtils.WeekOf Function

Returns the week of the year represented by a TDateTime value.

Pascal

```
function WeekOf(const AValue: TDateTime): Word;
```

C++

```
Word WeekOf(const TDateTime AValue);
```

File

DateUtils

Description

Call WeekOf to obtain the week of the year represented by a specified TDateTime value. WeekOf returns a value between 1 and 53.

WeekOf uses the ISO 8601 standard to define the week of the year. That is, a week is defined as running from Monday through Sunday, and the first week of the year is defined as the one the first calendar week of the year is the one that includes the first Thursday of the year (the first week that includes four or more days in the year). This means that if the first calendar day of the year is a Friday, Saturday, or Sunday, then for the first three, two, or one days of the calendar year, WeekOf returns the last week of the previous year. Similarly, if the last calendar day of the year is a Monday, Tuesday, or Wednesday, then for the last one, two, or three days of the calendar year, WeekOf returns 1 (the first week of the next calendar year).

Note: WeekOf returns the same value as the WeekOfTheYear (see page 6705) function.

See Also

WeekOfTheYear (see page 6705)

WeekOfTheMonth (see page 6704)

HourOf (see page 6638)

MilliSecondOf (see page 6656)

MinuteOf (see page 6663)

MonthOf (see page 6670)

RecodeDate (see page 6673)

SecondOf (see page 6682)

DayOf (see page 6618)

YearOf (see page 6714)

38.1.133 DateUtils.WeekOfTheMonth Function

Returns the week of the month represented by a TDateTime value.

Pascal

```
function WeekOfTheMonth(const AValue: TDateTime): Word; overload;
function WeekOfTheMonth(const AValue: TDateTime; var AYear: Word; var AMonth: Word): Word;
overload;
```

C++

```
Word WeekOfTheMonth(const TDateTime AValue);
Word WeekOfTheMonth(const TDateTime AValue, Word AYear, Word AMonth);
```

File

DateUtils

Description

Call WeekOfTheMonth to obtain the week of the month represented by a specified TDateTime value. WeekOfTheMonth returns a value between 1 and 6.

AYear and AMonth return the year and month in which WeekOfTheMonth occurs. Note that these values may not be the same as the year and month of AValue. This is because the first week of a month is defined as the first week with four or more days in that month. Thus, if the first day of the month is a Friday, Saturday, or Sunday, the first one, two, or three days of the month are defined as belonging to the last week of the previous month. Similarly, if the last day of the month is a Monday, Tuesday, or Wednesday, then the last one, two, or three days of the month are defined as belonging to the first week of the next month.

Tip: To count weeks based on the weekday of the date/time value, use the NthDayOfWeek (see page 6672) function instead. For example, if AValue represents a Saturday that is the first day of a month, WeekOfTheMonth returns 5 (or maybe 4), indicating the last week of the previous month, while NthDayOfWeek (see page 6672) returns 1 AValue is the first Saturday in the month.

Note: WeekOfTheMonth uses the ISO 8601 standard definition of a week. That is, a week is considered to start on a Monday and end on a Sunday.

StartOfTheMonth (see page 6692)

WeeksBetween (see page 6706)

38.1.134 DateUtils.WeekOfTheYear Function

Returns the week of the year represented by a TDateTime value.

Pascal

```
function WeekOfTheYear(const AValue: TDateTime): Word; overload;
function WeekOfTheYear(const AValue: TDateTime; var AYear: Word): Word; overload;
```

C++

```
Word WeekOfTheYear(const TDateTime AValue);
Word WeekOfTheYear(const TDateTime AValue, Word AYear);
```

File

DateUtils

Description

Call WeekOfTheYear to obtain the week of the year represented by a specified TDateTime value. WeekOfTheYear returns a value between 1 and 53.

AYear returns the year in which the specified week occurs. Note that this may not be the same as the year of AValue. This is because the first week of a year is defined as the first week with four or more days in that year. This means that if the first calendar day of the year is a Friday, Saturday, or Sunday, then for the first three, two, or one days of the calendar year, WeekOfTheYear returns the last week of the previous year. Similarly, if the last calendar day of the year is a Monday, Tuesday, or Wednesday, then for the last one, two, or three days of the calendar year, WeekOfTheYear returns 1 (the first week of the next calendar year).

Note: WeekOfTheYear uses the ISO 8601 standard definition of a week. That is, a week is considered to start on a Monday and end on a Sunday.

Note: WeekOfTheYear returns the same value as the WeekOf (see page 6703) function.

WeeksBetween (see page 6706)

WeeksInYear (see page 6707)

38.1.135 DateUtils.WeeksBetween Function

Returns the number of whole weeks between two specified TDateTime values.

Pascal

```
function WeeksBetween(const ANow: TDateTime; const AThen: TDateTime): Integer;
```

C++

```
int WeeksBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call WeeksBetween to obtain the difference, in weeks, between two TDateTime values. WeeksBetween counts only whole Weeks. Thus, WeeksBetween reports the difference between January 1 at 12:00 AM and Jan 6 at 11:58 PM as 0 because the difference is one minute short of an entire week.

See Also

WeekSpan (see page 6708)

HoursBetween (see page 6642)

YearsBetween (see page 6714)

WithinPastWeeks (see page 6712)

38.1.136 DateUtils.WeeksInAYear Function

Returns the number of weeks in a specified year.

Pascal

```
function WeeksInAYear(const AYear: Word): Word;
```

C++

```
Word WeeksInAYear(const Word AYear);
```

File

DateUtils

Description

Call WeeksInAYear to obtain the number of weeks in the year specified by AYear. AYear is a year between 1 and 9999 (inclusive).

Note: WeeksInAYear defines the first week of the year according to the ISO 8601 standard. That is, the first week of the year is the one that includes the first Thursday of the year (the first week that has 4 or more days in the year). This means that WeeksInAYear always returns either 52 or 53.

See Also

WeeksInYear (see page 6707)

WeeksBetween (see page 6706)

WeekOfTheYear (see page 6705)

IsLeapYear

38.1.137 DateUtils.WeeksInYear Function

Returns the number of weeks in the year of a specified TDateTime value.

Pascal

```
function WeeksInYear(const AValue: TDateTime): Word;
```

C++

```
Word WeeksInYear(const TDateTime AValue);
```

File

DateUtils

Description

Call WeeksInYear to obtain the number of weeks in the year of the TDateTime value specified by AValue.

Note: WeeksInYear defines the first week of the year according to the ISO 8601 standard. That is, the first week of the year is the one that includes the first Thursday of the year (the first week that has 4 or more days in the year). This means that WeeksInYear always returns either 52 or 53.

See Also

WeeksInAYear (see page 6706)

EndOfTheYear (see page 6638)

DaysInYear (see page 6623)

38.1.138 DateUtils.WeekSpan Function

Returns the number of weeks (including fractional weeks) between two specified TDateTime values.

Pascal

```
function WeekSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double WeekSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call WeekSpan to obtain the difference, in weeks, between two TDateTime values. Unlike the WeeksBetween (see page 6706) function, which only counts whole weeks, WeekSpan reports incomplete weeks as a fraction of an entire week.

See Also

WeeksBetween (see page 6706)

HourSpan (see page 6643)

MillisecondSpan

MinuteSpan (see page 6668)

MonthSpan (see page 6672)

YearSpan (see page 6715)

38.1.139 DateUtils.WithinPastDays Function

Indicates whether two dates are within a specified number of days of each other.

Pascal

```
function WithinPastDays(const ANow: TDateTime; const AThen: TDateTime; const ADays: Integer):
Boolean;
```

C++

```
Boolean WithinPastDays(const TDateTime ANow, const TDateTime AThen, const int ADays);
```

File

DateUtils

Description

Call WithinPastDays to determine whether the date specified by ANow is within ADays days of the date specified by AThen.

Note: WithinPastDays uses the DaysBetween (see page 6621) function, which means that fractional days do not count. If ANow and AThen are 2 and a half days apart, calling WithinPastDays with ADays set to 2 returns true.

See Also

DaysBetween (see page 6621)

WithinPastYears (see page 6713)

38.1.140 DateUtils.WithinPastHours Function

Indicates whether two date/time values are within a specified number of hours of each other.

Pascal

```
function WithinPastHours(const ANow: TDateTime; const AThen: TDateTime; const AHours: Int64):
Boolean;
```

C++

```
Boolean WithinPastHours(const TDateTime ANow, const TDateTime AThen, const Int64 AHours);
```

File

DateUtils

Description

Call WithinPastHours to determine whether the date and time specified by ANow is within AHours hours of the date and time specified by AThen.

Note: WithinPastHours uses the HoursBetween (see page 6642) function, which means that fractional hours do not count. If ANow and AThen are 2 and a half hours apart, calling WithinPastHours with AHours set to 2 returns true.

See Also

HoursBetween (see page 6642)

38.1.141 DateUtils.WithinPastMilliSeconds Function

Indicates whether two date/time values are within a specified number of milliseconds of each other.

Pascal

```
function WithinPastMilliSeconds(const ANow: TDateTime; const AThen: TDateTime; const
AMilliSeconds: Int64): Boolean;
```

C++

```
Boolean WithinPastMilliSeconds(const TDateTime ANow, const TDateTime AThen, const Int64
AMilliSeconds);
```

File

DateUtils

Description

Call WithinPastMilliSeconds to determine whether the date and time specified by ANow is within AMilliSeconds milliseconds of the date and time specified by AThen.

See Also

WithinPastYears (see page 6713)

38.1.142 DateUtils.WithinPastMinutes Function

Indicates whether two date/time values are within a specified number of minutes of each other.

Pascal

```
function WithinPastMinutes(const ANow: TDateTime; const AThen: TDateTime; const AMinutes:
Int64): Boolean;
```

C++

```
Boolean WithinPastMinutes(const TDateTime ANow, const TDateTime AThen, const Int64 AMinutes);
```

File

DateUtils

Description

Call WithinPastMinutes to determine whether the date and time specified by ANow is within AMinutes minutes of the date and time specified by AThen.

Note: WithinPastMinutes uses the MinutesBetween (see page 6668) function, which means that fractional minutes do not count. If ANow and AThen are 2 and a half minutes apart, calling WithinPastMinutes with AMinutes set to 2 returns true.

See Also

38.1.143 DateUtils.WithinPastMonths Function

Indicates whether two date/time values are within a specified number of months of each other.

Pascal

```
function WithinPastMonths(const ANow: TDateTime; const AThen: TDateTime; const AMonths:
Integer): Boolean;
```

C++

```
Boolean WithinPastMonths(const TDateTime ANow, const TDateTime AThen, const int AMonths);
```

File

DateUtils

Description

Call WithinPastMonths to determine whether the date specified by ANow is within AMonths months of the date specified by AThen.

Note: WithinPastMonths uses the MonthsBetween (see page 6671) function, which means that fractional months do not count. If ANow and AThen are 2 and a half months apart, calling WithinPastMonths with AMonths set to 2 returns true.

WithinPastMinutes (see page 6710)

WithinPastYears (see page 6713)

38.1.144 DateUtils.WithinPastSeconds Function

Indicates whether two date/time values are within a specified number of seconds of each other.

Pascal

```
function WithinPastSeconds(const ANow: TDateTime; const AThen: TDateTime; const ASeconds:
Int64): Boolean;
```

C++

```
Boolean WithinPastSeconds(const TDateTime ANow, const TDateTime AThen, const Int64 ASeconds);
```

File

DateUtils

Description

Call WithinPastSeconds to determine whether the date and time specified by ANow is within ASeconds seconds of the date and time specified by AThen.

Note: WithinPastSeconds uses the SecondsBetween (see page 6687) function, which means that fractional seconds do not count. If ANow and AThen are 2 and a half seconds apart, calling WithinPastSeconds with ASeconds set to 2 returns true.

See Also

SecondsBetween (see page 6687)

WithinPastDays (see page 6708)

WithinPastMilliSeconds (see page 6710)

WithinPastMinutes (see page 6710)

WithinPastHours (see page 6709)

WithinPastWeeks (see page 6712)

WithinPastMonths (see page 6711)

WithinPastYears (see page 6713)

38.1.145 DateUtils.WithinPastWeeks Function

Indicates whether two date/time values are within a specified number of weeks of each other.

Pascal

```
function WithinPastWeeks(const ANow: TDateTime; const AThen: TDateTime; const AWeeks:
Integer): Boolean;
```

C++

```
Boolean WithinPastWeeks(const TDateTime ANow, const TDateTime AThen, const int AWeeks);
```

File

DateUtils

Description

Call WithinPastWeeks to determine whether the date specified by ANow is within AWeeks weeks of the date specified by AThen.

Note: WithinPastWeeks uses the WeeksBetween (see page 6706) function, which means that fractional weeks do not count. If ANow and AThen are 2 and a half weeks apart, calling WithinPastWeeks with AWeeks set to 2 returns true.

See Also

WeeksBetween (see page 6706)

WithinPastDays (see page 6708)

WithinPastMilliSeconds (see page 6710)

WithinPastSeconds (see page 6712)

WithinPastHours (see page 6709)

WithinPastMinutes (see page 6710)

WithinPastMonths (see page 6711)

WithinPastYears (see page 6713)

38.1.146 DateUtils.WithinPastYears Function

Indicates whether two date/time values are within a specified number of years of each other.

Pascal

```
function WithinPastYears(const ANow: TDateTime; const AThen: TDateTime; const AYears:
Integer): Boolean;
```

C++

```
Boolean WithinPastYears(const TDateTime ANow, const TDateTime AThen, const int AYears);
```

File

DateUtils

Description

Call WithinPastYears to determine whether the date specified by ANow is within AYears years of the date specified by AThen.

Note: WithinPastYears uses the YearsBetween (see page 6714) function, which means that fractional years do not count. If ANow and AThen are 2 and a half years apart, calling WithinPastYears with AYears set to 2 returns true.

See Also

YearsBetween (see page 6714)

WithinPastDays (see page 6708)

WithinPastMilliSeconds (see page 6710)

WithinPastSeconds (see page 6712)

WithinPastHours (see page 6709)

WithinPastWeeks (see page 6712)

WithinPastMonths (see page 6711)

WithinPastMinutes (see page 6710)

38.1.147 DateUtils.YearOf Function

Returns the year represented by a TDateTime value.

Pascal

```
function YearOf(const AValue: TDateTime): Word;
```

C++

```
Word YearOf(const TDateTime AValue);
```

File

DateUtils

Description

Call YearOf to obtain the year represented by a specified TDateTime value. YearOf returns a value between 1 and 9999.

See Also

DecodeDate

DayOf (see page 6618)

MilliSecondOf (see page 6656)

MinuteOf (see page 6663)

HourOf (see page 6638)

RecodeDateYear

SecondOf (see page 6682)

WeekOf (see page 6703)

MonthOf (see page 6670)

38.1.148 DateUtils.YearsBetween Function

Returns the approximate number of years between two specified TDateTime values.

Pascal

```
function YearsBetween(const ANow: TDateTime; const AThen: TDateTime): Integer;
```

C++

```
int YearsBetween(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call YearsBetween to obtain the difference, in years, between two TDateTime values. Because years are not all the same length (e.g. leap years), YearsBetween returns an approximation based on an assumption of 365.25 days per year. Fractional years are

not counted. Thus, for example, YearsBetween reports the difference between Jan 1 and Dec 31 as 0 on non-leap years and 1 on leap years.

See Also

YearSpan (see page 6715)

DaysBetween (see page 6621)

MillisecondsBetween

MinutesBetween (see page 6668)

HoursBetween (see page 6642)

SecondsBetween (see page 6687)

WeeksBetween (see page 6706)

MonthsBetween (see page 6671)

WithinPastYears (see page 6713)

38.1.149 DateUtils.YearSpan Function

Returns the approximate number of years (including fractions thereof) between two specified TDateTime values.

Pascal

```
function YearSpan(const ANow: TDateTime; const AThen: TDateTime): Double;
```

C++

```
Double YearSpan(const TDateTime ANow, const TDateTime AThen);
```

File

DateUtils

Description

Call YearSpan to obtain the difference, in years, between two TDateTime values. Because years are not all the same length (e.g. leap years), YearsBetween (see page 6714) returns an approximation based on an assumption of 365.25 days per year. Unlike the YearsBetween (see page 6714) function, which does not report fractional years, YearSpan reports incomplete years as a fraction of a 365.25-day year.

See Also

YearsBetween (see page 6714)

DaySpan (see page 6624)

MillisecondSpan

MinuteSpan (see page 6668)

HourSpan (see page 6643)

SecondSpan (see page 6688)

WeekSpan (see page 6708)

MonthSpan (see page 6672)

38.1.150 DateUtils.Yesterday Function

Returns a TDateTime value that represents the preceding day.

Pascal

```
function Yesterday: TDateTime;
```

C++

```
TDateTime Yesterday();
```

File

DateUtils

Description

Yesterday returns a TDateTime value with the date portion set to the day before the current date and the time portion set to 0.

Tomorrow (see page 6695)

38.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ApproxDaysPerMonth (see page 6717)	This is variable DateUtils.ApproxDaysPerMonth.
ApproxDaysPerYear (see page 6717)	This is variable DateUtils.ApproxDaysPerYear.

38.2.1 DateUtils.ApproxDaysPerMonth Variable

Pascal

```
ApproxDaysPerMonth: Double = 30.4375;
```

C++

```
Double ApproxDaysPerMonth = 30.4375;
```

File

DateUtils

Description

This is variable DateUtils.ApproxDaysPerMonth.

38.2.2 DateUtils.ApproxDaysPerYear Variable

Pascal

```
ApproxDaysPerYear: Double = 365.25;
```

C++

```
Double ApproxDaysPerYear = 365.25;
```

File

DateUtils

Description

This is variable DateUtils.ApproxDaysPerYear.

38.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DayFriday (see page 6718)	This is constant DateUtils.DayFriday.
DayMonday (see page 6718)	This is constant DateUtils.DayMonday.
DaySaturday (see page 6719)	This is constant DateUtils.DaySaturday.
DaysPerWeek (see page 6719)	This is constant DateUtils.DaysPerWeek.
DaysPerYear (see page 6719)	This is constant DateUtils.DaysPerYear.
DaySunday (see page 6720)	This is constant DateUtils.DaySunday.
DayThursday (see page 6720)	This is constant DateUtils.DayThursday.
DayTuesday (see page 6720)	This is constant DateUtils.DayTuesday.
DayWednesday (see page 6721)	This is constant DateUtils.DayWednesday.
MonthsPerYear (see page 6721)	This is constant DateUtils.MonthsPerYear.
OneHour (see page 6721)	Delphi inverse time unit constants.
OneMillisecond (see page 6722)	This is constant DateUtils.OneMillisecond.
OneMinute (see page 6722)	This is constant DateUtils.OneMinute.
OneSecond (see page 6722)	This is constant DateUtils.OneSecond.
RecodeLeaveFieldAsIs (see page 6723)	This is constant DateUtils.RecodeLeaveFieldAsIs.
WeeksPerFortnight (see page 6723)	This is constant DateUtils.WeeksPerFortnight.
YearsPerCentury (see page 6723)	This is constant DateUtils.YearsPerCentury.
YearsPerDecade (see page 6724)	This is constant DateUtils.YearsPerDecade.
YearsPerMillennium (see page 6724)	This is constant DateUtils.YearsPerMillennium.

38.3.1 DateUtils.DayFriday Constant

Pascal

```
DayFriday = 5;
```

C++

```
DayFriday = 5;
```

File

DateUtils

Description

This is constant DateUtils.DayFriday.

38.3.2 DateUtils.DayMonday Constant

Pascal

```
DayMonday = 1;
```

C++

```
DayMonday = 1;
```

File

DateUtils

Description

This is constant DateUtils.DayMonday.

38.3.3 DateUtils.DaySaturday Constant

Pascal

```
DaySaturday = 6;
```

C++

```
DaySaturday = 6;
```

File

DateUtils

Description

This is constant DateUtils.DaySaturday.

38.3.4 DateUtils.DaysPerWeek Constant

Pascal

```
DaysPerWeek = 7;
```

C++

```
DaysPerWeek = 7;
```

File

DateUtils

Description

This is constant DateUtils.DaysPerWeek.

38.3.5 DateUtils.DaysPerYear Constant

Pascal

```
DaysPerYear: array [Boolean] of Word = (365, 366);
```

C++

```
array [Boolean] of Word DaysPerYear = (365, 366);
```

File

DateUtils

Description

This is constant DateUtils.DaysPerYear.

38.3.6 DateUtils.DaySunday Constant

Pascal

```
DaySunday = 7;
```

C++

```
DaySunday = 7;
```

File

DateUtils

Description

This is constant DateUtils.DaySunday.

38.3.7 DateUtils.DayThursday Constant

Pascal

```
DayThursday = 4;
```

C++

```
DayThursday = 4;
```

File

DateUtils

Description

This is constant DateUtils.DayThursday.

38.3.8 DateUtils.DayTuesday Constant

Pascal

```
DayTuesday = 2;
```

C++

```
DayTuesday = 2;
```

File

DateUtils

Description

This is constant DateUtils.DayTuesday.

38.3.9 DateUtils.DayWednesday Constant

Pascal

```
DayWednesday = 3;
```

C++

```
DayWednesday = 3;
```

File

DateUtils

Description

This is constant DateUtils.DayWednesday.

38.3.10 DateUtils.MonthsPerYear Constant

Pascal

```
MonthsPerYear = 12;
```

C++

```
MonthsPerYear = 12;
```

File

DateUtils

Description

This is constant DateUtils.MonthsPerYear.

38.3.11 DateUtils.OneHour Constant

Delphi inverse time unit constants.

Pascal

```
OneHour = 1 / HoursPerDay;
```

C++

```
OneHour = 1 / HoursPerDay;
```

File

DateUtils

Description

These constants are inverses of the time constants defined in the SysUtils (see page 22709) unit.

See Also

Time

38.3.12 DateUtils.OneMillisecond Constant

Pascal

```
OneMillisecond = 1 / MSecsPerDay;
```

C++

```
OneMillisecond = 1 / MSecsPerDay;
```

File

DateUtils

Description

This is constant DateUtils.OneMillisecond.

38.3.13 DateUtils.OneMinute Constant

Pascal

```
OneMinute = 1 / MinsPerDay;
```

C++

```
OneMinute = 1 / MinsPerDay;
```

File

DateUtils

Description

This is constant DateUtils.OneMinute.

38.3.14 DateUtils.OneSecond Constant

Pascal

```
OneSecond = 1 / SecsPerDay;
```

C++

```
OneSecond = 1 / SecsPerDay;
```

File

DateUtils

Description

This is constant DateUtils.OneSecond.

38.3.15 DateUtils.RecodeLeaveFieldAsIs Constant

Pascal

```
RecodeLeaveFieldAsIs = High(Word);
```

C++

```
RecodeLeaveFieldAsIs = High(Word);
```

File

DateUtils

Description

This is constant DateUtils.RecodeLeaveFieldAsIs.

38.3.16 DateUtils.WeeksPerFortnight Constant

Pascal

```
WeeksPerFortnight = 2;
```

C++

```
WeeksPerFortnight = 2;
```

File

DateUtils

Description

This is constant DateUtils.WeeksPerFortnight.

38.3.17 DateUtils.YearsPerCentury Constant

Pascal

```
YearsPerCentury = 100;
```

C++

```
YearsPerCentury = 100;
```

File

DateUtils

Description

This is constant DateUtils.YearsPerCentury.

38.3.18 DateUtils.YearsPerDecade Constant

Pascal

```
YearsPerDecade = 10;
```

C++

```
YearsPerDecade = 10;
```

File

DateUtils

Description

This is constant DateUtils.YearsPerDecade.

38.3.19 DateUtils.YearsPerMillennium Constant

Pascal

```
YearsPerMillennium = 1000;
```

C++

```
YearsPerMillennium = 1000;
```

File

DateUtils

Description

This is constant DateUtils.YearsPerMillennium.

39 DB Namespace

This is namespace DB.

Topics

Name	Description
Classes (see page 6730)	The following table lists classes in this documentation.
Interfaces (see page 7569)	The following table lists interfaces in this documentation.

Structs, Records, Enums (see page 7604)	The following table lists structs, records, enums in this documentation.
Types (see page 7625)	The following table lists types in this documentation.
Variables (see page 7641)	The following table lists variables in this documentation.
Constants (see page 7645)	The following table lists constants in this documentation.

Classes

	Name	Description
	EDatabaseError (see page 6731)	EDatabaseError is the exception class for database errors.
	EUpdateError (see page 6732)	EUpdateError is the exception class for dataset provider update errors.
	TADTField (see page 6736)	A TADTField object represents an ADT (Abstract Data Type) field in a dataset.
	TAggregateField (see page 6743)	TAggregate field represents a maintained aggregate in a client dataset.
	TArrayField (see page 6760)	TArrayField represents an Array field in a dataset.
	TAutoIncField (see page 6768)	TAutoIncField is a persistent field object for an autoincrement field in a dataset.
	TBCDField (see page 6776)	TBCDField represents a binary-coded decimal (BCD) field in a dataset.
	TBinaryField (see page 6791)	TBinaryField represents an untyped binary field in a dataset.
	TBlobField (see page 6801)	TBlobField represents a field in a dataset that holds a reference to a binary large object (BLOB).
	TBooleanField (see page 6822)	TBooleanField represents a field containing Boolean values.
	TBytesField (see page 6833)	TBytesField represents a bytes field in a dataset.
	TCheckConstraint (see page 6841)	TCheckConstraint represents a record-level constraint on a dataset component.
	TCheckConstraints (see page 6846)	TCheckConstraints contains a collection of check constraints for a dataset component.
	TCurrencyField (see page 6850)	TCurrencyField represents a field that contains currency (see page 6857) values in a dataset.
	TCustomConnection (see page 6858)	TCustomConnection is the base class for components that connect datasets to a remote source of data.
	TDataLink (see page 6876)	TDataLink is a helper class used by data-aware objects to coordinate the actions of TDataSource (see page 7070) and TDataSet (see page 6894), and to respond to data events.

	TDataSet (see page 6894)	TDataSet is the base class for all dataset components that represent data in rows and columns.
	TDataSetDesigner (see page 7056)	TDataSetDesigner is the base class for all dataset designers.
	TDataSetField (see page 7060)	TDataSetField provides access to nested datasets.
	TDataSource (see page 7070)	TDataSource provides an interface between a dataset component and data-aware controls on a form.
	TDateField (see page 7083)	TDateField represents a date field in a dataset.
	TDateTimeField (see page 7090)	TDateTimeField represents a date-time field in a dataset.
	TDefCollection (see page 7104)	TDefCollection holds the definition objects (TNamedItem (see page 7357)) that represent the specifications for database entities such as fields or indexes.
	TDetailDataLink (see page 7111)	TDetailDataLink is the ancestor to datalink classes that manage the relationships between datasets that are linked in master/detail relationships.
	TField (see page 7115)	TField is the common ancestor of all the field components.
	TFieldDef (see page 7184)	TFieldDef is a field definition that corresponds to a physical field of a record in a table underlying a dataset.
	TFieldDefList (see page 7195)	TFieldDefList lists the field definition (TFieldDef (see page 7184)) objects of a dataset in a flattened form.
	TFieldDefs (see page 7198)	TFieldDefs holds the field definition (TFieldDef (see page 7184)) objects that represent the physical fields underlying a dataset.
	TFieldList (see page 7207)	TFieldList lists the fields of a dataset, flattening out the structure of any object fields.
	TFields (see page 7211)	TFields holds the field (TField (see page 7115)) objects that represent the physical fields underlying a dataset or an object field such as TADTField (see page 6736) and TArrayField (see page 6760).
	TFieldsEnumerator (see page 7222)	Enumerates database fields.
	TFlatList (see page 7225)	TFlatList is an abstract base class for objects that represent a flattened list of fields or field definitions.
	TFloatField (see page 7229)	TFloatField represents a field that contains floating-point values in a dataset.
	TFMTBCDField (see page 7242)	TFMTBCDField represents a binary-coded decimal (BCD) field in a dataset.
	TGraphicField (see page 7257)	TGraphicField represents a graphics field in a dataset.
	TGuidField (see page 7265)	TGuidField represents a guid field in a dataset.
	TIDispatchField (see page 7274)	TIDispatchField represents an IDispatch field in a dataset.
	TIndexDef (see page 7283)	TIndexDef describes an index in a database table.
	TIndexDefs (see page 7292)	TIndexDefs holds the list of available index definitions for a table.
	TIntegerField (see page 7301)	TIntegerField represents a signed 32-bit integer field in a dataset.
	TInterfaceField (see page 7314)	TInterfaceField represents an interface field in a dataset.
	TLargeintField (see page 7323)	A TLargeintField object represents a large integer field in a dataset.
	TLookupList (see page 7336)	TLookupList maintains a list of lookup values associated with a set of key field values.
	TMasterDataLink (see page 7339)	TMasterDataLink allows a dataset to establish a master/detail relationship.
	TMemoField (see page 7348)	TMemoField represents a memo field in a dataset.
	TNamedItem (see page 7357)	TNamedItem is the base class for definitions used by datasets.
	TNumericField (see page 7361)	TNumericField is the common ancestor of all the numeric fields in a dataset.
	TObjectField (see page 7372)	TObjectField is the common ancestor of TADTField (see page 6736), TArrayField (see page 6760), TDataSetField (see page 7060), and TReferenceField (see page 7452) components in a dataset.
	TParam (see page 7386)	TParam represents a field parameter for a query or stored procedure.
	TParams (see page 7434)	TParams manages a list of field parameters.
	TReferenceField (see page 7452)	TReferenceField represents a REF field in a dataset.
	TSmallintField (see page 7461)	TSmallIntField represents a signed 16-bit integer field in a dataset.
	TSQLTimeStampField (see page 7469)	TSQLTimeStampField represents a date-time field in a DBExpress dataset.
	TStringField (see page 7483)	TStringField represents a string field in a dataset.
	TTimeField (see page 7499)	TTimeField represents a time field in a dataset.
	TVarBytesField (see page 7507)	TVarBytesField represents a variable-length untyped binary field in a dataset.
	TVariantField (see page 7514)	TVariantField represents a variant field in a dataset.
	TWideDataSet (see page 7526)	Base class for all dataset components that represent Unicode data in rows and columns.
	TWideMemoField (see page 7541)	TWideMemoField represents a memo field in a dataset.
	TWideStringField (see page 7549)	TWideStringField represents a large string field in a dataset.

	TWordField (see page 7560)	TWordField represents an unsigned 16-bit integer field in a dataset.

Constants

Name	Description
dsEditModes (see page 7645)	This is constant DB.dsEditModes.
dsMaxStringSize (see page 7645)	This is constant DB.dsMaxStringSize.
dsWriteModes (see page 7646)	This is constant DB.dsWriteModes.
FieldTypeNames (see page 7646)	This is constant DB.FieldTypeNames.
FieldTypeVarMap (see page 7646)	This is constant DB.FieldTypeVarMap.
ftFixedSizeTypes (see page 7647)	This is constant DB.ftFixedSizeTypes.
ftNonTextTypes (see page 7647)	This is constant DB.ftNonTextTypes.
ObjectFieldTypes (see page 7648)	This is constant DB.ObjectFieldTypes.
RegisterFieldsProc (see page 7648)	This is constant DB.RegisterFieldsProc.

Functions

	Name	Description
	BuffersEqual (see page 7599)	This is function DB.BuffersEqual.
	DatabaseError (see page 7599)	Creates and raises an EDatabaseError (see page 6731) exception.
	DatabaseErrorFmt (see page 7600)	Creates and raises an EDatabaseError (see page 6731) exception with a formatted error message.
	DisposeMem (see page 7600)	This is function DB.DisposeMem.
	ExtractFieldName (see page 7601)	Returns the next name in a semicolon-delimited string of field names.
	ExtractFieldName (see page 7601)	Returns the next name in a semicolon-delimited string of field names.
	GetFieldProperty (see page 7602)	Returns a TField (see page 7115) object for a dataset and data control.
	RegisterFields (see page 7602)	Registers a set of field components so that they appear in the Dataset designer.
	VarTypeToDataType (see page 7603)	Returns the field type value that most closely corresponds to a Variant type.

Interfaces

	Name	Description
	IDBApplication (see page 7569)	Interface for database application.
	IDBScreen (see page 7571)	Interface to display device.
	IDBSession (see page 7573)	IDBSession is the interface for database sessions.
	IProviderSupport (see page 7576)	IProviderSupport is the interface that datasets use to enable a provider to represent them.
	IProviderSupport2 (see page 7587)	Interface datasets use to enable providers to represent them with Unicode support.

Structs, Records, Enums

	Name	Description
	TAutoRefreshFlag (see page 7604)	TAutoRefreshFlag Indicates whether the server provides field values, and if so, why.
	TBlobStreamMode (see page 7605)	TBlobStreamMode indicates how a BLOB stream can be used.
	TBookmarkFlag (see page 7606)	This is record DB.TBookmarkFlag.
	TDataAction (see page 7606)	TDataAction indicates how an application should respond to a database error condition.
	TDataEvent (see page 7607)	TDataEvent identifies an event that occurs to a dataset.
	TDataSetState (see page 7608)	TDataSetState indicates the current operating mode of a dataset component.
	TDateTimeRec (see page 7610)	This is record DB.TDateTimeRec.
	TDBScreenCursor (see page 7610)	This is record DB.TDBScreenCursor.
	TFieldAttribute (see page 7611)	TFieldAttribute and TFieldAttributes (see page 7632) indicate various attributes of a field.
	TFieldKind (see page 7611)	TFieldKind indicates what type of information a field component represents.
	TFieldType (see page 7612)	TFieldType is a set of values that parallel the data types of fields in tables.
	TFilterOption (see page 7615)	TFilterOption and TFilterOptions (see page 7635) influence how filter strings are applied.
	TGetMode (see page 7615)	This is record DB.TGetMode.
	TGetResult (see page 7616)	This is record DB.TGetResult.

	TGroupPosInd (see page 7616)	TGroupPosInd and TGroupPosInds (see page 7636) indicate the position of the current record within its group.
	TIndexOption (see page 7617)	This is record DB.TIndexOption.
	TLocateOption (see page 7618)	This is record DB.TLocateOption.
	TLookupListEntry (see page 7618)	This is record DB.TLookupListEntry.
	TPacketAttribute (see page 7618)	This is record DB.TPacketAttribute.
	TParamType (see page 7619)	TParamType and TParamTypes (see page 7637) represent the use of parameters on datasets that represent queries or stored procedures.
	TProviderFlag (see page 7620)	TProviderFlag and TProviderFlags (see page 7638) indicate how a provider uses a field value when applying updates.
	TPSCommandType (see page 7621)	This is record DB.TPSCommandType.
	TUpdateAction (see page 7621)	TUpdateAction Indicates how an a dataset should proceed after an event handler has processed an update.
	TUpdateKind (see page 7622)	TUpdateKind defines the values for the UpdateKind parameter of OnUpdateError and OnUpdateRecord event handlers.
	TUpdateMode (see page 7623)	TUpdateMode indicates how to locate records so that they can be updated.
	TUpdateStatus (see page 7623)	TUpdateStatus indicates the update status of a record.

Types

Name	Description
Largeint (see page 7626)	This is type DB.Largeint.
PBookmarkFlag (see page 7626)	This is type DB.PBookmarkFlag.
PLookupListEntry (see page 7626)	This is type DB.PLookupListEntry.
PPacketAttribute (see page 7627)	This is type DB.PPacketAttribute.
TBlobByteData (see page 7627)	TBlobByteData stores the contents of a Binary Large Object (BLOB) field.
TBlobData (see page 7627)	This is type DB.TBlobData.
TBlobType (see page 7628)	TBlobType indicates the type of a BLOB field.
TBookmark (see page 7628)	TBookmark identifies a record in a dataset for later navigation.
TBookmarkStr (see page 7629)	TBookmarkStr is a bookmark, represented as a string.
TBufferList (see page 7629)	This is type DB.TBufferList.
TConnectChangeEvent (see page 7630)	This is type DB.TConnectChangeEvent.
TDataChangeEvent (see page 7630)	This is type DB.TDataChangeEvent.
TDataOperation (see page 7630)	This is type DB.TDataOperation.
TDataSetClass (see page 7631)	TDataSetClass is the class type of a TDataSet (see page 6894) descendant.
TDataSetErrorEvent (see page 7631)	This is type DB.TDataSetErrorEvent.
TDataSetNotifyEvent (see page 7631)	This is type DB.TDataSetNotifyEvent.
TDateTimeAlias (see page 7632)	This is type DB.TDateTimeAlias.
TDefUpdateMethod (see page 7632)	This is type DB.TDefUpdateMethod.
TFieldAttributes (see page 7632)	This is type DB.TFieldAttributes.
TFieldChars (see page 7633)	TFieldChars indicates the set of characters that are valid for field.
TFieldClass (see page 7633)	TFieldClass is the class type of a TField (see page 7115) descendant.
TFieldGetTextEvent (see page 7633)	This is type DB.TFieldGetTextEvent.
TFieldKinds (see page 7634)	This is type DB.TFieldKinds.
TFieldNotifyEvent (see page 7634)	This is type DB.TFieldNotifyEvent.
TFieldRef (see page 7634)	This is type DB.TFieldRef.
TFieldSetTextEvent (see page 7635)	This is type DB.TFieldSetTextEvent.
TFilterOptions (see page 7635)	This is type DB.TFilterOptions.
TFilterRecordEvent (see page 7635)	This is type DB.TFilterRecordEvent.
TGroupPosInds (see page 7636)	This is type DB.TGroupPosInds.
TIndexOptions (see page 7636)	TIndexOptions describes the attributes of an index.
TLocateOptions (see page 7637)	TLocateOptions defines the values for the Options parameter of the Locate method of a dataset.
TParamTypes (see page 7637)	This is type DB.TParamTypes.
TProviderFlags (see page 7638)	This is type DB.TProviderFlags.
TResyncMode (see page 7638)	TResyncMode is a set of flags that indicate operations a dataset should perform when resynchronizing data.
TSQLCommandType (see page 7638)	This is type DB.TSQLCommandType.

TUpdateErrorEvent (see page 7639)	This is type DB.TUpdateErrorEvent.
TUpdateRecordEvent (see page 7639)	This is type DB.TUpdateRecordEvent.
TUpdateRecordTypes (see page 7639)	This is type DB.TUpdateRecordTypes.
TUpdateStatusSet (see page 7640)	This is type DB.TUpdateStatusSet.

Variables

Name	Description
DBApplication (see page 7641)	This is variable DB.DBApplication.
DBScreen (see page 7641)	This is variable DB.DBScreen.
DefaultFieldClasses (see page 7642)	This is variable DB.DefaultFieldClasses.
LoginDialogExProc (see page 7642)	This is variable DB.LoginDialogExProc.
LoginDialogProc (see page 7642)	This is variable DB.LoginDialogProc.
PasswordDialog (see page 7643)	Displays a dialog box that prompts the user for the password of a local password-protected table.
RemoteLoginDialogProc (see page 7643)	This is variable DB.RemoteLoginDialogProc.
ScreenCursorProc (see page 7644)	This is variable DB.ScreenCursorProc.

39.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EDatabaseError (see page 6731)	EDatabaseError is the exception class for database errors.
	EUpdateError (see page 6732)	EUpdateError is the exception class for dataset provider update errors.
	TADTField (see page 6736)	A TADTField object represents an ADT (Abstract Data Type) field in a dataset.
	TAggregateField (see page 6743)	TAggregate field represents a maintained aggregate in a client dataset.
	TArrayField (see page 6760)	TArrayField represents an Array field in a dataset.
	TAutoIncField (see page 6768)	TAutoIncField is a persistent field object for an autoincrement field in a dataset.
	TBCDField (see page 6776)	TBCDField represents a binary-coded decimal (BCD) field in a dataset.
	TBinaryField (see page 6791)	TBinaryField represents an untyped binary field in a dataset.
	TBlobField (see page 6801)	TBlobField represents a field in a dataset that holds a reference to a binary large object (BLOB).
	TBooleanField (see page 6822)	TBooleanField represents a field containing Boolean values.
	TBytesField (see page 6833)	TBytesField represents a bytes field in a dataset.
	TCheckConstraint (see page 6841)	TCheckConstraint represents a record-level constraint on a dataset component.
	TCheckConstraints (see page 6846)	TCheckConstraints contains a collection of check constraints for a dataset component.
	TCurrencyField (see page 6850)	TCurrencyField represents a field that contains currency (see page 6857) values in a dataset.
	TCustomConnection (see page 6858)	TCustomConnection is the base class for components that connect datasets to a remote source of data.
	TDataLink (see page 6876)	TDataLink is a helper class used by data-aware objects to coordinate the actions of TDataSource (see page 7070) and TDataSet (see page 6894), and to respond to data events.
	TDataSet (see page 6894)	TDataSet is the base class for all dataset components that represent data in rows and columns.
	TDataSetDesigner (see page 7056)	TDataSetDesigner is the base class for all dataset designers.
	TDataSetField (see page 7060)	TDataSetField provides access to nested datasets.
	TDataSource (see page 7070)	TDataSource provides an interface between a dataset component and data-aware controls on a form.
	TDateField (see page 7083)	TDateField represents a date field in a dataset.
	TDateTimeField (see page 7090)	TDateTimeField represents a date-time field in a dataset.
	TDefCollection (see page 7104)	TDefCollection holds the definition objects (TNamedItem (see page 7357)) that represent the specifications for database entities such as fields or indexes.
	TDetailDataLink (see page 7111)	TDetailDataLink is the ancestor to datalink classes that manage the relationships between datasets that are linked in master/detail relationships.
	TField (see page 7115)	TField is the common ancestor of all the field components.
	TFieldDef (see page 7184)	TFieldDef is a field definition that corresponds to a physical field of a record in a table underlying a dataset.
	TFieldDefList (see page 7195)	TFieldDefList lists the field definition (TFieldDef (see page 7184)) objects of a dataset in a flattened form.
	TFieldDefs (see page 7198)	TFieldDefs holds the field definition (TFieldDef (see page 7184)) objects that represent the physical fields underlying a dataset.
	TFieldList (see page 7207)	TFieldList lists the fields of a dataset, flattening out the structure of any object fields.
	TFields (see page 7211)	TFields holds the field (TField (see page 7115)) objects that represent the physical fields underlying a dataset or an object field such as TADTField (see page 6736) and TArrayField (see page 6760).
	TFieldsEnumerator (see page 7222)	Enumerates database fields.
	TFlatList (see page 7225)	TFlatList is an abstract base class for objects that represent a flattened list of fields or field definitions.

	TFloatField (see page 7229)	TFloatField represents a field that contains floating-point values in a dataset.
	TFMTBCDField (see page 7242)	TFMTBCDField represents a binary-coded decimal (BCD) field in a dataset.
	TGraphicField (see page 7257)	TGraphicField represents a graphics field in a dataset.
	TGuidField (see page 7265)	TGuidField represents a guid field in a dataset.
	TIDispatchField (see page 7274)	TIDispatchField represents an IDispatch field in a dataset.
	TIndexDef (see page 7283)	TIndexDef describes an index in a database table.
	TIndexDefs (see page 7292)	TIndexDefs holds the list of available index definitions for a table.
	TIntegerField (see page 7301)	TIntegerField represents a signed 32-bit integer field in a dataset.
	TInterfaceField (see page 7314)	TInterfaceField represents an interface field in a dataset.
	TLargeintField (see page 7323)	A TLargeintField object represents a large integer field in a dataset.
	TLookupList (see page 7336)	TLookupList maintains a list of lookup values associated with a set of key field values.
	TMasterDataLink (see page 7339)	TMasterDataLink allows a dataset to establish a master/detail relationship.
	TMemoField (see page 7348)	TMemoField represents a memo field in a dataset.
	TNamedItem (see page 7357)	TNamedItem is the base class for definitions used by datasets.
	TNumericField (see page 7361)	TNumericField is the common ancestor of all the numeric fields in a dataset.
	TObjectField (see page 7372)	TObjectField is the common ancestor of TADTField (see page 6736), TArrayField (see page 6760), TDataSetField (see page 7060), and TReferenceField (see page 7452) components in a dataset.
	TParam (see page 7386)	TParam represents a field parameter for a query or stored procedure.
	TParams (see page 7434)	TParams manages a list of field parameters.
	TReferenceField (see page 7452)	TReferenceField represents a REF field in a dataset.
	TSmallintField (see page 7461)	TSmallIntField represents a signed 16-bit integer field in a dataset.
	TSQLTimeStampField (see page 7469)	TSQLTimeStampField represents a date-time field in a DBExpress dataset.
	TStringField (see page 7483)	TStringField represents a string field in a dataset.
	TTimeField (see page 7499)	TTimeField represents a time field in a dataset.
	TVarBytesField (see page 7507)	TVarBytesField represents a variable-length untyped binary field in a dataset.
	TVariantField (see page 7514)	TVariantField represents a variant field in a dataset.
	TWideDataSet (see page 7526)	Base class for all dataset components that represent Unicode data in rows and columns.
	TWideMemoField (see page 7541)	TWideMemoField represents a memo field in a dataset.
	TWideStringField (see page 7549)	TWideStringField represents a large string field in a dataset.
	TWordField (see page 7560)	TWordField represents an unsigned 16-bit integer field in a dataset.

39.1.1 EDatabaseError Class

EDatabaseError is the exception class for database errors.

Class Hierarchy

Pascal

```
EDatabaseError = class(Exception);
```

C++

```
class EDatabaseError : public Exception;
```

File

DB

Description

EDatabaseError is raised when a component detects a database error. Use EDatabaseError in an exception handling block or to create a database exception.

See Also

TDataSet (see page 6894)

DatabaseError

39.1.2 EUpdateError Class

EUpdateError is the exception class for dataset provider update errors.

Class Hierarchy

Pascal

```
EUpdateError = class(EDatabaseError);
```

C++

```
class EUpdateError : public EDatabaseError;
```

File

DB

Description

EUpdateError is raised if an error occurs when updates are applied by a provider component. raise this exception class for update errors when implementing the IProviderSupport (see page 7576) interface in a custom dataset.

See Also

TBaseProvider (see page 18423)

IProviderSupport (see page 7576)

39.1.2.1 EUpdateError Members

The following tables list the members exposed by EUpdateError.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6733)	Creates and initializes an instance of EUpdateError (see page 6732).
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.

	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 6734)	Destroys an instance of EUpdateError (see page 6732).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Context (see page 6734)	Contains context information from the error stack.
R	ErrorCode (see page 6735)	Indicates the error code that this exception represents.
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.
R	OriginalException (see page 6735)	Indicates the exception object that this update error represents.
R	PreviousError (see page 6736)	Indicates the previous error code for this update process.

39.1.2.2 EUpdateError.Create Constructor

Creates and initializes an instance of EUpdateError (see page 6732).

Pascal

```
constructor Create(NativeError: string; Context: string; ErrCode: Integer; PrevError: Integer;
E: Exception);
```

C++

```
__fastcall EUpdateError(AnsiString NativeError, AnsiString Context, int ErrCode, int
PrevError, Exception E);
```

Description

Create generates an EUpdateError (see page 6732) object to represent another error that is caught while applying updates.

NativeError specifies the error message for the exception.

Context (see page 6734) is a string providing additional context information. It becomes the value of the Context (see page

6734) property.

ErrCode and PrevError specify error codes for this exception or the previous exception in this update operation. If the current exception or previous exception does not have an error code, the corresponding argument is 0. The ErrCode and PrevError parameters initialize the ErrorCode (see page 6735) and PreviousError (see page 6736) properties.

Exception specifies the exception that was caught (which this EUpdateError (see page 6732) represents). It becomes the value of the OriginalException (see page 6735) property.

See Also

Context (see page 6734)

ErrorCode (see page 6735)

PreviousError (see page 6736)

EDBEngineError (see page 9854)

OriginalException (see page 6735)

39.1.2.3 EUpdateError.Destroy Destructor

Destroys an instance of EUpdateError (see page 6732).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~EUpdateError();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the EUpdateError (see page 6732) reference is not nil before calling Destroy.

See Also

Create (see page 6733)

Free (see page 22300)

39.1.2.4 EUpdateError Properties

The properties of the EUpdateError class are listed here.

Public Properties

	Name	Description
R	Context (see page 6734)	Contains context information from the error stack.
R	ErrorCode (see page 6735)	Indicates the error code that this exception represents.
R	OriginalException (see page 6735)	Indicates the exception object that this update error represents.
R	PreviousError (see page 6736)	Indicates the previous error code for this update process.

39.1.2.4.1 EUpdateError.Context Property

Contains context information from the error stack.

Pascal

```
property Context: string;
```

C++

```
__property AnsiString Context;
```

Description

Context contains additional information returned with the error message. If there is no additional context information, Context is an empty string.

See Also

ErrorCode (see page 6735)

39.1.2.4.2 EUpdateError.ErrorCode Property

Indicates the error code that this exception represents.

Pascal

```
property ErrorCode: Integer;
```

C++

```
__property int ErrorCode;
```

Description

EUpdateError (see page 6732) objects represent exceptions that occur when updating records. These exceptions can be generated in response to error codes from the data access mechanism (such as the BDE or ADO) or by other exceptions that are caught by resolver components. If the update error represents an error code returned by the data access mechanism, ErrorCode is that error code. Otherwise, ErrorCode is 0.

Note: DBExpress does not return error codes. This property merely provides a mechanism for using custom data-access components that generate error codes rather than exceptions.

Note: If ErrorCode is 0, use the OriginalException (see page 6735) property, which provides access to the exception that was caught.

See Also

OriginalException (see page 6735)

PreviousError (see page 6736)

39.1.2.4.3 EUpdateError.OriginalException Property

Indicates the exception object that this update error represents.

Pascal

```
property OriginalException: Exception;
```

C++

```
__property Exception OriginalException;
```

Description

EUpdateError (see page 6732) objects represent exceptions that occur when updating records. OriginalException is the exception object that is caught during the update process. Use this value to obtain more information about the problem that

occurred.

Note: If the EUpdateError (see page 6732) object represents an EDBEngineError, the ErrorCode (see page 6735) property provides immediate access to its BDE error code without going through the OriginalException property.

See Also

ErrorCode (see page 6735)

39.1.2.4.4 EUpdateError.PreviousError Property

Indicates the previous error code for this update process.

Pascal

```
property PreviousError: Integer;
```

C++

```
__property int PreviousError;
```

Description

PreviousError is the error code of the last update error in this update operation. If the last update error did not have an error code, PreviousError is 0.

See Also

ErrorCode (see page 6735)

39.1.3 TADTField Class

A TADTField object represents an ADT (Abstract Data Type) field in a dataset.

Class Hierarchy

Pascal

```
TADTField = class(TObjectField);
```

C++

```
class TADTField : public TObjectField;
```

File

DB

Description

ADT fields are database fields that contain Abstract Data Type (ADT) values. ADTs are user defined types created on the server, and are similar to records (Delphi) or structures (C++). An ADT can contain most scalar field types, including array fields, reference fields, nested dataset fields, or nested ADTs.

See Also

TField (see page 7115)

39.1.3.1 TADTField Members

The following tables list the members exposed by TADTField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CheckTypeSize (see page 7380)	This is CheckTypeSize, a member of class TObjectField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 7380)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	FreeBuffers (see page 7380)	This is FreeBuffers, a member of class TObjectField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
V	GetAsString (see page 7381)	This is GetAsString, a member of class TObjectField.
V	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
V	GetAsVariant (see page 7381)	This is GetAsVariant, a member of class TObjectField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetDefaultWidth (see page 7381)	This is GetDefaultWidth, a member of class TObjectField.

	GetFieldCount (see page 7381)	This is GetFieldCount, a member of class TObjectField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetFields (see page 7382)	This is GetFields, a member of class TObjectField.
	GetFieldValue (see page 7382)	This is GetFieldValue, a member of class TObjectField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetHasConstraints (see page 7382)	This is GetHasConstraints, a member of class TObjectField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 6743)	This is GetSize, a member of class TADTField.
	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 7382)	This is SetChildOrder, a member of class TObjectField.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataSet (see page 7383)	This is SetDataSet, a member of class TObjectField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetFieldKind (see page 7383)	This is SetFieldKind, a member of class TObjectField.
	SetFieldValue (see page 7383)	This is SetFieldValue, a member of class TObjectField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetParentField (see page 7383)	This is SetParentField, a member of class TObjectField.

	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetUnNamed (see page 7383)	This is SetUnNamed, a member of class TObjectField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetVarValue (see page 7384)	This is SetVarValue, a member of class TObjectField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6742)	Creates an instance of TADTField (see page 6736).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 7379)	Destroys an instance of TObjectField (see page 7372).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetChildren (see page 7381)	This is GetChildren, a member of class TObjectField.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.

	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldCount (see page 7384)	Indicates the number of child fields that comprise the object field.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	Fields (see page 7384)	Specifies the TFields (see page 7211) object that contains an array of child fields.
	FieldValues (see page 7385)	Provides access to the values for all child fields in the object field.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
R	UnNamed (see page 7386)	Indicates whether an object field in a nested table has a name associated with it.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.

	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectType (see page 7385)	Specifies the classification of the field object in Oracle.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.3.2 TADTField.Create Constructor

Creates an instance of TADTField (see page 6736).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TADTField(TComponent * AOwner);
```

Description

Call Create to create and initialize an instance of TADTField (see page 6736). Create calls the inherited constructor and then sets the DataType (see page 7159) to ftADT.

See Also

Create (see page 7121)

39.1.3.3 TADTField Methods

The methods of the TADTField class are listed here.

Protected Methods

	Name	Description
	GetSize (see page 6743)	This is GetSize, a member of class TADTField.

39.1.3.3.1 TADTField.GetSize Method

Pascal

```
function GetSize: Integer; override;
```

C++

```
virtual __fastcall int GetSize();
```

Description

This is GetSize, a member of class TADTField.

39.1.4 TAggregateField Class

TAggregate field represents a maintained aggregate in a client dataset.

Class Hierarchy

Pascal

```
TAggregateField = class(TField);
```

C++

```
class TAggregateField : public TField;
```

File

DB

Description

TAggregateField represents an aggregate value from a client dataset in a form that can be used by data-aware controls. Use the Fields Editor on a ClientDataSet to create a persistent aggregate field to which a TDBText control can bind.

As with TAggregate, TAggregateField has an Expression (see page 6756) property that represents a calculation summarizing

the data in a set of records. When using aggregate fields, you do not need to explicitly create the corresponding aggregate object in the client dataset: the Fields editor creates that object when you create a persistent aggregate field.

See Also

TAggregates (see page 8280)

TAggregate (see page 8268)

TCustomClientDataSet (see page 8373)

TDataSet (see page 6894)

TClientDataSet (see page 8289)

39.1.4.1 TAggregateField Members

The following tables list the members exposed by TAggregateField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 6750)	This is GetAsString, a member of class TAggregateField.
V	GetAsVariant (see page 6750)	This is GetAsVariant, a member of class TAggregateField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 6751)	This is GetText, a member of class TAggregateField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 7138)	This is ReadState, a member of class TField.
	Reset (see page 6751)	This is Reset, a member of class TAggregateField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
V	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
V	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
V	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
V	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
V	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
V	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
V	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
V	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
V	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
V	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDisplayFormat (see page 6751)	This is SetDisplayFormat, a member of class TAggregateField.
V	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
V	SetSize (see page 7143)	This is SetSize, a member of class TField.

	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6749)	Creates an instance of TAggregateField (see page 6743).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.

	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).

	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
	Handle (see page 6758)	Points to the aggregate handle.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	ResultType (see page 6759)	Indicates the data type of the aggregate field.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Active (see page 6752)	Indicates whether the aggregate should be calculated.
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	currency (see page 6752)	Determines whether the value in the field should be formatted as a currency value.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayFormat (see page 6753)	Determines how numeric and time values are formatted for display in a data-aware control.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayName (see page 6756)	Represents the name of the field for display purposes.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	Expression (see page 6756)	Specifies the formula used to calculate the aggregate value.
	FieldKind (see page 6757)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
	GroupingLevel (see page 6758)	Specifies the set of records summarized by this aggregate field.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	IndexName (see page 6758)	Specifies the index that is used to define subgroups of records.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	Precision (see page 6759)	Determines the precision used in formatting floating-point values.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 6760)	Determines whether the field appears in a data grid.

39.1.4.2 TAggregateField.Create Constructor

Creates an instance of TAggregateField (see page 6743).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAggregateField(TComponent * AOwner);
```

Description

Call Create to create and initialize an instance of TAggregateField (see page 6743) at runtime.

It is seldom necessary to call Create directly, because an aggregate field component is instantiated automatically when an aggregate field is added through the Fields Editor of a client dataset.

Create initializes DataType (see page 7159) to ftUnknown, FieldKind (see page 6757) to fkAggregate, Precision (see page 6759) to 15, and Visible (see page 6760) to false.

See Also

Create (see page 7121)

DataType (see page 7159)

FieldKind (see page 7164)

Precision (see page 6759)

Visible (see page 7181)

39.1.4.3 TAggregateField Methods

The methods of the TAggregateField class are listed here.

Protected Methods

	Name	Description
	GetAsString (see page 6750)	This is GetAsString, a member of class TAggregateField.
	GetAsVariant (see page 6750)	This is GetAsVariant, a member of class TAggregateField.
	GetText (see page 6751)	This is GetText, a member of class TAggregateField.
	Reset (see page 6751)	This is Reset, a member of class TAggregateField.
	SetDisplayFormat (see page 6751)	This is SetDisplayFormat, a member of class TAggregateField.

39.1.4.3.1 TAggregateField.GetAsString Method

Pascal

```
function GetAsString: string; override;
```

C++

```
virtual __fastcall AnsiString GetAsString();
```

Description

This is GetAsString, a member of class TAggregateField.

39.1.4.3.2 TAggregateField.GetAsVariant Method

Pascal

```
function GetAsVariant: Variant; override;
```

C++

```
virtual __fastcall Variant GetAsVariant();
```

Description

This is GetAsVariant, a member of class TAggregateField.

39.1.4.3.3 TAggregateField.GetText Method

Pascal

```
procedure GetText(var Text: string; DisplayText: Boolean); override;
```

C++

```
virtual __fastcall GetText(AnsiString Text, Boolean DisplayText);
```

Description

This is GetText, a member of class TAggregateField.

39.1.4.3.4 TAggregateField.Reset Method

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

This is Reset, a member of class TAggregateField.

39.1.4.3.5 TAggregateField.SetDisplayFormat Method

Pascal

```
procedure SetDisplayFormat(const Value: string);
```

C++

```
__fastcall SetDisplayFormat(const AnsiString Value);
```

Description

This is SetDisplayFormat, a member of class TAggregateField.

39.1.4.4 TAggregateField Properties

The properties of the TAggregateField class are listed here.

Public Properties

	Name	Description
	Handle (see page 6758)	Points to the aggregate handle.
	ResultType (see page 6759)	Indicates the data type of the aggregate field.

Published Properties

	Name	Description
	Active (see page 6752)	Indicates whether the aggregate should be calculated.
	currency (see page 6752)	Determines whether the value in the field should be formatted as a currency value.
	DisplayFormat (see page 6753)	Determines how numeric and time values are formatted for display in a data-aware control.
	DisplayName (see page 6756)	Represents the name of the field for display purposes.
	Expression (see page 6756)	Specifies the formula used to calculate the aggregate value.

	FieldKind (see page 6757)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	GroupingLevel (see page 6758)	Specifies the set of records summarized by this aggregate field.
	IndexName (see page 6758)	Specifies the index that is used to define subgroups of records.
	Precision (see page 6759)	Determines the precision used in formatting floating-point values.
	Visible (see page 6760)	Determines whether the field appears in a data grid.

39.1.4.4.1 TAggregateField.Active Property

Indicates whether the aggregate should be calculated.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Use the Active property to indicate that the aggregate field's value should be maintained when possible. If Active is false, the value of the aggregate is never calculated.

If Active is true, the aggregate field's value is calculated unless

It summarizes records over a group not defined by the current index.

The client dataset's AggregatesActive property is false.

Note: To determine whether the aggregate that corresponds to the field is currently maintained, read its InUse property.

See Also

AggregatesActive (see page 8461)

InUse (see page 8278)

39.1.4.4.2 TAggregateField.currency Property

Determines whether the value in the field should be formatted as a currency value.

Pascal

```
property currency: Boolean;
```

C++

```
__property Boolean currency;
```

Description

Use currency to specify the formatting of the field if its ResultType (see page 6759) is a floating-point type (ftFloat or ftCurrency).

Floating-point values are formatted for display using the DisplayFormat (see page 6753) property if it is assigned. If DisplayFormat (see page 6753) is not assigned, currency determines how the field is formatted for display. If currency is true, the value is formatted for display using the FloatToText function with the ffCurrency formatting code. If currency is false, the value is formatted with the ffGeneral format.

See Also

DisplayFormat (see page 6753)

DisplayText (see page 7162)

FloatToText (see page 22892)

FloatToTextFmt (see page 22893)

Text (see page 7179)

ResultType (see page 6759)

39.1.4.4.3 TAggregateField.DisplayFormat Property

Determines how numeric and time values are formatted for display in a data-aware control.

Pascal

```
property DisplayFormat: string;
```

C++

```
__property AnsiString DisplayFormat;
```

Description

Use the DisplayFormat property to override automatic formatting of a field for display purposes when ResultType (see page 6759) is ftFloat, ftCurrency, ftDate, ftTime, or ftDateTime.

When ResultType (see page 6759) is ftFloat or ftCurrency, the value of DisplayFormat is a string that encodes the formatting of data using the specifiers in the following table:

Specifier	Represents
0	Digit placeholder. If the value being formatted has a digit in the position where the "0" appears in the format string, then that digit is copied to the output string. Otherwise, a "0" is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the "#" appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first "." character in the format string determines the location of the decimal separator in the formatted value; any additional "." characters are ignored. The actual character used as a the decimal separator in the output string is determined by the DecimalSeparator global variable. The default value of DecimalSeparator is specified in the Number Format of the Regional Settings section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more "," characters, the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of "," characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as a the thousand separator in the output is determined by the ThousandSeparator global variable. The default value of ThousandSeparator is specified in the Number Format of the Regional Settings section in the Windows Control Panel.
E+	Scientific notation. If any of the strings "E+", "E-", "e+", or "e-" are contained in the format string, the number is formatted using scientific notation. A group of up to four "0" characters can immediately follow the "E+", "E-", "e+", or "e-" to determine the minimum number of digits in the exponent. The "E+" and "e+" formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The "E-" and "e-" formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.
c	The date using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.
d	The day as a number without a leading zero (1-31).
dd	The day as a number with a leading zero (01-31).
ddd	The day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames global variable.
dddd	The day as a full name (Sunday-Saturday) using the strings given by the LongDayNames global variable.

ddddd	The date using the format given by the ShortDateFormat global variable.
dddddd	The date using the format given by the LongDateFormat global variable.
m	The month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	The month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	The month as an abbreviation (Jan-Dec) using the strings given by the ShortMonthNames global variable.
mmmm	The month as a full name (January-December) using the strings given by the LongMonthNames global variable.
yy	The year as a two-digit number (00-99).
yyyy	The year as a four-digit number (0000-9999).
h	The hour without a leading zero (0-23).
hh	The hour with a leading zero (00-23).
n	The minute without a leading zero (0-59).
nn	The minute with a leading zero (00-59).
s	The second without a leading zero (0-59).
ss	The second with a leading zero (00-59).
t	The time using the format given by the ShortTimeFormat global variable.
tt	The time using the format given by the LongTimeFormat global variable.
am/pm	The time using the 12-hour clock for the preceding h or hh specifier, followed by "am" for any hour before noon, or "pm" for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	The time using the 12-hour clock for the preceding h or hh specifier, followed by "a" for any hour before noon, or "p" for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	The time using the 12-hour clock for the preceding h or hh specifier, followed by the contents of the TimeAMString global variable for any hour before noon, or the contents of the TimePMString global variable for any hour after noon.
/	The date separator character given by the DateSeparator global variable.
:	The time separator character given by the TimeSeparator global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, with no formatting changes.

The locations of the leftmost "0" before the decimal point in the format string and the rightmost "0" after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ("0" or "#") to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the "." character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain between one and three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If the section for negative values or the section for zero values is empty, that is, if there is nothing between the semicolons that delimit the section, the section for positive values is used instead.

If the section for positive values is empty, or if the entire format string is empty, the value is formatted using general floating-point formatting with 15 significant digits. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

When ResultType (see page 6759) is ftDate, ftTime, or ftDateTime, the value of DisplayFormat is a string that encodes the formatting of data using the specifiers in the following table:

Specifier	Displays
c	The date using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.
d	The day as a number without a leading zero (1-31).
dd	The day as a number with a leading zero (01-31).
ddd	The day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames global variable.
dddd	The day as a full name (Sunday-Saturday) using the strings given by the LongDayNames global variable.
ddddd	The date using the format given by the ShortDateFormat global variable.
dddddd	The date using the format given by the LongDateFormat global variable.
m	The month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	The month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	The month as an abbreviation (Jan-Dec) using the strings given by the ShortMonthNames global variable.
mmmm	The month as a full name (January-December) using the strings given by the LongMonthNames global variable.
yy	The year as a two-digit number (00-99).
yyyy	The year as a four-digit number (0000-9999).
h	The hour without a leading zero (0-23).
hh	The hour with a leading zero (00-23).
n	The minute without a leading zero (0-59).
nn	The minute with a leading zero (00-59).
s	The second without a leading zero (0-59).
ss	The second with a leading zero (00-59).
t	The time using the format given by the ShortTimeFormat global variable.
tt	The time using the format given by the LongTimeFormat global variable.
am/pm	The time using the 12-hour clock for the preceding h or hh specifier, followed by "am" for any hour before noon, or "pm" for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	The time using the 12-hour clock for the preceding h or hh specifier, followed by "a" for any hour before noon, or "p" for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	The time using the 12-hour clock for the preceding h or hh specifier, followed by the contents of the TimeAMString global variable for any hour before noon, or the contents of the TimePMString global variable for any hour after noon.

/	The date separator character given by the DateSeparator global variable.
:	The time separator character given by the TimeSeparator global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, with no formatting changes.

OnGetText (see page 7182)

FormatFloat (see page 22904)

ResultType (see page 6759)

39.1.4.4.4 TAggregateField.DisplayName Property

Represents the name of the field for display purposes.

Pascal

```
property DisplayName: WideString;
```

C++

```
__property BSTR DisplayName;
```

Description

Set DisplayName to give the aggregate a name that can be used to label values displayed to the user.

Note: When you create an aggregate field in the Fields editor, DisplayName is the same as the AggregateName property of the corresponding TAggregate object. However, if you change DisplayName, the aggregate's AggregateName is not updated as well.

See Also

AggregateName (see page 8275)

39.1.4.4.5 TAggregateField.Expression Property

Specifies the formula used to calculate the aggregate value.

Pascal

```
property Expression: String;
```

C++

```
__property AnsiString Expression;
```

Description

Set Expression to indicate how aggregate values should be calculated. Expression contains an expression that includes one or more of the summary operators in the following table:

Operator	Use
Sum	Totals the values for a numeric field or expression.
Avg	Computes the average value for a numeric or date-time field or expression.

Count	Specifies the number of non-blank values for a field or expression. Use count(*) to count the number of records in a dataset or subgroup.
Min	Indicates the minimum value for a string, numeric, or date-time field or expression.
Max	Indicates the maximum value for a string, numeric, or date-time field or expression.
Sum(Qty * Price)	{legal -- summary of an expression on fields }
Max(Field1) - Max(Field2)	{legal -- expression on summaries }
Avg(DiscountRate) * 100	{ legal -- expression of summary and constant }
Min(Sum(Field1))	{ illegal -- nested summaries }
Count(Field1) - Field2	{ illegal -- expression of summary and field }

The summary operators act on field values or on expressions built from field values using the same operators you use to create filters. (You can't nest summary operators, however.) You can create expressions by using operators on summarized values with other summarized values, or on summarized values and constants. However, you can't combine summarized values with field values, because such expressions are ambiguous (there is no indication of which record should supply the field value.) These rules are illustrated in the following expressions:

Note: To specify the set of records summarized by this expression, use the GroupingLevel (see page 6758) property.

See Also

GroupingLevel (see page 6758)

Filter (see page 8476)

39.1.4.4.6 TAggregateField.FieldKind Property

Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.

Pascal

```
property FieldKind: TFieldKind;
```

C++

```
__property TFieldKind FieldKind;
```

Description

Use FieldKind to determine if a field is a data field, a calculated field, a lookup field, or an aggregate field. The value of FieldKind can be changed programmatically, but in practice FieldKind is set at design time when creating Field components with the Fields editor.

Note: Fields calculated by SQL servers or the Borland Database Engine to display the results of a query that returns a live dataset

have a FieldKind of fkInternalCalc, not fkCalculated. This is because the field values are stored in the dataset. Calculated fields in a client dataset that are calculated in an OnCalcFields event handler but stored in the dataset also have a FieldKind of fkInternalCalc instead of fkCalculated. Unlike regular calculated fields, internally calculated fields can be used in filter expressions. They can be edited, but the changes are discarded. To prevent editing, set the ReadOnly property to true.

Note: The FieldKind property of a field is only stored with the field object if the value is fkInternalCalc.

See Also

Calculated (see page 7154)

Lookup (see page 7170)

ReadOnly (see page 7177)

39.1.4.4.7 TAggregateField.GroupingLevel Property

Specifies the set of records summarized by this aggregate field.

Pascal

```
property GroupingLevel: Integer;
```

C++

```
__property int GroupingLevel;
```

Description

Use GroupingLevel to indicate the groups of records over which the field's aggregate is calculated. When GroupingLevel is 0 (the default), the aggregate summarizes all the records in the client dataset. When GroupingLevel is greater than 0, the aggregate summarizes each group of records that has the same values on the first GroupingLevel fields of the index.

GroupingLevel can be any value from 0 to the number of fields in the index specified by IndexName (see page 6758).

See Also

TAggregate (see page 8268)

IndexName (see page 6758)

Expression (see page 6756)

39.1.4.4.8 TAggregateField.Handle Property

Points to the aggregate handle.

Pascal

```
property Handle: Pointer;
```

C++

```
__property void * Handle;
```

Description

TAggregateField (see page 6743) uses Handle internally to obtain its aggregated values. Most applications do not need to use this value.

Component writers can use Handle, if necessary, with the routines declared in the dsintf unit.

See Also

AggHandle (see page 8274)

39.1.4.4.9 TAggregateField.IndexName Property

Specifies the index that is used to define subgroups of records.

Pascal

```
property IndexName: String;
```

C++

```
__property AnsiString IndexName;
```

Description

Set IndexName to specify an index that sorts the records of the client dataset into subgroups. Each subgroup is defined as a set of records that all have the same values on a set of fields. This defining set of fields is the first GroupingLevel (see page 6758) fields of the index.

IndexName is required for any aggregate that does not summarize all the records in the client dataset (GroupingLevel (see page 6758) = 0). When the index associated with an aggregate is not the current index of the client dataset, its value is unavailable.

See Also

DataSet (see page 7157)

GroupingLevel (see page 6758)

IndexName (see page 8483)

InUse (see page 8278)

39.1.4.4.10 TAggregateField.Precision Property

Determines the precision used in formatting floating-point values.

Pascal

```
property Precision: Integer;
```

C++

```
__property int Precision;
```

Description

When the aggregate field represents a floating-point value (ResultType (see page 6759) is ftFloat or ftCurrency), use Precision to set the number of digits beyond the decimal point that appear before rounding begins. Precision affects the format of the floating-point value when it is displayed as a text string, not the actual value that is stored in the field.

The default value of Precision is 15 decimal places.

Note: Precision must be greater than or equal to 2. Trying to set Precision to a value less than 2 changes the value of Precision to 2.

See Also

DisplayFormat (see page 6753)

ResultType (see page 6759)

39.1.4.4.11 TAggregateField.ResultType Property

Indicates the data type of the aggregate field.

Pascal

```
property ResultType: TFieldType;
```

C++

```
__property TFieldType ResultType;
```

Description

Read ResultType to determine the type of data that the aggregate produces.

See Also

Expression (see page 6756)

39.1.4.4.12 TAggregateField.Visible Property

Determines whether the field appears in a data grid.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

To hide a field in a data grid, set Visible to false. If Visible is true, the field appears in the grid.

Note: The Visible property has no effect if the grid has an explicit Columns value for the field. It also has no effect on controls other than TDBGrid, such as TDBEdit.

See Also

Columns (see page 9653)

39.1.5 TArrayField Class

TArrayField represents an Array field in a dataset.

Class Hierarchy

Pascal

```
TArrayField = class(TObjectField);
```

C++

```
class TArrayField : public TObjectField;
```

File

DB

Description

Array fields consist of a set of subfields of the same type. The field type of all subfields can be scalar (for example, float, string), or non-scalar (an ADT), but an array field of arrays is not permitted. The SparseArrays property of TDataSet (see page 6894) determines whether a unique TField (see page 7115) object is created for each element of the array field.

See Also

TField (see page 7115)

39.1.5.1 TArrayField Members

The following tables list the members exposed by TArrayField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 6767)	This is Bind, a member of class TArrayField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CheckTypeSize (see page 7380)	This is CheckTypeSize, a member of class TObjectField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 7380)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	FreeBuffers (see page 7380)	This is FreeBuffers, a member of class TObjectField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
V	GetAsString (see page 7381)	This is GetAsString, a member of class TObjectField.
V	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
V	GetAsVariant (see page 7381)	This is GetAsVariant, a member of class TObjectField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetDefaultWidth (see page 7381)	This is GetDefaultWidth, a member of class TObjectField.

	GetFieldCount (see page 7381)	This is GetFieldCount, a member of class TObjectField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetFields (see page 7382)	This is GetFields, a member of class TObjectField.
	GetFieldValue (see page 7382)	This is GetFieldValue, a member of class TObjectField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetHasConstraints (see page 7382)	This is GetHasConstraints, a member of class TObjectField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 7382)	This is SetChildOrder, a member of class TObjectField.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataSet (see page 7383)	This is SetDataSet, a member of class TObjectField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetFieldKind (see page 7383)	This is SetFieldKind, a member of class TObjectField.
	SetFieldValue (see page 7383)	This is SetFieldValue, a member of class TObjectField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetParentField (see page 7383)	This is SetParentField, a member of class TObjectField.

	SetSize (see page 6767)	This is SetSize, a member of class TArrayField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetUnNamed (see page 7383)	This is SetUnNamed, a member of class TObjectField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetVarValue (see page 7384)	This is SetVarValue, a member of class TObjectField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6766)	Creates an instance of TArrayField (see page 6760).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 7379)	Destroys an instance of TObjectField (see page 7372).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetChildren (see page 7381)	This is GetChildren, a member of class TObjectField.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.

	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldCount (see page 7384)	Indicates the number of child fields that comprise the object field.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	Fields (see page 7384)	Specifies the TFields (see page 7211) object that contains an array of child fields.
	FieldValues (see page 7385)	Provides access to the values for all child fields in the object field.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 6768)	The number of elements in the array field.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
R	UnNamed (see page 7386)	Indicates whether an object field in a nested table has a name associated with it.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectType (see page 7385)	Specifies the classification of the field object in Oracle.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.5.2 TArrayField.Create Constructor

Creates an instance of TArrayField (see page 6760).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TArrayField(TComponent * AOwner);
```

Description

Most applications do not need to explicitly create TArrayField (see page 6760) instances. These are created automatically by the dataset.

Create calls the inherited TField (see page 7115) constructor, sets the DataType (see page 7159) to ftArray, and sets the Size (see page 6768) to 10. The AOwner parameter specifies the owner of the field (typically, the dataset). The owner is responsible for freeing the field component.

See Also

Create (see page 7121)

Owner (see page 2807)

39.1.5.3 TArrayField Methods

The methods of the TArrayField class are listed here.

Protected Methods

	Name	Description
	Bind (see page 6767)	This is Bind, a member of class TArrayField.
	SetSize (see page 6767)	This is SetSize, a member of class TArrayField.

39.1.5.3.1 TArrayField.Bind Method

Pascal

```
procedure Bind(Binding: Boolean); override;
```

C++

```
virtual __fastcall Bind(Boolean Binding);
```

Description

This is Bind, a member of class TArrayField.

39.1.5.3.2 TArrayField.SetSize Method

Pascal

```
procedure SetSize(Value: Integer); override;
```

C++

```
virtual __fastcall SetSize(int Value);
```

Description

This is SetSize, a member of class TArrayField.

39.1.5.4 TArrayField Properties

The properties of the TArrayField class are listed here.

Public Properties

	Name	Description
	Size (see page 6768)	The number of elements in the array field.

39.1.5.4.1 TArrayField.Size Property

The number of elements in the array field.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

Use Size property to get or set the number of elements in the array field.

39.1.6 TAutoIncField Class

TAutoIncField is a persistent field object for an autoincrement field in a dataset.

Class Hierarchy

Pascal

```
TAutoIncField = class(TIntegerField);
```

C++

```
class TAutoIncField : public TIntegerField;
```

File

DB

Description

TAutoIncField provides access to an autoincrement field in a table. Autoincrement fields can hold values in the range -2,147,483,648 to 2,147,483,647, and are used as a counter for the records in the dataset. Each record is given a unique value in an autoincrement field, with each record receiving the next highest integer from that of the previously inserted record. Autoincrement fields are commonly used to provide a unique primary key value for a record.

Note: Auto-incrementing fields are a function of the database back-end. An application should not attempt to set a field value for an autoincrement field (with or without a TAutoIncField object).

If you use the Fields editor at design time to create a persistent field component for the auto-incrementing field, you can access it by name at runtime. When using dynamic field components, you can access the TAutoIncField instance using the dataset's Fields property or FieldByName method.

39.1.6.1 TAutoIncField Members

The following tables list the members exposed by TAutoIncField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsFloat (see page 7310)	This is GetAsFloat, a member of class TIntegerField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsInteger (see page 7310)	This is GetAsInteger, a member of class TIntegerField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
V	GetAsString (see page 7311)	This is GetAsString, a member of class TIntegerField.
V	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
V	GetAsVariant (see page 7311)	This is GetAsVariant, a member of class TIntegerField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDataSize (see page 7311)	This is GetDataSize, a member of class TIntegerField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 7135)	This is GetText, a member of class TField.
V	GetText (see page 7311)	This is GetText, a member of class TIntegerField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetValue (see page 7312)	This is GetValue, a member of class TIntegerField.
V	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	RangeError (see page 7368)	This is RangeError, a member of class TNumericField.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
V	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
V	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
V	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
V	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
V	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
V	SetAsFloat (see page 7312)	This is SetAsFloat, a member of class TIntegerField.
V	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
V	SetAsInteger (see page 7312)	This is SetAsInteger, a member of class TIntegerField.
V	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
V	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
V	SetAsString (see page 7312)	This is SetAsString, a member of class TIntegerField.
V	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
V	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDisplayFormat (see page 7368)	This is SetDisplayFormat, a member of class TNumericField.
	SetEditFormat (see page 7368)	This is SetEditFormat, a member of class TNumericField.

	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetVarValue (see page 7312)	This is SetVarValue, a member of class TIntegerField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6775)	Creates an instance of TAutoIncField (see page 6768).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.

	Value (see page 7180)	Represents the data in a field component.
	Value (see page 7314)	Represents the value of the integer field.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	Alignment (see page 7369)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayFormat (see page 7369)	Determines how a numeric field's value is formatted for display in a data-aware control.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	EditFormat (see page 7371)	Determines how a numeric field's value is formatted when it is being edited in a data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	MaxValue (see page 7313)	Limits the maximum value in the integer field.
	MinValue (see page 7313)	Limits the minimum value in the integer field.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.6.2 TAutoIncField.Create Constructor

Creates an instance of TAutoIncField (see page 6768).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TAutoIncField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TAutoIncField (see page 6768). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

After calling the inherited constructor, Create sets the DataType (see page 7159) property to ftAutoInc. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TAutoIncField (see page 6768). After instantiating a TAutoIncField (see page 6768), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TAutoIncField (see page 6768) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TAutoIncField (see page 6768) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TAutoIncField (see page 6768) object for a field named ID accessed through a TSQLQuery named SQLQuery1.

```
var
  T: TAutoIncField;
begin
  SQLQuery1.Close;
  T := TAutoIncField.Create(SQLQuery1);
  T.FieldName := 'ID';
  T.Name := SQLQuery1.Name + T.FieldName;
  T.Index := SQLQuery1.FieldCount;
  T.DataSet := SQLQuery1;
  SQLQuery1.FieldDefs.UpDate;
  SQLQuery1.Open;
end;
TAutoIncField *T;
SQLQuery1->Close();
T = new TAutoIncField(SQLQuery1);
T->FieldName = "ID";
T->Name = SQLQuery1->Name + T->FieldName;
T->Index = SQLQuery1->FieldCount;
T->DataSet = SQLQuery1;
SQLQuery1->FieldDefs->UpDate();
SQLQuery1->Open();
```

39.1.7 TBCDField Class

TBCDField represents a binary-coded decimal (BCD) field in a dataset.

Class Hierarchy

Pascal

```
TBCDField = class(TNumericField);
```

C++

```
class TBCDField : public TNumericField;
```

File

DB

Description

TBCDField encapsulates the fundamental behavior common to binary-coded decimal (BCD) fields. BCD values provide greater precision and accuracy than floating-point numbers. BCD fields are often used for storing and manipulating monetary values.

The IDE uses two different field types for representing BCD fields: TBCDField and TFMTBCDField (see page 7242). TBCDField uses the Currency (Delphi) or System::Currency (see page 22145) (C++) type to manipulate BCD values. This is faster than storing and manipulating the value using a true BCD type, but limits the precision of the BCD values it can support to 4 decimal places and 20 significant digits.

TBCDField converts the data from a BCD value to a Currency value when it fetches the data from the database table, and converts it from a Currency value to a binary-coded decimal value when it posts the data. If the underlying database table contains a value that requires greater precision, TBCDField raises an exception. If your application requires BCD values with more than 4 decimal places or 20 significant digits, you should use TFMTBCDField (see page 7242) instead. TFMTBCDField (see page 7242) is a true BCD, with the precision of the binary-coded decimal type (TBCD) but with somewhat slower performance.

If you use the Fields editor at design time to create a persistent field component for the BCD field, you can access it by name at runtime. When using dynamic field components, you can access the TBCDField instance using the dataset's Fields property or FieldByName method.

39.1.7.1 TBCDField Members

The following tables list the members exposed by TBCDField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Bind (see page 7126)	This is Bind, a member of class TField.
	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
	CheckTypeSize (see page 6784)	This is CheckTypeSize, a member of class TBCDField.
	CopyData (see page 6784)	This is CopyData, a member of class TBCDField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
	GetAsBCD (see page 6784)	This is GetAsBCD, a member of class TBCDField.
	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
	GetAsCurrency (see page 6784)	This is GetAsCurrency, a member of class TBCDField.
	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
	GetAsFloat (see page 6785)	This is GetAsFloat, a member of class TBCDField.
	GetAsInteger (see page 6785)	This is GetAsInteger, a member of class TBCDField.
	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
	GetAsString (see page 6785)	This is GetAsString, a member of class TBCDField.
	GetAsVariant (see page 6785)	This is GetAsVariant, a member of class TBCDField.
	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
	GetDataSize (see page 6785)	This is GetDataSize, a member of class TBCDField.
	GetDefaultWidth (see page 6786)	This is GetDefaultWidth, a member of class TBCDField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 6786)	This is GetText, a member of class TBCDField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetValue (see page 6786)	This is GetValue, a member of class TBCDField.
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	RangeError (see page 7368)	This is RangeError, a member of class TNumericField.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 6786)	This is SetAsBCD, a member of class TBCDField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 6787)	This is SetAsCurrency, a member of class TBCDField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 6787)	This is SetAsFloat, a member of class TBCDField.
	SetAsInteger (see page 6787)	This is SetAsInteger, a member of class TBCDField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 6787)	This is SetAsString, a member of class TBCDField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDisplayFormat (see page 7368)	This is SetDisplayFormat, a member of class TNumericField.
	SetEditFormat (see page 7368)	This is SetEditFormat, a member of class TNumericField.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 6787)	This is SetVarValue, a member of class TBCDField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.

	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 7126)	Sets the value of the field to NULL.
V	Create (see page 6782)	Create creates an instance of TBCDField (see page 6776).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.

	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.

R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 6790)	Represents the value of the BCD field as a Currency value.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	Alignment (see page 7369)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	currency (see page 6788)	This is currency, a member of class TBCDField.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.

	DisplayFormat (see page 7369)	Determines how a numeric field's value is formatted for display in a data-aware control.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	EditFormat (see page 7371)	Determines how a numeric field's value is formatted when it is being edited in a data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	MaxValue (see page 6788)	Limits the maximum value in the binary-coded decimal field.
	MinValue (see page 6789)	Limits the minimum value in the binary-coded decimal field.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	Precision (see page 6789)	Specifies the number of digits of accuracy used to store the field value.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Size (see page 6789)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.7.2 TBCDField.Create Constructor

Create creates an instance of TBCDField (see page 6776).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBCDField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TBCDField (see page 6776). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

After calling the inherited constructor, Create sets the DataType (see page 7159) property to ftBCD and initializes Size (see page 6789) to 4. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TBCDField (see page 6776). After instantiating a TBCDField (see page 6776), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TBCDField (see page 6776) a unique identifier in the

Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TBCDField (see page 6776) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component. Specify the precision of the TBCDField (see page 6776) by setting the Precision (see page 6789) property.

The example below creates a TBCDField (see page 6776) object for a field named Amount accessed through a TSQLQuery named SQLQuery1.

```
var
  T: TBCDField;
begin
  SQLQuery1.Close;
  T := TBCDField.Create(SQLQuery1);
  T.FieldName := 'Amount';
  T.Name := SQLQuery1.Name + T.FieldName;
  T.Index := SQLQuery1.FieldCount;
  T.DataSet := SQLQuery1;
  T.Precision := 2;
  SQLQuery1.FieldDefs.UpDate;
  SQLQuery1.Open;
end;
SQLQuery1->Close();
TBCDField *T = new TBCDField(SQLQuery1);
T->FieldName = "Amount";
T->Name = SQLQuery1->Name + T->FieldName;
T->Index = SQLQuery1->FieldCount;
T->DataSet = SQLQuery1;
SQLQuery1->FieldDefs->UpDate();
SQLQuery1->Open();
```

39.1.7.3 TBCDField Methods

The methods of the TBCDField class are listed here.

Protected Methods

	Name	Description
	CheckTypeSize (see page 6784)	This is CheckTypeSize, a member of class TBCDField.
	CopyData (see page 6784)	This is CopyData, a member of class TBCDField.
	GetAsBCD (see page 6784)	This is GetAsBCD, a member of class TBCDField.
	GetAsCurrency (see page 6784)	This is GetAsCurrency, a member of class TBCDField.
	GetAsFloat (see page 6785)	This is GetAsFloat, a member of class TBCDField.
	GetAsInteger (see page 6785)	This is GetAsInteger, a member of class TBCDField.
	GetAsString (see page 6785)	This is GetAsString, a member of class TBCDField.
	GetAsVariant (see page 6785)	This is GetAsVariant, a member of class TBCDField.
	GetDataSize (see page 6785)	This is GetDataSize, a member of class TBCDField.
	GetDefaultWidth (see page 6786)	This is GetDefaultWidth, a member of class TBCDField.
	GetText (see page 6786)	This is GetText, a member of class TBCDField.
	GetValue (see page 6786)	This is GetValue, a member of class TBCDField.

	SetAsBCD (see page 6786)	This is SetAsBCD, a member of class TBCDField.
	SetAsCurrency (see page 6787)	This is SetAsCurrency, a member of class TBCDField.
	SetAsFloat (see page 6787)	This is SetAsFloat, a member of class TBCDField.
	SetAsInteger (see page 6787)	This is SetAsInteger, a member of class TBCDField.
	SetAsString (see page 6787)	This is SetAsString, a member of class TBCDField.
	SetVarValue (see page 6787)	This is SetVarValue, a member of class TBCDField.

39.1.7.3.1 TBCDField.CheckTypeSize Method

Pascal

```
class procedure CheckTypeSize(Value: Integer); override;
```

C++

```
virtual __fastcall CheckTypeSize(int Value);
```

Description

This is CheckTypeSize, a member of class TBCDField.

39.1.7.3.2 TBCDField.CopyData Method

Pascal

```
procedure CopyData(Source: Pointer; Dest: Pointer); override;
```

C++

```
virtual __fastcall CopyData(void * Source, void * Dest);
```

Description

This is CopyData, a member of class TBCDField.

39.1.7.3.3 TBCDField.GetAsBCD Method

Pascal

```
function GetAsBCD: TBcd; override;
```

C++

```
virtual __fastcall TBcd GetAsBCD();
```

Description

This is GetAsBCD, a member of class TBCDField.

39.1.7.3.4 TBCDField.GetAsCurrency Method

Pascal

```
function GetAsCurrency: Currency; override;
```

C++

```
virtual __fastcall Currency GetAsCurrency();
```

Description

This is GetAsCurrency, a member of class TBCDField.

39.1.7.3.5 TBCDField.GetAsFloat Method

Pascal

```
function GetAsFloat: Double; override;
```

C++

```
virtual __fastcall Double GetAsFloat();
```

Description

This is GetAsFloat, a member of class TBCDField.

39.1.7.3.6 TBCDField.GetAsInteger Method

Pascal

```
function GetAsInteger: Longint; override;
```

C++

```
virtual __fastcall Longint GetAsInteger();
```

Description

This is GetAsInteger, a member of class TBCDField.

39.1.7.3.7 TBCDField.GetAsString Method

Pascal

```
function GetAsString: string; override;
```

C++

```
virtual __fastcall AnsiString GetAsString();
```

Description

This is GetAsString, a member of class TBCDField.

39.1.7.3.8 TBCDField.GetAsVariant Method

Pascal

```
function GetAsVariant: Variant; override;
```

C++

```
virtual __fastcall Variant GetAsVariant();
```

Description

This is GetAsVariant, a member of class TBCDField.

39.1.7.3.9 TBCDField.GetDataSize Method

Pascal

```
function GetDataSize: Integer; override;
```

C++

```
virtual __fastcall int GetDataSize();
```

Description

This is GetDataSize, a member of class TBCDField.

39.1.7.3.10 TBCDField.GetDefaultWidth Method

Pascal

```
function GetDefaultWidth: Integer; override;
```

C++

```
virtual __fastcall int GetDefaultWidth();
```

Description

This is GetDefaultWidth, a member of class TBCDField.

39.1.7.3.11 TBCDField.GetText Method

Pascal

```
procedure GetText(var Text: string; DisplayText: Boolean); override;
```

C++

```
virtual __fastcall GetText(AnsiString Text, Boolean DisplayText);
```

Description

This is GetText, a member of class TBCDField.

39.1.7.3.12 TBCDField.GetValue Method

Pascal

```
function GetValue(var Value: Currency): Boolean;
```

C++

```
__fastcall Boolean GetValue(Currency Value);
```

Description

This is GetValue, a member of class TBCDField.

39.1.7.3.13 TBCDField.SetAsBCD Method

Pascal

```
procedure SetAsBCD(const Value: TBcd); override;
```

C++

```
virtual __fastcall SetAsBCD(const TBcd Value);
```

Description

This is SetAsBCD, a member of class TBCDField.

39.1.7.3.14 TBCDField.SetAsCurrency Method

Pascal

```
procedure SetAsCurrency(Value: Currency); override;
```

C++

```
virtual __fastcall SetAsCurrency(Currency Value);
```

Description

This is SetAsCurrency, a member of class TBCDField.

39.1.7.3.15 TBCDField.SetAsFloat Method

Pascal

```
procedure SetAsFloat(Value: Double); override;
```

C++

```
virtual __fastcall SetAsFloat(Double Value);
```

Description

This is SetAsFloat, a member of class TBCDField.

39.1.7.3.16 TBCDField.SetAsInteger Method

Pascal

```
procedure SetAsInteger(Value: Longint); override;
```

C++

```
virtual __fastcall SetAsInteger(Longint Value);
```

Description

This is SetAsInteger, a member of class TBCDField.

39.1.7.3.17 TBCDField.SetAsString Method

Pascal

```
procedure SetAsString(const Value: string); override;
```

C++

```
virtual __fastcall SetAsString(const AnsiString Value);
```

Description

This is SetAsString, a member of class TBCDField.

39.1.7.3.18 TBCDField.SetVarValue Method

Pascal

```
procedure SetVarValue(const Value: Variant); override;
```

C++

```
virtual __fastcall SetVarValue(const Variant Value);
```

Description

This is SetVarValue, a member of class TBCDField.

39.1.7.4 TBCDField Properties

The properties of the TBCDField class are listed here.

Public Properties

	Name	Description
	Value (see page 6790)	Represents the value of the BCD field as a Currency value.

Published Properties

	Name	Description
	currency (see page 6788)	This is currency, a member of class TBCDField.
	MaxValue (see page 6788)	Limits the maximum value in the binary-coded decimal field.
	MinValue (see page 6789)	Limits the minimum value in the binary-coded decimal field.
	Precision (see page 6789)	Specifies the number of digits of accuracy used to store the field value.
	Size (see page 6789)	Indicates the size used in the definition of the physical database field for data types that support different sizes.

39.1.7.4.1 TBCDField.currency Property

Pascal

```
property currency: Boolean;
```

C++

```
__property Boolean currency;
```

Description

This is currency, a member of class TBCDField.

39.1.7.4.2 TBCDField.MaxValue Property

Limits the maximum value in the binary-coded decimal field.

Pascal

```
property MaxValue: Currency;
```

C++

```
__property Currency MaxValue;
```

Description

Use MaxValue to get or set the maximum value that can be entered into the field. If a value greater than MaxValue is entered, TBCDField (see page 6776) raises an EDatabaseError (see page 6731) exception.

Newly created binary-coded decimal (BCD) fields set MaxValue to the maximum value that can be expressed by the Currency data type.

See Also

MinValue (see page 6789)

Value (see page 6790)

39.1.7.4.3 TBCDField.MinValue Property

Limits the minimum value in the binary-coded decimal field.

Pascal

```
property MinValue: Currency;
```

C++

```
__property Currency MinValue;
```

Description

Use MinValue to get or set the minimum value that can be entered into the field. If a value smaller than MinValue is entered, TBCDField (see page 6776) raises an EDatabaseError (see page 6731) exception.

Newly created integer fields set MinValue to the minimum value that can be expressed by the Currency data type.

See Also

MaxValue (see page 6788)

Value (see page 6790)

39.1.7.4.4 TBCDField.Precision Property

Specifies the number of digits of accuracy used to store the field value.

Pascal

```
property Precision: Integer;
```

C++

```
__property int Precision;
```

Description

Precision can be a value between 0 and 32. However, because TBCDField (see page 6776) uses the Currency type to work with data from BCD fields, TBCDField (see page 6776) limits the precision of the BCD values it can support to 4 decimal places and 20 significant digits. The underlying database table may include values that require greater precision, and setting precision to a value greater than 20 allows you to create a table with higher precision.

See Also

AsCurrency

SetData (see page 7141)

39.1.7.4.5 TBCDField.Size Property

Indicates the size used in the definition of the physical database field for data types that support different sizes.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

The interpretation of Size depends on the data type. The meaning of Size for data types that use it is given in the following table.

For all other data types, Size is not used and its value is always 0.

DataType	Meaning of Size
ftBCD	Size is the number of digits after the decimal place.
ftString	Size is the maximum number of characters in the string.
ftVarBytes	Size is the maximum number of bytes of data, not counting the first two bytes which indicate the actual number of bytes of data that were used.
ftBytes	Size is the maximum number of bytes of data.
ftBlob	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftDBaseOle	Size is the number of bytes from the dBASE OLE BLOB that are stored in the record buffer.
ftFMTBCD	Size is the number of digits after the decimal place.
ftFmtMemo	Size is the number of bytes from the memo that are stored in the record buffer.
ftGraphic	Size is the number of bytes from the image that are stored in the record buffer.
ftMemo	Size is the number of characters from the memo that are stored in the record buffer.
ftParadoxOle	Size is the number of bytes from the Paradox OLE BLOB that are stored in the record buffer.
ftTypedBinary	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftADT	Size is the total number of fields contained in the ADT field, including the fields of child fields that are of type ADT.
ftArray	Size is the number of elements in the array.

See Also

DataSize (see page 7157)

DataType (see page 7159)

39.1.7.4.6 TBCDField.Value Property

Represents the value of the BCD field as a Currency value.

Pascal

```
property Value: Currency;
```

C++

```
__property Currency Value;
```

Description

Unlike other field types, the Value of a binary-coded decimal (BCD) field does not correspond to the physical format of the data that is stored in the underlying database table. The IDE does not have a native type for BCD. Therefore, TBCDField (see page 6776) converts the data from a BCD value to a Currency value when it fetches the data from the database table, and converts it from a Currency value to a BCD value when it posts the data. For BCD fields, Value is the same as the AsCurrency (see page 7148) property.

Note: Because TBCDField (see page 6776) works with its data as a Currency value, simply getting the value of the field and posting that value back to the database table can alter the contents of the field. That is, the line below can alter the contents of the field in the database table.

```
MyBCDField.Value := MyBCDField.Value;
MyBCDField->Value = MyBCDField->Value;
```

SetData (see page 7141)

39.1.8 TBinaryField Class

TBinaryField represents an untyped binary field in a dataset.

Class Hierarchy

Pascal

```
TBinaryField = class(TField);
```

C++

```
class TBinaryField : public TField;
```

File

DB

Description

TBinaryField encapsulates the fundamental behavior common to untyped binary fields. In addition to the properties, methods, and events common to all fields that are introduced by the TField (see page 7115) class, TBinaryField reimplements the properties that are used to read and write binary data from or to the underlying database table.

If you use the Fields editor at design time to create a persistent field component for the binary field, you can access it by name at runtime. When using dynamic field components, you can access the TBinaryField instance using the dataset's Fields property or FieldByName method.

TMemoField (see page 7348)

TBlobField (see page 6801)

39.1.8.1 TBinaryField Members

The following tables list the members exposed by TBinaryField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 6798)	This is CheckTypeSize, a member of class TBinaryField.
V	CopyData (see page 6798)	This is CopyData, a member of class TBinaryField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 6799)	This is GetAsString, a member of class TBinaryField.
V	GetAsVariant (see page 6799)	This is GetAsVariant, a member of class TBinaryField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 6799)	This is GetText, a member of class TBinaryField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).

	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 6799)	This is SetAsString, a member of class TBinaryField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 6799)	This is SetText, a member of class TBinaryField.
	SetVarValue (see page 6800)	This is SetVarValue, a member of class TBinaryField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6797)	Creates an instance of TBinaryField (see page 6791).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.

V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.

	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.

	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Size (see page 6800)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.8.2 TBinaryField.Create Constructor

Creates an instance of TBinaryField (see page 6791).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBinaryField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TBinaryField (see page 6791). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TBinaryField (see page 6791). After instantiating a TBinaryField (see page 6791), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TBinaryField (see page 6791) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TBinaryField (see page 6791) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TBinaryField (see page 6791) object for a field named RawData accessed through a TSQLQuery named SQLQuery1.

```
var
  T: TBinaryField;
begin
  SQLQuery1.Close;
  T := TBinaryFieldCreate(SQLQuery1);
  T.FieldName := 'RawData';
  T.Name := SQLQuery1.Name + T.FieldName;
  T.Index := SQLQuery1.FieldCount;
  T.DataSet := SQLQuery1;
  SQLQuery1.FieldDefs.UpDate;
  SQLQuery1.Open;
end;
TBinaryField *T;
SQLQuery1->Close();
```

```
T = new TBinaryField(SQLQuery1);
T->FieldName = "RawData";
T->Name = SQLQuery1->Name + T->FieldName;
T->Index = SQLQuery1->FieldCount;
T->DataSet = SQLQuery1;
SQLQuery1->FieldDefs->UpDate();
SQLQuery1->Open();
```

39.1.8.3 TBinaryField Methods

The methods of the TBinaryField class are listed here.

Protected Methods

	Name	Description
	CheckTypeSize (see page 6798)	This is CheckTypeSize, a member of class TBinaryField.
	CopyData (see page 6798)	This is CopyData, a member of class TBinaryField.
	GetAsString (see page 6799)	This is GetAsString, a member of class TBinaryField.
	GetAsVariant (see page 6799)	This is GetAsVariant, a member of class TBinaryField.
	GetText (see page 6799)	This is GetText, a member of class TBinaryField.
	SetAsString (see page 6799)	This is SetAsString, a member of class TBinaryField.
	SetText (see page 6799)	This is SetText, a member of class TBinaryField.
	SetVarValue (see page 6800)	This is SetVarValue, a member of class TBinaryField.

39.1.8.3.1 TBinaryField.CheckTypeSize Method

Pascal

```
class procedure CheckTypeSize(Value: Integer); override;
```

C++

```
virtual __fastcall CheckTypeSize(int Value);
```

Description

This is CheckTypeSize, a member of class TBinaryField.

39.1.8.3.2 TBinaryField.CopyData Method

Pascal

```
procedure CopyData(Source: Pointer; Dest: Pointer); override;
```

C++

```
virtual __fastcall CopyData(void * Source, void * Dest);
```

Description

This is CopyData, a member of class TBinaryField.

39.1.8.3.3 TBinaryField.GetAsString Method

Pascal

```
function GetAsString: string; override;
```

C++

```
virtual __fastcall AnsiString GetAsString();
```

Description

This is GetAsString, a member of class TBinaryField.

39.1.8.3.4 TBinaryField.GetAsVariant Method

Pascal

```
function GetAsVariant: Variant; override;
```

C++

```
virtual __fastcall Variant GetAsVariant();
```

Description

This is GetAsVariant, a member of class TBinaryField.

39.1.8.3.5 TBinaryField.GetText Method

Pascal

```
procedure GetText(var Text: string; DisplayText: Boolean); override;
```

C++

```
virtual __fastcall GetText(AnsiString Text, Boolean DisplayText);
```

Description

This is GetText, a member of class TBinaryField.

39.1.8.3.6 TBinaryField.SetAsString Method

Pascal

```
procedure SetAsString(const Value: string); override;
```

C++

```
virtual __fastcall SetAsString(const AnsiString Value);
```

Description

This is SetAsString, a member of class TBinaryField.

39.1.8.3.7 TBinaryField.SetText Method

Pascal

```
procedure SetText(const Value: string); override;
```

C++

```
virtual __fastcall SetText(const AnsiString Value);
```

Description

This is SetText, a member of class TBinaryField.

39.1.8.3.8 TBinaryField.SetVarValue Method

Pascal

```
procedure SetVarValue(const Value: Variant); override;
```

C++

```
virtual __fastcall SetVarValue(const Variant Value);
```

Description

This is SetVarValue, a member of class TBinaryField.

39.1.8.4 TBinaryField Properties

The properties of the TBinaryField class are listed here.

Published Properties

	Name	Description
	Size (see page 6800)	Indicates the size used in the definition of the physical database field for data types that support different sizes.

39.1.8.4.1 TBinaryField.Size Property

Indicates the size used in the definition of the physical database field for data types that support different sizes.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

The interpretation of Size depends on the data type. The meaning of Size for data types that use it is given in the following table. For all other data types, Size is not used and its value is always 0.

DataType	Meaning of Size
ftBCD	Size is the number of digits after the decimal place.
ftString	Size is the maximum number of characters in the string.
ftVarBytes	Size is the maximum number of bytes of data, not counting the first two bytes which indicate the actual number of bytes of data that were used.
ftBytes	Size is the maximum number of bytes of data.
ftBlob	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftDBaseOle	Size is the number of bytes from the dBASE OLE BLOB that are stored in the record buffer.
ftFMTBCD	Size is the number of digits after the decimal place.
ftFmtMemo	Size is the number of bytes from the memo that are stored in the record buffer.
ftGraphic	Size is the number of bytes from the image that are stored in the record buffer.

ftMemo	Size is the number of characters from the memo that are stored in the record buffer.
ftParadoxOle	Size is the number of bytes from the Paradox OLE BLOB that are stored in the record buffer.
ftTypedBinary	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftADT	Size is the total number of fields contained in the ADT field, including the fields of child fields that are of type ADT.
ftArray	Size is the number of elements in the array.

DataType (see page 7159)

39.1.9 TBlobField Class

TBlobField represents a field in a dataset that holds a reference to a binary large object (BLOB).

Class Hierarchy

Pascal

```
TBlobField = class(TField);
```

C++

```
class TBlobField : public TField;
```

File

DB

Description

TBlobField encapsulates the fundamental behavior common to binary large object (BLOB) fields. BLOB fields are database fields that contain raw binary data of arbitrary length. BLOB fields can represent different arbitrarily large data types. These data types are distinguished in the header of the binary data.

In addition to the field types supported directly, TBlobField is the direct ancestor of two BLOB field components: TMemoField (see page 7348) (ftMemo) and TGraphicField (see page 7257) (ftGraphic). These descendants represent BLOB fields that have headers peculiar to memos or graphic data, respectively.

TBlobField introduces new methods to support streaming data to and from the BLOB field and to support copying raw binary data between the BLOB field and a binary file. You can also use the stream returned by a dataset's CreateBlobStream method to read or write the data managed by a BLOB field.

If you use the Fields editor at design time to create a persistent field component for the BLOB field, you can access it by name at runtime. When using dynamic field components, you can access the TBlobField instance using the dataset's Fields property or FieldByName method.

39.1.9.1 TBlobField Members

The following tables list the members exposed by TBlobField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 6810)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 6811)	This is FreeBuffers, a member of class TBlobField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.

	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
	GetAsString (see page 6811)	This is GetAsString, a member of class TBlobField.
	GetAsVariant (see page 6811)	This is GetAsVariant, a member of class TBlobField.
	GetAsWideString (see page 6812)	This is GetAsWideString, a member of class TBlobField.
	GetBlobSize (see page 6812)	This is GetBlobSize, a member of class TBlobField.
	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClassDesc (see page 6812)	This is GetClassDesc, a member of class TBlobField.
	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIsNull (see page 6812)	This is GetIsNull, a member of class TBlobField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 6812)	This is GetText, a member of class TBlobField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 6817)	This is SetAsString, a member of class TBlobField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 6817)	This is SetAsWideString, a member of class TBlobField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.

	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 6818)	This is SetText, a member of class TBlobField.
	SetVarValue (see page 6818)	This is SetVarValue, a member of class TBlobField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 6809)	Copies a value to the BLOB field.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 6810)	Clears the current value in the BLOB field.
	Create (see page 6808)	Creates an instance of a BLOB field component.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.

	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 6813)	Indicates that this is a BLOB field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	LoadFromFile (see page 6814)	Loads BLOB data from a file into the field.
	LoadFromStream (see page 6815)	Loads BLOB data from a stream into the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 6816)	Saves the contents of the BLOB field to a file.
	SaveToStream (see page 6816)	Saves the contents of the BLOB field to a stream.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 6817)	Specifies the type of the BLOB field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
R	BlobSize (see page 6819)	Indicates the number of bytes of data contained in the blob field on the current record.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	Modified (see page 6820)	Indicates whether a the value for the BLOB field was changed since it was last read from the underlying database.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.

	Transliterate (see page 6821)	Determines whether any text in the BLOB field should be converted to and from the character set identified by the dataset.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 6822)	Represents the data in the BLOB field.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	BlobType (see page 6819)	Identifies the type of the BLOB field associated with a BLOB field object.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
	GraphicHeader (see page 6820)	Indicates whether the field's value includes a Paradox graphic BLOB header.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Size (see page 6820)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.9.2 TBlobField.Create Constructor

Creates an instance of a BLOB field component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBlobField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TBlobField (see page 6801). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

Create initializes the DataType (see page 7159) property to ftBlob. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TBlobField (see page 6801). After instantiating a TBlobField (see page 6801), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TBlobField (see page 6801) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TBlobField (see page 6801) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TBlobField (see page 6801) object for a field named Images accessed through a TSQLDataSet named SQLDataSet1.

```
var
  T: TBlobField;
begin
  SQLDataSet1.Close;
  T := TBlobField.Create(SQLDataSet1);
  T.FieldName := 'Images';
  T.Name := SQLDataSet1.Name + T.FieldName;
  T.Index := SQLDataSet1.FieldCount;
  T.DataSet := SQLDataSet1;
  SQLDataSet1.FieldDefs.UpDate;
  SQLDataSet1.Open;
end;
SQLDataSet1->Close();
TBlobField *T = new TBlobField(SQLDataSet1);
T->FieldName = "Images";
T->Name = SQLDataSet1->Name + T->FieldName;
T->Index = SQLDataSet1->FieldCount;
T->DataSet = SQLDataSet1;
SQLDataSet1->FieldDefs->UpDate();
SQLDataSet1->Open();
```

39.1.9.3 TBlobField Methods

The methods of the TBlobField class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 6810)	Copies the properties of an object to a destination object.
	FreeBuffers (see page 6811)	This is FreeBuffers, a member of class TBlobField.
	GetAsString (see page 6811)	This is GetAsString, a member of class TBlobField.
	GetAsVariant (see page 6811)	This is GetAsVariant, a member of class TBlobField.
	GetAsWideString (see page 6812)	This is GetAsWideString, a member of class TBlobField.
	GetBlobSize (see page 6812)	This is GetBlobSize, a member of class TBlobField.
	GetClassDesc (see page 6812)	This is GetClassDesc, a member of class TBlobField.
	GetIsNull (see page 6812)	This is GetIsNull, a member of class TBlobField.
	GetText (see page 6812)	This is GetText, a member of class TBlobField.
	SetAsString (see page 6817)	This is SetAsString, a member of class TBlobField.
	SetAsWideString (see page 6817)	This is SetAsWideString, a member of class TBlobField.
	SetText (see page 6818)	This is SetText, a member of class TBlobField.
	SetVarValue (see page 6818)	This is SetVarValue, a member of class TBlobField.

Public Methods

	Name	Description
	Assign (see page 6809)	Copies a value to the BLOB field.
	Clear (see page 6810)	Clears the current value in the BLOB field.
	IsBlob (see page 6813)	Indicates that this is a BLOB field.
	LoadFromFile (see page 6814)	Loads BLOB data from a file into the field.
	LoadFromStream (see page 6815)	Loads BLOB data from a stream into the field.
	SaveToFile (see page 6816)	Saves the contents of the BLOB field to a file.
	SaveToStream (see page 6816)	Saves the contents of the BLOB field to a stream.
	SetFieldType (see page 6817)	Specifies the type of the BLOB field.

39.1.9.3.1 TBlobField.Assign Method

Copies a value to the BLOB field.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to copy data to the BLOB field. Assign copies the Value (see page 6822) of a BLOB field from

Another BLOB field

A TStrings object

A TPicture or TBitmap object, if the BlobType (see page 6819) is ftGraphic or ftTypedBinary

Any object that supports TBlobField (see page 6801) in its AssignTo (see page 6810) method

In the example below, the Assign method is used to copy the bitmap from a TImage component into a BLOB field through its TBlobField (see page 6801) field object:

```
if not (ClientDataSet1.State in [dsInsert, dsEdit]) then
```

```
  ClientDataSet1.Insert;
ClientDataSet1Images.Assign(Image1.Picture);
ClientDataSet1.Post;
if ((ClientDataSet1->State != dsInsert) &&
(ClientDataSet1->State != dsEdit))
  ClientDataSet1->Insert();
ClientDataSet1Images->Assign(Image1->Picture);
ClientDataSet1->Post();
```

See Also

TBitmap (see page 14396)

TPicture (see page 14584)

TStrings (see page 3029)

AssignTo (see page 2931)

Value (see page 6822)

39.1.9.3.2 TBlobField.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

39.1.9.3.3 TBlobField.Clear Method

Clears the current value in the BLOB field.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Use Clear to delete the current value in the field and leave the field without a value.

```
Query1Images.Clear;
```

See Also

IsNull

Required (see page 7177)

Value (see page 6822)

39.1.9.3.4 TBlobField.FreeBuffers Method

Pascal

```
procedure FreeBuffers; override;
```

C++

```
virtual __fastcall FreeBuffers();
```

Description

This is FreeBuffers, a member of class TBlobField.

39.1.9.3.5 TBlobField.GetAsString Method

Pascal

```
function GetAsString: string; override;
```

C++

```
virtual __fastcall AnsiString GetAsString();
```

Description

This is GetAsString, a member of class TBlobField.

39.1.9.3.6 TBlobField.GetAsVariant Method

Pascal

```
function GetAsVariant: Variant; override;
```

C++

```
virtual __fastcall Variant GetAsVariant();
```

Description

This is GetAsVariant, a member of class TBlobField.

39.1.9.3.7 TBlobField.GetAsWideString Method

Pascal

```
function GetAsWideString: WideString; override;
```

C++

```
virtual __fastcall BSTR GetAsWideString();
```

Description

This is GetAsWideString, a member of class TBlobField.

39.1.9.3.8 TBlobField.GetBlobSize Method

Pascal

```
function GetBlobSize: Integer; virtual;
```

C++

```
virtual __fastcall int GetBlobSize();
```

Description

This is GetBlobSize, a member of class TBlobField.

39.1.9.3.9 TBlobField.GetClassDesc Method

Pascal

```
function GetClassDesc: string; override;
```

C++

```
virtual __fastcall AnsiString GetClassDesc();
```

Description

This is GetClassDesc, a member of class TBlobField.

39.1.9.3.10 TBlobField.GetIsNull Method

Pascal

```
function GetIsNull: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetIsNull();
```

Description

This is GetIsNull, a member of class TBlobField.

39.1.9.3.11 TBlobField.GetText Method

Pascal

```
procedure GetText(var Text: string; DisplayText: Boolean); override;
```

C++

```
virtual __fastcall GetText(AnsiString Text, Boolean DisplayText);
```

Description

This is GetText, a member of class TBlobField.

39.1.9.3.12 TBlobField.IsBlob Method

Indicates that this is a BLOB field.

Pascal

```
class function IsBlob: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsBlob();
```

Description

Use IsBlob when working with a TField (see page 7115) object to determine whether it represents BLOB data. For example, before using the GetData (see page 7131) or SetData (see page 7141) method (which does not work with BLOB fields), call IsBlob to determine whether the method can be used. The IsBlob method for TBlobField (see page 6801) always returns true.

C++ Examples:

```
/*
This example requires a button, a test edit, and a populated
ClientDataSet.  Pipe the ClientDataSet through a DataSource
to a DGGrid or DBNavigator to control the current field.
Cast the data correctly according to the field type when
assigning to the test edit.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Retrieve the "raw" data from Field1
  if (!CDS->Fields->Fields[0]->IsBlob(__classid(TField))) // GetData does not work for BLOB
fields
  {
    void *MyBuffer = malloc(CDS->Fields->Fields[0]->DataSize);
    try
    {
      if (!CDS->Fields->Fields[0]->GetData(MyBuffer))
        MessageDlg(CDS->Fields->Fields[0]->DisplayName + "is blank.", mtInformation,
TMsgDlgButtons() << mbOK,0);
      else
        // Do something with the data;
        Edit1->Text = (char *)MyBuffer; // for a stringfield
    }
    __finally
    {
      free(MyBuffer);
    }
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  CDS->LoadFromFile("../CDS.XML");
}
```

Delphi Examples:

```
{
This example requires a button, a test edit, and a populated
ClientDataSet.  Pipe the ClientDataSet through a DataSource
to a DGGrid or DBNavigator to control the current field.
Cast the data correctly according to the field type when
```

```
  assigning to the test edit.
  }

  {$IFNDEF UNICODE}
  uses SwSystem;
  {$ENDIF}

  procedure TForm1.Button1Click(Sender: TObject);
  var MyBuffer: Pointer;
  begin
  { Retrieve the "raw" data from Field1 }
  with CDS.Fields[0] do
    begin
      if not IsBlob then { this does not work for BLOB fields }
      begin
        { Allocate space }
        MyBuffer:= GetMemory(DataSize);
        try
          if not GetData(MyBuffer) then
            MessageDlg(DisplayName + ' is NULL', mtInformation, [mbOK], 0)
          else
            { Do something with the data };
            Edit1.Text:= string(MyBuffer); // for a stringfield
        finally
          { Free the space }
          FreeMem(MyBuffer, DataSize);
        end;
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
  {$IFDEF UNICODE}
    CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
  {$ELSE}
    CDS.LoadFromFile(gsAppPath + 'CDS.XML');
  {$ENDIF}
  end;
```

See Also

GetData (see page 7131)

SetData (see page 7141)

39.1.9.3.13 TBlobField.LoadFromFile Method

Loads BLOB data from a file into the field.

Pascal

```
procedure LoadFromFile(const FileName: string);
```

C++

```
__fastcall LoadFromFile(const AnsiString FileName);
```

Description

Use LoadFromFile to load the contents of a file into a BLOB field. Specify the name of the file to load into the field as the value of the FileName parameter.

```
if not (Query.State in [dsInsert, dsEdit]) then Query1.Insert;
Query1Images.LoadFromFile('c:\Windows\Waves.bmp');
Query1.Post;
```

See Also

LoadFromStream (see page 6815)

SaveToFile (see page 6816)

CreateBlobStream (see page 6922)

39.1.9.3.14 TBlobField.LoadFromStream Method

Loads BLOB data from a stream into the field.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to copy the contents of a stream into the BLOB field. Specify the stream from which the field's value is copied as the value of the Stream parameter.

Note: The Stream parameter is typically not a BLOB stream. BLOB streams (returned by the dataset's CreateBlobStream method) provide a completely separate mechanism for streaming data into a BLOB field.

```
var
  MS: TMemoryStream;
begin
if not (ClientDataSet1.State in [dsInsert, dsEdit]) then
 ClientDataSet1.Insert;
  MS := TMemoryStream.Create();
try
Image1.Picture.Bitmap.SaveToStream(MS);
    ClientDataSet1Images.LoadFromStream(MS);
finally
    MS.Free;
end;
  ClientDataSet1.Post;
end;
if ((ClientDataSet1->State != dsInsert) &&
(ClientDataSet1->State != dsEdit))
  ClientDataSet1->Insert();
TMemoryStream *pMS = new TMemoryStream;
try
{
  Image1->Picture->Bitmap->SaveToStream(pMS);
  ClientDataSet1Images->LoadFromStream(pMS);
}
__finally
{
delete pMS;
}
ClientDataSet1->Post();
```

See Also

LoadFromFile (see page 6814)

SaveToStream (see page 6816)

CreateBlobStream (see page 6922)

39.1.9.3.15 TBlobField.SaveToFile Method

Saves the contents of the BLOB field to a file.

Pascal

```
procedure SaveToFile(const FileName: string);
```

C++

```
__fastcall SaveToFile(const AnsiString FileName);
```

Description

Use SaveToFile to save the contents of the BLOB field to a file. Specify the name of the file as the value of the FileName parameter.

```
Query1Files.SaveToFile('c:\Data\' + Query1FileName.AsString);
```

See Also

LoadFromFile (see page 6814)

SaveToStream (see page 6816)

39.1.9.3.16 TBlobField.SaveToStream Method

Saves the contents of the BLOB field to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to copy the contents of a BLOB field to a stream. Specify the name of the stream to which the field's value is saved as the value of the Stream parameter.

Note: The Stream parameter is typically not a BLOB stream. BLOB streams (returned by the dataset's CreateBlobStream method) provide a completely separate mechanism for streaming data from a BLOB field.

```
var
  MS: TMemoryStream;
begin
  MS := TMemoryStream.Create;
try
    SQLDataSet1Images.SaveToStream(MS);
    Image1.Picture.Bitmap.LoadFromStream(MS);
finally
    MS.Free;
end;
end;
TMemoryStream *pMS = new TMemoryStream;
try
{
  SQLDataSet1Images->SaveToStream(pMS);
  Image1->Picture->Bitmap->LoadFromStream(pMS);
}
__finally
{
```

```
delete pMS;
}
```

See Also

LoadFromStream (see page 6815)

SaveToFile (see page 6816)

CreateBlobStream (see page 6922)

39.1.9.3.17 TBlobField.SetAsString Method

Pascal

```
procedure SetAsString(const Value: string); override;
```

C++

```
virtual __fastcall SetAsString(const AnsiString Value);
```

Description

This is SetAsString, a member of class TBlobField.

39.1.9.3.18 TBlobField.SetAsWideString Method

Pascal

```
procedure SetAsWideString(const Value: WideString); override;
```

C++

```
virtual __fastcall SetAsWideString(const BSTR Value);
```

Description

This is SetAsWideString, a member of class TBlobField.

39.1.9.3.19 TBlobField.SetFieldType Method

Specifies the type of the BLOB field.

Pascal

```
procedure SetFieldType(Value: TFieldType); override;
```

C++

```
virtual __fastcall SetFieldType(TFieldType Value);
```

Description

Use SetFieldType to change the field type of a BLOB field, overriding the default type.

Normally, the type of the physical database field is checked and a TFieldType (see page 7612) is selected that matches most closely. BLOB fields can indicate more explicitly what kind of BLOB is in the database. Specify the BLOB type as the value of the Value (see page 6822) parameter.

The following table contains the possible values for BLOB fields. Calling SetFieldType with any other data type does nothing.

Value (see page 6822)	Description
ftBlob	Binary Large Object field
ftMemo	Text (see page 7179) memo field

ftGraphic	Bitmap field
ftFmtMemo	Formatted text memo field
ftParadoxOle	Paradox OLE field
ftDBaseOle	dBASE OLE field
ftTypedBinary	Typed binary field
ftOraBlob	BLOB fields in Oracle 8 tables
ftOraClob	CLOB fields in Oracle 8 tables

Note: Calling SetFieldType does the same thing as setting the BlobType (see page 6819) property.

See Also

BlobType (see page 6819)

DataType (see page 7159)

39.1.9.3.20 TBlobField.SetText Method

Pascal

```
procedure SetText(const Value: string); override;
```

C++

```
virtual __fastcall SetText(const AnsiString Value);
```

Description

This is SetText, a member of class TBlobField.

39.1.9.3.21 TBlobField.SetVarValue Method

Pascal

```
procedure SetVarValue(const Value: Variant); override;
```

C++

```
virtual __fastcall SetVarValue(const Variant Value);
```

Description

This is SetVarValue, a member of class TBlobField.

39.1.9.4 TBlobField Properties

The properties of the TBlobField class are listed here.

Public Properties

	Name	Description
R	BlobSize (see page 6819)	Indicates the number of bytes of data contained in the blob field on the current record.
	Modified (see page 6820)	Indicates whether a the value for the BLOB field was changed since it was last read from the underlying database.
	Transliterate (see page 6821)	Determines whether any text in the BLOB field should be converted to and from the character set identified by the dataset.
	Value (see page 6822)	Represents the data in the BLOB field.

Published Properties

	Name	Description
	BlobType (see page 6819)	Identifies the type of the BLOB field associated with a BLOB field object.
	GraphicHeader (see page 6820)	Indicates whether the field's value includes a Paradox graphic BLOB header.
	Size (see page 6820)	Indicates the size used in the definition of the physical database field for data types that support different sizes.

39.1.9.4.1 TBlobField.BlobSize Property

Indicates the number of bytes of data contained in the blob field on the current record.

Pascal

```
property BlobSize: Integer;
```

C++

```
__property int BlobSize;
```

Description

Read BlobSize to determine the amount of memory required to store the contents of the BLOB field. Use BlobSize instead of the DataSize (see page 7157) property, which always returns 0 for BLOB fields.

Note: Unlike the DataSize (see page 7157) property, which specifies the size for field data on any record, BlobSize gives the size of the BLOB data for the current record only.

In the Delphi example below, a handler for the AfterScroll event of a TQuery, the value of the BlobSize property is displayed in the Caption of a form.

```
procedure TForm1.Query1AfterScroll(DataSet: TDataSet);
begin
  Caption := 'BLOB size: ' +
    IntToStr(TBlobField(Query1.FieldByName('BITMAP')).BlobSize);
end;
```

See Also

DataSize (see page 7157)

39.1.9.4.2 TBlobField.BlobType Property

Identifies the type of the BLOB field associated with a BLOB field object.

Pascal

```
property BlobType: TBlobType;
```

C++

```
__property TBlobType BlobType;
```

Description

Use BlobType to set or read the data type for the BLOB data associated with the field component.

Specify BlobType when using a TBlobField (see page 6801) object to represent a BLOB field type that isn't directly supported (such as a formatted memo BLOB). BlobType ensures that the BLOB type in the dataset matches the expected field type.

See Also

DataType (see page 7159)

SetFieldType (see page 6817)

39.1.9.4.3 TBlobField.GraphicHeader Property

Indicates whether the field's value includes a Paradox graphic BLOB header.

Pascal

```
property GraphicHeader: Boolean;
```

C++

```
__property Boolean GraphicHeader;
```

Description

Use GraphicHeader to specify whether the BLOB field represents a Paradox graphic field. TBlobField (see page 6801) checks GraphicHeader to determine whether it must write out a Paradox graphic BLOB header when writing the field's data to the dataset.

GraphicHeader is ignored unless the DataType (see page 7159) property is ftGraphic or ftTypedBinary.

See Also

DataType (see page 7159)

SetData (see page 7141)

39.1.9.4.4 TBlobField.Modified Property

Indicates whether a the value for the BLOB field was changed since it was last read from the underlying database.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

If the value of the BLOB field is set by using the properties or methods of TBlobField (see page 6801), the BLOB stream returned by a dataset's CreateBlobStream method, or a data-aware control, Modified is automatically set to true. Set Modified to true when changing the value of a BLOB field using direct Borland (see page 1761) Database Engine (BDE) API calls.

BLOB fields use the Modified property to trigger data events and to indicate when the dataset may need BDE needs to clean up any buffers used to store BLOB data.

AsString

AsVariant

CreateBlobStream (see page 6922)

Value (see page 6822)

39.1.9.4.5 TBlobField.Size Property

Indicates the size used in the definition of the physical database field for data types that support different sizes.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

The interpretation of Size depends on the data type. The meaning of Size for data types that use it is given in the following table. For all other data types, Size is not used and its value is always 0.

DataType	Meaning of Size
ftBCD	Size is the number of digits after the decimal place.
ftString	Size is the maximum number of characters in the string.
ftVarBytes	Size is the maximum number of bytes of data, not counting the first two bytes which indicate the actual number of bytes of data that were used.
ftBytes	Size is the maximum number of bytes of data.
ftBlob	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftDBaseOle	Size is the number of bytes from the dBASE OLE BLOB that are stored in the record buffer.
ftFMTBCD	Size is the number of digits after the decimal place.
ftFmtMemo	Size is the number of bytes from the memo that are stored in the record buffer.
ftGraphic	Size is the number of bytes from the image that are stored in the record buffer.
ftMemo	Size is the number of characters from the memo that are stored in the record buffer.
ftParadoxOle	Size is the number of bytes from the Paradox OLE BLOB that are stored in the record buffer.
ftTypedBinary	Size is the number of bytes from the BLOB that are stored in the record buffer.
ftADT	Size is the total number of fields contained in the ADT field, including the fields of child fields that are of type ADT.
ftArray	Size is the number of elements in the array.

See Also

DataSize (see page 7157)

DataType (see page 7159)

39.1.9.4.6 TBlobField.Transliterate Property

Determines whether any text in the BLOB field should be converted to and from the character set identified by the dataset.

Pascal

```
property Transliterate: Boolean;
```

C++

```
__property Boolean Transliterate;
```

Description

Use Transliterate when the physical database table identified by the dataset does not use an ANSI language driver and the data may contain extended ASCII characters uses a different character set than UTF-8 (on Linux) or ANSI (on Windows) and the BLOB field contains text.

When Transliterate is true, BLOB fields call the dataset's Translate method to translate ANSI UTF-8 characters to the character set used by the dataset when the value is changed using the Value (see page 6822) property, the AsString (see page 7151) property, or the AsVariant (see page 7152) property. When these properties are read to obtain the value of the BLOB field, the

Translate method translates the characters in the database table to the UTF-8 (Linux) or ANSI (Windows) character set.

Note: BLOB streams (returned by the dataset's CreateBlobStream method) also check the Transliterate property when reading from or writing to a BLOB field.

Translate (see page 7001)

CreateBlobStream (see page 6922)

39.1.9.4.7 TBlobField.Value Property

Represents the data in the BLOB field.

Pascal

```
property Value: string;
```

C++

```
__property AnsiString Value;
```

Description

Use Value to read data directly from and write data directly to a BLOB field component at runtime. For BLOB fields, the Value property is equivalent to the AsString (see page 7151) property.

Note: The string data (Delphi) or AnsiString (C++) type can store binary data as well as text. Thus, even BLOB fields for nontextual BLOB types such as ftGraphic or ftTypedBinary can get or set their data using a string (Delphi) or an AnsiString (C++).

AsString

BlobType (see page 6819)

39.1.10 TBooleanField Class

TBooleanField represents a field containing Boolean values.

Class Hierarchy

Pascal

```
TBooleanField = class(TField);
```

C++

```
class TBooleanField : public TField;
```

File

DB

Description

TBooleanField encapsulates the fundamental behavior common to Boolean data. Boolean fields can hold values of true or false.

In addition to the properties, methods, and events common to all fields that are introduced by the TField (see page 7115) class, TBooleanField introduces new properties to convert between boolean values and other data types, and to provide display strings that represent various interpretations of the data.

If you use the Fields editor at design time to create a persistent field component for the boolean field, you can access it by name at runtime. When using dynamic field components, you can access the TBooleanField instance using the dataset's Fields property or FieldByName method.

See Also

TDataSet (see page 6894)

TDataSet (see page 6894)

TDataSet (see page 6894)

TField (see page 7115)

39.1.10.1 TBooleanField Members

The following tables list the members exposed by TBooleanField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
	GetAsBoolean (see page 6830)	This is GetAsBoolean, a member of class TBooleanField.
	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
	GetAsString (see page 6830)	This is GetAsString, a member of class TBooleanField.
	GetAsVariant (see page 6830)	This is GetAsVariant, a member of class TBooleanField.
	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
	GetDataSize (see page 6830)	This is GetDataSize, a member of class TBooleanField.
	GetDefaultWidth (see page 6831)	This is GetDefaultWidth, a member of class TBooleanField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 6831)	This is SetAsBoolean, a member of class TBooleanField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 6831)	This is SetAsString, a member of class TBooleanField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.

	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 6831)	This is SetVarValue, a member of class TBooleanField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 6828)	Instantiates a Boolean field object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.

	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.

	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.

	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 6833)	Represents the value of the data in the Boolean field.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayValues (see page 6832)	Controls (see page 5711) how the Boolean field is translated to and from display format.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.10.2 TBooleanField.Create Constructor

Instantiates a Boolean field object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBooleanField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TBooleanField (see page 6822). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

Create sets the DataType (see page 7159) property to ftBoolean and initializes the strings associated with Boolean values to 'True' and 'False'. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TBooleanField (see page 6822). After instantiating a TBooleanField (see page 6822), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TBooleanField (see page 6822) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TBooleanField (see page 6822) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TBooleanField (see page 6822) object for a field named PaidInFull accessed through a TClientDataSet named ClientDataSet1.

```
var
  T: TBooleanField;
begin
  ClientDataSet1.Close;
  T := TBooleanField.Create(ClientDataSet1);
  T.FieldName := 'PaidInFull';
  T.Name := ClientDataSet1.Name + T.FieldName;
  T.Index := ClientDataSet1.FieldCount;
  T.DataSet := ClientDataSet1;
  ClientDataSet1.FieldDefs.UpDate;
  ClientDataSet1.Open;
end;
ClientDataSet1->Close();
TBooleanField *T = new TBooleanField(ClientDataSet1);
T->FieldName = "PaidInFull";
T->Name = ClientDataSet1->Name + T->FieldName;
T->Index = ClientDataSet1->FieldCount;
T->DataSet = ClientDataSet1;
ClientDataSet1->FieldDefs->UpDate();
ClientDataSet1->Open();
```

39.1.10.3 TBooleanField Methods

The methods of the TBooleanField class are listed here.

Protected Methods

	Name	Description
	GetAsBoolean (see page 6830)	This is GetAsBoolean, a member of class TBooleanField.
	GetAsString (see page 6830)	This is GetAsString, a member of class TBooleanField.
	GetAsVariant (see page 6830)	This is GetAsVariant, a member of class TBooleanField.
	GetDataSize (see page 6830)	This is GetDataSize, a member of class TBooleanField.
	GetDefaultWidth (see page 6831)	This is GetDefaultWidth, a member of class TBooleanField.
	SetAsBoolean (see page 6831)	This is SetAsBoolean, a member of class TBooleanField.
	SetAsString (see page 6831)	This is SetAsString, a member of class TBooleanField.
	SetVarValue (see page 6831)	This is SetVarValue, a member of class TBooleanField.

39.1.10.3.1 TBooleanField.GetAsBoolean Method

Pascal

```
function GetAsBoolean: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetAsBoolean();
```

Description

This is GetAsBoolean, a member of class TBooleanField.

39.1.10.3.2 TBooleanField.GetAsString Method

Pascal

```
function GetAsString: string; override;
```

C++

```
virtual __fastcall AnsiString GetAsString();
```

Description

This is GetAsString, a member of class TBooleanField.

39.1.10.3.3 TBooleanField.GetAsVariant Method

Pascal

```
function GetAsVariant: Variant; override;
```

C++

```
virtual __fastcall Variant GetAsVariant();
```

Description

This is GetAsVariant, a member of class TBooleanField.

39.1.10.3.4 TBooleanField.GetDataSize Method

Pascal

```
function GetDataSize: Integer; override;
```

C++

```
virtual __fastcall int GetDataSize();
```

Description

This is GetDataSize, a member of class TBooleanField.

39.1.10.3.5 TBooleanField.GetDefaultWidth Method

Pascal

```
function GetDefaultWidth: Integer; override;
```

C++

```
virtual __fastcall int GetDefaultWidth();
```

Description

This is GetDefaultWidth, a member of class TBooleanField.

39.1.10.3.6 TBooleanField.SetAsBoolean Method

Pascal

```
procedure SetAsBoolean(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAsBoolean(Boolean Value);
```

Description

This is SetAsBoolean, a member of class TBooleanField.

39.1.10.3.7 TBooleanField.SetAsString Method

Pascal

```
procedure SetAsString(const Value: string); override;
```

C++

```
virtual __fastcall SetAsString(const AnsiString Value);
```

Description

This is SetAsString, a member of class TBooleanField.

39.1.10.3.8 TBooleanField.SetVarValue Method

Pascal

```
procedure SetVarValue(const Value: Variant); override;
```

C++

```
virtual __fastcall SetVarValue(const Variant Value);
```

Description

This is SetVarValue, a member of class TBooleanField.

39.1.10.4 TBooleanField Properties

The properties of the TBooleanField class are listed here.

Public Properties

	Name	Description
	Value (see page 6833)	Represents the value of the data in the Boolean field.

Published Properties

	Name	Description
	DisplayValues (see page 6832)	Controls (see page 5711) how the Boolean field is translated to and from display format.

39.1.10.4.1 TBooleanField.DisplayValues Property

Controls (see page 5711) how the Boolean field is translated to and from display format.

Pascal

```
property DisplayValues: string;
```

C++

```
__property AnsiString DisplayValues;
```

Description

Use DisplayValues to specify strings the field uses to represent Boolean values. Use any pair of phrases, separated by a semicolon. For example, to have the true and false values correspond to the letters T and F, respectively, set DisplayValues as follows:

On Windows:

```
Table1LogicalField.DisplayValues := 'T;F';
```

On cross-platform:

```
ClientDataSet1LogicalField.DisplayValues := 'T;F';
```

On Windows:

```
Table1LogicalField->DisplayValues = "T;F";
```

On cross-platform:

```
ClientDataSet1LogicalField->DisplayValues = "T;F";
```

Similarly, to set the values of true and false to the strings Yes and No, set DisplayValues to:

On Windows:

```
Table1LogicalField.DisplayValues := 'Yes;No';
```

On cross-platform:

```
ClientDataSet1LogicalField.DisplayValues := 'Yes;No';
```

On Windows:

```
Table1LogicalField ->DisplayValues = "Yes;No";
```

On cross-platform:

```
ClientDataSet1LogicalField ->DisplayValues = "Yes;No";
```

The string associated with true or false can be an empty string. To set the value for true to an empty string, set DisplayValues to a string that begins with a semicolon. For example, to associate false with the string Fail, and true with an empty string, set DisplayValues to:

On Windows:

```
Table1LogicalField.DisplayValues := ';Fail';
```

On cross-platform:

```
ClientDataSet1LogicalField.DisplayValues := ';Fail';
```

On Windows:

```
Table1LogicalField ->DisplayValues = ";Fail";
```

On cross-platform:

```
ClientDataSet1LogicalField ->DisplayValues = ";Fail";
```

To associate false with an empty string, set DisplayValues to the string for true, with no semicolon at all.

The strings associated with true and false by DisplayValues appear in data-aware controls when they display the data for a Boolean field. If one of the strings is an empty string, boolean values associated with that string appear blank in data-aware controls.

These strings are also used when getting or setting the Boolean field's AsString (see page 7151) property.

See Also

AsString

39.1.10.4.2 TBooleanField.Value Property

Represents the value of the data in the Boolean field.

Pascal

```
property Value: Boolean;
```

C++

```
__property Boolean Value;
```

Description

Use Value to read data from and write data to a Boolean field object at runtime. Using Value is the same as using the AsBoolean (see page 7147) property. Use Value when you know the field component is a Boolean field. Use AsBoolean (see page 7147) when working with a generic field component.

See Also

AsBoolean

39.1.11 TBytesField Class

TBytesField represents a bytes field in a dataset.

Class Hierarchy

Pascal

```
TBytesField = class(TBinaryField);
```

C++

```
class TBytesField : public TBinaryField;
```

File

DB

Description

TBytesField encapsulates the fundamental behavior common to bytes fields. A bytes field value is a set of unformatted bytes of fixed size.

If you use the Fields editor at design time to create a persistent field component for the bytes field, you can access it by name at runtime. When using dynamic field components, you can access the TBytesField instance using the dataset's Fields property or FieldByName method.

Defining a Data Field

Defining a Lookup Field

Defining a Calculated Field

39.1.11.1 TBytesField Members

The following tables list the members exposed by TBytesField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.

	Bind (see page 7126)	This is Bind, a member of class TField.
	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
	CheckTypeSize (see page 6798)	This is CheckTypeSize, a member of class TBinaryField.
	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
	CopyData (see page 6798)	This is CopyData, a member of class TBinaryField.
	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
	GetAsString (see page 6799)	This is GetAsString, a member of class TBinaryField.
	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
	GetAsVariant (see page 6799)	This is GetAsVariant, a member of class TBinaryField.
	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
	GetDataSize (see page 6841)	This is GetDataSize, a member of class TBytesField.
	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 6799)	This is GetText, a member of class TBinaryField.
	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.

	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
V	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
V	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
V	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
V	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
V	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
V	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
V	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
V	SetAsString (see page 6799)	This is SetAsString, a member of class TBinaryField.
V	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
V	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
V	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
V	SetSize (see page 7143)	This is SetSize, a member of class TField.
V	SetText (see page 6799)	This is SetText, a member of class TBinaryField.
V	SetText (see page 7144)	This is SetText, a member of class TField.
V	SetVarValue (see page 6800)	This is SetVarValue, a member of class TBinaryField.
V	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
V	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.

	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 7126)	Sets the value of the field to NULL.
V	Create (see page 6840)	Creates an instance of TBytesField (see page 6833).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.

R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.

	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Size (see page 6800)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.11.2 TBytesField.Create Constructor

Creates an instance of TBytesField (see page 6833).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBytesField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TBytesField (see page 6833). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

Create sets the DataType (see page 7159) property to ftBytes. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TBytesField (see page 6833). After instantiating a TBytesField (see page 6833), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TBytesField (see page 6833) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TBytesField (see page 6833) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TBytesField (see page 6833) object for a field named BytesField accessed through a TSQLDataSet named SQLDataSet1.

```
var
  T: TBytesField;
begin
  SQLDataSet1.Close;
  T := TBytesField.Create(SQLDataSet1);
  T.FieldName := 'BytesField';
  T.Name := SQLDataSet1.Name + T.FieldName;
  T.Index := SQLDataSet1.FieldCount;
  T.DataSet := SQLDataSet1;
  SQLDataSet1.FieldDefs.UpDate;
  SQLDataSet1.Open;
end;
SQLDataSet1->Close();
TBytesField *T = new TBytesField(SQLDataSet1);
T->FieldName = "BytesField";
T->Name = SQLDataSet1->Name + T->FieldName;
```

```
T->Index = SQLDataSet1->FieldCount;
T->DataSet = SQLDataSet1;
SQLDataSet1->FieldDefs->UpDate();
SQLDataSet1->Open();
```

39.1.11.3 TBytesField Methods

The methods of the TBytesField class are listed here.

Protected Methods

	Name	Description
	GetDataSize (see page 6841)	This is GetDataSize, a member of class TBytesField.

39.1.11.3.1 TBytesField.GetDataSize Method

Pascal

```
function GetDataSize: Integer; override;
```

C++

```
virtual __fastcall int GetDataSize();
```

Description

This is GetDataSize, a member of class TBytesField.

39.1.12 TCheckConstraint Class

TCheckConstraint represents a record-level constraint on a dataset component.

Class Hierarchy

System::TObject → Classes.TPersistent → Classes.TCollectionItem → DB.TCheckConstraint

Pascal

```
TCheckConstraint = class(TCollectionItem);
```

C++

```
class TCheckConstraint : public TCollectionItem;
```

File

DB

Description

BDE-enabled and C client dataset components implement a Constraints property that uses check constraints to represent record-level constraints. These constraints can be derived from the server or the data dictionary, and can be customized in

applications. Each TCheckConstraint object represents an individual constraint associated with a dataset.

Constraining Data Values

39.1.12.1 TCheckConstraint Members

The following tables list the members exposed by TCheckConstraint.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 6843)	Assigns one constraint to another.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2757)	Creates and initializes a TCollectionItem (see page 2755) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2757)	Destroys the TCollectionItem (see page 2755) instance and frees its memory.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetDisplayName (see page 6843)	Retrieves the current text for a constraint.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

Published Properties

	Name	Description
	CustomConstraint (see page 6844)	Contains the SQL text representation of a constraint defined on a record by an application.
	ErrorMessage (see page 6845)	Contains the text of an error message to display if data entered in a record by a user violates the constraint condition.
	FromDictionary (see page 6845)	Indicates whether to fetch a check constraint from the Data Dictionary. Reserved for future use.
	ImportedConstraint (see page 6845)	Contains the SQL text for a check constraint imported from the Data Dictionary or a remote SQL database server.

39.1.12.2 TCheckConstraint Methods

The methods of the TCheckConstraint class are listed here.

Public Methods

	Name	Description
V	Assign (see page 6843)	Assigns one constraint to another.
V	GetDisplayName (see page 6843)	Retrieves the current text for a constraint.

39.1.12.2.1 TCheckConstraint.Assign Method

Assigns one constraint to another.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the SQL that defines the constraint of another TCheckConstraint (see page 6841) object into this one. Source is the TCheckConstraint (see page 6841) from which to read text.

39.1.12.2.2 TCheckConstraint.GetDisplayName Method

Retrieves the current text for a constraint.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

Call GetDisplayName to retrieve the current text for a check constraint. GetDisplayName returns the current value of the ImportedConstraint (see page 6845) property, unless it is an empty string. In that case it returns the current value of the CustomConstraint (see page 6844) property. If it, too, is an empty string, GetDisplayName returns the class name of the object.

See Also

CustomConstraint (see page 6844)

ImportedConstraint (see page 6845)

39.1.12.3 TCheckConstraint Properties

The properties of the TCheckConstraint class are listed here.

Published Properties

	Name	Description
	CustomConstraint (see page 6844)	Contains the SQL text representation of a constraint defined on a record by an application.
	ErrorMessage (see page 6845)	Contains the text of an error message to display if data entered in a record by a user violates the constraint condition.
	FromDictionary (see page 6845)	Indicates whether to fetch a check constraint from the Data Dictionary. Reserved for future use.
	ImportedConstraint (see page 6845)	Contains the SQL text for a check constraint imported from the Data Dictionary or a remote SQL database server.

39.1.12.3.1 TCheckConstraint.CustomConstraint Property

Contains the SQL text representation of a constraint defined on a record by an application.

Pascal

```
property CustomConstraint: string;
```

C++

```
__property AnsiString CustomConstraint;
```

Description

Use CustomConstraint to store the SQL text that defines a check constraint defined by the application for a dataset component. Custom constraints are local to the application and do not get applied by the server when an application writes its changes to a database.

Note: Custom constraints are SQL expressions. Because of this, always use a period (.) as a floating-point separator. This may be inconsistent with international Windows

settings.

FromDictionary (see page 6845)

ImportedConstraint (see page 6845)

Constraining Data Values

39.1.12.3.2 TCheckConstraint.ErrorMessage Property

Contains the text of an error message to display if data entered in a record by a user violates the constraint condition.

Pascal

```
property ErrorMessage: string;
```

C++

```
__property AnsiString ErrorMessage;
```

Description

Use ErrorMessage to set the error message string to display in an exception message dialog if a user enters data in a record that violates a check constraint condition.

See Also

CustomConstraint (see page 6844)

ImportedConstraint (see page 6845)

39.1.12.3.3 TCheckConstraint.FromDictionary Property

Indicates whether to fetch a check constraint from the Data Dictionary. Reserved for future use.

Pascal

```
property FromDictionary: Boolean;
```

C++

```
__property Boolean FromDictionary;
```

Description

FromDictionary is only implemented for the Windows product, which has a data dictionary.

Use FromDictionary to indicate whether this check constraint is derived from the Data Dictionary (True) (true) , or is local to the application (False) (false) .

See Also

CustomConstraint (see page 6844)

ImportedConstraint (see page 6845)

39.1.12.3.4 TCheckConstraint.ImportedConstraint Property

Contains the SQL text for a check constraint imported from the Data Dictionary or a remote SQL database server.

Pascal

```
property ImportedConstraint: string;
```

C++

```
__property AnsiString ImportedConstraint;
```

Description

ImportedConstraint stores the SQL text for a check constraint that is imported from the server or Data Dictionary. Although an application can set this property at runtime, ordinarily the text in ImportedConstraint is automatically provided to the application.

Note:

CustomConstraint (see page 6844)

FromDictionary (see page 6845)

39.1.13 TCheckConstraints Class

TCheckConstraints contains a collection of check constraints for a dataset component.

Class Hierarchy

Pascal

```
TCheckConstraints = class(TCollection);
```

C++

```
class TCheckConstraints : public TCollection;
```

File

DB

Description

BDE-enabled and c Client dataset components support check constraints that define the values that can be entered into a single record. The TCheckConstraints object maintains the collection of check constraints that apply to a given dataset.

See Also

TDataSet (see page 6894)

39.1.13.1 TCheckConstraints Members

The following tables list the members exposed by TCheckConstraints.

Protected Methods

	Name	Description
	Added (see page 2736)	Responds when items are added to the collection.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
	GetOwner (see page 6849)	Returns the owner of an object.
	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.

V	Update (see page 2747)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 6848)	Adds a check constraint to the list maintained by this collection object.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 6848)	Instantiates an instance of a check constraint collection object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 6849)	Maintains an indexed array of check constraints.

39.1.13.2 TCheckConstraints.Create Constructor

Instantiates an instance of a check constraint collection object.

Pascal

```
constructor Create(Owner: TPersistent);
```

C++

```
__fastcall TCheckConstraints(TPersistent * Owner);
```

Description

Most applications do not need to instantiate TCheckConstraints (see page 6846). This object is created by the dataset that uses it to implement its Constraints property.

Call Create to instantiate a check constraint collection at runtime when you need a collection object and it has not been created automatically for you. Create calls its inherited constructor, and sets the collection's owner object to Owner.

See Also

Constraints (see page 7013)

39.1.13.3 TCheckConstraints Methods

The methods of the TCheckConstraints class are listed here.

Protected Methods

	Name	Description
V	GetOwner (see page 6849)	Returns the owner of an object.

Public Methods

	Name	Description
	Add (see page 6848)	Adds a check constraint to the list maintained by this collection object.

39.1.13.3.1 TCheckConstraints.Add Method

Adds a check constraint to the list maintained by this collection object.

Pascal

```
function Add: TCheckConstraint;
```

C++

```
__fastcall TCheckConstraint Add();
```

Description

Call Add to add another check constraint to those known to the dataset component that owns this check constraint object. After adding a check constraint, set its properties to provide the SQL that defines the constraint.

See Also

Items (see page 6849)

39.1.13.3.2 TCheckConstraints.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

39.1.13.4 TCheckConstraints Properties

The properties of the TCheckConstraints class are listed here.

Public Properties

	Name	Description
	Items (see page 6849)	Maintains an indexed array of check constraints.

39.1.13.4.1 TCheckConstraints.Items Property

Maintains an indexed array of check constraints.

Pascal

```
property Items [Index: Integer]: TCheckConstraint;
```

C++

```
__property TCheckConstraint Items[int Index];
```

Description

Use Items to access individual check constraints that apply to the dataset component that owns this check constraint collection.

39.1.14 TCurrencyField Class

TCurrencyField represents a field that contains currency (see page 6857) values in a dataset.

Class Hierarchy

Pascal

```
TCurrencyField = class(TFloatField);
```

C++

```
class TCurrencyField : public TFloatField;
```

File

DB

Description

TCurrencyField encapsulates the fundamental behavior common to currency (see page 6857) fields. TCurrencyField differs from its immediate ancestor TFloatField (see page 7229) only in having a DataType (see page 7159) of ftCurrency, and in formatting the value using a currency (see page 6857) format (one that represents monetary values) by default. Currency fields can hold values in the range from (positive or negative) 5.0 * 10^-324 to 1.7 * 10^308 with an accuracy of 15 digits.

Do not confuse TCurrencyField with the Currency data type. Currency fields use the double data type to store and manipulate their values. This data type is the format used by the physical database tables for currency (see page 6857) fields. The TBCDField (see page 6776) class uses the Currency data type to store and manipulate its value.

If you use the Fields editor at design time to create a persistent field component for the currency (see page 6857) field, you can access it by name at runtime. When using dynamic field components, you can access the TCurrencyField instance using the dataset's Fields property or FieldByName method.

Using Default Formatting for Numeric

39.1.14.1 TCurrencyField Members

The following tables list the members exposed by TCurrencyField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsFloat (see page 7237)	This is GetAsFloat, a member of class TFloatField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsInteger (see page 7237)	This is GetAsInteger, a member of class TFloatField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
V	GetAsString (see page 7238)	This is GetAsString, a member of class TFloatField.
V	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
V	GetAsVariant (see page 7238)	This is GetAsVariant, a member of class TFloatField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
V	GetDataSize (see page 7238)	This is GetDataSize, a member of class TFloatField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 7135)	This is GetText, a member of class TField.
V	GetText (see page 7238)	This is GetText, a member of class TFloatField.

	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	RangeError (see page 7368)	This is RangeError, a member of class TNumericField.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsFloat (see page 7239)	This is SetAsFloat, a member of class TFloatField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsInteger (see page 7239)	This is SetAsInteger, a member of class TFloatField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
	SetAsString (see page 7239)	This is SetAsString, a member of class TFloatField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDisplayFormat (see page 7368)	This is SetDisplayFormat, a member of class TNumericField.
	SetEditFormat (see page 7368)	This is SetEditFormat, a member of class TNumericField.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetVarValue (see page 7239)	This is SetVarValue, a member of class TFloatField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.

	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 7126)	Sets the value of the field to NULL.
V	Create (see page 6856)	Creates an instance of TCurrencyField (see page 6850).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.

	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.

	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	Value (see page 7242)	Specifies the value of the floating-point field.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	Alignment (see page 7369)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.

	currency (see page 6857)	Determines whether the value in the field should be formatted as a currency value.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayFormat (see page 7369)	Determines how a numeric field's value is formatted for display in a data-aware control.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	EditFormat (see page 7371)	Determines how a numeric field's value is formatted when it is being edited in a data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	MaxValue (see page 7240)	Limits the maximum value in the floating-point field.
	MinValue (see page 7241)	Limits the minimum value in the floating-point field.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	Precision (see page 7241)	Determines the precision used in formatting the value in a floating-point field.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.14.2 TCurrencyField.Create Constructor

Creates an instance of TCurrencyField (see page 6850).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCurrencyField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TCurrencyField (see page 6850). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

Create sets the DataType (see page 7159) property to ftCurrency and the Currency property to true. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TCurrencyField (see page 6850). After instantiating a TCurrencyField (see page 6850), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TCurrencyField (see page 6850) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TCurrencyField (see page 6850) with a dataset component by setting its DataSet (see page 7157) property to the name of the dataset component.

The example below creates a TCurrencyField (see page 6850) object for a field named Amount accessed through a TSQLDataSet named SQLDataSet1.

```
var
  T: TCurrencyField;
begin
  SQLDataSet1.Close;
  T := TCurrencyField.Create(SQLDataSet1);
  T.FieldName := 'Amount';
  T.Name := SQLDataSet1.Name + T.FieldName;
  T.Index := SQLDataSet1.FieldCount;
  T.DataSet := SQLDataSet1;
  SQLDataSet1.FieldDefs.UpDate;
  SQLDataSet1.Open;
end;
SQLDataSet1->Close();
TCurrencyField *T = new TCurrencyField(SQLDataSet1);
T->FieldName = "Amount";
T->Name = SQLDataSet1->Name + T->FieldName;
T->Index = SQLDataSet1->FieldCount;
T->DataSet = SQLDataSet1;
SQLDataSet1->FieldDefs->UpDate();
SQLDataSet1->Open();
```

39.1.14.3 TCurrencyField Properties

The properties of the TCurrencyField class are listed here.

Published Properties

	Name	Description
	currency (see page 6857)	Determines whether the value in the field should be formatted as a currency value.

39.1.14.3.1 TCurrencyField.currency Property

Determines whether the value in the field should be formatted as a currency value.

Pascal

```
property currency: Boolean;
```

C++

```
__property Boolean currency;
```

Description

Use the currency property to specify the formatting of the field for viewing and editing in a data-aware control.

The field is formatted for display using the DisplayFormat property if it is assigned. If DisplayFormat is not assigned, currency determines how the field is formatted for display. If currency is true, the value is formatted for display using the FloatToText function with the ffCurrency formatting code. If currency is false, the value is formatted with the ffGeneral format.

The field is formatted for editing purposes using the EditFormat (or DisplayFormat) property if it is assigned. If neither EditFormat nor DisplayFormat is assigned, currency determines how the field is formatted for editing. If currency is true, the value is formatted for editing using the FloatToText function with the ffFixed formatting code. If currency is false, the value is formatted with the ffGeneral format.

39.1.15 TCustomConnection Class

TCustomConnection is the base class for components that connect datasets to a remote source of data.

Class Hierarchy

Pascal

```
TCustomConnection = class(TComponent);
```

C++

```
class TCustomConnection : public TComponent;
```

File

DB

Description

Use TCustomConnection as a base class for components that represent a remote source of the data contained in a dataset. This source can be a remote database server, the middle tier of a multi-tiered database application, an interface such as the one used by ActiveX Data Objects (ADO), or any other driver that provides the information represented in a dataset. TCustomConnection introduces:

Methods for connecting to and disconnecting from the source of data.

Login support for providing a user name and password when establishing a connection.

Properties for keeping track of the datasets that use the connection component.

Do not create instances of TCustomConnection. To add a component that represents the connection to a source of data, use a TCustomConnection descendant such as TDatabase, TADOConnection, TSQLConnection, or one of the DataSnap connection components such as TDCOMConnection TSQLConnection or TSOAPConnection.

Connecting to Databases: Overview

39.1.15.1 TCustomConnection Members

The following tables list the members exposed by TCustomConnection.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoConnect (see page 6864)	Provides the interface for a method that opens a connection.
V	DoDisconnect (see page 6864)	Provides the interface for a method that terminates the connection.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetConnected (see page 6865)	Returns the value of the Connected (see page 6868) property.
V	GetDataSet (see page 6865)	Returns a dataset, given its index in the DataSets (see page 6870) property array.
V	GetDataSetCount (see page 6865)	Returns the value of the DataSetCount (see page 6869) property.

	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 6866)	Initializes the connection component after all objects in the form or data module have been loaded.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RegisterClient (see page 6866)	Registers an object that uses the connection component.
	SendConnectEvent (see page 6867)	Informs all registered clients that use the connection component when a connection is opened or closed.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetConnected (see page 6867)	Changes the value of the Connected (see page 6868) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	UnRegisterClient (see page 6868)	Removes a registered client so that it is no longer associated with the connection component.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	StreamedConnected (see page 6874)	Indicates whether the Connected (see page 6868) property was true when the connection component was loaded from a stream.

Public Events

	Name	Description
	AfterConnect (see page 6874)	Occurs after a connection is established.
	AfterDisconnect (see page 6875)	Occurs after the connection closes.
	BeforeConnect (see page 6875)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 6875)	Occurs immediately before the connection closes.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.

	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Close (see page 6863)	Closes the connection.
	Create (see page 6862)	Creates an instance of TCustomConnection (see page 6858).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 6863)	Destroys the instance of a connection component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Open (see page 6866)	Opens the connection.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)

V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Connected (see page 6868)	Determines whether a connection has been established to the remote source of data.
R	DataSetCount (see page 6869)	Indicates the number of datasets associated with the connection component.
R	DataSets (see page 6870)	Lists the datasets currently using this connection component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	LoginPrompt (see page 6872)	Specifies whether a login dialog appears immediately before opening a new connection.
	OnLogin (see page 6873)	Occurs when a communication channel opens to the server.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

39.1.15.2 TCustomConnection.Create Constructor

Creates an instance of TCustomConnection (see page 6858).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomConnection(TComponent * AOwner);
```

Description

Call Create to instantiate a connection component at runtime. Connection components added to forms or data modules at design time are created automatically.

The Owner parameter specifies another component (usually a form or data module) that is responsible for freeing the connection component.

See Also

Owner (see page 2807)

39.1.15.3 TCustomConnection.Destroy Destructor

Destroys the instance of a connection component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomConnection();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which verifies that the reference to the connection component is not nil before calling Destroy

Destroy closes all active datasets and closes its connection before freeing all internal resources.

Create (see page 6862)

Free (see page 22300)

39.1.15.4 TCustomConnection Methods

The methods of the TCustomConnection class are listed here.

Protected Methods

	Name	Description
	DoConnect (see page 6864)	Provides the interface for a method that opens a connection.
	DoDisconnect (see page 6864)	Provides the interface for a method that terminates the connection.
	GetConnected (see page 6865)	Returns the value of the Connected (see page 6868) property.
	GetDataSet (see page 6865)	Returns a dataset, given its index in the DataSets (see page 6870) property array.
	GetDataSetCount (see page 6865)	Returns the value of the DataSetCount (see page 6869) property.
	Loaded (see page 6866)	Initializes the connection component after all objects in the form or data module have been loaded.
	RegisterClient (see page 6866)	Registers an object that uses the connection component.
	SendConnectEvent (see page 6867)	Informs all registered clients that use the connection component when a connection is opened or closed.
	SetConnected (see page 6867)	Changes the value of the Connected (see page 6868) property.
	UnRegisterClient (see page 6868)	Removes a registered client so that it is no longer associated with the connection component.

Public Methods

	Name	Description
	Close (see page 6863)	Closes the connection.
	Open (see page 6866)	Opens the connection.

39.1.15.4.1 TCustomConnection.Close Method

Closes the connection.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Call Close to disconnect from the remote source of database information. Before the connection component is deactivated, all associated datasets are closed. Calling Close is the same as setting the Connected (see page 6868) property to false.

In most cases, closing a connection frees system resources allocated to the connection.

Note: If a previously active connection is closed and then reopened, any associated datasets must be individually reopened; reopening the connection does not automatically reopen associated datasets.

See Also

Connected (see page 6868)

Disconnecting from a Database Server

39.1.15.4.2 TCustomConnection.DoConnect Method

Provides the interface for a method that opens a connection.

Pascal

```
procedure DoConnect; virtual;
```

C++

```
virtual __fastcall DoConnect();
```

Description

The Connected (see page 6868) property uses DoConnect to establish a connection. Descendant classes override the DoConnect method to establish their connection as appropriate. As implemented in TCustomConnection (see page 6858), DoConnect does nothing.

See Also

Connected (see page 6868)

DoDisconnect (see page 6864)

39.1.15.4.3 TCustomConnection.DoDisconnect Method

Provides the interface for a method that terminates the connection.

Pascal

```
procedure DoDisconnect; virtual;
```

C++

```
virtual __fastcall DoDisconnect();
```

Description

The Connected (see page 6868) property uses DoDisconnect to close a connection. Descendant classes override the DoDisconnect method to drop a connection. As implemented in TCustomConnection (see page 6858), DoDisconnect does nothing.

See Also

Connected (see page 6868)

DoConnect (see page 6864)

39.1.15.4.4 TCustomConnection.GetConnected Method

Returns the value of the Connected (see page 6868) property.

Pascal

```
function GetConnected: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected (see page 6868) property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection (see page 6858), GetConnected always returns false.

See Also

Connected (see page 6868)

SetConnected (see page 6867)

39.1.15.4.5 TCustomConnection.GetDataSet Method

Returns a dataset, given its index in the DataSets (see page 6870) property array.

Pascal

```
function GetDataSet(Index: Integer): TDataSet; virtual;
```

C++

```
virtual __fastcall TDataSet GetDataSet(int Index);
```

Description

GetDataSet is the protected read implementation of the DataSets (see page 6870) property.

See Also

DataSets (see page 6870)

39.1.15.4.6 TCustomConnection.GetDataSetCount Method

Returns the value of the DataSetCount (see page 6869) property.

Pascal

```
function GetDataSetCount: Integer; virtual;
```

C++

```
virtual __fastcall int GetDataSetCount();
```

Description

GetDataSetCount is the protected read implementation of the DataSetCount (see page 6869) property.

See Also

DataSetCount (see page 6869)

39.1.15.4.7 TCustomConnection.Loaded Method

Initializes the connection component after all objects in the form or data module have been loaded.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. It is called automatically after the form or data module that contains the connection component has loaded all its owned objects. TCustomConnection (see page 6858) overrides the inherited method to establish a connection if the Connected (see page 6868) property is true.

See Also

StreamedConnected (see page 6874)

Loaded (see page 2782)

39.1.15.4.8 TCustomConnection.Open Method

Opens the connection.

Pascal

```
procedure Open; overload;
```

C++

```
__fastcall Open();
```

Description

Call Open to establish a connection to the remote source of database information. Open sets the Connected (see page 6868) property to true.

See Also

Connected (see page 6868)

Connecting to a Database Server

39.1.15.4.9 TCustomConnection.RegisterClient Method

Registers an object that uses the connection component.

Pascal

```
procedure RegisterClient(Client: TObject; Event: TConnectChangeEvent = nil); virtual;
```

C++

```
virtual __fastcall RegisterClient(TObject * Client, TConnectChangeEvent Event = nil);
```

Description

RegisterClient is used internally to associate objects with the connection component. Registered components can supply an event handler that responds when the connection is created or terminated.

Client is the object to register. If Client is a dataset, it is added to the DataSets (see page 6870) property.

Event is an event handler that is called after the connection is established or before it is terminated.

Datasets call this method when they start using the connection component. For BDE-enabled datasets, ADO datasets, and dbExpress datasets, this is when they are activated. For client datasets, this is when the RemoteServer property is assigned.

See Also

DataSets (see page 6870)

UnRegisterClient (see page 6868)

39.1.15.4.10 TCustomConnection.SendConnectEvent Method

Informs all registered clients that use the connection component when a connection is opened or closed.

Pascal

```
procedure SendConnectEvent(Connecting: Boolean);
```

C++

```
__fastcall SendConnectEvent(Boolean Connecting);
```

Description

SendConnectEvent is used internally to ensure that registered clients are informed when their connection is opened or closed. It is called automatically when the Connected (see page 6868) property changes.

SendConnectEvent iterates through all registered clients. For each client that supplied an event handler to the RegisterClient (see page 6866) method, SendConnectEvent calls that event handler to inform the client that a connection has just been opened (when Connecting is true) or that the connection is about to close (when Connecting is false). If the client is a dataset, it is informed about the change even if it did not supply an event handler to RegisterClient (see page 6866).

See Also

DataSets (see page 6870)

Connected (see page 6868)

RegisterClient (see page 6866)

39.1.15.4.11 TCustomConnection.SetConnected Method

Changes the value of the Connected (see page 6868) property.

Pascal

```
procedure SetConnected(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetConnected(Boolean Value);
```

Description

SetConnected is the protected write implementation of the Connected (see page 6868) property. Most descendants of TCustomConnection (see page 6858) do not override this method to change the implementation of Connected (see page 6868). Instead, they override the DoConnect (see page 6864) and DoDisconnect (see page 6864) methods to change the way the connection is opened and closed.

See Also

Connected (see page 6868)

DoConnect (see page 6864)

DoDisconnect (see page 6864)

39.1.15.4.12 TCustomConnection.UnRegisterClient Method

Removes a registered client so that it is no longer associated with the connection component.

Pascal

```
procedure UnRegisterClient(Client: TObject); virtual;
```

C++

```
virtual __fastcall UnRegisterClient(TObject * Client);
```

Description

UnRegisterClient is used internally to remove objects from the internal list of objects that are informed when a connection is created or terminated.

Client is the object that is removed from the list. It should be an object that was previously registered by a call to RegisterClient (see page 6866). If Client is a dataset, it is removed from the DataSets (see page 6870) property list.

Datasets call this method when they stop using the connection component. For BDE-enabled datasets, ADO datasets, and dbExpress datasets, this is when they are deactivated. For client datasets, this is when the RemoteServer property is changed.

See Also

DataSets (see page 6870)

RegisterClient (see page 6866)

39.1.15.5 TCustomConnection Properties

The properties of the TCustomConnection class are listed here.

Protected Properties

	Name	Description
	StreamedConnected (see page 6874)	Indicates whether the Connected (see page 6868) property was true when the connection component was loaded from a stream.

Public Properties

	Name	Description
	Connected (see page 6868)	Determines whether a connection has been established to the remote source of data.
R	DataSetCount (see page 6869)	Indicates the number of datasets associated with the connection component.
R	DataSets (see page 6870)	Lists the datasets currently using this connection component.
	LoginPrompt (see page 6872)	Specifies whether a login dialog appears immediately before opening a new connection.
	OnLogin (see page 6873)	Occurs when a communication channel opens to the server.

39.1.15.5.1 TCustomConnection.Connected Property

Determines whether a connection has been established to the remote source of data.

Pascal

```
property Connected: Boolean;
```

C++

```
__property Boolean Connected;
```

Description

Set Connected to true to open the connection. Set Connected to false to terminate the connection.

Setting Connected to true generates a BeforeConnect (see page 6875) event, calls the protected DoConnect (see page 6864) method to establish the connection, and generates an AfterConnect (see page 6874) event. In addition, when setting Connected to true, TCustomConnection (see page 6858) may display a login dialog, depending on the value of LoginPrompt (see page 6872).

Setting Connected to false generates a BeforeDisconnect (see page 6875) event, calls the protected DoConnect (see page 6864) method to drop the connection, and generates an AfterDisconnect (see page 6875) event.

When deriving custom connection components from TCustomConnection (see page 6858), override GetConnected (see page 6865) to return true when a connection is established, and override DoConnect (see page 6864) and DoDisconnect (see page 6864) to create and drop the connection.

See Also

DataSets (see page 6870)

LoginPrompt (see page 6872)

Disconnecting from a Database Server

Connecting to a Database Server

39.1.15.5.2 TCustomConnection.DataSetCount Property

Indicates the number of datasets associated with the connection component.

Pascal

```
property DataSetCount: Integer;
```

C++

```
__property int DataSetCount;
```

Description

Use DataSetCount to determine the number of datasets listed by the DataSets (see page 6870) property. Depending on the TCustomConnection (see page 6858) descendant, DataSets (see page 6870) may include only the active datasets that use the connection component (as is the case with TDatabase and TSQLConnection), or it may list all datasets, regardless of whether they are active (as is the case with TADODatabase and DataSnap connection components TSOAPConnection). If DataSets (see page 6870) includes only active datasets, the value of DataSetCount changes when datasets are opened and closed.

Use DataSetCount as an upper bound when iterating through the DataSets (see page 6870) property.

Delphi Examples:

```
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

See Also

DataSets (see page 6870)

Active (see page 7004)

Working with Associated Datasets

39.1.15.5.3 TCustomConnection.DataSets Property

Lists the datasets currently using this connection component.

Pascal

```
property DataSets [Index: Integer]: TDataSet;
```

C++

```
__property TDataSet DataSets[int Index];
```

Description

Use DataSets to access the datasets that are currently using the connection component. Depending on the TCustomConnection (see page 6858) descendant, DataSets may include only the active datasets that use the connection component (as is the case with TDatabase and TSQLConnection), or it may list all datasets, regardless of whether they are active (as is the case with TADODatabase and DataSnap connection components TSOAPConnection). If DataSets includes only active datasets, its value changes when datasets are opened and closed.

Note: If a client dataset with an internal provider (for example TSQLClientDataSet or TBDEClientDataSet

) uses the connection component to connect to a database server, DataSets lists the internal dataset that the client dataset creates to access data, not the client dataset itself.

Delphi Examples:

```
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

See Also

DataSetCount (see page 6869)

Active (see page 7004)

Working with Associated Datasets

39.1.15.5.4 TCustomConnection.LoginPrompt Property

Specifies whether a login dialog appears immediately before opening a new connection.

Pascal

```
property LoginPrompt: Boolean;
```

C++

```
__property Boolean LoginPrompt;
```

Description

Set LoginPrompt to true to provide login support when establishing a connection. LoginPrompt controls two things: the occurrence of the OnLogin (see page 6873) event, and the appearance of a default login dialog that prompts users for a name and password when you include DBLogDlg.hpp in your unit (C++) or add DBLogDlg (see page 9775) to your uses clause (Delphi). When the OnLogin (see page 6873) event occurs and when the default login dialog appears depend on the type of connection component:

For TDatabase, TIBDatabase, and TSQLConnection, the dialog appears after the BeforeConnect (see page 6875) event and before the AfterConnect (see page 6874) event, unless you supply an OnLogin (see page 6873) event handler. If there is an OnLogin (see page 6873) event handler, that event occurs in place of the login dialog, and there is no need to include DBLogDlg.hpp in your unit (C++) or add DBLogDlg (see page 9775) to your uses clause (Delphi). If correct values for the user name and password are not supplied in the dialog or by the OnLogin (see page 6873) event handler, the connection fails. The OnLogin (see page 6873) event does not fire unless LoginPrompt is set to true.

For TADOConnection components, the dialog appears after the OnWillConnect event and before the BeforeConnect (see page 6875) event. If there is an OnLogin (see page 6873) event handler, that event occurs after the login dialog. If you do not include DBLogDlg.hpp in your unit (C++) or add DBLogDlg (see page 9775) to your uses clause (Delphi), the OnLogin (see page 6873) event occurs but there is no default login dialog. If correct values for the user name and password are not supplied in the dialog or by the OnLogin (see page 6873) event handler, the connection fails. The OnLogin (see page 6873) event does not fire unless LoginPrompt is set to true.

For DataSnap SOAP connection components, the dialog appears after the OnGetUsername event and before the BeforeConnect (see page 6875), AfterConnect (see page 6874), and OnLogin (see page 6873) events. If the user cancels from the login dialog, no attempt is made to open a connection.

When LoginPrompt is false, the application must supply user name and password values programmatically:

For TDatabase, the user name and password can be supplied as USER NAME and PASSWORD parameters in the Params property.

For TADOConnection, the user name and password can be supplied as the ConnectionString property.

For TSQLConnection, the user name, password, and database can be supplied as UserName, Password, and Database parameters in the Params property, or provided as connection parameters associated with the connection name.

For DataSnap SOAP connection components, there is no built-in use for the user name and password supplied by the login dialog. (The UserName and Password properties of TWebConnection are unrelated).

Warning: Storing hard-coded user name and password entries as property values or in code for an OnLogin (see page 6873) event handler can compromise server security.

See Also

OnLogin (see page 6873)

BeforeConnect (see page 6875)

AfterConnect (see page 6874)

OnGetUserName (see page 8533)

OnLogin (see page 20259)

OnLogin (see page 9994)

Controlling Server Login

39.1.15.5.5 TCustomConnection.OnLogin Property

Occurs when a communication channel opens to the server.

Pascal

```
property OnLogin: TLoginEvent;
```

C++

```
__property TLoginEvent OnLogin;
```

Description

OnLogin occurs when connections are opened if the LoginPrompt (see page 6872) property is true.

For DataSnap SOAP connection components, the following sequence of events occurs when opening a connection to an application server:

1. An OnGetUsername event occurs, where the application can supply an initial user name for the login dialog.
2. The login dialog appears, where the user can supply a user name and password.
3. A BeforeConnect (see page 6875) event occurs, the connection is opened, and an AfterConnect (see page 6874) event occurs.
4. The OnLogin event occurs, where you can write code to log in to the application server using the username and password that were provided in the remote login dialog.

   Note: Do not use the OnLogin event if the connection component provides a different scheme for logging in. For example, TWebConnection uses the Username and Password properties instead.

   For ADO connection components, the following sequence of events occurs when opening a connection to an application server:

1. A BeforeConnect (see page 6875) event occurs.

2. An OnWillConnect event occurs, where the application can supply an initial user name and password for the login dialog, as well as the connection options and status.

3. The login dialog appears, where the user can supply a user name and password.

4. The OnLogin event occurs, where you can write code to respond to the user-supplied values. (For example, you could convert an application-specific user name and password to database user name and password).

5. The connection is opened, and an AfterConnect (see page 6874) event occurs.

Note: Some

C connection components that do not connect to an application server in a multitiered database application replace the OnLogin event defined in TCustomConnection (see page 6858) with a different event that occurs before a connection is established.

Connected (see page 6868)

Open (see page 6866)

OnGetUserName (see page 8533)

BeforeConnect (see page 6875)

AfterConnect (see page 6874)

LoginPrompt (see page 6872)

OnWillConnect (see page 1039)

39.1.15.5.6 TCustomConnection.StreamedConnected Property

Indicates whether the Connected (see page 6868) property was true when the connection component was loaded from a stream.

Pascal

```
property StreamedConnected: Boolean;
```

C++

```
__property Boolean StreamedConnected;
```

Description

StreamedConnected is used internally to ensure that the connection component does not open a connection until all objects on the form or data module are loaded into memory. This property is set instead of the Connected (see page 6868) property when loading the connection component. In the Loaded (see page 6866) method, after all objects in the form or data module have been loaded into memory, the value of StreamedConnected is used to set the Connected (see page 6868) property.

See Also

Connected (see page 6868)

Loaded (see page 6866)

39.1.15.6 TCustomConnection Events

The events of the TCustomConnection class are listed here.

Public Events

	Name	Description
	AfterConnect (see page 6874)	Occurs after a connection is established.
	AfterDisconnect (see page 6875)	Occurs after the connection closes.
	BeforeConnect (see page 6875)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 6875)	Occurs immediately before the connection closes.

39.1.15.6.1 TCustomConnection.AfterConnect Event

Occurs after a connection is established.

Pascal

```
property AfterConnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterConnect;
```

Description

Write an AfterConnect event handler to take application-specific actions immediately after the connection component opens a

connection to the remote source of database information.

See Also

BeforeConnect (see page 6875)

Connected (see page 6868)

Connecting to a Database Server

39.1.15.6.2 TCustomConnection.AfterDisconnect Event

Occurs after the connection closes.

Pascal

```
property AfterDisconnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterDisconnect;
```

Description

Write an AfterDisconnect event handler to take application-specific actions after the connection component drops a connection.

See Also

BeforeDisconnect (see page 6875)

Connected (see page 6868)

Disconnecting from a Database Server

39.1.15.6.3 TCustomConnection.BeforeConnect Event

Occurs immediately before establishing a connection.

Pascal

```
property BeforeConnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeConnect;
```

Description

Write a BeforeConnect event handler to take application-specific actions before the connection component opens a connection to the remote source of database information.

See Also

AfterConnect (see page 6874)

Connected (see page 6868)

Connecting to a Database Server

39.1.15.6.4 TCustomConnection.BeforeDisconnect Event

Occurs immediately before the connection closes.

Pascal

```
property BeforeDisconnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeDisconnect;
```

Description

Write a BeforeDisconnect event handler to take application-specific actions before dropping a connection.

Delphi Examples:

```
{
This BeforeDisconnect event handler makes sure that the
client dataset has applied all its pending updates before
terminating the connection to the server.
}
procedure TForm1.RemoteServer1BeforeDisconnect(Sender: TObject);
begin
  if (ClientDataSet1.ChangeCount > 0) then
    ClientDataSet1.ApplyUpdates(-1);
end;
```

Connected (see page 6868)

Disconnecting from a Database Server

39.1.16 TDataLink Class

TDataLink is a helper class used by data-aware objects to coordinate the actions of TDataSource (see page 7070) and TDataSet (see page 6894), and to respond to data events.

Class Hierarchy

Pascal

```
TDataLink = class(TPersistent);
```

C++

```
class TDataLink : public TPersistent;
```

File

DB

Description

Use TDataLink or one of its descendants in any data-aware object that implements a DataSource (see page 6891) property to represent its link to a dataset or that needs to respond to data events.

The constructor of the data-aware object should call the constructor of TDataLink, and initialize any relevant properties. The data-aware object can then link to a TDataSource (see page 7070) by using the DataSource (see page 6891) property of the TDataLink.

Data-aware objects that link to a single field in a dataset should use a TFieldDataLink instead.

See Also

TFieldDataLink (see page 9487)

TDataSet (see page 6894)

TDataSource (see page 7070)

39.1.16.1 TDataLink Members

The following tables list the members exposed by TDataLink.

Protected Methods

	Name	Description
	ActiveChanged (see page 6880)	Responds to changes in the Active (see page 6888) property.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CheckBrowseMode (see page 6880)	Allows the data-aware object to respond just before an event that changes the dataset state.
	DataEvent (see page 6881)	Responds to various events that occur while working with data.
	DataSetChanged (see page 6881)	Responds to changes in the dataset.
	DataSetScrolled (see page 6882)	Allows a response to scrolling the representation of the dataset within the data-aware object.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	EditingChanged (see page 6883)	Responds to changes in the editing state of the data source.
	FocusControl (see page 6884)	Provides the interface for a method to force focus to the data-aware component associated with the TDataLink (see page 6876).
	GetActiveRecord (see page 6884)	This is GetActiveRecord, a member of class TDataLink.
	GetBOF (see page 6884)	This is GetBOF, a member of class TDataLink.
	GetBufferCount (see page 6884)	This is GetBufferCount, a member of class TDataLink.
	GetEOF (see page 6885)	This is GetEOF, a member of class TDataLink.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetRecordCount (see page 6885)	This is GetRecordCount, a member of class TDataLink.
	LayoutChanged (see page 6885)	Responds to changes in the representation of the data by the data-aware object.
	MoveBy (see page 6885)	Repositions the dataset to another record relative to its active record.
	RecordChanged (see page 6886)	Responds to changes in the contents of the current record or field of the dataset.
	SetActiveRecord (see page 6886)	This is SetActiveRecord, a member of class TDataLink.
	SetBufferCount (see page 6887)	This is SetBufferCount, a member of class TDataLink.
	UpdateData (see page 6887)	Provides an interface for writing edits to a record in the dataset.

Protected Properties

	Name	Description
	VisualControl (see page 6894)	Indicates whether a visual control uses the datalink.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 6878)	Creates an instance of TDataLink (see page 6876).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.

V	Destroy (see page 6879)	Destroys an instance of TDataLink (see page 6876).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6882)	Attempts to drive the data source into an editing state if it is not already in one.
	ExecuteAction (see page 6883)	Invokes an action with the datasource as its target.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	UpdateAction (see page 6887)	Updates an action to reflect the current state of the TDataLink (see page 6876).
	UpdateRecord (see page 6888)	Responds to notifications that edits should be posted to the dataset.

Public Properties

	Name	Description
R	Active (see page 6888)	Specifies whether the dataset that TDataLink (see page 6876) manages is active.
	ActiveRecord (see page 6889)	Specifies the index of the current record within the internal record buffer maintained by the dataset for the Owner of the TDataLink (see page 6876) object.
R	BOF (see page 6889)	Indicates whether the first record in a dataset is active.
	BufferCount (see page 6890)	Specifies the number of records cached by the dataset for the Owner of the TDataLink (see page 6876) object.
R	DataSet (see page 6890)	Specifies the TDataSet (see page 6894) object that represents the data that this TDataLink (see page 6876) is tracking.
	DataSource (see page 6891)	Specifies the TDataSource (see page 7070) object that the Owner of the TDataLink (see page 6876) uses to connect to the dataset.
	DataSourceFixed (see page 6891)	Indicates whether the DataSource (see page 6891) property can be set.
R	Editing (see page 6892)	Indicates whether the DataSource (see page 6891) is in edit mode.
R	Eof (see page 6892)	Indicates whether the last record in a dataset is active.
	ReadOnly (see page 6893)	Indicates whether the dataset for this TDataLink (see page 6876) can be modified.
R	RecordCount (see page 6893)	Indicates the number of records in the internal record buffer maintained by the dataset.

39.1.16.2 TDataLink.Create Constructor

Creates an instance of TDataLink (see page 6876).

Pascal

```
constructor Create;
```

C++

```
__fastcall TDataLink();
```

Description

Create is called from the constructor of any data-aware object that uses a TDataLink (see page 6876) to implement its DataSource (see page 6891) property.

After calling the inherited constructor, Create initializes the BufferCount (see page 6890) property to 1. Data-aware objects that use a TDataLink (see page 6876) object to manage their link to a DataSource (see page 6891) should change the BufferCount (see page 6890) property to the number or records they represent, after calling the inherited constructor.

See Also

BufferCount (see page 6890)

39.1.16.3 TDataLink.Destroy Destructor

Destroys an instance of TDataLink (see page 6876).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataLink();
```

Description

The TDataLink (see page 6876) object should be destroyed in the destructor of its Owner, where that Owner calls Create (see page 6878) from its constructor.

Do not call Destroy directly in an application. Instead, call the Free method. Free checks that the TDataLink (see page 6876) reference is not nil and only then calls Destroy.

Before calling the inherited destructor, Destroy removes any reference to the TDataLink (see page 6876) from the data source object.

See Also

DataSource (see page 6891)

Free (see page 22300)

39.1.16.4 TDataLink Methods

The methods of the TDataLink class are listed here.

Protected Methods

	Name	Description
	ActiveChanged (see page 6880)	Responds to changes in the Active (see page 6888) property.
	CheckBrowseMode (see page 6880)	Allows the data-aware object to respond just before an event that changes the dataset state.
	DataEvent (see page 6881)	Responds to various events that occur while working with data.
	DataSetChanged (see page 6881)	Responds to changes in the dataset.
	DataSetScrolled (see page 6882)	Allows a response to scrolling the representation of the dataset within the data-aware object.
	EditingChanged (see page 6883)	Responds to changes in the editing state of the data source.
	FocusControl (see page 6884)	Provides the interface for a method to force focus to the data-aware component associated with the TDataLink (see page 6876).
	GetActiveRecord (see page 6884)	This is GetActiveRecord, a member of class TDataLink.

	GetBOF (see page 6884)	This is GetBOF, a member of class TDataLink.
	GetBufferCount (see page 6884)	This is GetBufferCount, a member of class TDataLink.
	GetEOF (see page 6885)	This is GetEOF, a member of class TDataLink.
	GetRecordCount (see page 6885)	This is GetRecordCount, a member of class TDataLink.
	LayoutChanged (see page 6885)	Responds to changes in the representation of the data by the data-aware object.
	MoveBy (see page 6885)	Repositions the dataset to another record relative to its active record.
	RecordChanged (see page 6886)	Responds to changes in the contents of the current record or field of the dataset.
	SetActiveRecord (see page 6886)	This is SetActiveRecord, a member of class TDataLink.
	SetBufferCount (see page 6887)	This is SetBufferCount, a member of class TDataLink.
	UpdateData (see page 6887)	Provides an interface for writing edits to a record in the dataset.

Public Methods

	Name	Description
	Edit (see page 6882)	Attempts to drive the data source into an editing state if it is not already in one.
	ExecuteAction (see page 6883)	Invokes an action with the datasource as its target.
	UpdateAction (see page 6887)	Updates an action to reflect the current state of the TDataLink (see page 6876).
	UpdateRecord (see page 6888)	Responds to notifications that edits should be posted to the dataset.

39.1.16.4.1 TDataLink.ActiveChanged Method

Responds to changes in the Active (see page 6888) property.

Pascal

```
procedure ActiveChanged; virtual;
```

C++

```
virtual __fastcall ActiveChanged();
```

Description

The ActiveChanged method defined by TDataLink (see page 6876) merely provides an interface for a method that can respond to changes in the Active (see page 6888) property. Derived objects that do not need to respond to such changes can allow the inherited method to ignore them.

See Also

Active (see page 6888)

39.1.16.4.2 TDataLink.CheckBrowseMode Method

Allows the data-aware object to respond just before an event that changes the dataset state.

Pascal

```
procedure CheckBrowseMode; virtual;
```

C++

```
virtual __fastcall CheckBrowseMode();
```

Description

The CheckBrowseMode method defined by TDataLink (see page 6876) merely provides an interface for a method that can update any state information just before a change to the dataset occurs. Derived objects that do not need to respond to these events can allow the inherited method to ignore them.

See Also

DataSet (see page 6890)

39.1.16.4.3 TDataLink.DataEvent Method

Responds to various events that occur while working with data.

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); virtual;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

DataEvent is called automatically when various data events occur. Event indicates the event that just occurred. Info provides additional context information for some events.

DataEvent dispatches these events by calling the appropriate methods, as indicated in the following table.

Data event	Info	Method called
deFieldChange | deRecordChange	The field that changed	RecordChanged (see page 6886)
deDataSetChange	Current index into the record buffer	DataSetChanged (see page 6881)
deDataSetScroll	Current index into the record buffer	DataSetScrolled (see page 6882)
deLayoutChange	Current index into the record buffer	LayoutChanged (see page 6885)
deUpdateRecord	UpdateRecord (see page 6888)	
deUpdateState	EditingChanged (see page 6883) or ActiveChanged (see page 6880)	
deCheckBrowseMode	CheckBrowseMode (see page 6880)	
deFocusControl	FocusControl (see page 6884)	

See Also

DataSetScrolled (see page 6882)

LayoutChanged (see page 6885)

RecordChanged (see page 6886)

DataSetChanged (see page 6881)

UpdateRecord (see page 6888)

CheckBrowseMode (see page 6880)

FocusControl (see page 6884)

ActiveChanged (see page 6880)

EditingChanged (see page 6883)

39.1.16.4.4 TDataLink.DataSetChanged Method

Responds to changes in the dataset.

Pascal

```
procedure DataSetChanged; virtual;
```

C++

```
virtual __fastcall DataSetChanged();
```

Description

DataSetChanged responds to changes to the contents of the dataset. Anything that changes the contents of the dataset, whether it is editing the data, inserting or deleting records, or changing the key triggers this method. Changes specific to the representation of the data within the data-aware object, such as scrolling the dataset or changing the layout of data elements within the object, also trigger this method. DataSetChanged simply calls RecordChanged (see page 6886). Derived classes can override this procedure to make additional adjustments to changes in the dataset.

See Also

DataSetScrolled (see page 6882)

LayoutChanged (see page 6885)

RecordChanged (see page 6886)

39.1.16.4.5 TDataLink.DataSetScrolled Method

Allows a response to scrolling the representation of the dataset within the data-aware object.

Pascal

```
procedure DataSetScrolled(Distance: Integer); virtual;
```

C++

```
virtual __fastcall DataSetScrolled(int Distance);
```

Description

DataSetScrolled ignores the Distance parameter and calls DataSetChanged (see page 6881). Derived classes can override this procedure to make additional adjustments when the dataset scrolls.

See Also

DataSetChanged (see page 6881)

39.1.16.4.6 TDataLink.Edit Method

Attempts to drive the data source into an editing state if it is not already in one.

Pascal

```
function Edit: Boolean;
```

C++

```
__fastcall Boolean Edit();
```

Description

Use Edit to try to ensure that the current record can be modified. A return value of true indicates that the data source was already in an editing state, or that it was successfully changed to allow editing. A return value of false indicates that the data source could not be changed to allow editing. For example, if the ReadOnly (see page 6893) property is true, Edit will not allow editing and will return false.

See Also

ActiveRecord (see page 6889)

DataSource (see page 6891)

Editing (see page 6892)

ReadOnly (see page 6893)

39.1.16.4.7 TDataLink.EditingChanged Method

Responds to changes in the editing state of the data source.

Pascal

```
procedure EditingChanged; virtual;
```

C++

```
virtual __fastcall EditingChanged();
```

Description

The EditingChanged method defined by TDataLink (see page 6876) merely provides an interface for a method that can respond to changes in the editing state of the data source. EditingChanged is called immediately after the Editing (see page 6892) property has changed its value. Derived objects that do not need to respond to such changes can allow the inherited method to ignore them.

See Also

Edit (see page 6882)

Editing (see page 6892)

39.1.16.4.8 TDataLink.ExecuteAction Method

Invokes an action with the datasource as its target.

Pascal

```
function ExecuteAction(Action: TBasicAction): Boolean; dynamic;
```

C++

```
__fastcall Boolean ExecuteAction(TBasicAction Action);
```

Description

ExecuteAction is called automatically when the user invokes an action with the Owner as a target. The Action parameter specifies the action that was invoked. ExecuteAction checks whether the associated datasource can handle the action, and if so, forwards the action to the datasource.

ExecuteAction returns true if the action was successfully dispatched, and false if the TDataLink (see page 6876) could not handle the action.

See Also

UpdateAction (see page 6887)

DataSource (see page 6891)

39.1.16.4.9 TDataLink.FocusControl Method

Provides the interface for a method to force focus to the data-aware component associated with the TDataLink (see page 6876).

Pascal

```
procedure FocusControl(Field: TFieldRef); virtual;
```

C++

```
virtual __fastcall FocusControl(TFieldRef Field);
```

Description

The FocusControl method defined by TDataLink (see page 6876) merely provides an interface for a method that can force the input focus to a data-aware object associated with the TDataLink (see page 6876). Derived objects that do not need this capability can allow the inherited method to ignore the request.

See Also

TabStop

SetFocus

39.1.16.4.10 TDataLink.GetActiveRecord Method

Pascal

```
function GetActiveRecord: Integer; virtual;
```

C++

```
virtual __fastcall int GetActiveRecord();
```

Description

This is GetActiveRecord, a member of class TDataLink.

39.1.16.4.11 TDataLink.GetBOF Method

Pascal

```
function GetBOF: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetBOF();
```

Description

This is GetBOF, a member of class TDataLink.

39.1.16.4.12 TDataLink.GetBufferCount Method

Pascal

```
function GetBufferCount: Integer; virtual;
```

C++

```
virtual __fastcall int GetBufferCount();
```

Description

This is GetBufferCount, a member of class TDataLink.

39.1.16.4.13 TDataLink.GetEOF Method

Pascal

```
function GetEOF: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetEOF();
```

Description

This is GetEOF, a member of class TDataLink.

39.1.16.4.14 TDataLink.GetRecordCount Method

Pascal

```
function GetRecordCount: Integer; virtual;
```

C++

```
virtual __fastcall int GetRecordCount();
```

Description

This is GetRecordCount, a member of class TDataLink.

39.1.16.4.15 TDataLink.LayoutChanged Method

Responds to changes in the representation of the data by the data-aware object.

Pascal

```
procedure LayoutChanged; virtual;
```

C++

```
virtual __fastcall LayoutChanged();
```

Description

The LayoutChanged method simply calls the DataSetChanged (see page 6881) method. LayoutChanged is intended to provide an interface for a method that can respond after changes in the representation of the data by the data-aware object. An example of such a change would be changing the number or order of the columns in a TCustomDBGrid.

See Also

DataSetChanged (see page 6881)

39.1.16.4.16 TDataLink.MoveBy Method

Repositions the dataset to another record relative to its active record.

Pascal

```
function MoveBy(Distance: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int MoveBy(int Distance);
```

Description

The MoveBy record changes the active record in the associated dataset, based on the Distance parameter. If Distance is greater than 0, MoveBy causes the dataset to move forward by that number of records. If Distance is less than 0, MoveBy causes the dataset to move backward. MoveBy returns the number of records actually moved (which may be less than the absolute value of Distance if the dataset encountered the first or last record before moving the indicated number of records).

MoveBy calls the MoveBy method of the associated dataset.

See Also

MoveBy (see page 6971)

DataSet (see page 6890)

39.1.16.4.17 TDataLink.RecordChanged Method

Responds to changes in the contents of the current record or field of the dataset.

Pascal

```
procedure RecordChanged(Field: TField); virtual;
```

C++

```
virtual __fastcall RecordChanged(TField Field);
```

Description

The RecordChanged method defined by TDataLink (see page 6876) merely provides an interface for a method that can respond to changes to the contents of the current record. RecordChanged is called after changes have been posted to the current record in the dataset, and from DataSetChanged (see page 6881).

The Field parameter indicates which field of the current record has changed in value. If Field is nil (Delphi) or NULL (C++), any number of fields within the current record may have changed.

Derived objects that do not need to respond to such changes can allow the inherited method to ignore them.

See Also

ActiveRecord (see page 6889)

DataSetChanged (see page 6881)

OnDataChange (see page 7080)

OnChange (see page 7181)

39.1.16.4.18 TDataLink.SetActiveRecord Method

Pascal

```
procedure SetActiveRecord(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetActiveRecord(int Value);
```

Description

This is SetActiveRecord, a member of class TDataLink.

39.1.16.4.19 TDataLink.SetBufferCount Method

Pascal

```
procedure SetBufferCount(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetBufferCount(int Value);
```

Description

This is SetBufferCount, a member of class TDataLink.

39.1.16.4.20 TDataLink.UpdateAction Method

Updates an action to reflect the current state of the TDataLink (see page 6876).

Pascal

```
function UpdateAction(Action: TBasicAction): Boolean; dynamic;
```

C++

```
__fastcall Boolean UpdateAction(TBasicAction Action);
```

Description

UpdateAction is called automatically when the application is idle to give the TDataLink (see page 6876) an opportunity to update associated actions. This allows actions to be grayed, checked, or to otherwise reflect the status of the TDataLink (see page 6876) they target.

The Action parameter specifies the action component that should be updated. UpdateAction returns true if the action component now reflects the state of the component, and false if it did not know how to update the action.

See Also

ExecuteAction (see page 6883)

39.1.16.4.21 TDataLink.UpdateData Method

Provides an interface for writing edits to a record in the dataset.

Pascal

```
procedure UpdateData; virtual;
```

C++

```
virtual __fastcall UpdateData();
```

Description

The UpdateData method defined by TDataLink (see page 6876) merely provides an interface for a method that writes updates to the current record in the dataset while avoiding calls to RecordChanged (see page 6886) that posting the changes may trigger. Derived objects that do not need to write edits to the dataset can allow the inherited method to do nothing.

See Also

RecordChanged (see page 6886)

OnUpdateData (see page 7082)

UpdateRecord (see page 6888)

39.1.16.4.22 TDataLink.UpdateRecord Method

Responds to notifications that edits should be posted to the dataset.

Pascal

```
procedure UpdateRecord;
```

C++

```
__fastcall UpdateRecord();
```

Description

UpdateRecord calls UpdateData (see page 6887) after guarding against calls to RecordChanged (see page 6886), which may arise while UpdateData (see page 6887) is executing.

See Also

RecordChanged (see page 6886)

OnUpdateRecord (see page 9957)

UpdateData (see page 6887)

39.1.16.5 TDataLink Properties

The properties of the TDataLink class are listed here.

Protected Properties

	Name	Description
	VisualControl (see page 6894)	Indicates whether a visual control uses the datalink.

Public Properties

	Name	Description
R	Active (see page 6888)	Specifies whether the dataset that TDataLink (see page 6876) manages is active.
	ActiveRecord (see page 6889)	Specifies the index of the current record within the internal record buffer maintained by the dataset for the Owner of the TDataLink (see page 6876) object.
R	BOF (see page 6889)	Indicates whether the first record in a dataset is active.
	BufferCount (see page 6890)	Specifies the number of records cached by the dataset for the Owner of the TDataLink (see page 6876) object.
R	DataSet (see page 6890)	Specifies the TDataSet (see page 6894) object that represents the data that this TDataLink (see page 6876) is tracking.
	DataSource (see page 6891)	Specifies the TDataSource (see page 7070) object that the Owner of the TDataLink (see page 6876) uses to connect to the dataset.
	DataSourceFixed (see page 6891)	Indicates whether the DataSource (see page 6891) property can be set.
R	Editing (see page 6892)	Indicates whether the DataSource (see page 6891) is in edit mode.
R	Eof (see page 6892)	Indicates whether the last record in a dataset is active.
	ReadOnly (see page 6893)	Indicates whether the dataset for this TDataLink (see page 6876) can be modified.
R	RecordCount (see page 6893)	Indicates the number of records in the internal record buffer maintained by the dataset.

39.1.16.5.1 TDataLink.Active Property

Specifies whether the dataset that TDataLink (see page 6876) manages is active.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Read Active to determine whether the dataset for this TDataLink (see page 6876) is Active. When Active is false, the dataset is closed, and the dataset cannot read data from or write data to the database. When Active is true, data can be read from and written to the dataset.

See Also

ActiveChanged (see page 6880)

DataSet (see page 6890)

Active (see page 7004)

39.1.16.5.2 TDataLink.ActiveRecord Property

Specifies the index of the current record within the internal record buffer maintained by the dataset for the Owner of the TDataLink (see page 6876) object.

Pascal

```
property ActiveRecord: Integer;
```

C++

```
__property int ActiveRecord;
```

Description

Use ActiveRecord to discover or set the current record in the set of one or more records managed by the dataset. The set of records managed by the dataset corresponds to the number of records from the dataset visible at one time. For example, when the TDataLink (see page 6876) object is owned by a data-aware grid, the set of records managed by the dataset corresponds to the number of rows shown by the grid, and the ActiveRecord represents the current row.

Note: Unidirectional datasets do not buffer records. When the data link is used with a unidirectional dataset, ActiveRecord is always 0.

See Also

BufferCount (see page 6890)

DataSet (see page 6890)

DataSource (see page 6891)

39.1.16.5.3 TDataLink.BOF Property

Indicates whether the first record in a dataset is active.

Pascal

```
property BOF: Boolean;
```

C++

```
__property Boolean BOF;
```

Description

Inspect BOF to determine if the dataset component associated with the TDataLink (see page 6876) is positioned on its first record. If BOF is true, the active record is unequivocally the first row in the dataset. BOF is also true when:

A dataset is first opened.

A call is made to the dataset's First method.

A call is made to the dataset's Prior method, and the method fails because the first row is already active.

A call is made to the dataset's SetRange, resulting in an empty result set.

BOF is false in all other cases. An application should assume BOF is false unless one of the conditions above is met and the application tests the property directly.

Tip: If both Eof (see page 6892) and BOF are true, a dataset or range is empty.

See Also

Bof (see page 7008)

Eof (see page 6892)

39.1.16.5.4 TDataLink.BufferCount Property

Specifies the number of records cached by the dataset for the Owner of the TDataLink (see page 6876) object.

Pascal

```
property BufferCount: Integer;
```

C++

```
__property int BufferCount;
```

Description

Set BufferCount to tell the dataset how many records to buffer together to service the owner of the TDataLink (see page 6876) object. For example, a data-aware grid sets BufferCount to the number of rows visible in the grid.

Read BufferCount to iterate through all the records buffered by the dataset. For example, a data-aware object can paint itself by cycling through the set of records, moving the ActiveRecord (see page 6889) to visit each record in turn.

Note: Unidirectional datasets do not buffer records. Do not use BufferCount when the datalink is associated with a unidirectional dataset.

See Also

ActiveRecord (see page 6889)

DataSet (see page 6890)

DataSource (see page 6891)

RecordCount (see page 6893)

39.1.16.5.5 TDataLink.DataSet Property

Specifies the TDataSet (see page 6894) object that represents the data that this TDataLink (see page 6876) is tracking.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Read DataSet to determine the dataset that this TDataLink (see page 6876) helps manage. The TDataLink (see page 6876) responds to data events that are received by the DataSet, and makes changes to the dataset on behalf of the object that owns the TDataLink (see page 6876) object.

See Also

RecordCount (see page 6893)

UpdateData (see page 6887)

UpdateRecord (see page 6888)

39.1.16.5.6 TDataLink.DataSource Property

Specifies the TDataSource (see page 7070) object that the Owner of the TDataLink (see page 6876) uses to connect to the dataset.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Use DataSource to determine or set the TDataSource (see page 7070) object that connects to the dataset. TDataLink (see page 6876) responds to data events that the DataSource receives.

Note: To implement the DataSource property of a data-aware object which owns a TDataLink (see page 6876) or its descendant, create a method that gets or sets the DataSource property of the TDataLink (see page 6876) derived member.

See Also

DataSourceFixed (see page 6891)

39.1.16.5.7 TDataLink.DataSourceFixed Property

Indicates whether the DataSource (see page 6891) property can be set.

Pascal

```
property DataSourceFixed: Boolean;
```

C++

```
__property Boolean DataSourceFixed;
```

Description

Use DataSourceFixed to determine whether the DataSource (see page 6891) property can be changed. By default, DataSourceFixed is false, allowing the DataSource (see page 6891) property to be changed.

When there is a chance that an asynchronous event might change the DataSource (see page 6891) before an operation completes, set DataSourceFixed to true before performing the operation to ensure that the DataSource (see page 6891) is constant throughout the operation. After the data operation is complete, DataSourceFixed can be set back to false.

Set DataSourceFixed to prevent the DataSource (see page 6891) of a data-aware object that owns the TDataLink (see page 6876) from being changed once it is set.

See Also

DataSource (see page 6891)

39.1.16.5.8 TDataLink.Editing Property

Indicates whether the DataSource (see page 6891) is in edit mode.

Pascal

```
property Editing: Boolean;
```

C++

```
__property Boolean Editing;
```

Description

Read Editing to determine whether the DataSource (see page 6891) is inserting a new record into the dataset, or modifying the current record. To change the dataset into edit mode, and hence the Editing property to true, use the Edit (see page 6882) method.

See Also

Edit (see page 6882)

EditingChanged (see page 6883)

Edit (see page 7076)

39.1.16.5.9 TDataLink.Eof Property

Indicates whether the last record in a dataset is active.

Pascal

```
property Eof: Boolean;
```

C++

```
__property Boolean Eof;
```

Description

Inspect Eof to determine if the dataset component associated with the TDataLink (see page 6876) is positioned on its last record. If Eof is true, the active record is unequivocally the last row in the dataset. Eof is true when:

The associated dataset is empty.

A call is made to the dataset's Last method and the dataset is not unidirectional.

A call is made to the dataset's Next method, and the method fails because the last row is already active.

A call to the dataset's SetRange method is made resulting in an empty result set.

Eof is false in all other cases. An application should assume Eof is false unless one of the conditions above is met and the application tests the property directly.

Tip: If both Eof and BOF (see page 6889) are true, a dataset or range is empty.

See Also

Eof (see page 7015)

BOF (see page 6889)

39.1.16.5.10 TDataLink.ReadOnly Property

Indicates whether the dataset for this TDataLink (see page 6876) can be modified.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to determine whether the dataset for this TDataLink (see page 6876) can be modified. Setting ReadOnly to true causes any subsequent calls to the Edit (see page 6882) method to fail, and changes the DataSource (see page 6891) out of an editing state if it is in one. Setting ReadOnly to false enables changes to the data in the dataset.

See Also

Edit (see page 6882)

Editing (see page 6892)

39.1.16.5.11 TDataLink.RecordCount Property

Indicates the number of records in the internal record buffer maintained by the dataset.

Pascal

```
property RecordCount: Integer;
```

C++

```
__property int RecordCount;
```

Description

Read RecordCount to determine the number of actual records in the buffer maintained by the dataset for the Owner of this TDataLink (see page 6876).

In most cases, RecordCount is the same as BufferCount (see page 6890). RecordCount indicates the number of records actually in the record buffer of the dataset, as opposed to the number of records that the dataset can possibly maintain. For example, a data-aware grid with four rows could have one record actually showing data. In this case, BufferCount (see page 6890) would be 4, while RecordCount would be 1.

See Also

BufferCount (see page 6890)

DataSet (see page 6890)

39.1.16.5.12 TDataLink.VisualControl Property

Indicates whether a visual control uses the datalink.

Pascal

```
property VisualControl: Boolean;
```

C++

```
__property Boolean VisualControl;
```

Description

Descendants of TDataLink (see page 6876) set VisualControl to indicate whether the control that uses the link is a visual control. A value of true indicates a visual control.

TfieldDataLink

TNavDataLink (see page 9513)

TDataSourceLink (see page 8577)

TListSourceLink (see page 9498)

39.1.17 TDataSet Class

TDataSet is the base class for all dataset components that represent data in rows and columns.

Class Hierarchy

Pascal

```
TDataSet = class(TComponent, IProviderSupport);
```

C++

```
class TDataSet : public TComponent, public IProviderSupport;
```

File

DB

Description

TDataSet introduces the basic properties, events, and methods for working with data.

Many of these properties, events, and methods are abstract (Delphi) or pure virtual (C++) in TDataSet. Abstract or pure virtual declarations are declarations without implementations. At the TDataSet level they cannot be used or accessed. Developers must

use or derive descendants of TDataSet that redeclare and implement these abstract or pure virtual methods. Many of the other TDataSet methods are declared and implemented in TDataSet as virtual methods, but the implementations are merely stubs that are reimplemented in descendants.

TDataSet has two several descendants: TBDEDataSet, TCustomADONETConnector, TIBCustomDataSet, TCustomSQLDataSet, TCustomClientDataSet and TWideDataSet (see page 7526).

TBDEDataSet is the base class for datasets that access their data using the Borland (see page 1761) Database Engine (BDE). TBDEDataSet descendants include TTable, TQuery, and TStoredProc. Developers who create custom dataset components that use the BDE derive them from TBDEDataSet, TDBDataSet, TQuery, TStoredProc, or TTable.

TCustomADONETConnector is the base class for datasets that access their data using ActiveX Data Objects (ADO). TCustomADONETConnector descendants include TADODataSet, TADOTable, TADOQuery, and TADOStoredProc. Developers who create custom dataset components that use ADO derive them from CustomADODataSet.

TIBCustomDataSet is the base class for datasets that directly access the data in InterBase tables. TIBCustomDataSet descendants include TIBDataSet, TIBTable, TIBQuery, and TIBStoredProc. Developers who create custom dataset components that directly access data in an InterBase database derive from TIBCustomDataSet.

TCustomSQLDataSet is the base class for unidirectional datasets. Unidirectional datasets are read-only datasets that permit only forward navigation. TCustomSQLDataSet descendants include the dbExpress datasets TSQLDataSet, TSQLQuery, TSQLTable, and TSQLStoredProc. Developers who create custom dataset components that use dbExpress to access their data derive from TCustomSQLDataSet.

TCustomClientDataSet is the base class for in-memory datasets. Client datasets can work with data from files on disk or with data provided by another component via a provider. They cache that data in memory, maintain a record of any changes in a change log, and apply cached updates at a later point back to the source of the data. Developers who create custom datasets that store their data in an in-memory cache derive from TCustomClientDataSet.

TWideDataSet (see page 7526) provides dataset support for wide strings.

Developer's can also derive custom dataset components directly from TDataSet, providing their own mechanisms for accessing and manipulating the data.

Marking and Returning to Records

Understanding Datasets: Overview

Distributing Database Applications

Connecting to Databases with TDatabase

39.1.17.1 TDataSet Members

The following tables list the members exposed by TDataSet.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
V	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
V	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
V	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
V	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
V	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
V	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
V	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
V	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
V	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
V	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
V	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
V	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
V	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
V	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.

	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.

	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 6982)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 6982)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 6985)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 6989)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.

	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
V	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
V	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
V	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
V	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
V	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
V	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
V	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
V	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
V	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
V	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
V	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
V	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
V	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.

	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.

	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
	Create (see page 6904)	Creates an instance of a TDataSet (see page 6894) component.
	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
	Destroy (see page 6904)	Destroys the TDataSet (see page 6894) instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.

V	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
V	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
	Last (see page 6968)	Moves to the last record in the dataset.
V	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
V	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.

	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

39.1.17.2 TDataSet.Create Constructor

Creates an instance of a TDataSet (see page 6894) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDataSet(TComponent * AOwner);
```

Description

Call Create to instantiate a dataset component at runtime. TDataSet (see page 6894) contains abstract methods, and is not intended to be used in applications. Instead, applications instantiate dataset descendants such as TClientDataSet, TADODataSet, TTable, TQuery, TStoredProc, or TSQLDataSet.

AOwner is the component, typically a form or data module, that is responsible for freeing the dataset. It becomes the value of the Owner property.

Create creates the auxiliary objects such as empty field and field definition lists and initializes default property values (such as setting AutoCalcFields (see page 7006) to true).

See Also

AutoCalcFields (see page 7006)

Destroy (see page 6904)

Owner (see page 2807)

39.1.17.3 TDataSet.Destroy Destructor

Destroys the TDataSet (see page 6894) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataSet();
```

Description

Do not call Destroy directly in an application. Usually destruction of datasets is handled automatically by Delphi. If an application creates its own instances of a dataset, however, and does not assign an Owner that is responsible for freeing the dataset, then the application should call Free, which checks that the dataset reference is not nil before calling Destroy.

FieldDefs (see page 7019)

Create (see page 6904)

Free (see page 22300)

Owner (see page 2807)

39.1.17.4 TDataSet Methods

The methods of the TDataSet class are listed here.

Protected Methods

	Name	Description
	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.

V	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
V	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
V	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
V	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
V	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
V	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
V	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
V	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
V	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
V	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
V	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
V	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
V	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
V	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
V	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
V	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
V	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
A	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
V	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
V	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
V	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
V	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
V	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
V	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
V	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
A	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
V	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
V	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
V	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
V	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
A	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
A	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
V	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
V	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
V	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
A	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
V	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
V	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
V	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
A	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
V	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
V	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
V	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
V	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
V	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
V	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
V	PSGetCommandText (see page 6982)	Gets the SQL command to be executed by PSExecute.
V	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
V	PSGetCommandType (see page 6982)	Gets the command type to be executed by PSExecute.
V	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.

	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 6985)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 6989)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.

Public Methods

	Name	Description
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.

	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
V	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
V	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
V	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
V	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
V	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
	Last (see page 6968)	Moves to the last record in the dataset.
V	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
V	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
	Prior (see page 6979)	Moves to the previous record in the dataset.

	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	SetFields (see page 6997)	Sets the values for all fields in a record
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.

39.1.17.4.1 TDataSet.ActivateBuffers Method

Pascal

```
procedure ActivateBuffers; virtual;
```

C++

```
virtual __fastcall ActivateBuffers();
```

Description

This is ActivateBuffers, a member of class TDataSet.

39.1.17.4.2 TDataSet.ActiveBuffer Method

Returns a pointer to the buffer for the active record.

Pascal

```
function ActiveBuffer: PChar;
```

C++

```
__fastcall const char * ActiveBuffer();
```

Description

ActiveBuffer is used internally by many dataset methods to ensure that the active buffer points to the buffer for the active record. If an application uses existing dataset methods, the active buffer is always set correctly, so there is usually no need to call ActiveBuffer directly.

Note: Unidirectional datasets do not buffer records. On Unidirectional datasets, ActiveBuffer returns a meaningless value.

ActiveBuffer is used by bookmarking methods to index into the active record buffer to retrieve bookmark information.

Applications that provide custom dataset routines may need to call ActiveBuffer to access the buffer data.

Prior (see page 6979)

39.1.17.4.3 TDataSet.AllocRecordBuffer Method

Pascal

```
function AllocRecordBuffer: PChar; virtual;
```

C++

```
virtual __fastcall const char * AllocRecordBuffer();
```

Description

This is AllocRecordBuffer, a member of class TDataSet.

39.1.17.4.4 TDataSet.Append Method

Adds a new, empty record to the end of the dataset.

Pascal

```
procedure Append;
```

C++

```
__fastcall Append();
```

Description

For datasets that permit editing, call Append to:

1Open (see page 6976) a new, empty record at the end of the dataset.

2Set the active record to the new record.

After a call to Append, an application can enable users to enter data in the fields of the record, and can then post those changes to the database or change log using Post (see page 6977) (Client datasets can subsequently apply updates in the change log back to the database by calling ApplyUpdates.) A newly appended record is posted to the database in one of three ways:

For indexed Paradox and dBASE tables, the record is inserted into the dataset in a position based on its index.

For unindexed Paradox and dBASE tables, the record is added to the end of the dataset.

For SQL databases, the physical location of the appended record is implementation-specific. For indexed tables, the index is updated with the new record information.

After the new record is applied back to the database server, its physical location is database-specific. For indexed tables, the index is updated with the new record information.

Delphi Examples:

```
{
This example appends a new record to a table or client
dataset when the user clicks a button. The two fields
Field1 and Field2 are filled from the contents of two edit
controls.  This example requires a populated TTable or
TDataSet with the appropriate field values.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Append;
  Customers.FieldValues['Field1'] := StrToInt(Edit1.text);
  Customers.FieldValues['Field2'] := Edit2.text;
  Customers.Post;
end;
```

See Also

AppendRecord (see page 6911)

ApplyUpdates (see page 8394)

Insert (see page 6959)

Post (see page 6977)

CanModify (see page 7012)

Adding New Records

Posting Data

39.1.17.4.5 TDataSet.AppendRecord Method

Adds a new, populated record to the end of the dataset and posts it.

Pascal

```
procedure AppendRecord(const Values: array of const);
```

C++

```
__fastcall AppendRecord(const array of const Values);
```

Description

Call AppendRecord to create a new, empty record at the end of the dataset, populate it with the field values in Values, and post the values to the database or change log.

In C++, the Values parameter is an array of field values. The Values_Size parameter is the index of the last value (one less than the total number of values).

A newly appended record is posted to the database in one of three ways:

For indexed Paradox and dBASE tables, the record is inserted into the dataset in a position based on its index.

For unindexed Paradox and dBASE tables, the record is added to the end of the dataset.

For SQL databases, the physical location of the append is implementation-specific. For indexed tables, the index is updated with the new record information.

The newly appended record becomes the active record.

C++ Examples:

```
/*
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ProgressBar1->Min = 0;
  ProgressBar1->Max = Customers->RecordCount;
  Customers->First();
  for (int i = ProgressBar1->Min; i <= ProgressBar1->Max; i++)
  {
    ProgressBar1->Position = i;
    Customers->Next();
    // do something with the current record
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Customers = new TTable(Form1);
  Customers->Active = false; // The Table component must not be active
  Customers->DatabaseName = "DBDEMOS";
  Customers->TableType = ttParadox;
  Customers->TableName = "CustInfo";
  Customers->Active = False;
  if (Customers->Exists) // Don't overwrite an existing table
  {
    Customers->Close();
    Customers->DeleteTable();
```

```
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Customers->FieldDefs->Clear();
  TFieldDef *pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Customers->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Customers->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Customers->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Customers->CreateTable();
  Customers->Active = True;
  for (int i = 1; i <= 20; i++)
    Customers->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Customers;
  DBGrid2->DataSource->DataSet = Customers;
  Customers->Active = True;
}
```

Delphi Examples:

```
{
This statement appends a record to the MyCustInfo data. Note
that Nulls are entered for some of the values, but are not
required for missing values at the end of the array argument,
i.e. after the Field3 field.  InsertRecord behaves differently
depending on the indexing of the table.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.InsertRecord([Edit1.Text, Edit2.Text, Null, Edit3.Text]);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'MyCustInfo';
    ReadOnly:= False;

//    Don't overwrite an existing table
    if (not Customers.Exists) then CreateMyTable
    else
    begin
      if (Customers.Exists AND
        (MessageDlg('MyCustInfo table already exists.  Do you want to rebuild it?',
mtConfirmation, [mbYes, mbNo], 0) = mrYes)) then
      begin
        Customers.Close;
        Customers.DeleteTable;
        CreateMyTable;
      end;
    end;
  end;
```

```
    DS2.DataSet:= Customers;
    DBGrid2.DataSource.DataSet:= Customers;
    Customers.Active:= True;
  end;

  procedure CreateMyTable();
  var
    i: Integer;
  begin
  //      The Table component must not be active
  //      First, describe the type of table and give
  //      it a name
  //      Next, describe the fields in the table
    with Customers do
    begin
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;

39.1.17.4.6 TDataSet.BindFields Method

Pascal

```
procedure BindFields(Binding: Boolean);
```

C++

```
__fastcall BindFields(Boolean Binding);
```

Description

This is BindFields, a member of class TDataSet.

39.1.17.4.7 TDataSet.BlockReadNext Method

Pascal

```
procedure BlockReadNext; virtual;
```

C++

```
virtual __fastcall BlockReadNext();
```

Description

This is BlockReadNext, a member of class TDataSet.

39.1.17.4.8 TDataSet.BookmarkAvailable Method

Pascal

```
function BookmarkAvailable: Boolean;
```

C++

```
__fastcall Boolean BookmarkAvailable();
```

Description

This is BookmarkAvailable, a member of class TDataSet.

39.1.17.4.9 TDataSet.BookmarkValid Method

Indicates the validity of a specified bookmark.

Pascal

```
function BookmarkValid(Bookmark: TBookmark): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean BookmarkValid(TBookmark Bookmark);
```

Description

This function returns false in all cases, indicating that any bookmark is invalid because the TDataSet (see page 6894) class does not implement support for bookmarks.

Descendant classes that implement bookmark support override BookmarkValid to test bookmarks for validity and indicate when a bookmark is valid by returning true.

Marking and Returning to Records

39.1.17.4.10 TDataSet.CalculateFields Method

Pascal

```
procedure CalculateFields(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall CalculateFields(const char * Buffer);
```

Description

This is CalculateFields, a member of class TDataSet.

39.1.17.4.11 TDataSet.Cancel Method

Cancels modifications to the active record if those changes are not yet posted.

Pascal

```
procedure Cancel; virtual;
```

C++

```
virtual __fastcall Cancel();
```

Description

Call Cancel to undo modifications made to one or more fields belonging to the active record. As long as those changes are not already posted, Cancel returns the record to its previous state, and sets the dataset state to dsBrowse.

Typically Cancel is used to back out of changes in response to user request, or in field validation routines that back out illegal field values. The TDBNavigator object contains a Cancel button that calls Cancel.

Note: If the dataset is not in an editing state (dsEdit or dsInsert), Cancel does nothing.

Delphi Examples:

```
{
The following fragment prompts the user to confirm changes
to a record; if the user clicks Yes, the record is posted to
the table, otherwise the changes are cancelled.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
if MessageDlg('Update Record?', mtConfirmation, [mbYes, mbNo], 0) =
              mrYes then
  Table1.Post
else
  Table1.Cancel;
end;
```

Canceling Changes

Editing Records

Connecting to Databases with TDatabase

39.1.17.4.12 TDataSet.CheckActive Method

Pascal

```
procedure CheckActive; virtual;
```

C++

```
virtual __fastcall CheckActive();
```

Description

This is CheckActive, a member of class TDataSet.

39.1.17.4.13 TDataSet.CheckBiDirectional Method

Pascal

```
procedure CheckBiDirectional;
```

C++

```
__fastcall CheckBiDirectional();
```

Description

This is CheckBiDirectional, a member of class TDataSet.

39.1.17.4.14 TDataSet.CheckBrowseMode Method

Automatically posts or cancels data changes when the active record changes.

Pascal

```
procedure CheckBrowseMode;
```

C++

```
__fastcall CheckBrowseMode();
```

Description

CheckBrowseMode is used internally by many dataset methods to ensure that modifications to the active record are posted when a dataset's state is dsEdit, dsInsert, or dsSetKey and a method switches to a different record.

If State (see page 7036) is dsEdit or dsInsert, CheckBrowseMode calls UpdateRecord (see page 7002), and, if the Modified (see page 7029) property for the dataset is true, calls Post (see page 6977). If Modified (see page 7029) is false, CheckBrowseMode calls Cancel (see page 6916).

If State (see page 7036) is dsSetKey, CheckBrowseMode calls Post (see page 6977).

If State (see page 7036) is dsInactive, CheckBrowseMode raises an exception.

If an application uses existing dataset methods, CheckBrowseMode is always called when necessary, so there is usually no need to call CheckBrowseMode directly.

Applications that provide custom dataset routines may need to call CheckBrowseMode inside those routines to guarantee that changes are posted when switching to a different record.

SetKey (see page 8449)

39.1.17.4.15 TDataSet.CheckFieldCompatibility Method

Pascal

```
procedure CheckFieldCompatibility(Field: TField; FieldDef: TFieldDef); virtual;
```

C++

```
virtual __fastcall CheckFieldCompatibility(TField Field, TFieldDef FieldDef);
```

Description

This is CheckFieldCompatibility, a member of class TDataSet.

39.1.17.4.16 TDataSet.CheckInactive Method

Pascal

```
procedure CheckInactive; virtual;
```

C++

```
virtual __fastcall CheckInactive();
```

Description

This is CheckInactive, a member of class TDataSet.

39.1.17.4.17 TDataSet.ClearBuffers Method

Pascal

```
procedure ClearBuffers; virtual;
```

C++

```
virtual __fastcall ClearBuffers();
```

Description

This is ClearBuffers, a member of class TDataSet.

39.1.17.4.18 TDataSet.ClearCalcFields Method

Pascal

```
procedure ClearCalcFields(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall ClearCalcFields(const char * Buffer);
```

Description

This is ClearCalcFields, a member of class TDataSet.

39.1.17.4.19 TDataSet.ClearFields Method

Clears the contents of all fields for the active record.

Pascal

```
procedure ClearFields;
```

C++

```
__fastcall ClearFields();
```

Description

Call ClearFields to erase the current contents of all fields in the active record. If the dataset is not in either dsInsert or dsEdit state, ClearFields raises an exception.

If a SetKey operation is not under way, ClearFields recalculates all calculated fields, and generates an OnDataChange event on the data source component associated with the dataset.

See Also

CheckBrowseMode (see page 6918)

SetKey (see page 10208)

OnDataChange (see page 7080)

SetKey (see page 8449)

39.1.17.4.20 TDataSet.Close Method

Closes a dataset.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Call Close to set the Active (see page 7004) property of a dataset to false. When Active (see page 7004) is false, the dataset is closed; it cannot read or write data and data-aware controls can't use it to fetch data or post edits.

An application must close the dataset before changing properties that affect the status of the database or the controls that display data in an application. For example, to change the DataSource (see page 7014) property for a dataset, the dataset must be closed. Closing the dataset puts it into the dsInactive state.

See Also

Active (see page 7004)

DataSource (see page 7014)

Opening and Closing Datasets

Posting Data

39.1.17.4.21 TDataSet.CloseBlob Method

Pascal

```
procedure CloseBlob(Field: TField); virtual;
```

C++

```
virtual __fastcall CloseBlob(TField Field);
```

Description

This is CloseBlob, a member of class TDataSet.

39.1.17.4.22 TDataSet.CloseCursor Method

Pascal

```
procedure CloseCursor; virtual;
```

C++

```
virtual __fastcall CloseCursor();
```

Description

This is CloseCursor, a member of class TDataSet.

39.1.17.4.23 TDataSet.CompareBookmarks Method

Implements a virtual function to compare two bookmarks.

Pascal

```
function CompareBookmarks(Bookmark1: TBookmark; Bookmark2: TBookmark): Integer; virtual;
```

C++

```
virtual __fastcall int CompareBookmarks(TBookmark Bookmark1, TBookmark Bookmark2);
```

Description

As implemented in TDataSet (see page 6894), CompareBookmarks always returns 0, indicating no difference between the bookmarks. This is because TDataSet (see page 6894) does not implement support for bookmarks.

Descendant classes that provide bookmark support override this method to return a value less than 0 if Bookmark1 is less than Bookmark2, 0 if the bookmarks are identical, and a value greater than 0 if Bookmark1 is greater than Bookmark2.

TClientDataSet (see page 8289)

Marking and Returning to Records

39.1.17.4.24 TDataSet.ControlsDisabled Method

Indicates whether data-aware controls update their display to reflect changes to the dataset.

Pascal

```
function ControlsDisabled: Boolean;
```

C++

```
__fastcall Boolean ControlsDisabled();
```

Description

Call ControlsDisabled to ascertain whether the updating of data display in data-aware controls is currently disabled. If ControlsDisabled is true, controls are currently disabled. ControlsDisabled is true as long as the reference count that keeps track of disabling for the dataset is greater than zero. This count is incremented every time the DisableControls (see page 6925) method is called and decremented when EnableControls (see page 6934) is called. Applications call DisableControls (see page 6925) to improve performance and prevent constant updates during automated iterations through records in the dataset.

In complex applications, when controls may be disabled multiple times by different processes, you can use ControlsDisabled as a check in a procedure to reenable controls should each call to DisableControls (see page 6925) not be paired with a subsequent call to EnableControls (see page 6934). For example,

```
procedure ReEnableControls (DataSet: TDataSet);
begin
while DataSet.ControlsDisabled do
  DataSet.EnableControls;
end;
void __fastcall TForm1::ReEnableControls(TDataSet *DataSet)
{
while (DataSet->ControlsDisabled())
    DataSet->EnableControls();
}
```

See Also

DisableControls (see page 6925)

EnableControls (see page 6934)

39.1.17.4.25 TDataSet.CopyFields Method

Pascal

```
function CopyFields(Source: TDataSet): Integer;
```

C++

```
__fastcall int CopyFields(TDataSet Source);
```

Description

This is CopyFields, a member of class TDataSet.

39.1.17.4.26 TDataSet.CreateBlobStream Method

Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.

Pascal

```
function CreateBlobStream(Field: TField; Mode: TBlobStreamMode): TStream; virtual;
```

C++

```
virtual __fastcall TStream CreateBlobStream(TField Field, TBlobStreamMode Mode);
```

Description

Call CreateBlobStream to obtain a stream for reading and writing the value of the field specified by the Field parameter. The Mode parameter indicates whether the stream will be used for reading the field's value (bmRead), writing the field's value (bmWrite), or modifying the field's value (bmReadWrite).

Blob streams are created in a specific mode for a specific field on a specific record. Applications create a new blob stream every time the record in the dataset changes: do not reuse an existing blob stream.

As implemented in TDataSet (see page 6894), CreateBlobStream always returns nil (Delphi) or NULL (C++). Descendants of TDataSet (see page 6894) override this method to create the TStream descendant that reads and writes BLOB data in the format that dataset type uses to store BLOB fields.

Tip: It is preferable to call CreateBlobStream rather than creating a blob stream directly in code. This ensures that the stream is appropriate to the dataset, and may also ensure that datasets that do not always store BLOB data in memory fetch the blob data before creating the stream.

39.1.17.4.27 TDataSet.CreateFields Method

Pascal

```
procedure CreateFields; virtual;
```

C++

```
virtual __fastcall CreateFields();
```

Description

This is CreateFields, a member of class TDataSet.

39.1.17.4.28 TDataSet.CreateNestedDataSet Method

Pascal

```
function CreateNestedDataSet(DataSetField: TDataSetField): TDataSet; virtual;
```

C++

```
virtual __fastcall TDataSet CreateNestedDataSet(TDataSetField DataSetField);
```

Description

This is CreateNestedDataSet, a member of class TDataSet.

39.1.17.4.29 TDataSet.CursorPosChanged Method

Marks the internal cursor position as invalid.

Pascal

```
procedure CursorPosChanged;
```

C++

```
__fastcall CursorPosChanged();
```

Description

CursorPosChanged is an internal method that invalidates the variable that tracks the physical cursor position relative to the logical cursor position. CurPosChanged is called by the Locate (see page 6970) and Lookup (see page 6970) methods prior to searching for a requested record. These methods, if successful, reposition the current record at the first matching record found.

See Also

Locate (see page 6970)

Lookup (see page 6970)

39.1.17.4.30 TDataSet.DataConvert Method

Pascal

```
procedure DataConvert(Field: TField; Source: Pointer; Dest: Pointer; ToNative: Boolean);
virtual;
```

C++

```
virtual __fastcall DataConvert(TField Field, void * Source, void * Dest, Boolean ToNative);
```

Description

This is DataConvert, a member of class TDataSet.

39.1.17.4.31 TDataSet.DataEvent Method

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); virtual;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

This is DataEvent, a member of class TDataSet.

39.1.17.4.32 TDataSet.DefChanged Method

Pascal

```
procedure DefChanged(Sender: TObject); virtual;
```

C++

```
virtual __fastcall DefChanged(TObject * Sender);
```

Description

This is DefChanged, a member of class TDataSet.

39.1.17.4.33 TDataSet.Delete Method

Deletes the active record and positions the dataset on the next record.

Pascal

```
procedure Delete;
```

C++

```
__fastcall Delete();
```

Description

Call Delete to remove the active record from the database. If the dataset is inactive, Delete raises an exception. Otherwise, Delete:

- Verifies that the dataset is not empty (and raises an exception if it is).
- Calls CheckBrowseMode (see page 6918) to post any pending changes to a prior record if necessary.
- Calls the BeforeDelete (see page 7049) event handler.

- Deletes the record.
- Frees any buffers allocated for the record.
- Puts the dataset into dsBrowse mode.
- Resynchronizes the dataset to make the next undeleted record active. If the record deleted was the last record in the dataset, then the previous record becomes the current record.
- Calls the AfterDelete (see page 7041) event handler.

See Also

State (see page 7036)

AfterDelete (see page 7041)

BeforeDelete (see page 7049)

CheckBrowseMode (see page 6918)

Edit (see page 6932)

Insert (see page 6959)

Post (see page 6977)

Deleting Records

39.1.17.4.34 TDataSet.DestroyFields Method

Pascal

```
procedure DestroyFields; virtual;
```

C++

```
virtual __fastcall DestroyFields();
```

Description

This is DestroyFields, a member of class TDataSet.

39.1.17.4.35 TDataSet.DisableControls Method

Disables data display in data-aware controls associated with the dataset.

Pascal

```
procedure DisableControls;
```

C++

```
__fastcall DisableControls();
```

Description

Call DisableControls prior to iterating through a large number of records in the dataset to prevent data-aware controls from updating every time the active record changes. Disabling controls prevents flicker and speeds performance because data does not need to be written to the display.

If controls are not already disabled, DisableControls records the current state of the dataset, broadcasts the state change to all associated data-aware controls and detail datasets, and increments the dataset's disabled count variable. Otherwise, DisableControls just increments the disabled count variable.

The disabled count is used internally to determine whether to display data in data-aware controls. When the disable count variable is greater than zero, data is not updated.

If the dataset is the master of a master/detail relationship, calling DisableControls also disables the master/detail relationship. Setting BlockReadSize (see page 7007) instead of calling DisableControls updates the detail datasets as you scroll through the dataset, but does not update data-aware controls.

Note: Calls to DisableControls can be nested. Only when all calls to DisableControls is matched to a corresponding call to EnableControls (see page 6934) does the dataset update data controls and detail datasets.

Delphi Examples:

```
{
Usually DisableControls is called within the context of a
try...finally block that reenables the controls even if an
exception occurs. For example:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  ListBox1.Clear;
  ListBox1.Items[0]:= 'Destination Airports:';
  with Flights do
  begin
    DisableControls;
    try
      First;
      i:= 1;
      ListBox1.Items[0]:= 'Destination Airports:';
      while not Eof do
      begin
        ListBox1.Items[i]:= Fields[2].Value;;
        i:= i + 1;
        Next;
      end;
    finally
      EnableControls;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Flights:= TTable.Create(Form1);
  with Flights do
  begin
    TableName := 'Flights';
    DatabaseName := 'Flights';

  end;
  DS2.DataSet:= Flights;
  DBGrid2.DataSource.DataSet:=
    c:\Documents and Settings\All Users\Documents\RAD
Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data;
  Flights.Active:= True;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
    I: Integer;
  begin
    if not RemoteServer1.Connected then
      RemoteServer1.Connected := True;
    ClientDataSet1.Close;
    with RemoteServer1 do
    begin
      for I := 0 to DataSetCount - 1 do
        DataSets[I].EnableControls;
    end;
    ClientDataSet1.Open;
  end;

  procedure TForm1.Button3Click(Sender: TObject);
  var
    I: Integer;
  begin
    ClientDataSet1.Close;
    RemoteServer1.Connected := False;
    with RemoteServer1 do
    begin
      for I := 0 to DataSetCount - 1 do
        DataSets[I].DisableControls;
    end;
  end;

  procedure TForm1.CheckButtonActive(DataSet: TDataSet);
  begin
    Button1.Enabled := not ClientDataSet1.Active;
    Button2.Enabled := ClientDataSet1.Active;
    Button3.Enabled := ClientDataSet1.Active;
  end;
```

Disabling and Enabling Data Display

Enabling and Disabling the Data Source

39.1.17.4.36 TDataSet.DoAfterCancel Method

Pascal

```
procedure DoAfterCancel; virtual;
```

C++

```
virtual __fastcall DoAfterCancel();
```

Description

This is DoAfterCancel, a member of class TDataSet.

39.1.17.4.37 TDataSet.DoAfterClose Method

Pascal

```
procedure DoAfterClose; virtual;
```

C++

```
virtual __fastcall DoAfterClose();
```

Description

This is DoAfterClose, a member of class TDataSet.

39.1.17.4.38 TDataSet.DoAfterDelete Method

Pascal

```
procedure DoAfterDelete; virtual;
```

C++

```
virtual __fastcall DoAfterDelete();
```

Description

This is DoAfterDelete, a member of class TDataSet.

39.1.17.4.39 TDataSet.DoAfterEdit Method

Pascal

```
procedure DoAfterEdit; virtual;
```

C++

```
virtual __fastcall DoAfterEdit();
```

Description

This is DoAfterEdit, a member of class TDataSet.

39.1.17.4.40 TDataSet.DoAfterInsert Method

Pascal

```
procedure DoAfterInsert; virtual;
```

C++

```
virtual __fastcall DoAfterInsert();
```

Description

This is DoAfterInsert, a member of class TDataSet.

39.1.17.4.41 TDataSet.DoAfterOpen Method

Pascal

```
procedure DoAfterOpen; virtual;
```

C++

```
virtual __fastcall DoAfterOpen();
```

Description

This is DoAfterOpen, a member of class TDataSet.

39.1.17.4.42 TDataSet.DoAfterPost Method

Pascal

```
procedure DoAfterPost; virtual;
```

C++

```
virtual __fastcall DoAfterPost();
```

Description

This is DoAfterPost, a member of class TDataSet.

39.1.17.4.43 TDataSet.DoAfterRefresh Method

Pascal

```
procedure DoAfterRefresh; virtual;
```

C++

```
virtual __fastcall DoAfterRefresh();
```

Description

This is DoAfterRefresh, a member of class TDataSet.

39.1.17.4.44 TDataSet.DoAfterScroll Method

Pascal

```
procedure DoAfterScroll; virtual;
```

C++

```
virtual __fastcall DoAfterScroll();
```

Description

This is DoAfterScroll, a member of class TDataSet.

39.1.17.4.45 TDataSet.DoBeforeCancel Method

Pascal

```
procedure DoBeforeCancel; virtual;
```

C++

```
virtual __fastcall DoBeforeCancel();
```

Description

This is DoBeforeCancel, a member of class TDataSet.

39.1.17.4.46 TDataSet.DoBeforeClose Method

Pascal

```
procedure DoBeforeClose; virtual;
```

C++

```
virtual __fastcall DoBeforeClose();
```

Description

This is DoBeforeClose, a member of class TDataSet.

39.1.17.4.47 TDataSet.DoBeforeDelete Method

Pascal

```
procedure DoBeforeDelete; virtual;
```

C++

```
virtual __fastcall DoBeforeDelete();
```

Description

This is DoBeforeDelete, a member of class TDataSet.

39.1.17.4.48 TDataSet.DoBeforeEdit Method

Pascal

```
procedure DoBeforeEdit; virtual;
```

C++

```
virtual __fastcall DoBeforeEdit();
```

Description

This is DoBeforeEdit, a member of class TDataSet.

39.1.17.4.49 TDataSet.DoBeforeInsert Method

Pascal

```
procedure DoBeforeInsert; virtual;
```

C++

```
virtual __fastcall DoBeforeInsert();
```

Description

This is DoBeforeInsert, a member of class TDataSet.

39.1.17.4.50 TDataSet.DoBeforeOpen Method

Pascal

```
procedure DoBeforeOpen; virtual;
```

C++

```
virtual __fastcall DoBeforeOpen();
```

Description

This is DoBeforeOpen, a member of class TDataSet.

39.1.17.4.51 TDataSet.DoBeforePost Method

Pascal

```
procedure DoBeforePost; virtual;
```

C++

```
virtual __fastcall DoBeforePost();
```

Description

This is DoBeforePost, a member of class TDataSet.

39.1.17.4.52 TDataSet.DoBeforeRefresh Method

Pascal

```
procedure DoBeforeRefresh; virtual;
```

C++

```
virtual __fastcall DoBeforeRefresh();
```

Description

This is DoBeforeRefresh, a member of class TDataSet.

39.1.17.4.53 TDataSet.DoBeforeScroll Method

Pascal

```
procedure DoBeforeScroll; virtual;
```

C++

```
virtual __fastcall DoBeforeScroll();
```

Description

This is DoBeforeScroll, a member of class TDataSet.

39.1.17.4.54 TDataSet.DoOnCalcFields Method

Pascal

```
procedure DoOnCalcFields; virtual;
```

C++

```
virtual __fastcall DoOnCalcFields();
```

Description

This is DoOnCalcFields, a member of class TDataSet.

39.1.17.4.55 TDataSet.DoOnNewRecord Method

Pascal

```
procedure DoOnNewRecord; virtual;
```

C++

```
virtual __fastcall DoOnNewRecord();
```

Description

This is DoOnNewRecord, a member of class TDataSet.

39.1.17.4.56 TDataSet.Edit Method

Enables editing of data in the dataset.

Pascal

```
procedure Edit;
```

C++

```
__fastcall Edit();
```

Description

Call Edit to permit editing of the active record in a dataset. Edit determines the current state of the dataset. If the dataset is empty, Edit calls Insert (see page 6959). Otherwise Edit

Calls CheckBrowseMode (see page 6918) to post any pending changes to a prior record if necessary.

Checks the CanModify (see page 7012) property and raises an exception if the dataset can't be edited.

Calls the BeforeEdit (see page 7049) event handler.

Retrieves the record.

Puts the dataset into dsEdit state, enabling the application or user to modify fields in the record.

Broadcasts the state change to associated controls.

Calls the AfterEdit (see page 7044) event handler.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
{
The following example copies the data in the Notes field of
Table1 or SQLDataSet1 to the Remarks field of ClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Stream1: TBlobStream;
```

```
    Stream2: TStream;
    blobType : TBlobType;
  begin
    blobType := Table1Notes.BlobType;
    Stream1 := TBlobStream.Create(Table1Notes, bmRead);
    try
      CDS2.Edit;
      { here's a different way to create a blob stream }
      Stream2 := CDS2.CreateBlobStream(CDS2.FieldByName('Remarks'), bmReadWrite);
      try
        Stream2.CopyFrom(Stream1, Stream1.Size);
//      CDS2.Post;
//      CDS2.Active := True;
      finally
        Stream2.Free;
      end;
    finally
      Stream1.Free;
    end;
  end;
  {
  This example uses a button to copy the value of a field in
  the previous record into the corresponding field in the
  current record.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
     SavePlace: TBookmark;
     PrevValue: Variant;
  begin
     with Customers do
     begin
      { get a bookmark so that we can return to the same record }
      SavePlace := GetBookmark;
      try
        { move to prior record}
        FindPrior;
        { get the value }
        PrevValue := Fields[1].Value;
        {Move back to the bookmark
        this may not be the next record anymore
        if something else is changing the dataset asynchronously }
        GotoBookmark(SavePlace);
        { Set the value }
        Edit;
        Fields[1].Value := PrevValue;
        { Free the bookmark }
      finally
        FreeBookmark(SavePlace);
      end;
    end;
  end;

  {
  To ensure that the button is disabled when there is no
  previous record, the OnDataChange event of the DataSource
  detects when the user moves to the beginning of file (BOF
  property becomes true), and disables the button.  Detection
  occurs on scrolling and editing, not selection with the mouse.
  }
  procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
  begin
    if Customers.Bof then
      Button1.Enabled := False
    else
      Button1.Enabled := True;
```

```
end;

Enabling Editing in Controls On User Entry

Editing Records

Modifying Entire Records

39.1.17.4.57 TDataSet.EnableControls Method

Re-enables data display in data-aware controls associated with the dataset.

Pascal

```
procedure EnableControls;
```

C++

```
__fastcall EnableControls();
```

Description

Call EnableControls to permit data display in data-aware controls after a prior call to DisableControls (see page 6925). EnableControls decrements the disabled count variable for the dataset if it is not already zero. If the disable count variable is zero, EnableControls updates the current state of the dataset, if necessary, and then tells associated controls to re-enable display.

Delphi Examples:

```
{
Usually DisableControls is called within the context of a
try...finally block that reenables the controls even if an
exception occurs. For example:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  ListBox1.Clear;
  ListBox1.Items[0]:= 'Destination Airports:';
  with Flights do
  begin
    DisableControls;
    try
      First;
      i:= 1;
      ListBox1.Items[0]:= 'Destination Airports:';
      while not Eof do
      begin
        ListBox1.Items[i]:= Fields[2].Value;;
        i:= i + 1;
```

```
        Next;
      end;
    finally
      EnableControls;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Flights:= TTable.Create(Form1);
  with Flights do
  begin
    TableName := 'Flights';
    DatabaseName := 'Flights';

  end;
  DS2.DataSet:= Flights;
  DBGrid2.DataSource.DataSet:=
    c:\Documents and Settings\All Users\Documents\RAD
Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data;
  Flights.Active:= True;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

Disabling and Enabling Data Display

Enabling and Disabling the Data Source

39.1.17.4.58 TDataSet.FieldByName Method

Finds a field based on its name.

Pascal

```
function FieldByName(const FieldName: WideString): TField;
```

C++

```
__fastcall TField FieldByName(const BSTR FieldName);
```

Description

Call FieldByName to retrieve field information for a field given its name. FieldName is the name of an existing field. FieldByName returns the TField (see page 7115) component that represents the specified field. If the specified field does not exist, FieldByName raises an EDatabaseError (see page 6731) exception.

FieldName can be the name of a simple field, the name of a subfield of an object field that has been qualified by the parent field's name, or the name of an aggregated field. Because of this flexibility, it is often preferable to use FieldByName rather than the Fields (see page 7023) property or the AggFields (see page 7006) property.

An application can directly access specific properties and methods of the field returned by FieldByName. For example, the following statement determines if a specified field is a calculated field:

```
if Customers.FieldByName('FullName').Calculated then
  MessageDlg(Format('%s is a calculated field. ', ['FullName']), mtInformation, [mbOK], 0);
if (Customers->FieldByName("FullName")->Calculated)
  Application.ShowMessage("This is a calculated field", "FullName", MB_OK);
```

FieldByName is especially useful at design time for developers who are creating database applications, but do not have access to the underlying table and therefore cannot use persistent field components.

Tip: To retrieve or set the value for a specific field, call the default dataset method FieldValues (see page 7025) instead of FieldByName.

Delphi Examples:

```
{
The following example copies the data in the Notes field of
Table1 or SQLDataSet1 to the Remarks field of ClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Stream1: TBlobStream;
  Stream2: TStream;
  blobType : TBlobType;
begin
  blobType := Table1Notes.BlobType;
  Stream1 := TBlobStream.Create(Table1Notes, bmRead);
  try
    CDS2.Edit;
    { here’s a different way to create a blob stream }
```

```
    Stream2 := CDS2.CreateBlobStream(CDS2.FieldByName('Remarks'), bmReadWrite);
    try
      Stream2.CopyFrom(Stream1, Stream1.Size);
//    CDS2.Post;
//    CDS2.Active := True;
    finally
      Stream2.Free;
    end;
  finally
    Stream1.Free;
  end;
end;
{
This example uses the BeforeInsert event to do data
validation. If the StrToInt function raises an exception,
the edit control’s contents are set to a valid value so
that the assignment to the INTEGER field in the dataset
will succeed.  Continuing after the exception causes a
'0' to be placed in the PORTA field.
DataSet design:
This example requires a ClientDataSet, a DBGrid, a
DataSource and a DBNavigator.  Name the ClientDataSet CDS.
Set the DataSet property in the DataSource to CDS and name
that DataSource DS.  Set the DataSource in the DBNavigator
to DS the DataSource in the DBGrid to DS.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
attribute name of HOST with an attribute type of string and
an attribute name of PORTA with an attribute type of integer.
Add DB, DBCtrls, Grids, DBGrids and DBClient to the uses clause.
}
{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button3Click(Sender: TObject);
begin
  CDS.Insert;
  CDS.FieldByName('PORTA').AsInteger := StrToInt(Edit1.Text);
  CDS.Post;
end;

procedure TForm1.CDSBeforeInsert(DataSet: TDataSet);
begin
  try
  { Make sure edit field can be converted to integer --
   this will raise an exception if it can’t }
    StrToInt(Edit1.Text);
  except
    Edit1.Text := '0';
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
```

```
end;
```

Specifying Ranges

Accessing Field Values with a Dataset'sFieldByName Method

39.1.17.4.59 TDataSet.FieldByNumber Method

Pascal

```
function FieldByNumber(FieldNo: Integer): TField;
```

C++

```
__fastcall TField FieldByNumber(int FieldNo);
```

Description

This is FieldByNumber, a member of class TDataSet.

39.1.17.4.60 TDataSet.FindField Method

Searches for a specified field in the dataset.

Pascal

```
function FindField(const FieldName: WideString): TField;
```

C++

```
__fastcall TField FindField(const BSTR FieldName);
```

Description

Call FindField to determine if a specified field component exists in a dataset. FieldName is the name of the field for which to search. This name can be the the name of a simple field, the name of a subfield of an object field that has been qualified by the parent field's name, or the name of an aggregated field.

If FindField finds a field with a matching name, it returns the TField (see page 7115) component for the specified field. Otherwise it returns nil (Delphi) or NULL (C++).

FindField is the same as the FieldByName (see page 6936) method, except that it returns nil (Delphi) or NULL (C++) rather than raising an exception when the field is not found.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.  The field to copy is specified by using
FindField and the name of the field.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
    SavePlace: TBookmark;
    PrevValue: Variant;
  begin
    with Customers do
    begin
     { get a bookmark so that we can return to the same record }
     SavePlace := GetBookmark;
     try
       { move to prior record}
       FindPrior;
       { get the value }
       { This is the safe way to get 'CustNo' field }
       PrevValue := FindField('Field2').Value;
       { This is *not* the safe way to change 'CustNo' field }
//     PrevValue := Fields[1].Value;
       { Move back to the bookmark
       this may not be the next record anymore
       if something else is changing the dataset asynchronously }
       GotoBookmark(SavePlace);
       { Set the value }
       Edit;
       { This is the safe way to change 'CustNo' field }
       FindField('Field2').AsString := PrevValue;
       { This is *not* the safe way to change 'CustNo' field }
//       Fields[1].AsString := PrevValue;
       { Free the bookmark }
     finally
       FreeBookmark(SavePlace);
     end;
   end;
  end;
```

Obtaining Aggregate Values

39.1.17.4.61 TDataSet.FindFirst Method

Implements a virtual method for positioning the dataset on the first record, respecting any filters.

Pascal

```
function FindFirst: Boolean;
```

C++

```
__fastcall Boolean FindFirst();
```

Description

This function returns false, indicating that the active record was not successfully changed. Descendant classes override FindFirst to make the first record active, honoring any filters that are in effect. In descendant classes, FindFirst returns true if the active record is successfully changed.

See Also

Filter (see page 7026)

Filtered (see page 7027)

OnFilterRecord (see page 7055)

FindLast (see page 6940)

FindNext (see page 6940)

FindPrior (see page 6941)

First (see page 6942)

39.1.17.4.62 TDataSet.FindLast Method

Implements a virtual method for positioning the dataset on the last record, respecting any filters.

Pascal

```
function FindLast: Boolean;
```

C++

```
__fastcall Boolean FindLast();
```

Description

This function returns false, indicating that the active record was not successfully changed. Descendant classes override FindLast to make the last record active, honoring any filters that are in effect. In descendants, FindLast returns true if the active record is successfully changed.

See Also

Filter (see page 7026)

Filtered (see page 7027)

FindPrior (see page 6941)

Last (see page 6968)

39.1.17.4.63 TDataSet.FindNext Method

Implements a virtual method for positioning the dataset on the next record, respecting any filters.

Pascal

```
function FindNext: Boolean;
```

C++

```
__fastcall Boolean FindNext();
```

Description

This function returns false, indicating that the active record was not successfully changed. Descendant classes override FindNext to move to the next record of the dataset, honoring any filters that are in effect. In descendants, FindNext returns true if the active record is successfully changed.

See Also

Filter (see page 7026)

Filtered (see page 7027)

FindFirst (see page 6939)

FindLast (see page 6940)

FindPrior (see page 6941)

Next (see page 6973)

Navigating Records in a Filtered Dataset

39.1.17.4.64 TDataSet.FindPrior Method

Implements a virtual method for positioning the dataset on the previous record, respecting any filters.

Pascal

```
function FindPrior: Boolean;
```

C++

```
__fastcall Boolean FindPrior();
```

Description

This function returns false, indicating that the active record was not successfully changed. Descendant classes override FindPrior to move to the previous record of the dataset, honoring any filters that are in effect. In descendants, FindPrior returns true if the active record is successfully changed.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
    { get a bookmark so that we can return to the same record }
    SavePlace := GetBookmark;
    try
      { move to prior record}
      FindPrior;
      { get the value }
      PrevValue := Fields[1].Value;
      {Move back to the bookmark
      this may not be the next record anymore
      if something else is changing the dataset asynchronously }
      GotoBookmark(SavePlace);
      { Set the value }
      Edit;
      Fields[1].Value := PrevValue;
      { Free the bookmark }
    finally
      FreeBookmark(SavePlace);
    end;
  end;
end;

{
To ensure that the button is disabled when there is no
previous record, the OnDataChange event of the DataSource
```

```
  detects when the user moves to the beginning of file (BOF
  property becomes true), and disables the button.  Detection
  occurs on scrolling and editing, not selection with the mouse.
  }
  procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
  begin
    if Customers.Bof then
      Button1.Enabled := False
    else
      Button1.Enabled := True;
  end;
```

See Also

FindLast (see page 6940)

FindNext (see page 6940)

Prior (see page 6979)

39.1.17.4.65 TDataSet.FindRecord Method

Pascal

```
function FindRecord(Restart: Boolean; GoForward: Boolean): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean FindRecord(Boolean Restart, Boolean GoForward);
```

Description

This is FindRecord, a member of class TDataSet.

39.1.17.4.66 TDataSet.First Method

Moves to the first record in the dataset.

Pascal

```
procedure First;
```

C++

```
__fastcall First();
```

Description

Call First to make the first record in the dataset active. First posts any changes to the active record and:

Clears the record buffers.

Fetches the first record and makes it the active record.

Fetches any additional records required for display, such as those needed to fill out a grid control.

Sets the Bof (see page 7008) property to true.

Broadcasts the record change so that data controls and linked detail sets can update.

Note: TDataSet (see page 6894) uses internal, protected methods to reposition the active record and to fetch additional records required for display. In TDataSet (see page 6894), these internal methods are empty stubs. Descendant classes implement these methods to enable the First method to work.

C++ Examples:

```
/*
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ProgressBar1->Min = 0;
  ProgressBar1->Max = Customers->RecordCount;
  Customers->First();
  for (int i = ProgressBar1->Min; i <= ProgressBar1->Max; i++)
  {
    ProgressBar1->Position = i;
    Customers->Next();
    // do something with the current record
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Customers = new TTable(Form1);
  Customers->Active = false; // The Table component must not be active
  Customers->DatabaseName = "DBDEMOS";
  Customers->TableType = ttParadox;
  Customers->TableName = "CustInfo";
  Customers->Active = False;
  if (Customers->Exists) // Don't overwrite an existing table
  {
    Customers->Close();
    Customers->DeleteTable();
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Customers->FieldDefs->Clear();
  TFieldDef *pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Customers->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Customers->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Customers->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Customers->CreateTable();
  Customers->Active = True;
  for (int i = 1; i <= 20; i++)
    Customers->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Customers;
  DBGrid2->DataSource->DataSet = Customers;
  Customers->Active = True;
}
```

Delphi Examples:

```
{
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  with ProgressBar1 do
  begin
    Min := 0;
    Max := Customers.RecordCount;
    Customers.First;
    for i := Min to Max do
    begin
      Position := i;
      Customers.Next;
      // do something with the current record
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Active := False;
//  Overwrite any existing table
    if Customers.Exists then
    begin
      Customers.Close;
      Customers.DeleteTable;
    end;
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftString;
          Size := 30;
        end;
      end;
      { Next, describe any indexes }
      with IndexDefs do
      begin
        Clear;
```

```
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Customers.Active:= True;
        for i := 1 to 100 do
          Customers.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Customers;
    DBGrid2.DataSource.DataSet:= Customers;
    Customers.Active:= True;
  end;
```

Using Unidirectional Datasets

39.1.17.4.67 TDataSet.FreeBookmark Method

Frees the resources allocated for a specified bookmark.

Pascal

```
procedure FreeBookmark(Bookmark: TBookmark); virtual;
```

C++

```
virtual __fastcall FreeBookmark(TBookmark Bookmark);
```

Description

Call FreeBookmark to free an existing bookmark before reassigning it. FreeBookmark releases the memory allocated for a specified bookmark when the bookmark is no longer needed.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
```

```
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
    { get a bookmark so that we can return to the same record }
    SavePlace := GetBookmark;
    try
      { move to prior record}
      FindPrior;
      { get the value }
      PrevValue := Fields[1].Value;
      {Move back to the bookmark
      this may not be the next record anymore
      if something else is changing the dataset asynchronously }
      GotoBookmark(SavePlace);
      { Set the value }
      Edit;
      Fields[1].Value := PrevValue;
      { Free the bookmark }
    finally
      FreeBookmark(SavePlace);
    end;
  end;
end;

{
To ensure that the button is disabled when there is no
previous record, the OnDataChange event of the DataSource
detects when the user moves to the beginning of file (BOF
property becomes true), and disables the button.  Detection
occurs on scrolling and editing, not selection with the mouse.
}
procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);

Pascal

```
procedure FreeRecordBuffer(var Buffer: PChar); virtual;
```

C++

```
virtual __fastcall FreeRecordBuffer(const char * Buffer);
```

Description

This is FreeRecordBuffer, a member of class TDataSet.

39.1.17.4.70 TDataSet.GetAggRecordCount Method

Pascal

```
function GetAggRecordCount(Grp: TGroupPosInd): Integer; virtual;
```

C++

```
virtual __fastcall int GetAggRecordCount(TGroupPosInd Grp);
```

Description

This is GetAggRecordCount, a member of class TDataSet.

39.1.17.4.71 TDataSet.GetAggregateValue Method

Pascal

```
function GetAggregateValue(Field: TField): Variant; virtual;
```

C++

```
virtual __fastcall Variant GetAggregateValue(TField Field);
```

Description

This is GetAggregateValue, a member of class TDataSet.

39.1.17.4.72 TDataSet.GetBlobFieldData Method

Reads BLOB data into a buffer.

Pascal

```
function GetBlobFieldData(FieldNo: Integer; var Buffer: TBlobByteData): Integer; virtual;
```

C++

```
virtual __fastcall int GetBlobFieldData(int FieldNo, TBlobByteData Buffer);
```

Description

GetBlobFieldData reads blob data from the field specified by FieldNo into a Buffer. The buffer is a dynamic array of bytes, so that it can grow to accommodate the size of the BLOB data. GetBlobFieldData returns the size of the buffer.

GetBlobFieldData is intended primarily for internal use. Applications should use the BLOB stream returned by the CreateBlobStream (see page 6922) method to access BLOB data.

See Also

BlobFieldCount (see page 7007)

GetFieldData (see page 6952)

CreateBlobStream (see page 6922)

39.1.17.4.73 TDataSet.GetBookmark Method

Allocates a bookmark for the active record in the dataset.

Pascal

```
function GetBookmark: TBookmark; virtual;
```

C++

```
virtual __fastcall TBookmark GetBookmark();
```

Description

Call GetBookmark to establish a bookmark for the active record in the dataset. Establishing a bookmark for a record enables a dataset to return to that record at any time while the bookmark exists.

GetBookmark requires that a variable for the bookmark (for Delphi, of type TBookmark (see page 7628)) already be declared in the application. Use GetBookmark to assign a value to the variable. This value can then be referenced by subsequent calls to GotoBookmark (see page 6957) and FreeBookmark (see page 6945).

Applications that create bookmarks with GetBookmark must subsequently release the system resource allocated to them by calling FreeBookmark (see page 6945) when the bookmarks are no longer needed.

Note: GetBookmark relies on a protected method to obtain the bookmark value. TDataSet (see page 6894) descendants implement this method to provide their own type of bookmark support. Unidirectional datasets do not support bookmarks, and so do not return a meaningful value.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
    { get a bookmark so that we can return to the same record }
    SavePlace := GetBookmark;
    try
      { move to prior record}
      FindPrior;
      { get the value }
      PrevValue := Fields[1].Value;
      {Move back to the bookmark
      this may not be the next record anymore
      if something else is changing the dataset asynchronously }
      GotoBookmark(SavePlace);
      { Set the value }
      Edit;
```

```
        Fields[1].Value := PrevValue;
        { Free the bookmark }
      finally
        FreeBookmark(SavePlace);
      end;
    end;
  end;

  {
  To ensure that the button is disabled when there is no
  previous record, the OnDataChange event of the DataSource
  detects when the user moves to the beginning of file (BOF
  property becomes true), and disables the button.  Detection
  occurs on scrolling and editing, not selection with the mouse.
  }
  procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
  begin
    if Customers.Bof then
      Button1.Enabled := False
    else
      Button1.Enabled := True;
  end;
```

Marking and Returning to Records

39.1.17.4.74 TDataSet.GetBookmarkData Method

Pascal

```
procedure GetBookmarkData(Buffer: PChar; Data: Pointer); virtual;
```

C++

```
virtual __fastcall GetBookmarkData(const char * Buffer, void * Data);
```

Description

This is GetBookmarkData, a member of class TDataSet.

39.1.17.4.75 TDataSet.GetBookmarkFlag Method

Pascal

```
function GetBookmarkFlag(Buffer: PChar): TBookmarkFlag; virtual;
```

C++

```
virtual __fastcall TBookmarkFlag GetBookmarkFlag(const char * Buffer);
```

Description

This is GetBookmarkFlag, a member of class TDataSet.

39.1.17.4.76 TDataSet.GetBookmarkStr Method

Pascal

```
function GetBookmarkStr: TBookmarkStr; virtual;
```

C++

```
virtual __fastcall TBookmarkStr GetBookmarkStr();
```

Description

This is GetBookmarkStr, a member of class TDataSet.

39.1.17.4.77 TDataSet.GetCalcFields Method

Pascal

```
procedure GetCalcFields(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall GetCalcFields(const char * Buffer);
```

Description

This is GetCalcFields, a member of class TDataSet.

39.1.17.4.78 TDataSet.GetCanModify Method

Pascal

```
function GetCanModify: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetCanModify();
```

Description

This is GetCanModify, a member of class TDataSet.

39.1.17.4.79 TDataSet.GetChildren Method

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

This is GetChildren, a member of class TDataSet.

39.1.17.4.80 TDataSet.GetCurrentRecord Method

Implements a virtual function to retrieve the current record in a buffer.

Pascal

```
function GetCurrentRecord(Buffer: PChar): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetCurrentRecord(const char * Buffer);
```

Description

This function always returns false, indicating failure. For TDataSet (see page 6894) descendants that override this method to retrieve the value of the current record, GetCurrentRecord returns true if Buffer is successfully filled with the value of the current

record.

See Also

ActiveBuffer (see page 6909)

CurrentRecord (see page 7013)

39.1.17.4.81 TDataSet.GetDataSource Method

Pascal

```
function GetDataSource: TDataSource; virtual;
```

C++

```
virtual __fastcall TDataSource GetDataSource();
```

Description

This is GetDataSource, a member of class TDataSet.

39.1.17.4.82 TDataSet.GetDetailDataSets Method

Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.

Pascal

```
procedure GetDetailDataSets(List: TList); virtual;
```

C++

```
virtual __fastcall GetDetailDataSets(TList List);
```

Description

Datasets can represent master/detail relationships in two ways: as linked cursors or as nested dataset fields. GetDetailDataSets lists all detail datasets of the active record into List if they are not the value of a nested dataset field. To obtain a list of the detail datasets that are the values of nested dataset fields, use the NestedDataSets (see page 7030) property instead.

See Also

TDetailDataLink (see page 7111)

GetDetailLinkFields (see page 6951)

NestedDataSets (see page 7030)

39.1.17.4.83 TDataSet.GetDetailLinkFields Method

Introduces a method to list the field components that link this dataset as a detail of a master dataset.

Pascal

```
procedure GetDetailLinkFields(MasterFields: TList; DetailFields: TList); virtual;
```

C++

```
virtual __fastcall GetDetailLinkFields(TList MasterFields, TList DetailFields);
```

Description

As implemented in TDataSet (see page 6894), GetDetailLinkFields does nothing. Descendants override this method to fill the two lists with field components that define a master-detail relationship between this dataset and another (master) dataset. The MasterFields list is filled with fields from the master table whose values must equal the values of the fields in the DetailFields list.

The DetailFields list is filled with fields from the calling dataset.

39.1.17.4.84 TDataSet.GetFieldClass Method

Pascal

```
function GetFieldClass(FieldType: TFieldType): TFieldClass; virtual;
```

C++

```
virtual __fastcall TFieldClass GetFieldClass(TFieldType FieldType);
```

Description

This is GetFieldClass, a member of class TDataSet.

39.1.17.4.85 GetFieldData Method

This is the overview for the GetFieldData method overload.

Overload List

	Name	Description
	TDataSet.GetFieldData (Integer, Pointer) (see page 6952)	Retrieves the current value of a field into a buffer.
	TDataSet.GetFieldData (TField, Pointer) (see page 6952)	Retrieves the current value of a field into a buffer.
	TDataSet.GetFieldData (TField, Pointer, Boolean) (see page 6952)	Retrieves the current value of a field into a buffer.

39.1.17.4.85.1 TDataSet.GetFieldData Method (Integer, Pointer)

Retrieves the current value of a field into a buffer.

Pascal

```
function GetFieldData(Field: TField; Buffer: Pointer): Boolean; virtual; overload;
function GetFieldData(FieldNo: Integer; Buffer: Pointer): Boolean; virtual; overload;
function GetFieldData(Field: TField; Buffer: Pointer; NativeFormat: Boolean): Boolean;
virtual; overload;
```

C++

```
virtual __fastcall Boolean GetFieldData(TField Field, void * Buffer);
virtual __fastcall Boolean GetFieldData(int FieldNo, void * Buffer);
virtual __fastcall Boolean GetFieldData(TField Field, void * Buffer, Boolean NativeFormat);
```

Description

Most applications do not need to call GetFieldData. TField (see page 7115) objects call this method to implement their GetData method.

The Field or FieldNo parameter indicates the field whose data should be fetched. Field specifies the component itself, while FieldNo indicates its field number. The Buffer parameter is a memory buffer with sufficient space to accept the value of the field as it exists in the database (unformatted and untranslated). NativeFormat indicates whether the dataset fetches the field in the IDE's native format for the field type. When NativeFormat is false, the dataset must convert the field value to the native type. This allows the field to handle data from different types of datasets (ADO-based, BDE-based, and so on) in a uniform manner.

GetFieldData returns a value that indicates whether the data was successfully fetched.

As implemented in TDataSet (see page 6894), GetFieldData always returns false, indicating that no data was fetched from the

specified field. Descendants override this method to fetch data in whatever way is appropriate to the implementation of the dataset.

GetFieldList (see page 6953)

GetData (see page 7131)

39.1.17.4.86 TDataSet.GetFieldFullName Method

Pascal

```
function GetFieldFullName(Field: TField): string; virtual;
```

C++

```
virtual __fastcall AnsiString GetFieldFullName(TField Field);
```

Description

This is GetFieldFullName, a member of class TDataSet.

39.1.17.4.87 TDataSet.GetFieldList Method

Retrieves a specified set of field objects into a list.

Pascal

```
procedure GetFieldList(List: TList; const FieldNames: WideString);
```

C++

```
__fastcall GetFieldList(TList List, const BSTR FieldNames);
```

Description

Call GetFieldList to copy a specified set of field objects into a list object created and maintained by the application.

List is the TList object into which to copy the field objects. FieldNames is a string containing the name of the fields to copy. Each field name in the string must be separated from other field names with a semicolon. GetFieldList builds a list that contains only the field objects for which it finds a matching name in the dataset's list of field objects.

Note: Applications do not normally call GetFieldList to copy field objects. Field objects are directly accessible through the dataset itself. In some cases, however, it can be useful to work with a copy of a field object or its data instead of working on the actual object in the dataset.

FieldDefs (see page 7019)

Fields (see page 7023)

FieldByName (see page 6936)

FindField (see page 6938)

GetFieldNames (see page 6954)

39.1.17.4.88 GetFieldNames Method

This is the overview for the GetFieldNames method overload.

Overload List

	Name	Description
	TDataSet.GetFieldNames (TStrings) (see page 6954)	Retrieves a list of names for all fields in a dataset.
	TDataSet.GetFieldNames (TWideStrings) (see page 6954)	Retrieves a list of names for all fields in a dataset.

39.1.17.4.88.1 TDataSet.GetFieldNames Method (TStrings)

Retrieves a list of names for all fields in a dataset.

Pascal

```
procedure GetFieldNames(List: TStrings); virtual; overload; deprecated;
procedure GetFieldNames(List: TWideStrings); virtual; overload;
```

C++

```
virtual __fastcall GetFieldNames(TStrings List);
virtual __fastcall GetFieldNames(TWideStrings List);
```

Description

Call GetFieldNames to get a list of names for all fields in a dataset. List is a TStrings object created and maintained by the application. For example, to load a list box with the field names of a table,

```
SQLDataSet1.GetFieldNames(ListBox1.Items);
SQLDataSet1->GetFieldNames(ListBox1->Items);
```

Retrieving a list of field names is especially useful for applications that work with datasets whose field objects are created dynamically at runtime. By retrieving a list of field names, the application can be restricted to working only with fields that exist at runtime.

Note: GetFieldNames does not add the names of any aggregated fields to the list.

39.1.17.4.89 TDataSet.GetIndexDefs Method

Pascal

```
function GetIndexDefs(IndexDefs: TIndexDefs; IndexTypes: TIndexOptions): TIndexDefs;
```

C++

```
__fastcall TIndexDefs GetIndexDefs(TIndexDefs IndexDefs, TIndexOptions IndexTypes);
```

Description

This is GetIndexDefs, a member of class TDataSet.

39.1.17.4.90 TDataSet.GetIsIndexField Method

Pascal

```
function GetIsIndexField(Field: TField): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetIsIndexField(TField Field);
```

Description

This is GetIsIndexField, a member of class TDataSet.

39.1.17.4.91 TDataSet.GetNextRecord Method

Pascal

```
function GetNextRecord: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetNextRecord();
```

Description

This is GetNextRecord, a member of class TDataSet.

39.1.17.4.92 TDataSet.GetNextRecords Method

Pascal

```
function GetNextRecords: Integer; virtual;
```

C++

```
virtual __fastcall int GetNextRecords();
```

Description

This is GetNextRecords, a member of class TDataSet.

39.1.17.4.93 TDataSet.GetPriorRecord Method

Pascal

```
function GetPriorRecord: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetPriorRecord();
```

Description

This is GetPriorRecord, a member of class TDataSet.

39.1.17.4.94 TDataSet.GetPriorRecords Method

Pascal

```
function GetPriorRecords: Integer; virtual;
```

C++

```
virtual __fastcall int GetPriorRecords();
```

Description

This is GetPriorRecords, a member of class TDataSet.

39.1.17.4.95 TDataSet.GetRecNo Method

Pascal

```
function GetRecNo: Integer; virtual;
```

C++

```
virtual __fastcall int GetRecNo();
```

Description

This is GetRecNo, a member of class TDataSet.

39.1.17.4.96 TDataSet.GetRecord Method

Pascal

```
function GetRecord(Buffer: PChar; GetMode: TGetMode; DoCheck: Boolean): TGetResult; virtual;
abstract;
```

C++

```
virtual __fastcall TGetResult GetRecord(const char * Buffer, TGetMode GetMode, Boolean
DoCheck) = 0;
```

Description

This is GetRecord, a member of class TDataSet.

39.1.17.4.97 TDataSet.GetRecordCount Method

Pascal

```
function GetRecordCount: Integer; virtual;
```

C++

```
virtual __fastcall int GetRecordCount();
```

Description

This is GetRecordCount, a member of class TDataSet.

39.1.17.4.98 TDataSet.GetRecordSize Method

Pascal

```
function GetRecordSize: Word; virtual;
```

C++

```
virtual __fastcall Word GetRecordSize();
```

Description

This is GetRecordSize, a member of class TDataSet.

39.1.17.4.99 TDataSet.GetStateFieldValue Method

Pascal

```
function GetStateFieldValue(State: TDataSetState; Field: TField): Variant; virtual;
```

C++

```
virtual __fastcall Variant GetStateFieldValue(TDataSetState State, TField Field);
```

Description

This is GetStateFieldValue, a member of class TDataSet.

39.1.17.4.100 TDataSet.GotoBookmark Method

Implements a virtual method to position the dataset on the record to which a specified bookmark points.

Pascal

```
procedure GotoBookmark(Bookmark: TBookmark);
```

C++

```
__fastcall GotoBookmark(TBookmark Bookmark);
```

Description

GotoBookmark calls an internal method that is an empty stub in TDataSet (see page 6894). Descendants of TDataSet (see page 6894) redeclare and implement the internal method so that GotoBookmark makes the record identified by the Bookmark (see page 7009) parameter active.

Note: Unidirectional datasets do not support bookmarks. Calling GotoBookmark on a unidirectional dataset does not change the active record.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
    { get a bookmark so that we can return to the same record }
    SavePlace := GetBookmark;
    try
      { move to prior record}
      FindPrior;
      { get the value }
      PrevValue := Fields[1].Value;
      {Move back to the bookmark
      this may not be the next record anymore
      if something else is changing the dataset asynchronously }
      GotoBookmark(SavePlace);
      { Set the value }
      Edit;
      Fields[1].Value := PrevValue;
      { Free the bookmark }
    finally
      FreeBookmark(SavePlace);
    end;
  end;
end;
```

```
{
To ensure that the button is disabled when there is no
previous record, the OnDataChange event of the DataSource
detects when the user moves to the beginning of file (BOF
property becomes true), and disables the button.  Detection
occurs on scrolling and editing, not selection with the mouse.
}
procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
begin
  if Customers.Bof then
    Button1.Enabled := False
  else
    Button1.Enabled := True;
end;
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

39.1.17.4.101 TDataSet.InitFieldDefs Method

Pascal

```
procedure InitFieldDefs; virtual;
```

C++

```
virtual __fastcall InitFieldDefs();
```

Description

This is InitFieldDefs, a member of class TDataSet.

39.1.17.4.102 TDataSet.InitFieldDefsFromFields Method

Pascal

```
procedure InitFieldDefsFromFields;
```

C++

```
__fastcall InitFieldDefsFromFields();
```

Description

This is InitFieldDefsFromFields, a member of class TDataSet.

39.1.17.4.103 TDataSet.InitRecord Method

Pascal

```
procedure InitRecord(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall InitRecord(const char * Buffer);
```

Description

This is InitRecord, a member of class TDataSet.

39.1.17.4.104 TDataSet.Insert Method

Inserts a new, empty record in the dataset.

Pascal

```
procedure Insert;
```

C++

```
__fastcall Insert();
```

Description

Call Insert to:

1Open (see page 6976) a new, empty record in the dataset.

2Set the active record to the new record.

After a call to Insert, an application can allow users to enter data in the fields of the record, and then post those changes to the database or change log using Post (see page 6977). (Client datasets can subsequently apply updates in the change log back to the database by calling ApplyUpdates.) A newly inserted record is posted in one of three ways:

For Paradox tables with primary indexes, the record is inserted into the dataset in a position based on its index.

For Paradox tables without primary indexes, the record is inserted into the dataset at the current position.

For dBASE, FoxPro, and Access tables, the record is physically appended to the dataset at the end. If an index happens to be active, the new record may appear in a position relative to the index, but the record is still actually stored at the end of the table.

For SQL databases, the physical location of the insert is implementation-specific. For indexed tables, the index is updated with the new record information.

After the new record is applied back to the database server, its physical location is database-specific. For indexed tables, the index is updated with the new record information.

Delphi Examples:

```
{
This example uses the BeforeInsert event to do data
validation. If the StrToInt function raises an exception,
the edit control’s contents are set to a valid value so
that the assignment to the INTEGER field in the dataset
will succeed.  Continuing after the exception causes a
'0' to be placed in the PORTA field.
DataSet design:
This example requires a ClientDataSet, a DBGrid, a
DataSource and a DBNavigator.  Name the ClientDataSet CDS.
Set the DataSet property in the DataSource to CDS and name
that DataSource DS.  Set the DataSource in the DBNavigator
to DS the DataSource in the DBGrid to DS.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
attribute name of HOST with an attribute type of string and
an attribute name of PORTA with an attribute type of integer.
Add DB, DBCtrls, Grids, DBGrids and DBClient to the uses clause.
}
{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button3Click(Sender: TObject);
begin
  CDS.Insert;
  CDS.FieldByName('PORTA').AsInteger := StrToInt(Edit1.Text);
  CDS.Post;
end;

procedure TForm1.CDSBeforeInsert(DataSet: TDataSet);
begin
  try
  { Make sure edit field can be converted to integer --
   this will raise an exception if it can’t }
    StrToInt(Edit1.Text);
  except
    Edit1.Text := '0';
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;
```

InsertRecord (see page 6961)

Post (see page 6977)

Adding New Records

Posting Data

39.1.17.4.105 TDataSet.InsertRecord Method

Inserts a new, populated record to the dataset and posts it.

Pascal

```
procedure InsertRecord(const Values: array of const);
```

C++

```
__fastcall InsertRecord(const array of const Values);
```

Description

Call InsertRecord to create a new, empty record in the dataset, populate it with the field values in Values, and post the values to the database or change log. In C++, the Values_Size parameter indicates the index of the last value in the Values array (one less than the number of values).

A newly inserted record is posted to the database in one of three ways:

For indexed Paradox and dBASE tables, the record is inserted into the dataset in a position based on its index.

For unindexed Paradox tables, the record is inserted into the dataset at the current position.

For unindexed dBASE, FoxPro, and Access tables, the record is inserted into the dataset at the end.

For SQL databases, the physical location of the insert is implementation-specific. For indexed tables, the index is updated with the new record information.

The newly inserted record becomes the active record.

Delphi Examples:

```
{
This statement inserts a record to the MyCustInfo data. Note
that Nulls are entered for some of the values, but are not
required for missing values at the end of the array argument,
i.e. after the Field3 field.  InsertRecord behaves differently
depending on the indexing of the table.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.InsertRecord([Edit1.Text, Edit2.Text, Null, Edit3.Text]);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'MyCustInfo';
    ReadOnly:= False;

//    Don't overwrite an existing table
    if (not Customers.Exists) then CreateMyTable
    else
    begin
      if (Customers.Exists AND
        (MessageDlg('MyCustInfo table already exists.  Do you want to rebuild it?',
mtConfirmation, [mbYes, mbNo], 0) = mrYes)) then
```

```
        begin
          Customers.Close;
          Customers.DeleteTable;
          CreateMyTable;
        end;
      end;
    end;
    DS2.DataSet:= Customers;
    DBGrid2.DataSource.DataSet:= Customers;
    Customers.Active:= True;
  end;

  procedure CreateMyTable();
  var
    i: Integer;
  begin
  //      The Table component must not be active
  //      First, describe the type of table and give
  //      it a name
  //      Next, describe the fields in the table
    with Customers do
    begin
        with FieldDefs do

Modifying Entire Records

39.1.17.4.106 TDataSet.InternalAddRecord Method

Pascal

```
procedure InternalAddRecord(Buffer: Pointer; Append: Boolean); virtual;
```

C++

```
virtual __fastcall InternalAddRecord(void * Buffer, Boolean Append);
```

Description

This is InternalAddRecord, a member of class TDataSet.

39.1.17.4.107 TDataSet.InternalCancel Method

Pascal

```
procedure InternalCancel; virtual;
```

C++

```
virtual __fastcall InternalCancel();
```

Description

This is InternalCancel, a member of class TDataSet.

39.1.17.4.108 TDataSet.InternalClose Method

Pascal

```
procedure InternalClose; virtual; abstract;
```

C++

```
virtual __fastcall InternalClose() = 0;
```

Description

This is InternalClose, a member of class TDataSet.

39.1.17.4.109 TDataSet.InternalDelete Method

Pascal

```
procedure InternalDelete; virtual;
```

C++

```
virtual __fastcall InternalDelete();
```

Description

This is InternalDelete, a member of class TDataSet.

39.1.17.4.110 TDataSet.InternalEdit Method

Pascal

```
procedure InternalEdit; virtual;
```

C++

```
virtual __fastcall InternalEdit();
```

Description

This is InternalEdit, a member of class TDataSet.

39.1.17.4.111 TDataSet.InternalFirst Method

Pascal

```
procedure InternalFirst; virtual;
```

C++

```
virtual __fastcall InternalFirst();
```

Description

This is InternalFirst, a member of class TDataSet.

39.1.17.4.112 TDataSet.InternalGotoBookmark Method

Pascal

```
procedure InternalGotoBookmark(Bookmark: Pointer); virtual;
```

C++

```
virtual __fastcall InternalGotoBookmark(void * Bookmark);
```

Description

This is InternalGotoBookmark, a member of class TDataSet.

39.1.17.4.113 TDataSet.InternalHandleException Method

Pascal

```
procedure InternalHandleException; virtual; abstract;
```

C++

```
virtual __fastcall InternalHandleException() = 0;
```

Description

This is InternalHandleException, a member of class TDataSet.

39.1.17.4.114 TDataSet.InternalInitFieldDefs Method

Pascal

```
procedure InternalInitFieldDefs; virtual; abstract;
```

C++

```
virtual __fastcall InternalInitFieldDefs() = 0;
```

Description

This is InternalInitFieldDefs, a member of class TDataSet.

39.1.17.4.115 TDataSet.InternalInitRecord Method

Pascal

```
procedure InternalInitRecord(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall InternalInitRecord(const char * Buffer);
```

Description

This is InternalInitRecord, a member of class TDataSet.

39.1.17.4.116 TDataSet.InternalInsert Method

Pascal

```
procedure InternalInsert; virtual;
```

C++

```
virtual __fastcall InternalInsert();
```

Description

This is InternalInsert, a member of class TDataSet.

39.1.17.4.117 TDataSet.InternalLast Method

Pascal

```
procedure InternalLast; virtual;
```

C++

```
virtual __fastcall InternalLast();
```

Description

This is InternalLast, a member of class TDataSet.

39.1.17.4.118 TDataSet.InternalOpen Method

Pascal

```
procedure InternalOpen; virtual; abstract;
```

C++

```
virtual __fastcall InternalOpen() = 0;
```

Description

This is InternalOpen, a member of class TDataSet.

39.1.17.4.119 TDataSet.InternalPost Method

Pascal

```
procedure InternalPost; virtual;
```

C++

```
virtual __fastcall InternalPost();
```

Description

This is InternalPost, a member of class TDataSet.

39.1.17.4.120 TDataSet.InternalRefresh Method

Pascal

```
procedure InternalRefresh; virtual;
```

C++

```
virtual __fastcall InternalRefresh();
```

Description

This is InternalRefresh, a member of class TDataSet.

39.1.17.4.121 TDataSet.InternalSetToRecord Method

Pascal

```
procedure InternalSetToRecord(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall InternalSetToRecord(const char * Buffer);
```

Description

This is InternalSetToRecord, a member of class TDataSet.

39.1.17.4.122 TDataSet.IsCursorOpen Method

Pascal

```
function IsCursorOpen: Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean IsCursorOpen() = 0;
```

Description

This is IsCursorOpen, a member of class TDataSet.

39.1.17.4.123 TDataSet.IsEmpty Method

Indicates whether the dataset contains no records.

Pascal

```
function IsEmpty: Boolean;
```

C++

```
__fastcall Boolean IsEmpty();
```

Description

Call IsEmpty to determine if a dataset has records. IsEmpty returns true if the dataset does not contain any records. Otherwise it returns false.

See Also

Bof (see page 7008)

Eof (see page 7015)

39.1.17.4.124 TDataSet.IsLinkedTo Method

Indicates whether a dataset is linked to a specified data source.

Pascal

```
function IsLinkedTo(DataSource: TDataSource): Boolean;
```

C++

```
__fastcall Boolean IsLinkedTo(TDataSource DataSource);
```

Description

Call IsLinkedTo to verify that a dataset provides data through a specific data source. DataSource (see page 7014) is the data source component to test.

Note: IsLinkedTo is mainly provided for developers deriving custom components based on TDataSet (see page 6894). It is not intended or needed for general data access.

If the datasource provides data from the dataset or one of its nested dataset fields (or a nested dataset nested in a dataset field...), IsLinkedTo returns true. If the datasource provides data from some other dataset, or if the data source does not already have a dataset of its own, IsLinkedTo returns false.

Note: IsLinkedTo is mainly provided for developers deriving custom components based on TDataSet (see page 6894). It is not intended or needed for general data access.

See Also

DataSource (see page 7014)

39.1.17.4.125 TDataSet.IsSequenced Method

Indicates whether the underlying database table uses record numbers to indicate the order of records.

Pascal

```
function IsSequenced: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsSequenced();
```

Description

Use IsSequenced to determine whether the underlying database table supports sequence numbers, or whether these are computed by the dataset component. When IsSequenced returns true, applications can safely use the RecNo (see page 7031) property to navigate to records in the dataset.

As implemented in TDataSet (see page 6894), IsSequenced always returns true. Descendants of TDataSet (see page 6894) reimplement this method to return a value that depends on the underlying table type.

See Also

RecNo (see page 7031)

RecordCount (see page 7032)

39.1.17.4.126 TDataSet.Last Method

Moves to the last record in the dataset.

Pascal

```
procedure Last;
```

C++

```
__fastcall Last();
```

Description

Call Last to make the last record in the dataset active. If the dataset is not unidirectional Last posts any changes to the active record and

Clears the record buffers.

Fetches the last record and makes it the active record.

Fetches any additional records required for display, such as those needed to fill out a grid control.

Sets the Eof (see page 7015) property to true.

Broadcasts the record change so that data controls and linked detail sets can update.

For unidirectional datasets, Last raises an EDatabaseError (see page 6731) exception.

Note: TDataSet (see page 6894) uses internal, protected methods to reposition the active record and to fetch additional records required for display. In TDataSet (see page 6894), these internal methods are empty stubs. Descendant classes implement these methods to enable the Last method to work.

Delphi Examples:

```
{
This example shows how to use the BeforeGetRecords event
handler (a TRemoteEventType value) to send the provider
information it needs for incremental data fetching. Before
fetching the next data packet, the client dataset packages
up the key value of the last record so that the provider
knows where to begin the next data packet. It also sends
```

```
some application-specific information, which is stored in
Memo1.  This method is used to pass the sql statement and the
value of the first field for the last record to the server so
that the server can return the correct records. The complete
project using this code example is in
Demos/DelphiWin32/VCLWin32/MIDAS/Pooler.
}
procedure TForm1.ClientDataSet1BeforeGetRecords(Sender: TObject; var OwnerData: OleVariant);
var
  LastValue: OleVariant;
  CDSClone: TClientDataSet;
begin
  if ClientDataSet1.Active then
  begin
    CDSClone := TClientDataSet.Create(Form1);
    try
      CDSClone.CloneCursor(ClientDataSet1, True);
      { turn off FetchOnDemand so that the clone only fetches
        the last LOCAL record }
      CDSClone.FetchOnDemand := False;
      CDSClone.Last;
      LastValue := CDSClone.Fields[0].AsString;
      CDSClone.Close;
    finally
      CDSClone.Free;
    end;
  end else
    LastValue := NULL;
  OwnerData := VarArrayOf([Memo1.Lines.Text, LastValue]);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  ClientDataSet1.PacketRecords := StrToInt(Edit1.Text);
  ClientDataSet1.GetNextPacket;
end;
```

Adding New Records

Posting Data

Using the First and Last Methods

39.1.17.4.127 TDataSet.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling pointers can be used after being streamed in.

As implemented in TComponent, Loaded clears the csLoading flag in the ComponentState property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

ComponentState (see page 2804)

Create (see page 2766)

TReader (see page 2933)

39.1.17.4.128 TDataSet.Locate Method

Implements a virtual method for searching a dataset for a specified record and making it the active record.

Pascal

```
function Locate(const KeyFields: string; const KeyValues: Variant; Options: TLocateOptions):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Locate(const AnsiString KeyFields, const Variant KeyValues,
TLocateOptions Options);
```

Description

This function:

Checks whether the dataset is unidirectional, and if so, raises an EDatabaseError (see page 6731) exception.

Returns false, indicating that a matching record was not found and the active record was not changed.

Descendant classes that are not unidirectional override this method so that it locates the record where the fields identified by the semicolon-separated list of fields in KeyFields have the values specified by the Variant or Variant array KeyValues. Options indicates whether the search is case insensitive and whether partial matches are supported. Locate returns true if a record is found that matches the specified criteria and that record is now active.

FindField (see page 6938)

Lookup (see page 6970)

Using Indexes to Search for Records

Using Locate

39.1.17.4.129 TDataSet.Lookup Method

Implements a virtual method to retrieve field values from a record that matches specified search values.

Pascal

```
function Lookup(const KeyFields: string; const KeyValues: Variant; const ResultFields:
string): Variant; virtual;
```

C++

```
virtual __fastcall Variant Lookup(const AnsiString KeyFields, const Variant KeyValues, const
AnsiString ResultFields);
```

Description

This function:

Checks whether the dataset is unidirectional, and if so, raises an EDatabaseError (see page 6731) exception.

Returns a Variant with the value false, indicating that a matching record was not found.

Descendant classes that are not unidirectional override this method so that it locates the record where the fields identified by the comma-delimited string KeyFields have the values specified by the Variant or Variant array KeyValues. In classes that implement Lookup, it returns a Variant or Variant array that contains the value or values of the fields specified by the comma-delimited string ResultFields on the specified record.

Locate (see page 6970)

Using Indexes to Search for Records

Using Locate

Using Lookup

39.1.17.4.130 TDataSet.MoveBy Method

Moves to another record relative to the active record in the dataset.

Pascal

```
function MoveBy(Distance: Integer): Integer;
```

C++

```
__fastcall int MoveBy(int Distance);
```

Description

Call MoveBy to move the active record by the number of records specified by Distance. A positive value for Distance indicates forward progress through the dataset, while a negative value indicates backward progress. For example, the following statement moves backward through the dataset by 10 records:

```
MoveBy(-10);
DataSet1->MoveBy(-10);
```

MoveBy posts any changes to the active record and

Sets the Bof (see page 7008) and Eof (see page 7015) properties to false.

If Distance is positive, repeatedly fetches Distance subsequent records (if possible), and makes the last record fetched active. If an attempt is made to move past the end of the file, MoveBy sets Eof (see page 7015) to true.

If Distance is negative, repeatedly fetches the appropriate number of previous records (if possible), and makes the last record fetched active. If an attempt is made to move past the start of the file, MoveBy sets Bof (see page 7008) to true. If the dataset is unidirectional, the dataset raises an EDatabaseError (see page 6731) exception when MoveBy tries to fetch a prior record.

Broadcasts information about the record change so that data-aware controls and linked datasets can update.

Returns the number of records moved. In most cases, Result is the absolute value of Distance, but if MoveBy encounters the beginning-of-file or end-of-file before moving Distance records, Result will be less than the absolute value of Distance.

C++ Examples:

```
/*
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
*/
void __fastcall TForm1::UpDownClick(TObject *Sender)
{
  CDS2->MoveBy(((TComponent *)Sender)->Tag);
  DBGrid2->SetFocus();
}

void __fastcall TForm1::LeftRightClick(TObject *Sender)
{
  DBGrid2->SelectedIndex = DBGrid2->SelectedIndex + ((TComponent *)Sender)->Tag;
  DBGrid2->SetFocus();
}
```

Delphi Examples:

```
{
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
}
procedure TForm1.UpDownClick(Sender: TObject);
begin
  CDS.MoveBy(TComponent(Sender).Tag);
  DBGrid1.SetFocus;
end;

procedure TForm1.LeftRightClick(Sender: TObject);
begin
  DBGrid1.SelectedIndex := DBGrid1.SelectedIndex + TComponent(Sender).Tag;
  DBGrid1.SetFocus;
end;
```

Next (see page 6973)

Prior (see page 6979)

Using the MoveBy Method

39.1.17.4.131 TDataSet.Next Method

Moves to the next record in the dataset.

Pascal

```
procedure Next;
```

C++

```
__fastcall Next();
```

Description

Call Next to move to the next record in the dataset, making it the active record. Next posts any changes to the active record and

Sets the Bof (see page 7008) and Eof (see page 7015) properties to false.

Fetches the next record and makes it the active record.

If the dataset is not unidirectional, fetches any additional records required for display, such as those needed to fill out a grid control.

Sets the Eof (see page 7015) property to true if the last record in the dataset was already active.

Broadcasts the record change so that data controls and linked detail sets can update.

Note: TDataSet (see page 6894) uses internal, protected methods to move the active record and to fetch additional records required for display. In TDataSet (see page 6894), these internal methods are empty stubs. Descendant classes implement these methods to enable the Next method to work.

C++ Examples:

```
/*
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ProgressBar1->Min = 0;
  ProgressBar1->Max = Customers->RecordCount;
  Customers->First();
  for (int i = ProgressBar1->Min; i <= ProgressBar1->Max; i++)
  {
    ProgressBar1->Position = i;
    Customers->Next();
    // do something with the current record
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Customers = new TTable(Form1);
  Customers->Active = false; // The Table component must not be active
  Customers->DatabaseName = "DBDEMOS";
  Customers->TableType = ttParadox;
  Customers->TableName = "CustInfo";
  Customers->Active = False;
  if (Customers->Exists) // Don't overwrite an existing table
  {
    Customers->Close();
    Customers->DeleteTable();
  }
  // The Table component must not be active
```

```
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Customers->FieldDefs->Clear();
  TFieldDef *pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Customers->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Customers->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Customers->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Customers->CreateTable();
  Customers->Active = True;
  for (int i = 1; i <= 20; i++)
    Customers->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Customers;
  DBGrid2->DataSource->DataSet = Customers;
  Customers->Active = True;
}
```

Delphi Examples:

```
{
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  with ProgressBar1 do
  begin
    Min := 0;
    Max := Customers.RecordCount;
    Customers.First;
    for i := Min to Max do
    begin
      Position := i;
      Customers.Next;
      // do something with the current record
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Active := False;
//  Overwrite any existing table
    if Customers.Exists then
    begin
      Customers.Close;
      Customers.DeleteTable;
```

```
      end;
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Customers.Active:= True;
        for i := 1 to 100 do
          Customers.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Customers;
    DBGrid2.DataSource.DataSet:= Customers;
    Customers.Active:= True;
  end;
```

Using Unidirectional Datasets

39.1.17.4.132 TDataSet.Open Method

Opens the dataset.

Pascal

```
procedure Open;
```

C++

```
__fastcall Open();
```

Description

Call Open to set the Active (see page 7004) property for the dataset to true. When Active (see page 7004) is true, data can be populated with data. It can read data from a database or other source (such as a provider). Depending on the CanModify (see page 7012) property, active datasets can post changes.

Setting Active (see page 7004) to true:

Triggers the BeforeOpen (see page 7051) event handler if one is defined for the dataset.

Sets the dataset state to dsBrowse.

Establishes a way to fetch data (typically by opening a cursor).

Triggers the After Open event handler if one is defined for the dataset.

If an error occurs during the dataset open, dataset state is set to dsInactive, and any cursor is closed.

Opening and Closing Datasets

Fetching the Data

39.1.17.4.133 TDataSet.OpenCursor Method

Pascal

```
procedure OpenCursor(InfoQuery: Boolean = False); virtual;
```

C++

```
virtual __fastcall OpenCursor(Boolean InfoQuery = False);
```

Description

This is OpenCursor, a member of class TDataSet.

39.1.17.4.134 TDataSet.OpenCursorComplete Method

Pascal

```
procedure OpenCursorComplete;
```

C++

```
__fastcall OpenCursorComplete();
```

Description

This is OpenCursorComplete, a member of class TDataSet.

39.1.17.4.135 TDataSet.OpenParentDataSet Method

Pascal

```
procedure OpenParentDataSet(ParentDataSet: TDataSet);
```

C++

```
__fastcall OpenParentDataSet(TDataSet ParentDataSet);
```

Description

This is OpenParentDataSet, a member of class TDataSet.

39.1.17.4.136 TDataSet.Post Method

Implements a virtual method to write a modified record to the database or change log.

Pascal

```
procedure Post; virtual;
```

C++

```
virtual __fastcall Post();
```

Description

TDataSet (see page 6894) implements a virtual method to write a modified record to the database or change log. Dataset methods that change the dataset state, such as Edit (see page 6932), Insert (see page 6959), or Append (see page 6910), or that move from one record to another, such as First (see page 6942), Last (see page 6968), Next (see page 6973), and Prior (see page 6979) automatically call Post.

Different types of datasets handle posting differently:

BDE-enabled datasets post records directly to the database server unless CachedUpdates is true. When caching updates, BDE-enabled datasets post records to an internal change log until they are applied to the database by calling ApplyUpdates.

ADO and InterBaseExpress datasets post records directly to the database server.

Client datasets post records to an internal change log until they are applied to the database by calling ApplyUpdates or merged with the client dataset's data by calling MergeChangeLog.

Unidirectional datasets are read-only and do not post records at all.

Designers of custom datasets can choose whether to implement Post by writing records to the database server or to an internal change log.

Delphi Examples:

```
{
```

```
This example appends a new record to a table or client
dataset when the user clicks a button. The two fields
Field1 and Field2 are filled from the contents of two edit
controls.  This example requires a populated TTable or
TDataSet with the appropriate field values.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Append;
  Customers.FieldValues['Field1'] := StrToInt(Edit1.text);
  Customers.FieldValues['Field2'] := Edit2.text;
  Customers.Post;
end;
{
The following fragment prompts the user to confirm changes
to a record; if the user clicks Yes, the record is posted to
the table, otherwise the changes are cancelled.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
if MessageDlg('Update Record?', mtConfirmation, [mbYes, mbNo], 0) =
              mrYes then
  Table1.Post
else
  Table1.Cancel;
end;
```

Adding New Records

Calculating Fields

Canceling Changes

Editing Records

Modifying Entire Records

Posting Data

39.1.17.4.137 TDataSet.Prior Method

Moves to the previous record in the dataset.

Pascal

```
procedure Prior;
```

C++

```
__fastcall Prior();
```

Description

Call Prior to move to the previous record in the dataset, making it the active record. Prior posts any changes to the active record and

Sets the Bof (see page 7008) and Eof (see page 7015) properties to false.

Fetches the previous record and makes it the active record. If the dataset is unidirectional, it raises an EDatabaseError (see page 6731) exception at this point.

Fetches any additional records required for display, such as those needed to fill out a grid control.

Sets the Bof (see page 7008) property to true if the first record in the dataset was already active.

Broadcasts the record change so that data controls and linked detail sets can update.

Note: TDataSet (see page 6894) uses internal, protected methods to move the active record and to fetch additional records required for display. In TDataSet (see page 6894), these internal methods are empty stubs. Descendant classes implement these methods to enable the Prior method to work.

Using the Eof and Bof Properties

Using the Next and Prior Methods

39.1.17.4.138 TDataSet.PSEndTransaction Method

Ends a transaction that was started by a call to PSStartTransaction.

Pascal

```
procedure PSEndTransaction(Commit: Boolean); virtual;
```

C++

```
virtual __fastcall PSEndTransaction(Boolean Commit);
```

Description

The provider component applies updates within a transaction, if possible. To do so, it uses PSEndTransaction in conjunction with the PSStartTransaction method.

The Commit parameter indicates whether the dataset should commit the current transaction (Commit is true), or roll it back (Commit is false).

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there is no transaction already established. That is, it does not assume nested transaction support is available. Thus, there is no need to ensure that PSEndTransaction does not terminate a transaction that was not started by the provider.

See Also

PSStartTransaction (see page 7586)

PSInTransaction (see page 7583)

applyupdates (see page 18459)

39.1.17.4.139 TDataSet.PSExecute Method

Executes the SQL command associated with the dataset.

Pascal

```
procedure PSExecute; virtual;
```

C++

```
virtual __fastcall PSExecute();
```

Description

The provider component calls PSExecute to implement its Execute method. If the dataset represents a query or stored procedure that does not return a cursor, this method executes the query or stored procedure. If the provider Options includes poAllowCommandText and the dataset supports the PSSetCommandText method, the statement specified by PSSetCommandText may be executed instead.

If there is not statement to execute, PSExecute raises an EDatabaseError exception.

See Also

PSSetCommandText (see page 7585)

Execute (see page 18466)

Options (see page 18440)

39.1.17.4.140 PSExecuteStatement Method

This is the overview for the PSExecuteStatement method overload.

Overload List

	Name	Description
	TDataSet.PSExecuteStatement (string, TParams, Pointer) (see page 6981)	Executes a specified SQL command.
	TDataSet.PSExecuteStatement (WideString, TParams, Pointer) (see page 6981)	This is PSExecuteStatement, a member of class TDataSet.

39.1.17.4.140.1 TDataSet.PSExecuteStatement Method (WideString, TParams, Pointer)

Pascal

```
function PSExecuteStatement(const ASQL: WideString; AParams: TParams; ResultSet: Pointer =
nil): Integer; virtual; overload;
```

C++

```
virtual __fastcall int PSExecuteStatement(const BSTR ASQL, TParams AParams, void * ResultSet =
nil);
```

Description

This is PSExecuteStatement, a member of class TDataSet.

39.1.17.4.140.2 TDataSet.PSExecuteStatement Method (string, TParams, Pointer)

Executes a specified SQL command.

Pascal

```
function PSExecuteStatement(const ASQL: string; AParams: TParams; ResultSet: Pointer = nil):
Integer; virtual; overload; deprecated;
```

C++

```
virtual __fastcall int PSExecuteStatement(const AnsiString ASQL, TParams AParams, void *
ResultSet = nil);
```

Description

If the value its ResolveToDataSet property is false, a provider component calls PSExecuteStatement (indirectly) to execute SQL statements that it generates for applying updates. Usually, the dataset passes these statements on to its database server for execution.

The ASQL parameter specifies the SQL command to execute.

AParams contains any parameter values that should be applied to ASQL before execution.

ResultSet allows PSExecuteStatement to return a dataset component that contains the results of a SELECT statement. If ResultSet is not nil (Delphi) or NULL (C++), PSExecuteStatement creates a new dataset component as the target of this pointer and fills it with the result set. The caller is responsible for freeing the dataset.

PSExecuteStatement returns the number of rows affected by executing ASQL.

See Also

PSUpdateRecord (see page 7586)

applyupdates (see page 18459)

ResolveToDataSet (see page 18531)

39.1.17.4.141 TDataSet.PSGetAttributes Method

Returns information that is stored in data packets as Name/Value pairs.

Pascal

```
procedure PSGetAttributes(List: TList); virtual;
```

C++

```
virtual __fastcall PSGetAttributes(TList List);
```

Description

The provider component calls PSGetAttributes to add information about the dataset to the metadata stored with generated data packets. This information is stored as Name/Value pairs that are added to the list specified by the List parameter.

See Also

DoGetProviderAttributes (see page 18521)

39.1.17.4.142 TDataSet.PSGetCommandText Method

Gets the SQL command to be executed by PSExecute.

Pascal

```
function PSGetCommandText: string; virtual; deprecated;
```

C++

```
virtual __fastcall AnsiString PSGetCommandText();
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSSetCommandText (see page 7585)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

39.1.17.4.143 TDataSet.PSGetCommandTextW Method

Pascal

```
function PSGetCommandTextW: WideString; virtual;
```

C++

```
virtual __fastcall BSTR PSGetCommandTextW();
```

Description

This is PSGetCommandTextW, a member of class TDataSet.

39.1.17.4.144 TDataSet.PSGetCommandType Method

Gets the command type to be executed by PSExecute.

Pascal

```
function PSGetCommandType: TPSCommandType; virtual;
```

C++

```
virtual __fastcall TPSCommandType PSGetCommandType();
```

Description

PSGetCommandType gets the command type executed by PSExecute. The type may be a type of SQL command or other command types, such as stored procedures.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSGetCommandText (see page 7579)

Execute (see page 18466)

Options (see page 18440)

39.1.17.4.145 TDataSet.PSGetDefaultOrder Method

Returns the definition of an index that imposes the default order on the data included in data packets.

Pascal

```
function PSGetDefaultOrder: TIndexDef; virtual;
```

C++

```
virtual __fastcall TIndexDef PSGetDefaultOrder();
```

Description

The provider component calls PSGetDefaultOrder to generate a default index, called DEFAULT_ORDER, for the records that appear in data packets. This index defines the default sort order for records when they appear in the client dataset on the client.

PSGetDefaultOrder creates a TIndexDef object to describe the default index. The provider that calls PSGetDefaultOrder subsequently frees this TIndexDef object.

See Also

CreateDataPacket (see page 18518)

39.1.17.4.146 TDataSet.PSGetIndexDefs Method

Returns the definitions of all specified indexes defined for the dataset.

Pascal

```
function PSGetIndexDefs(IndexTypes: TIndexOptions): TIndexDefs; virtual;
```

C++

```
virtual __fastcall TIndexDefs PSGetIndexDefs(TIndexOptions IndexTypes);
```

Description

The provider component calls PSGetIndexDefs to locate an index that contains information it needs. For example, it uses PSGetIndexDefs to locate an index that contains the key fields returned by PSGetKeyFields. This information allows the provider to locate the records that need to change when it applies updates. The provider also calls this method to locate indexes that it adds to the metadata of data packets.

IndexTypes indicates the options required of the returned indexes. PSGetIndexDefs returns all indexes whose Options property

includes the specified flags.

PSGetIndexDefs returns a TIndexDefs object that contains all the indexes of the dataset that match the IndexTypes parameter.

See Also

Options (see page 7291)

PSGetKeyFields (see page 7581)

PSGetDefaultOrder (see page 7580)

39.1.17.4.147 TDataSet.PSGetKeyFields Method

Returns the names of all fields required to uniquely identify records in the data packet.

Pascal

```
function PSGetKeyFields: string; virtual; deprecated;
```

C++

```
virtual __fastcall AnsiString PSGetKeyFields();
```

Description

The provider component calls PSGetKeyFields to determine what information is required to uniquely identify records in the data packet. This information allows it to locate the records that need to change when it applies updates.

PSGetKeyFields returns a semicolon-delimited string that lists the names of the key fields of the dataset. By default (as implemented by TDataSet), these are the fields with pfInKey included in their ProviderFlags property.

See Also

PSGetDefaultOrder (see page 7580)

ProviderFlags (see page 7176)

PSGetIndexDefs (see page 7581)

39.1.17.4.148 TDataSet.PSGetKeyFieldsW Method

Pascal

```
function PSGetKeyFieldsW: WideString; virtual;
```

C++

```
virtual __fastcall BSTR PSGetKeyFieldsW();
```

Description

This is PSGetKeyFieldsW, a member of class TDataSet.

39.1.17.4.149 TDataSet.PSGetParams Method

Returns the current parameter values of the dataset.

Pascal

```
function PSGetParams: TParams; virtual;
```

C++

```
virtual __fastcall TParams PSGetParams();
```

Description

The provider component calls PSGetParams to implement its GetParams method.

PSGetParams returns a TParams object that describes the current values of all parameters of the dataset. If the dataset does not have any parameters, PSGetParams returns nil (Delphi) or NULL (C++).

Note: The PSGetParams method should not create a new instance of TParams for the return value. The provider that calls PSGetParams does not free the returned value.

See Also

GetParams (see page 18467)

39.1.17.4.150 TDataSet.PSGetQuoteChar Method

Returns the character or characters to use in generated SQL statements to enclose quoted strings.

Pascal

```
function PSGetQuoteChar: string; virtual; deprecated;
```

C++

```
virtual __fastcall AnsiString PSGetQuoteChar();
```

Description

The provider component calls PSGetQuoteChar (indirectly) when generating the dynamic SQL statements that apply updates. These statements are subsequently executed by a call to PSExecuteStatement.

PSGetQuoteChar returns the character or characters that delimit quoted strings in the generated SQL. This string appears both before and after quoted strings.

See Also

applyupdates (see page 18459)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

39.1.17.4.151 TDataSet.PSGetQuoteCharW Method

Pascal

```
function PSGetQuoteCharW: WideString; virtual;
```

C++

```
virtual __fastcall BSTR PSGetQuoteCharW();
```

Description

This is PSGetQuoteCharW, a member of class TDataSet.

39.1.17.4.152 TDataSet.PSGetTableName Method

Returns the name of the dataset table that appears in generated SQL statements.

Pascal

```
function PSGetTableName: string; virtual; deprecated;
```

C++

```
virtual __fastcall AnsiString PSGetTableName();
```

Description

PSGetTableName returns the name of the underlying database table against which updates are applied when the provider's ResolveToDataSet property is false. This value is used for generating the SQL statements that apply updates. The generated SQL statements are subsequently executed by a call to PSExecuteStatement.

If PSGetTableName does not return a table name, the provider must have an OnGetTableName event handler to supply this value.

See Also

applyupdates (see page 18459)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

ongettablename (see page 18542)

39.1.17.4.153 TDataSet.PSGetTableNameW Method

Pascal

```
function PSGetTableNameW: WideString; virtual;
```

C++

```
virtual __fastcall BSTR PSGetTableNameW();
```

Description

This is PSGetTableNameW, a member of class TDataSet.

39.1.17.4.154 TDataSet.PSGetUpdateException Method

Generates an EUpdateError object based on another exception object.

Pascal

```
function PSGetUpdateException(E: Exception; Prev: EUpdateError): EUpdateError; virtual;
```

C++

```
virtual __fastcall EUpdateError PSGetUpdateException(Exception E, EUpdateError Prev);
```

Description

The provider component calls PSGetUpdateException when the exception E occurs while applying updates. This method allows the provider to create a single EUpdateError object that encapsulates all the exceptions that occur in an update operation.

PSGetUpdateError determines the error message, context string, and error code from the exception specified by E and creates a new EUpdateError exception that includes that information as well as the information about a previous error as specified by Prev. The context string and error code for E may be specific to the Exception class associated with the dataset. By default, TDataSet generates an EUpdateError with an error code of 1 and an empty context string.

See Also

Create (see page 6733)

39.1.17.4.155 TDataSet.PSInTransaction Method

Indicates whether actions against the dataset occur in the context of a transaction.

Pascal

```
function PSInTransaction: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PSInTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it first checks whether a transaction is already underway, and if not, generates one using PSStartTransaction. To determine whether a transaction is already underway, the provider calls PSInTransaction.

PSInTransaction returns true if there is a transaction underway, and false otherwise.

See Also

PSStartTransaction (see page 7586)

PSEndTransaction (see page 7578)

39.1.17.4.156 TDataSet.PSIsSQLBased Method

Indicates whether the dataset includes native SQL support.

Pascal

```
function PSIsSQLBased: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PSIsSQLBased();
```

Description

The provider calls PSIsSQLBased to determine whether the dataset supports some form of native SQL. This information is used when generating SQL commands that are executed by PSExecuteStatement.

Even if the dataset is not SQL-based, it may still allow the provider to execute SQL statements for applying updates. For example, BDE-enabled local databases such as Paradox and DBASE provide SQL support via the BDE's local SQL engine, but are not SQL-based. However, table and field names are not specified in the same way for the local SQL engine as they are for native SQL. The provider uses PSIsSQLBased to determine how these names should appear in generated SQL.

Note: The PSIsSQLSupported method indicates whether the dataset can execute SQL commands at all, regardless of whether the dataset is SQL-based.

See Also

PSIsSQLSupported (see page 7584)

PSExecuteStatement (see page 7579)

39.1.17.4.157 TDataSet.PSIsSQLSupported Method

Indicates whether the dataset can execute SQL statements.

Pascal

```
function PSIsSQLSupported: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PSIsSQLSupported();
```

Description

PSIsSQLSupported indicates whether the provider can call PSExecuteStatement to execute an SQL statement. When PSIsSQLSupported returns false, calling PSExecuteStatement generates an exception. The provider can still work with a dataset that returns false from PSIsSQLSupported, but it must set the ResolveToDataSet property to true, or provide data on a read-only basis.

See Also

PSIsSQLBased (see page 7584)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

39.1.17.4.158 TDataSet.PSReset Method

Resets the dataset so that it is positioned on the first record.

Pascal

```
procedure PSReset; virtual;
```

C++

```
virtual __fastcall PSReset();
```

Description

The provider calls PSReset to reposition the dataset on the first record before fetching records.

See Also

GetRecords (see page 18468)

AS_GetRecords (see page 16455)

39.1.17.4.159 PSSetCommandText Method

This is the overview for the PSSetCommandText method overload.

Overload List

	Name	Description
	TDataSet.PSSetCommandText (string) (see page 6989)	Assigns a specified SQL command to be executed by PSExecute.
	TDataSet.PSSetCommandText (WideString) (see page 6988)	This is PSSetCommandText, a member of class TDataSet.

39.1.17.4.159.1 TDataSet.PSSetCommandText Method (WideString)

Pascal

```
procedure PSSetCommandText(const CommandText: WideString); virtual; overload;
```

C++

```
virtual __fastcall PSSetCommandText(const BSTR CommandText);
```

Description

This is PSSetCommandText, a member of class TDataSet.

39.1.17.4.159.2 TDataSet.PSSetCommandText Method (string)

Assigns a specified SQL command to be executed by PSExecute.

Pascal

```
procedure PSSetCommandText(const CommandText: string); virtual; overload; deprecated;
```

C++

```
virtual __fastcall PSSetCommandText(const AnsiString CommandText);
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

The value of the CommandText parameter replaces the dataset's SQL statement (if it has one), or replaces the name of an underlying database table or stored procedure.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

39.1.17.4.160 TDataSet.PSSetParams Method

Assigns the specified parameter values to the dataset.

Pascal

```
procedure PSSetParams(AParams: TParams); virtual;
```

C++

```
virtual __fastcall PSSetParams(TParams AParams);
```

Description

PSSetParams assigns the parameter values specified by AParams to the parameters of the dataset.

See Also

Params (see page 8489)

PSGetParams (see page 7582)

39.1.17.4.161 TDataSet.PSStartTransaction Method

Starts a transaction that encapsulates all activity until a call to PSEndTransaction.

Pascal

```
procedure PSStartTransaction; virtual;
```

C++

```
virtual __fastcall PSStartTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it calls PSStartTransaction to start a transaction before applying updates, and calls PSEndTransaction when all updates are applied or too many errors are encountered.

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there is no transaction already established. That is, it does not assume nested transaction support is available.

See Also

PSEndTransaction (see page 7578)

PSInTransaction (see page 7583)

applyupdates (see page 18459)

39.1.17.4.162 TDataSet.PSUpdateRecord Method

Applies a single update to the underlying database table or tables.

Pascal

```
function PSUpdateRecord(UpdateKind: TUpdateKind; Delta: TDataSet): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PSUpdateRecord(TUpdateKind UpdateKind, TDataSet Delta);
```

Description

Before the provider generates SQL statements to apply an update, it calls PSUpdateRecord to let the dataset apply the update in some other fashion. For example, BDE-enabled datasets generate an OnUpdateRecord to allow the application to apply the update and, if the OnUpdateRecord event handler does not apply the update, uses any associated TUpdateSQL object to apply the update.

UpdateKind indicates whether the update is an insertion (ukInsert), deletion (ukDelete), or modification (ukModify).

Delta is the delta datapacket. The current record represents the record to be updated.

PSUpdateRecord returns true if it updates the record, false otherwise. If PSUpdateRecord returns false, the provider generates dynamic SQL to perform the update and calls PSExecuteStatement.

Note: PSUpdateRecord is only called if the provider's ResolveToDataSet property is false.

See Also

OnUpdateRecord (see page 9957)

TUpdateSQL (see page 10229)

applyupdates (see page 18459)

ResolveToDataSet (see page 18531)

PSExecuteStatement (see page 7579)

39.1.17.4.163 TDataSet.Refresh Method

Re-fetches data from the database to update a dataset's view of data.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh to ensure that an application has the latest data from a database. For example, when an application turns off filtering for a dataset, it should immediately call Refresh to display all records in the dataset, not just those that used to meet the filter condition.

Note: The Refresh method does not work for all TDataSet (see page 6894) descendants. In particular, TQuery components do not support the Refresh method if the query is not "live". To refresh a static TQuery, close and reopen the dataset.

TDataSet (see page 6894) generates a BeforeRefresh (see page 7052) event before refreshing the records and an AfterRefresh (see page 7047) event afterwards.

Note: Most datasets try to maintain the current record position when you call refresh. However, this is not always possible. For example, the current record may have been deleted from the server by another user. Unidirectional datasets have no mechanism for locating the current record after a refresh, and always move back to the first record.

Warning: Unidirectional datasets refresh the data by closing and reopening the cursor. This can have unintended side effects if, for example, you have code in the BeforeClose (see page 7048), AfterClose (see page 7040), BeforeOpen (see page 7051), or AfterOpen (see page 7045) event handlers.

Delphi Examples:

```
{
The following example sets a range for a dataset. The form
requires two edit boxes, a data source, a client dataset or
table, a db grid, and a button.  Make sure that the Table1
info in FormActivate agrees with the table used.  Also, the
caption for the button must be initialized to '&ApplyRange'.
}

procedure TForm1.FormActivate(Sender: TObject);
begin
  Table1.DatabaseName := 'DBDEMOS';
  Table1.TableName := 'CustInfo';
  Table1.Active := True;
  Table1.IndexName := '';
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  if Button2.Caption = '&Apply Range' then
    begin
      Table1.SetRange([Edit1.Text],[Edit2.Text]);
      Button2.Caption := '&Drop Range';
    end
  else
    begin
      Table1.CancelRange;
```

```
      Table1.Refresh;
      Button2.Caption := '&Apply Range';
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else

Refreshing Data Display

Refreshing Records

39.1.17.4.164 TDataSet.RefreshInternalCalcFields Method

Pascal

```
procedure RefreshInternalCalcFields(Buffer: PChar); virtual;
```

C++

```
virtual __fastcall RefreshInternalCalcFields(const char * Buffer);
```

Description

This is RefreshInternalCalcFields, a member of class TDataSet.

39.1.17.4.165 TDataSet.ResetAggField Method

Pascal

```
procedure ResetAggField(Field: TField); virtual;
```

C++

```
virtual __fastcall ResetAggField(TField Field);
```

Description

This is ResetAggField, a member of class TDataSet.

39.1.17.4.166 TDataSet.RestoreState Method

Pascal

```
procedure RestoreState(const Value: TDataSetState);
```

C++

```
__fastcall RestoreState(const TDataSetState Value);
```

Description

This is RestoreState, a member of class TDataSet.

39.1.17.4.167 TDataSet.Resync Method

Re-fetches the active record and the records that precede and follow it.

Pascal

```
procedure Resync(Mode: TResyncMode); virtual;
```

C++

```
virtual __fastcall Resync(TResyncMode Mode);
```

Description

Resync is used internally by other dataset methods to resynchronize the dataset with underlying physical data when making calls that may change the internal cursor position. Applications should use the Refresh (see page 6991) method instead of calling Resync.

Mode indicates optional processing that Resync should handle. If Mode contains rmExact, Resync raises an exception if Resync is called when the cursor is not positioned on a valid record. If Mode contains rmCenter, Resync positions the active record in the center of all buffered records.

Regardless of Mode, Resync also activates the buffers for the active record, retrieves prior and subsequent records for display purposes, and triggers a dataset change event.

Refresh (see page 6991)

39.1.17.4.168 TDataSet.SetActive Method

Pascal

```
procedure SetActive(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetActive(Boolean Value);
```

Description

This is SetActive, a member of class TDataSet.

39.1.17.4.169 TDataSet.SetBlockReadSize Method

Pascal

```
procedure SetBlockReadSize(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetBlockReadSize(int Value);
```

Description

This is SetBlockReadSize, a member of class TDataSet.

39.1.17.4.170 TDataSet.SetBookmarkData Method

Pascal

```
procedure SetBookmarkData(Buffer: PChar; Data: Pointer); virtual;
```

C++

```
virtual __fastcall SetBookmarkData(const char * Buffer, void * Data);
```

Description

This is SetBookmarkData, a member of class TDataSet.

39.1.17.4.171 TDataSet.SetBookmarkFlag Method

Pascal

```
procedure SetBookmarkFlag(Buffer: PChar; Value: TBookmarkFlag); virtual;
```

C++

```
virtual __fastcall SetBookmarkFlag(const char * Buffer, TBookmarkFlag Value);
```

Description

This is SetBookmarkFlag, a member of class TDataSet.

39.1.17.4.172 TDataSet.SetBookmarkStr Method

Pascal

```
procedure SetBookmarkStr(const Value: TBookmarkStr); virtual;
```

C++

```
virtual __fastcall SetBookmarkStr(const TBookmarkStr Value);
```

Description

This is SetBookmarkStr, a member of class TDataSet.

39.1.17.4.173 TDataSet.SetBufListSize Method

Pascal

```
procedure SetBufListSize(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetBufListSize(int Value);
```

Description

This is SetBufListSize, a member of class TDataSet.

39.1.17.4.174 TDataSet.SetChildOrder Method

Pascal

```
procedure SetChildOrder(Component: TComponent; Order: Integer); override;
```

C++

```
virtual __fastcall SetChildOrder(TComponent * Component, int Order);
```

Description

This is SetChildOrder, a member of class TDataSet.

39.1.17.4.175 TDataSet.SetCurrentRecord Method

Pascal

```
procedure SetCurrentRecord(Index: Integer); virtual;
```

C++

```
virtual __fastcall SetCurrentRecord(int Index);
```

Description

This is SetCurrentRecord, a member of class TDataSet.

39.1.17.4.176 TDataSet.SetDataSetField Method

Pascal

```
procedure SetDataSetField(const Value: TDataSetField); virtual;
```

C++

```
virtual __fastcall SetDataSetField(const TDataSetField Value);
```

Description

This is SetDataSetField, a member of class TDataSet.

39.1.17.4.177 TDataSet.SetDefaultFields Method

Pascal

```
procedure SetDefaultFields(const Value: Boolean);
```

C++

```
__fastcall SetDefaultFields(const Boolean Value);
```

Description

This is SetDefaultFields, a member of class TDataSet.

39.1.17.4.178 SetFieldData Method

This is the overview for the SetFieldData method overload.

Overload List

	Name	Description
	TDataSet.SetFieldData (TField, Pointer) (see page 6996)	This is SetFieldData, a member of class TDataSet.
	TDataSet.SetFieldData (TField, Pointer, Boolean) (see page 6997)	This is SetFieldData, a member of class TDataSet.

39.1.17.4.178.1 TDataSet.SetFieldData Method (TField, Pointer)

Pascal

```
procedure SetFieldData(Field: TField; Buffer: Pointer); virtual; overload;
```

C++

```
virtual __fastcall SetFieldData(TField Field, void * Buffer);
```

Description

This is SetFieldData, a member of class TDataSet.

39.1.17.4.178.2 TDataSet.SetFieldData Method (TField, Pointer, Boolean)

Pascal

```
procedure SetFieldData(Field: TField; Buffer: Pointer; NativeFormat: Boolean); virtual;
overload;
```

C++

```
virtual __fastcall SetFieldData(TField Field, void * Buffer, Boolean NativeFormat);
```

Description

This is SetFieldData, a member of class TDataSet.

39.1.17.4.179 TDataSet.SetFields Method

Sets the values for all fields in a record

Pascal

```
procedure SetFields(const Values: array of const);
```

C++

```
__fastcall SetFields(const array of const Values);
```

Description

Call SetFields to set values for some or all fields in the active record at the same time.

Values contains the values to insert into each field. Values are assigned to the record based on the order of columns in the table or tables underlying the dataset. These values can be literals, variables, NULL, or nil (Delphi). If Values contains fewer values than there are fields in the record, all records for which values are not provided are assigned a NULL value. A NULL value overwrites any existing value in such fields.

In C++, Values_Size is the index of the last value in the Values array (one less than the total number of values).

Before calling SetFields, call Edit (see page 6932) to put the dataset into dsEdit state. After calling SetFields, call Post (see page 6977) to write the changes to the database or change log.

Note: To set values for some fields while retaining existing values for others, pass nil (Delphi) or NULL (C++) (explicitly casting it to void * in C++) for each field that should not change.

39.1.17.4.180 TDataSet.SetFiltered Method

Pascal

```
procedure SetFiltered(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetFiltered(Boolean Value);
```

Description

This is SetFiltered, a member of class TDataSet.

39.1.17.4.181 TDataSet.SetFilterOptions Method

Pascal

```
procedure SetFilterOptions(Value: TFilterOptions); virtual;
```

C++

```
virtual __fastcall SetFilterOptions(TFilterOptions Value);
```

Description

This is SetFilterOptions, a member of class TDataSet.

39.1.17.4.182 TDataSet.SetFilterText Method

Pascal

```
procedure SetFilterText(const Value: string); virtual;
```

C++

```
virtual __fastcall SetFilterText(const AnsiString Value);
```

Description

This is SetFilterText, a member of class TDataSet.

39.1.17.4.183 TDataSet.SetFound Method

Pascal

```
procedure SetFound(const Value: Boolean);
```

C++

```
__fastcall SetFound(const Boolean Value);
```

Description

This is SetFound, a member of class TDataSet.

39.1.17.4.184 TDataSet.SetModified Method

Pascal

```
procedure SetModified(Value: Boolean);
```

C++

```
__fastcall SetModified(Boolean Value);
```

Description

This is SetModified, a member of class TDataSet.

39.1.17.4.185 TDataSet.SetName Method

Sets the value of the Name property.

Pascal

```
procedure SetName(const Value: TComponentName); override;
```

C++

```
virtual __fastcall SetName(const TComponentName Value);
```

Description

SetName is the virtual property setter for the Name property. It calls the ChangeName method, which performs the actual name change.

ChangeName is not virtual; override SetName instead when modifying the behavior of the Name property.

Warning: Using SetName to change the name of a component at runtime causes any references to the old name to become undefined. Any subsequent code that uses the old name will cause an exception.

39.1.17.4.186 TDataSet.SetObjectView Method

Pascal

```
procedure SetObjectView(const Value: Boolean);
```

C++

```
__fastcall SetObjectView(const Boolean Value);
```

Description

This is SetObjectView, a member of class TDataSet.

39.1.17.4.187 TDataSet.SetOnFilterRecord Method

Pascal

```
procedure SetOnFilterRecord(const Value: TFilterRecordEvent); virtual;
```

C++

```
virtual __fastcall SetOnFilterRecord(const TFilterRecordEvent Value);
```

Description

This is SetOnFilterRecord, a member of class TDataSet.

39.1.17.4.188 TDataSet.SetRecNo Method

Pascal

```
procedure SetRecNo(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetRecNo(int Value);
```

Description

This is SetRecNo, a member of class TDataSet.

39.1.17.4.189 TDataSet.SetState Method

Pascal

```
procedure SetState(Value: TDataSetState);
```

C++

```
__fastcall SetState(TDataSetState Value);
```

Description

This is SetState, a member of class TDataSet.

39.1.17.4.190 TDataSet.SetStateFieldValue Method

Pascal

```
procedure SetStateFieldValue(State: TDataSetState; Field: TField; const Value: Variant);
virtual;
```

C++

```
virtual __fastcall SetStateFieldValue(TDataSetState State, TField Field, const Variant Value);
```

Description

This is SetStateFieldValue, a member of class TDataSet.

39.1.17.4.191 TDataSet.SetTempState Method

Pascal

```
function SetTempState(const Value: TDataSetState): TDataSetState;
```

C++

```
__fastcall TDataSetState SetTempState(const TDataSetState Value);
```

Description

This is SetTempState, a member of class TDataSet.

39.1.17.4.192 TDataSet.SetUniDirectional Method

Pascal

```
procedure SetUniDirectional(const Value: Boolean);
```

C++

```
__fastcall SetUniDirectional(const Boolean Value);
```

Description

This is SetUniDirectional, a member of class TDataSet.

39.1.17.4.193 TDataSet.TempBuffer Method

Pascal

```
function TempBuffer: PChar;
```

C++

```
__fastcall const char * TempBuffer();
```

Description

This is TempBuffer, a member of class TDataSet.

39.1.17.4.194 TDataSet.Translate Method

Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.

Pascal

```
function Translate(Src: PChar; Dest: PChar; ToOem: Boolean): Integer; virtual;
```

C++

```
virtual __fastcall int Translate(const char * Src, const char * Dest, Boolean ToOem);
```

Description

As implemented by TDataSet (see page 6894), Translate copies a source string to a destination string, and ignores the value passed in ToOem. Translate provides a fallback method for derived dataset objects that do not reimplement Translate.

In BDE-enabled datasets, Translate converts the source string from ANSI (the native character mapping for the VCL) to OEM (the native character mapping for the BDE) when ToOem is true, and reverses that translation when ToOem is false.

Custom datasets can use Translate to convert strings between ANSI UTF-8 (the native character mapping for dataset components) and any character mapping used by the underlying data access mechanism. When ToOem is true, Translate converts from ANSI to the underlying data access mapping. When ToOem is false, Translate reverses that conversion.

39.1.17.4.195 TDataSet.UpdateBufferCount Method

Pascal

```
procedure UpdateBufferCount;
```

C++

```
__fastcall UpdateBufferCount();
```

Description

This is UpdateBufferCount, a member of class TDataSet.

39.1.17.4.196 TDataSet.UpdateCursorPos Method

Positions the cursor on the active record.

Pascal

```
procedure UpdateCursorPos;
```

C++

```
__fastcall UpdateCursorPos();
```

Description

UpdateCursorPos is an internal routine used by many dataset methods to ensure that the physical cursor is positioned on the active record. Normally an application should not need to call UpdateCursorPos. Typically UpdateCursorPos is called to ensure that the physical cursor position matches the logical cursor position.

See Also

RecNo (see page 7031)

CursorPosChanged (see page 6923)

Refresh (see page 6991)

Resync (see page 6994)

CurrentRecord (see page 7013)

39.1.17.4.197 TDataSet.UpdateIndexDefs Method

Pascal

```
procedure UpdateIndexDefs; virtual;
```

C++

```
virtual __fastcall UpdateIndexDefs();
```

Description

This is UpdateIndexDefs, a member of class TDataSet.

39.1.17.4.198 TDataSet.UpdateRecord Method

Ensures that data-aware controls and detail datasets reflect record updates.

Pascal

```
procedure UpdateRecord;
```

C++

```
__fastcall UpdateRecord();
```

Description

UpdateRecord is used internally by some dataset methods to inform data-aware controls of updates and trigger an OnUpdateRecord event if cached updates are enabled. Applications should not need to call UpdateRecord directly unless they provide custom dataset methods that bypass TDataSet (see page 6894) methods.

See Also

OnUpdateRecord (see page 9957)

39.1.17.4.199 TDataSet.UpdateStatus Method

Reports the update status for the active record.

Pascal

```
function UpdateStatus: TUpdateStatus; virtual;
```

C++

```
virtual __fastcall TUpdateStatus UpdateStatus();
```

Description

As implemented in TDataSet (see page 6894), UpdateStatus always returns usUnmodified. Descendant classes override this method to reflect whether the active record has been modified, and if so, how.

39.1.17.5 TDataSet Properties

The properties of the TDataSet class are listed here.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.

	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.

39.1.17.5.1 TDataSet.Active Property

Specifies whether or not a dataset is open.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Use Active to determine or set whether a dataset is populated with data. When Active is false, the dataset is closed; the dataset cannot read or write data and data-aware controls can not use it to fetch data or post edits. When Active is true, the dataset can be populated with data. It can read data from a database or other source (such as a provider). Depending on the CanModify (see page 7012) property, active datasets can post changes.

Setting Active to true:

1. Generates a BeforeOpen (see page 7051) event.
2. Sets the dataset state to dsBrowse.
3. Establishes a way to fetch data (typically by opening a cursor).
4. Generates an AfterOpen (see page 7045) event.

If an error occurs while opening the dataset, dataset state is set to dsInactive, and any cursor is closed.

Setting Active to false:

1. Triggers a BeforeClose (see page 7048) event.
2. Sets the State (see page 7036) property to dsInactive.
3. Closes the cursor.
4. Triggers an AfterClose (see page 7040) event.

An application must set Active to false before changing other properties that affect the status of a database or the controls that display data in an application.

Note: Calling the Open (see page 6976) method sets Active to true; calling the Close (see page 6920) method sets Active to false.

Delphi Examples:

```
{
```

```
  This example requires a database with the following name or
  in the form of a *.DB file in the following path.  The table
  should be closed when changing the database.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Customers.Active := False;
    try
    { First try to use an alias }
      Customers.DatabaseName := 'DBDEMOS';
      Customers.Active := True;
    except
      on EDatabaseError do
      begin
        { If that fails, try to use the drive and directory }
        Customers.TableName := 'Flights';
        Customers.DatabaseName :=
          'c:\Documents and Settings\All Users\Documents\RAD
  Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data';
        Customers.Active := True;
      end;
    end;
  end;
```

Opening and Closing Datasets

Fetching the Data

39.1.17.5.2 TDataSet.ActiveRecord Property

Indicates the index of the active record in the internal cache of records.

Pascal

```
property ActiveRecord: Integer;
```

C++

```
__property int ActiveRecord;
```

Description

Most TDataSet (see page 6894) descendants maintain an internal cache of records from the underlying database table. This cache is used, for example, when the dataset is used to populate a data-aware grid, in which case it includes a record for each

row in the grid. ActiveRecord indicates the offset in this cache of the record buffer for the active record. This active record is the value returned by the public ActiveBuffer (see page 6909) method.

Note: Unidirectional datasets never cache records. For unidirectional datasets, the ActiveRecord property is meaningless (and always 0).

See Also

CurrentRecord (see page 7013)

RecNo (see page 7031)

Bookmark (see page 7009)

ActiveBuffer (see page 6909)

BufferCount (see page 6890)

Buffers (see page 7011)

IsUniDirectional (see page 7029)

39.1.17.5.3 TDataSet.AggFields Property

Contains any aggregate fields.

Pascal

```
property AggFields: TFields;
```

C++

```
__property TFields AggFields;
```

Description

Some TDataSet (see page 6894) descendants, such as TClientDataSet, support aggregate fields. Aggregate fields summarize data over groups of records from the dataset (as opposed to calculated fields, which can only summarize data over the fields of a single record). AggFields is a collection of all aggregate fields that are supported by the dataset.

Note: The Fields (see page 7023) property is a collection of all the dataset's fields that are not aggregate fields. Thus, AggFields and Fields (see page 7023) are mutually exclusive collections of the dataset's fields. These two properties contain all of the dataset's fields between them.

Obtaining Aggregate Values

39.1.17.5.4 TDataSet.AutoCalcFields Property

Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.

Pascal

```
property AutoCalcFields: Boolean;
```

C++

```
__property Boolean AutoCalcFields;
```

Description

Set AutoCalcFields to control when the OnCalcFields (see page 7053) event is triggered to update calculated fields and when lookup fields are calculated.

A calculated field is one that derives its value from the values of one or more fields in the active record, sometimes with additional processing. Lookup (see page 6970) fields are fields whose values come from a secondary dataset or lookup cache.

Note: Unidirectional datasets support calculated fields but not unidirectional fields. For unidirectional datasets, OnCalcFields (see page 7053) only controls when calculated fields are updated.

When AutoCalcFields is true (the default), Lookup (see page 6970) fields are recalculated and OnCalcFields (see page 7053) is triggered when:

The dataset is opened.

The dataset is put into dsEdit state.

Focus moves from one visual control to another, or from one column to another in a data-aware grid and modifications have been made to the record.

When AutoCalcFields is false, Lookup (see page 6970) fields are recalculated and the OnCalcFields (see page 7053) event occurs only when

The dataset is opened.

The dataset is put into dsEdit state.

A record is retrieved from a database.

If an application permits users to change data, OnCalcFields (see page 7053) is frequently triggered. In these cases an application may set AutoCalcFields to false to reduce the frequency with which the OnCalcFields (see page 7053) event occurs and with which lookup values are fetched.

OnCalcFields (see page 7053)

Calculating Fields

39.1.17.5.5 TDataSet.BlobFieldCount Property

Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.

Pascal

```
property BlobFieldCount: Integer;
```

C++

```
__property int BlobFieldCount;
```

Description

Descendants of TDataSet (see page 6894) use BlobFieldCount when determining how to handle BLOB information.

39.1.17.5.6 TDataSet.BlockReadSize Property

Determines how many record buffers are read in each block.

Pascal

```
property BlockReadSize: Integer;
```

C++

```
__property int BlockReadSize;
```

Description

Setting BlockReadSize to a value greater than 0 puts the dataset in the dsBlockRead state. It remains in that state until you set BlockReadSize to 0 or change the dataset's state in some other manner (such as putting it in edit mode).

For all TDataSet (see page 6894) descendants, data-aware controls are not updated and data events are not triggered when the dataset is in the dsBlockRead state. Thus, you can set BlockReadSize to a positive value to scan through the entire dataset quickly without updating data-aware controls.

For BDE-enabled datasets, setting BlockReadSize also causes the dataset to fetch database information in blocks of BlockReadSize records, which it then buffers. This minimizes traffic between your application and the database server.

See Also

State (see page 7036)

Next (see page 6973)

39.1.17.5.7 TDataSet.Bof Property

Indicates whether the first record in the dataset is active.

Pascal

```
property Bof: Boolean;
```

C++

```
__property Boolean Bof;
```

Description

Test Bof (beginning of file) to determine if the dataset is positioned at the first record. If Bof is true, the active record is unequivocally the first row in the dataset. Bof is true when an application.

Opens a dataset.

Calls a dataset's First (see page 6942) method.

Call a dataset's Prior (see page 6979) method, and the method fails because the first row is already active.

Calls SetRange on an empty range or dataset.

Bof is false in all other cases.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
```

```
      { get a bookmark so that we can return to the same record }
      SavePlace := GetBookmark;
      try
        { move to prior record}
        FindPrior;
        { get the value }
        PrevValue := Fields[1].Value;
        {Move back to the bookmark
        this may not be the next record anymore
        if something else is changing the dataset asynchronously }
        GotoBookmark(SavePlace);
        { Set the value }
        Edit;
        Fields[1].Value := PrevValue;
        { Free the bookmark }
      finally
        FreeBookmark(SavePlace);
      end;
    end;
  end;

  {
  To ensure that the button is disabled when there is no
  previous record, the OnDataChange event of the DataSource
  detects when the user moves to the beginning of file (BOF
  property becomes true), and disables the button.  Detection
  occurs on scrolling and editing, not selection with the mouse.
  }
  procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
  begin
    if Customers.Bof then
      Button1.Enabled := False
    else
      Button1.Enabled := True;
  end;
```

39.1.17.5.8 TDataSet.Bookmark Property

Specifies the current bookmark in the dataset.

Pascal

```
property Bookmark: TBookmarkStr;
```

C++

```
__property TBookmarkStr Bookmark;
```

Description

Bookmark gets or sets the current bookmark in a dataset. A bookmark marks a location in a dataset so that an application can easily return to that location quickly.

An application can read Bookmark to retrieve the bookmark associated with the current record, and it can change the current record in the dataset by assigning a saved bookmark value to this property.

Note: Unidirectional datasets do not support bookmarks.

See Also

GetBookmark (see page 6948)

GotoBookmark (see page 6957)

FreeBookmark (see page 6945)

Marking and Returning to Records

39.1.17.5.9 TDataSet.BookmarkSize Property

Indicates the number of bytes used to represent a bookmark.

Pascal

```
property BookmarkSize: Integer;
```

C++

```
__property int BookmarkSize;
```

Description

Bookmarks mark a location in a dataset so that an application can easily return to that location quickly. Descendants of TDataSet (see page 6894) can use different mechanisms for storing enough information to identify records when applications set bookmarks. BookmarkSize indicates the number of bytes required to specify bookmark information for a particular dataset.

Note: Unidirectional datasets do not support bookmarks.

See Also

Bookmark (see page 7009)

GetBookmark (see page 6948)

FreeBookmark (see page 6945)

39.1.17.5.10 TDataSet.BufferCount Property

Indicates the number of records in the internal cache.

Pascal

```
property BufferCount: Integer;
```

C++

```
__property int BufferCount;
```

Description

All TDataSet (see page 6894) descendants except for unidirectional datasets maintain an internal cache of records from the underlying database tables. For example, if the dataset is used to populate a data-aware grid, the cache includes a record for each row in the grid. BufferCount indicates the size of this cache.

BufferCount is read-only. An associated TDataLink (see page 6876) object determines its value.

See Also

CurrentRecord (see page 7013)

ActiveBuffer (see page 6909)

BufferCount (see page 6890)

ActiveRecord (see page 7005)

Buffers (see page 7011)

39.1.17.5.11 TDataSet.Buffers Property

Provides indexed access to the record buffers in the internal cache.

Pascal

```
property Buffers [Index: Integer]: PChar;
```

C++

```
__property const char * Buffers[int Index];
```

Description

All TDataSet (see page 6894) descendants except for unidirectional datasets maintain an internal cache of records from the underlying database table. For example, if the dataset is used to populate a data-aware grid, the cache includes a record for each row in the grid.

For datasets that cache records, each entry in Buffers points to a record buffer in the internal cache. The BufferCount (see page 7010) property specifies the total number of record buffers in the cache.

See Also

BufferCount (see page 7010)

CurrentRecord (see page 7013)

39.1.17.5.12 TDataSet.CalcBuffer Property

Points to the record buffer used during an OnCalcFields (see page 7053) event.

Pascal

```
property CalcBuffer: PChar;
```

C++

```
__property const char * CalcBuffer;
```

Description

Datasets use CalcBuffer to retrieve and store values when in the dsCalcFields state. The values of lookup fields and calculated fields are set in CalcBuffer, based on data field values retrieved from this buffer.

Most applications do not need to explicitly reference CalcBuffer. It is used automatically when the dataset is in the dsCalcFields state.

See Also

OnCalcFields (see page 7053)

State (see page 7036)

39.1.17.5.13 TDataSet.CalcFieldsSize Property

Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.

Pascal

```
property CalcFieldsSize: Integer;
```

C++

```
__property int CalcFieldsSize;
```

Description

TDataSet (see page 6894) uses CalcFieldsSize to determine whether there are any calculated fields or lookup fields to calculate. Descendants of TDataSet (see page 6894) use this property when locating fields in a record buffer.

See Also

CalcBuffer (see page 7011)

39.1.17.5.14 TDataSet.CanModify Property

Indicates whether the dataset permits write access to data.

Pascal

```
property CanModify: Boolean;
```

C++

```
__property Boolean CanModify;
```

Description

As implemented in TDataSet (see page 6894), this property is false if the dataset is unidirectional, and true otherwise. Descendant classes reimplement this property as follows

For unidirectional datasets, CanModify is always false.

For client datasets, CanModify reflects the value of the ReadOnly property and whether a data provider supplied a read-only data packet.

Other datasets reflect whether the dataset has write access to data.

DataSource (see page 7014)

AutoEdit (see page 7077)

ReadOnly (see page 8493)

Editing Data in a Control

Editing in the Grid

Adding New Records

Controlling Read/Write Access to Tables

Editing Records

Using Unidirectional Datasets

39.1.17.5.15 TDataSet.Constraints Property

Specifies record-level constraints that must be met when editing the data.

Pascal

```
property Constraints: TCheckConstraints;
```

C++

```
__property TCheckConstraints Constraints;
```

Description

Use Constraints to read or add record-level constraints to the dataset. Record-level constraints usually impose relationships between the fields in a single record. Constraints that limit the value of a single field should be added to the individual field components.

See Also

TCheckConstraint (see page 6841)

CustomConstraint (see page 7156)

ImportedConstraint (see page 7167)

Constraining Data Values

39.1.17.5.16 TDataSet.CurrentRecord Property

Indicates the index of the current record in the internal cache of record buffers.

Pascal

```
property CurrentRecord: Integer;
```

C++

```
__property int CurrentRecord;
```

Description

Most TDataSet (see page 6894) descendants maintain an internal cache of records from the underlying database table. For example, if the dataset is used to populate a data-aware grid, the cache includes a record for each row in the grid. CurrentRecord indicates the offset in this cache of the record buffer for the current record.

The current record is the record currently in use by the dataset. This can differ from the active record (which the end user sees as active) when the dataset performs operations involving other records. For example, when painting a data-aware grid, CurrentRecord cycles through all the visible records, while ActiveRecord (see page 7005) remains constant.

Note: For unidirectional datasets, CurrentRecord is meaningless.

See Also

GetCurrentRecord (see page 6950)

ActiveRecord (see page 7005)

39.1.17.5.17 TDataSet.DataSetField Property

Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.

Pascal

```
property DataSetField: TDataSetField;
```

C++

```
__property TDataSetField DataSetField;
```

Description

Use DataSetField when the dataset is the nested detail set of another dataset, such as an Oracle8 nested dataset. Read DataSetField to access the data set field component in the master dataset that includes this dataset as a detail. Set DataSetField to a field component in the master dataset to assign this dataset as the value of that field.

Note: When setting the DataSetField property, the dataset must be of (or a descendant of) the class specified by the master dataset's NestedDataSetClass (see page 7030) property. Otherwise, setting DataSetField raises an exception. Further, setting DataSetField to a TDataSetField (see page 7060) that is contained in the same dataset raises an exception (A dataset can't be nested in itself).

TNestedTable (see page 10040)

NestedDataSet (see page 7070)

NestedDataSetClass (see page 7030)

Using Nested Detail Tables

Working with DataSet Fields

Working with Reference Fields

39.1.17.5.18 TDataSet.DataSource Property

Represents the data source of another dataset that supplies values to the dataset.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

As implemented in TDataSet (see page 6894), the DataSource property is always nil (Delphi) or NULL (C++).

Descendant dataset classes that support specifying a data source redeclare and implement methods for getting and setting the DataSource property.

See Also

Active (see page 7004)

IsLinkedTo (see page 6967)

Establishing Master/detail Relationships Using Parameters

39.1.17.5.19 TDataSet.DefaultFields Property

Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.

Pascal

```
property DefaultFields: Boolean;
```

C++

```
__property Boolean DefaultFields;
```

Description

Read DefaultFields to determine whether a dataset uses dynamically generated field components or persistent field components. If DefaultFields is true, the dataset uses dynamically allocated field components. If DefaultFields is false, the dataset uses persistent field components.

Unless persistent field components are assigned to a dataset at design time using the Fields (see page 7023) editor, the dataset creates dynamic field components based on the structure of its underlying data when it is opened.

See Also

Active (see page 7004)

Fields (see page 7023)

Open (see page 6976)

39.1.17.5.20 TDataSet.Designer Property

Returns a pointer to the Dataset designer for the dataset.

Pascal

```
property Designer: TDataSetDesigner;
```

C++

```
__property TDataSetDesigner Designer;
```

Description

Use Designer to determine whether the dataset is currently being designed and, if so, to access the dataset designer. When a dataset designer, such as the Fields (see page 7023) editor, is created for a dataset at design time, it sets the Designer property to itself. When the dataset designer is destroyed, the Designer property is set back to nil (Delphi) or NULL (C++). A Dataset designer enables a developer to specify the fields that belong to a dataset at design time.

See Also

DefaultFields (see page 7014)

Fields (see page 7023)

39.1.17.5.21 TDataSet.Eof Property

Indicates whether a dataset is positioned at the last record.

Pascal

```
property Eof: Boolean;
```

C++

```
__property Boolean Eof;
```

Description

Test Eof (end-of-file) to determine if the active record in a dataset is the last record. If Eof is true, the current record is unequivocally the last row in the dataset. Eof is true when an application:

Opens an empty dataset.

Calls a dataset's Last (see page 6968) method. (Unless it is a unidirectional dataset)

Call a dataset's Next (see page 6973) method, and the method fails because the current record is already the last row in the dataset.

Calls SetRange on an empty range or dataset.

Eof is false in all other cases.

Tip: If both Eof and Bof (see page 7008) are true, the dataset or range is empty.

Delphi Examples:

```
{
Usually DisableControls is called within the context of a
try...finally block that reenables the controls even if an
exception occurs. For example:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  ListBox1.Clear;
  ListBox1.Items[0]:= 'Destination Airports:';
  with Flights do
  begin
    DisableControls;
    try
      First;
      i:= 1;
      ListBox1.Items[0]:= 'Destination Airports:';
      while not Eof do
      begin
        ListBox1.Items[i]:= Fields[2].Value;;
        i:= i + 1;
        Next;
      end;
    finally
      EnableControls;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Flights:= TTable.Create(Form1);
  with Flights do
  begin
    TableName := 'Flights';
    DatabaseName := 'Flights';

  end;
  DS2.DataSet:= Flights;
  DBGrid2.DataSource.DataSet:=
    c:\Documents and Settings\All Users\Documents\RAD
Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data;
  Flights.Active:= True;
end;
```

39.1.17.5.22 TDataSet.FieldCount Property

Indicates the number of field components associated with the dataset.

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

Examine FieldCount to determine the number of fields listed by the Fields (see page 7023) property. For datasets with dynamically created fields, FieldCount may differ each time a dataset is opened. For datasets with persistent fields, FieldCount should be unchanged each time a dataset is open.

Note: FieldCount includes only the fields listed by the Fields (see page 7023) property. Any aggregated fields listed by the AggFields (see page 7006) property are not included in the count.

Delphi Examples:

```
{
This example displays a message box with the names of all
fields in a table.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   i: Integer;
   Info: String;
begin
   Info := 'The fields of table ' + Table1.TableName +
           ' are:'#13#10#13#10;
   for i := 0 to Table1.FieldCount - 1 do
      Info := Info + Table1.Fields[i].FieldName + #13#10;
  ShowMessage(Info);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
```

```
      DatabaseName := 'DBDEMOS';
      TableType := ttParadox;
      TableName := 'CustInfo';
      Table1.Active := False;
      { Don't overwrite an existing table }
      if not Table1.Exists then
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= True;
  end;
```

See Also

DefaultFields (see page 7014)

Designer (see page 7015)

Fields (see page 7023)

39.1.17.5.23 TDataSet.FieldDefList Property

Points to the list of field definitions for the dataset.

Pascal

```
property FieldDefList: TFieldDefList;
```

C++

```
__property TFieldDefList FieldDefList;
```

Description

FieldDefList points to an internal list of field definitions for the dataset. FieldDefList represents a flattened view of the data, meaning that object fields in the dataset may be represented by several simple field definitions that represent the constituents of the object field. To determine the definitions in a hierarchical view, use FieldDefs (see page 7019) instead.

To access fields and field values in a dataset, use the Fields (see page 7023), AggFields (see page 7006), and FieldValues (see page 7025) properties, and the FieldByName (see page 6936) method.

See Also

FieldDefs (see page 7019)

ObjectView (see page 7031)

TObjectField (see page 7372)

Fields (see page 7023)

AggFields (see page 7006)

FieldValues (see page 7025)

FieldByName (see page 6936)

39.1.17.5.24 TDataSet.FieldDefs Property

Points to the list of field definitions for the dataset.

Pascal

```
property FieldDefs: TFieldDefs;
```

C++

```
__property TFieldDefs FieldDefs;
```

Description

FieldDefs lists the field definitions for a dataset. While an application can examine FieldDefs to explore the field definitions for a dataset, it should not change these definitions unless creating a new table with CreateTable or CreateDataSet.

To access fields and field values in a dataset, use the Fields (see page 7023), AggFields (see page 7006), and FieldValues (see page 7025) properties, and the FieldsByName method.

Note: If the dataset includes object field descendants, FieldDefs represents a hierarchical view of the data, meaning that the definitions include object field definitions. To determine the definitions in a flattened view, use FieldDefList (see page 7019) instead.

C++ Examples:

```
/*
The following code creates and activates a client dataset in
the form's OnCreate event handler.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TFieldDefs *pDefs = CDS2->FieldDefs;
  TFieldDef *pDef = pDefs->AddFieldDef();
  pDef->DataType = ftInteger;
  pDef->Name = "Field1";

  pDef = pDefs->AddFieldDef();
  pDef->DataType = ftString;
  pDef->Size = 10;
  pDef->Name = "Field2";

  TIndexDef *pIDef = CDS2->IndexDefs->AddIndexDef();
  pIDef->Fields = "Field1";
  pIDef->Name = "IntIndex";

  CDS2->CreateDataSet();
}
```

Delphi Examples:

```
{
The following code creates and activates a client dataset in
the form's OnCreate event handler.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with CDS2 do
  begin
    with FieldDefs.AddFieldDef do
    begin
      DataType := ftInteger;
      Name := 'Field1';
    end;
    with FieldDefs.AddFieldDef do
    begin
      DataType := ftString;
      Size := 10;
      Name := 'Field2';
    end;
    with IndexDefs.AddIndexDef do
    begin
      Fields := 'Field1';
      Name := 'IntIndex';
    end;
    CreateDataSet;
  end;
end;
{ The following example shows how to create a table. }
procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Close;
  Table1.DeleteTable;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
```

```
      TableType := ttParadox;
      TableName := 'CustInfo';
      Table1.Active := False;
      { Don't overwrite an existing table }
      if Table1.Exists then
        MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
      else
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= True;
  end;
```

Creating and Deleting Tables

39.1.17.5.25 TDataSet.FieldList Property

Lists the field components of a dataset.

Pascal

```
property FieldList: TFieldList;
```

C++

```
__property TFieldList FieldList;
```

Description

FieldList contains the names of all field components in the dataset. The fields are stored sequentially, or flattened out, meaning any child fields of an object field are stored as siblings in the TFieldList (see page 7207) . ::Fields (see page 7023) array.

See Also

Fields (see page 7023)

39.1.17.5.26 TDataSet.FieldNoOfs Property

Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.

Pascal

```
property FieldNoOfs: Integer;
```

C++

```
__property int FieldNoOfs;
```

Description

Add FieldNoOfs to a field index to obtain its FieldNo property.

See Also

Fields (see page 7023)

FieldList (see page 7022)

FieldNo (see page 7166)

39.1.17.5.27 TDataSet.Fields Property

Lists all non-aggregate field components of the dataset.

Pascal

```
property Fields: TFields;
```

C++

```
__property TFields Fields;
```

Description

Use Fields to access field components. If fields are generated dynamically at runtime, the order of field components in Fields corresponds directly to the order of columns in the table or tables underlying a dataset. If a dataset uses persistent fields, then the order of field components corresponds to the ordering of fields specified in the Fields editor at design time.

When ObjectView (see page 7031) is true, the fields are stored hierarchically, meaning any child fields of an object field are referenced by the object field and don't appear sequentially after the object field in the TFields (see page 7211) . :: Fields array. When ObjectView (see page 7031) is false, the fields are stored sequentially, or flattened out, meaning any child fields of an object field are stored sequentially in the TFields (see page 7211) . :: Fields array.

Accessing fields with the Fields property is useful for applications that:

Iterate over some or all fields in a dataset.

Work with underlying tables whose internal data structure is unknown at runtime.

If an application knows the data types of individual fields, then it can read or write individual field values through the Fields property. For example, the following statement assigns a field value to the Text property of an edit box:

```
Edit1.Text := CustTable.Fields.Fields[6].AsString;
Edit1->Text = CustTable->Fields->Fields[0]->AsString;
```

Note: The preferred method for retrieving and assigning field values is to use persistent fields or the FieldByName (see page 6936) method.

Note: The AggFields (see page 7006) property is a collection of all the dataset's aggregated fields. AggFields (see page 7006) and Fields are mutually exclusive collections of the dataset's fields. These two properties contain all of the dataset's fields between them.

Delphi Examples:

```
{
This example displays a message box with the names of all
fields in a table.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   i: Integer;
   Info: String;
begin
   Info := 'The fields of table ' + Table1.TableName +
           ' are:'#13#10#13#10;
   for i := 0 to Table1.FieldCount - 1 do
      Info := Info + Table1.Fields[i].FieldName + #13#10;
  ShowMessage(Info);
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if not Table1.Exists then
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftString;
          Size := 30;
        end;
      end;
      { Next, describe any indexes }
      with IndexDefs do
      begin
        Clear;
        { The 1st index has no name because it is
        { a Paradox primary key }
        with AddIndexDef do
        begin
          Name := '';
          Fields := 'Field1';
          Options := [ixPrimary];
        end;
        with AddIndexDef do
        begin
          Name := 'Fld2Indx';
          Fields := 'Field2';
          Options := [ixCaseInsensitive];
        end;
      end;
      { Call the CreateTable method to create the table }
      CreateTable;
    end;
  end;
  DS2.DataSet:= Table1;
  DBGrid2.DataSource.DataSet:= Table1;
  Table1.Active:= True;
end;
```

Accessing Field Values with a Dataset's Fields Property

Working with Reference Fields

39.1.17.5.28 TDataSet.FieldValues Property

Provides access to the values for all fields in the active record for the dataset

Pascal

```
property FieldValues [const FieldName: string]: Variant;
```

C++

```
__property Variant FieldValues[AnsiString const FieldName];
```

Description

Use FieldValues to read and write values for fields in a dataset. FieldName is the name of a field to read from or write to.

FieldName can represent simple field names, qualified field names for subfields of an object field, or aggregated fields such as can be found in the AggFields (see page 7006) property. Because of this flexibility, it is often preferable to use the FieldValues property (or the FieldByName (see page 6936) method) rather than the Fields (see page 7023), FieldList (see page 7022), or AggFields (see page 7006) properties, all of which present a more limited selection of the dataset's fields.

FieldValues accepts and returns a Variant, so it can handle and convert fields of any type. Because FieldValues is the default property for TDataSet (see page 6894), you can omit the property name when referencing this property. For example, the following statements are semantically identical and write the value from an edit box into an integer field:

```
Customers.FieldValues['CustNo'] := Edit1.Text;
Customers['CustNo'] := Edit1.Text;
Customers->FieldValues["CustNo"] = Edit1->Text;
```

Note: Because FieldValues always uses Variants (see page 23567), it may be a somewhat slower method of accessing data, than using a field's native format (for example, using a field's AsXXX property), especially in applications that process large amounts of data.

Delphi Examples:

```
{
This example appends a new record to a table or client
dataset when the user clicks a button. The two fields
Field1 and Field2 are filled from the contents of two edit
controls.  This example requires a populated TTable or
TDataSet with the appropriate field values.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
```

```
  Customers.Append;
  Customers.FieldValues['Field1'] := StrToInt(Edit1.text);
  Customers.FieldValues['Field2'] := Edit2.text;
  Customers.Post;
end;
```

operator_sb

39.1.17.5.29 TDataSet.Filter Property

Specifies the text of the current filter for a dataset.

Pascal

```
property Filter: string;
```

C++

```
__property AnsiString Filter;
```

Description

Use Filter to specify a dataset filter. When filtering is applied to a dataset, only those records that meet a filter's conditions are available. Filter describes the filter condition. For example, the following filter condition displays only those records where the State (see page 7036) field is 'CA' or 'MA':

```
State = 'CA' or State = 'MA'
```

When a filter is set, Blank records do not appear unless explicitly included in the filter. For example:

```
State <> 'CA' or State = NULL
```

When a field name contains spaces, you must enclose the field name in brackets. For example:

```
[Home State] = 'CA' or [Home State] = 'MA'
```

Filter expressions on remote SQL tables and on client datasets support field comparisons. For example:

```
Field1 > Field2
```

Field comparisons are not supported against local tables (Paradox, dBASE, Access, FoxPro).

For a complete list of operators you can use in filter strings, see SettingTheFilterProperty.

Note: Filters are not supported on unidirectional datasets. If you set the Filter property of a unidirectional dataset, it raises an exception.

The FilterOptions (see page 7027) property controls case sensitivity and filtering on partial comparisons.

Tip: Applications can set Filter at runtime to change the dataset's filtering condition (for example, in response to user input).

Creating Filters

Navigating Records in a Filtered Dataset

Setting the Filter Property

Displaying and Editing a Subset of Data Using Filters

39.1.17.5.30 TDataSet.Filtered Property

Specifies whether or not filtering is active for a dataset.

Pascal

```
property Filtered: Boolean;
```

C++

```
__property Boolean Filtered;
```

Description

Check Filtered to determine whether or not dataset filtering is in effect. If Filtered is true, then filtering is active. To apply filter conditions specified in the Filter (see page 7026) property or the OnFilterRecord (see page 7055) event handler, set Filtered to true. Because unidirectional datasets do not support filters, when you set Filtered to true on a unidirectional dataset, it raises an exception.

Note: When filtering is enabled, user edits to a record may mean that the record no longer meets a filter's test condition. The next time an attempt is made to the read the record from the dataset while the filter is in effect, the record is not visible. If that happens, the next record that passes the filter condition becomes the active record.

Enabling and Disabling Filtering

Setting the Filter Property

39.1.17.5.31 TDataSet.FilterOptions Property

Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.

Pascal

```
property FilterOptions: TFilterOptions;
```

C++

```
__property TFilterOptions FilterOptions;
```

Description

Set FilterOptions to specify whether or not filtering is case insensitive when filtering on string or character fields, and whether or not partial comparisons for matching filter conditions is allowed.

Note: Because unidirectional datasets do not support filters, when you set the FilterOptions property of a unidirectional dataset, it raises an exception.

By default, FilterOptions is set to an empty set. For filters based on string fields, set FilterOptions to foCaseInsensitive to catch all variations on a string regardless of capitalization.

When a string in a filter ends with an asterisk (*), it can be used to match partial strings. To disable matching of partial strings and to treat the asterisk as a literal character in string comparisons, set FilterOptions to include foNoPartialCompare.

Setting Filter Options

39.1.17.5.32 TDataSet.Found Property

Indicates whether or not moving to a different record is successful.

Pascal

```
property Found: Boolean;
```

C++

```
__property Boolean Found;
```

Description

Check the status of Found to determine if a call to FindFirst (see page 6939), FindLast (see page 6940), FindNext (see page 6940) or, FindPrior (see page 6941) succeeds. If Found is true, success is indicated. If false, the move to a different record failed.

See Also

Filter (see page 7026)

FindLast (see page 6940)

FindNext (see page 6940)

FindPrior (see page 6941)

Navigating Records in a Filtered Dataset

39.1.17.5.33 TDataSet.InternalCalcFields Property

Indicates whether the dataset includes internally calculated fields.

Pascal

```
property InternalCalcFields: Boolean;
```

C++

```
__property Boolean InternalCalcFields;
```

Description

Read InternalCalcFields to discover if the dataset includes fields whose values are provided by the data source but that are not a fields in the physical database table or query. Internally calculated fields are calculated by SQL servers or the Borland (see page 1761) Database Engine in a live query view.

On TClientDataSet, internally calculated fields are stored with the rest of the data, allowing the developer to sort and filter on the calculated fields. However, internally calculated fields on client datasets are not updated when the data they depend on is updated.

Note: Do not confuse internally calculated fields with calculated fields, which are computed in an OnCalcFields (see page 7053) event.

See Also

InternalCalcField (see page 7192)

39.1.17.5.34 TDataSet.IsUniDirectional Property

Indicates whether the dataset is unidirectional.

Pascal

```
property IsUniDirectional: Boolean;
```

C++

```
__property Boolean IsUniDirectional;
```

Description

IsUniDirectional indicates whether the dataset is a descendant of TCustomSQLDataSet. Unidirectional datasets raise exceptions on all navigation methods except for First (see page 6942) and Next (see page 6973). They do not support filters, bookmarks, lookup fields, or any other features that require an internal record buffer. You can't use a unidirectional dataset as the source to a data-aware grid.

See Also

TCustomSQLDataSet (see page 20150)

39.1.17.5.35 TDataSet.Modified Property

Indicates whether the active record is modified.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Check Modified to determine if the active record is modified. If Modified is true, the active record is modified. If false, the active record is not modified.

Note: In general, an application need not check the status of Modified. Properties, events, and methods of TDataSet (see page 6894) and its descendants that modify records generally check this status automatically and take appropriate actions based on its value.

See Also

State (see page 7036)

Delete (see page 6924)

Edit (see page 6932)

Insert (see page 6959)

Post (see page 6977)

39.1.17.5.36 TDataSet.NestedDataSetClass Property

Indicates the class type to use when creating nested datasets.

Pascal

```
property NestedDataSetClass: TDataSetClass;
```

C++

```
__property TDataSetClass NestedDataSetClass;
```

Description

TDataSet (see page 6894) descendants use NestedDataSetClass to specify the class that can be used for nested datasets. By default, this value is the same as the class of the dataset instance.

NestedDataSetClass is used to check that nested detail sets are the appropriate type when they are assigned to a data set field (by assigning a value to their DataSetField (see page 7013) property).

See Also

NestedDataSets (see page 7030)

DataSetField (see page 7013)

39.1.17.5.37 TDataSet.NestedDataSets Property

Lists all nested datasets.

Pascal

```
property NestedDataSets: TList;
```

C++

```
__property TList NestedDataSets;
```

Description

NestedDataSets is a list of the nested detail sets belonging to the data set. Each entry in the list is a dataset of the type specified by NestedDataSetClass (see page 7030).

Do not use NestedDataSets to assign values to dataset fields. Instead, set the DataSetField (see page 7013) property of the detail set to reference the appropriate field component.

See Also

NestedDataSetClass (see page 7030)

TDataSetField (see page 7060)

DataSetField (see page 7013)

39.1.17.5.38 TDataSet.ObjectView Property

Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.

Pascal

```
property ObjectView: Boolean;
```

C++

```
__property Boolean ObjectView;
```

Description

ObjectView affects the way the Fields (see page 7023) property stores object fields and the way data-aware grids display ADT and array fields.

When ObjectView is true, the fields are stored hierarchically in the Fields (see page 7023) property, meaning any child fields of an object field are referenced by the object field and don't appear sequentially after the object field in the TFields (see page 7211):: .Fields (see page 7023) array. When ObjectView is false, the fields are stored sequentially in the Fields (see page 7023) property, meaning any child fields of an object field are stored after the object field as siblings in the Fields (see page 7023) array.

When ObjectView is false, object field types, such as TADTField (see page 6736), are not created. This switch is provided for increased compatibility with older data-aware controls, which may not handle object field types properly. The default is false for TBDEDataSet, and true for TClientDataSet.

Note: If the ObjectView property of the dataset provided to a TClientDataSet is false, then the TClientDataSet's ObjectView property always acts as false, since the data received is already flattened.

Working with Array Fields

39.1.17.5.39 TDataSet.RecNo Property

Indicates the active record in the dataset.

Pascal

```
property RecNo: Integer;
```

C++

```
__property int RecNo;
```

Description

As implemented in TDataSet (see page 6894), the value of RecNo is always -1. Ordinarily an application does not access

RecNo at the TDataSet (see page 6894) level. Instead a re-implemented RecNo property in a descendant class such as TTable TClientDataSet is accessed. RecNo provides a fallback property for derived datasets that do not support record numbers.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
```

See Also

RecordCount (see page 7032)

Last (see page 6968)

MoveBy (see page 6971)

Next (see page 6973)

Prior (see page 6979)

39.1.17.5.40 TDataSet.RecordCount Property

Indicates the total number of records associated with the dataset.

Pascal

```
property RecordCount: Integer;
```

C++

```
__property int RecordCount;
```

Description

As implemented in TDataSet (see page 6894), RecordCount is always -1. Ordinarily an application does not access RecordCount at the TDataSet (see page 6894) level. Instead a redeclared and implemented RecordCount property in a descendant class is accessed. RecordCount provides a fallback property for derived dataset classes that do not reimplement the property access method.

C++ Examples:

```
/*
Reads through all records in the Customers table.
```

```
Updates the ProgressBar accordingly.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ProgressBar1->Min = 0;
  ProgressBar1->Max = Customers->RecordCount;
  Customers->First();
  for (int i = ProgressBar1->Min; i <= ProgressBar1->Max; i++)
  {
    ProgressBar1->Position = i;
    Customers->Next();
    // do something with the current record
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Customers = new TTable(Form1);
  Customers->Active = false; // The Table component must not be active
  Customers->DatabaseName = "DBDEMOS";
  Customers->TableType = ttParadox;
  Customers->TableName = "CustInfo";
  Customers->Active = False;
  if (Customers->Exists) // Don't overwrite an existing table
  {
    Customers->Close();
    Customers->DeleteTable();
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Customers->FieldDefs->Clear();
  TFieldDef *pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Customers->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Customers->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Customers->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Customers->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Customers->CreateTable();
  Customers->Active = True;
  for (int i = 1; i <= 20; i++)
    Customers->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Customers;
  DBGrid2->DataSource->DataSet = Customers;
  Customers->Active = True;
}
```

Delphi Examples:

```
{
Reads through all records in the Customers table.
Updates the ProgressBar accordingly.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  with ProgressBar1 do
```

```
    begin
      Min := 0;
      Max := Customers.RecordCount;
      Customers.First;
      for i := Min to Max do
      begin
        Position := i;
        Customers.Next;
        // do something with the current record
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    Customers:= TTable.Create(Form1);
    with Customers do
    begin
      DatabaseName := 'DBDEMOS';
      TableType := ttParadox;
      TableName := 'CustInfo';
      Active := False;
  //  Overwrite any existing table
      if Customers.Exists then
      begin
        Customers.Close;
        Customers.DeleteTable;
      end;
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
```

```
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Customers.Active:= True;
        for i := 1 to 100 do
          Customers.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Customers;
    DBGrid2.DataSource.DataSet:= Customers;
    Customers.Active:= True;
  end;
```

39.1.17.5.41 TDataSet.RecordSize Property

Indicates the size of a record in the dataset.

Pascal

```
property RecordSize: Word;
```

C++

```
__property Word RecordSize;
```

Description

RecordSize indicates the size needed for internal record buffers. In TDataSet (see page 6894), the value of RecordSize is always 0 because TDataSet (see page 6894) does not implement record buffering. Descendant classes that buffer records override the property getter to return the number of bytes in a record buffer.

See Also

RecordCount (see page 7032)

RecNo (see page 7031)

Open (see page 6976)

39.1.17.5.42 TDataSet.Reserved Property

For internal use only.

Pascal

```
property Reserved: Pointer;
```

C++

```
__property void * Reserved;
```

Description

Do not use the Reserved property. It is for internal use only.

39.1.17.5.43 TDataSet.SparseArrays Property

Determines whether a unique TField (see page 7115) object is created for each element of an array field.

Pascal

```
property SparseArrays: Boolean;
```

C++

```
__property Boolean SparseArrays;
```

Description

When opening a dataset with an array field, SparseArrays determines whether a unique field component is created for each element of the array field. The default is false, where a TField (see page 7115) descendant is created for each element of the array field. If you plan to bind data-aware controls to elements of the array field, SparseArrays must be set to false. Setting SparseArrays to true conserves memory, but does not allow applications to reference individual elements of the array field.

Working with Array Fields

39.1.17.5.44 TDataSet.State Property

Indicates the current operating mode of the dataset.

Pascal

```
property State: TDataSetState;
```

C++

```
__property TDataSetState State;
```

Description

Examine State to determine the current operating mode of the dataset. State determines what can be done with data in a dataset, such as editing existing records or inserting new ones. The dataset state constantly changes as an application processes data.

Opening a dataset changes State from dsInactive to dsBrowse. An application can call Edit (see page 6932) to put a dataset into dsEdit state, or call Insert (see page 6959) to put a dataset into dsInsert state. If a dataset is a TTable or TClientDataSet object, an application can call SetKey or SetRange to put the dataset into dsSetKey state.

Posting or canceling edits, insertions, or deletions, changes State from its current state to dsBrowse. Closing a dataset changes its state to dsInactive.

Some states, such as dsCalcFields, dsFilter, dsNewValue, dsOldValue, and dsCurValue cannot be seen or set directly by an application. These states are automatically set when OnCalcFields (see page 7053) and OnFilterRecord (see page 7055) events occur, or when an application accesses certain field properties.

39.1.17.6 TDataSet Events

The events of the TDataSet class are listed here.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.

	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

39.1.17.6.1 TDataSet.AfterCancel Event

Occurs after an application completes a request to cancel modifications to the active record.

Pascal

```
property AfterCancel: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterCancel;
```

Description

Write an AfterCancel event handler to take specific action after an application cancels changes to the active record. AfterCancel is called by the Cancel (see page 6916) method after it updates the current position, releases the lock on the active record if necessary, and sets the dataset state to dsBrowse. If an application requires additional processing before returning control to a user after a Cancel (see page 6916) event, code it in the AfterCancel event.

Delphi Examples:

```
{
This example updates the form's status bar with a message
when an AfterCancel event occurs.  Set the StatusBar
SimplePanel property to True.
}
procedure TForm1.Table1AfterCancel(DataSet: TDataSet);
begin
  StatusBar1.SimpleText := 'Record changes cancelled for ' + DataSet.Name;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Table1.Cancel;
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  Table1.Post
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Name := 'CustInfo';
```

```
      Table1.Active := False;
      { Don't overwrite an existing table }
      if Table1.Exists then
      begin
          Table1.Close;
          Table1.DeleteTable;
      end;
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.AfterCancel:= Table1AfterCancel;
    Table1.Active:= True;
  end;
```

See Also

BeforeCancel (see page 7048)

State (see page 7036)

39.1.17.6.2 TDataSet.AfterClose Event

Occurs after an application closes a dataset.

Pascal

```
property AfterClose: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterClose;
```

Description

Write an AfterClose event handler to take specific action immediately after an application closes a dataset. For example, as a security measure, an application might clear a PASSWORD entry from the Params property of a TSQLConnection component when the dataset is closed.

AfterClose is called after a dataset is closed and the dataset state is set to dsInactive.

Delphi Examples:

```
{
This example adds an entry to a memo with a message when an
AfterOpen event or an AfterClose event occurs.  Populate the
ClientDataSet events with CheckButtonActive.
}
procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  if (Button1.Enabled) then
    Memo2.Lines.Add('Now that the dataset is open, record information is available.')
  else
    Memo2.Lines.Add('Now that the dataset is closed, record information is not available.');
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
```

```
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

Opening and Closing Datasets

39.1.17.6.3 TDataSet.AfterDelete Event

Occurs after an application deletes a record.

Pascal

```
property AfterDelete: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterDelete;
```

Description

Write an AfterDelete event handler to take specific action immediately after an application deletes the active record in a dataset. AfterDelete is called by Delete (see page 6924) after it deletes the record, sets the dataset state to dsBrowse, and repositions the current record.

C++ Examples:

```
/*
This example displays a message on the form's status bar
indicating the record count after a record is deleted.  Set
the StatusBar SimplePanel property to True.
*/
void __fastcall TForm1::Table1AfterDelete(TDataSet *DataSet)
{
  StatusBar1->SimpleText = Format(
    "There are now %d records in the table",
    ARRAYOFCONST(((int)DataSet->RecordCount)));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Table1->Delete();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Table1 = new TTable(Form1);
  Table1->Active = false; // The Table component must not be active
```

```
  Table1->DatabaseName = "DBDEMOS";
  Table1->TableType = ttParadox;
  Table1->TableName = "CustInfo";
  Table1->Active = False;
  if (!Table1->Exists) // Don't overwrite an existing table
  {
    Table1->Close();
    Table1->DeleteTable();
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Table1->FieldDefs->Clear();
  TFieldDef *pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Table1->IndexDefs->Clear();
  /* the 1st index has no name because it is a Paradox primary key */
  Table1->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Table1->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Table1->CreateTable();
  Table1->Active = True;
  for (int i = 1; i <= 20; i++)
    Table1->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Table1;
  DBGrid2->DataSource->DataSet = Table1;
  Table1->AfterDelete = Table1AfterDelete;
  Table1->Active = True;
}
```

Delphi Examples:

```
{
This example displays a message on the form’s status bar
indicating the record count after a record is deleted.  Set
the StatusBar SimplePanel property to True.
}
procedure TForm1.Table1AfterDelete(DataSet: TDataSet);
begin
  StatusBar1.SimpleText := Format('There are now %d records in the table',
[DataSet.RecordCount]);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Delete;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Name := 'CustInfo';
```

```
      Table1.Active := False;
      { Don't overwrite an existing table }
      if Table1.Exists then
      begin
          Table1.Close;
          Table1.DeleteTable;
      end;
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.AfterDelete:= Table1AfterDelete;
    Table1.Active:= True;
  end;
```

Delete (see page 6924)

39.1.17.6.4 TDataSet.AfterEdit Event

Occurs after an application starts editing a record.

Pascal

```
property AfterEdit: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterEdit;
```

Description

Write an AfterEdit event handler to take specific action immediately after dataset enters edit mode. AfterEdit is called by Edit (see page 6932) after it enables editing of a record, recalculates calculated fields, and calls the data event handler to process a record change.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
```

See Also

BeforeEdit (see page 7049)

Edit (see page 6932)

39.1.17.6.5 TDataSet.AfterInsert Event

Occurs after an application inserts a new record.

Pascal

```
property AfterInsert: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterInsert;
```

Description

Write an AfterInsert event handler to take specific action immediately after an application inserts a record. The Insert (see page 6959) and Append (see page 6910) methods generate an AfterInsert event after inserting or appending a new record.

Delphi Examples:

```
{
This example updates a memo with a message when an
AfterInsert event or a BeforeInsert event occurs.
}
procedure TForm1.ClientDataSet1AfterInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After inserting a record');
end;

procedure TForm1.ClientDataSet1BeforeInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before inserting a record');
end;
```

See Also

BeforeInsert (see page 7050)

Append (see page 6910)

Insert (see page 6959)

39.1.17.6.6 TDataSet.AfterOpen Event

Occurs after an application completes opening a dataset and before any data access occurs.

Pascal

```
property AfterOpen: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterOpen;
```

Description

Write an AfterOpen event handler to take specific action immediately after an application opens the dataset. AfterOpen is called after the dataset establishes access to its data and the dataset is put into dsBrowse state. For example, an AfterOpen event handler might check an ini file to determine the last record touched in the dataset the previous time the application ran, and position the dataset at that record.

Delphi Examples:

```
{
This example adds an entry to a memo with a message when an
AfterOpen event or an AfterClose event occurs.  Populate the
ClientDataSet events with CheckButtonActive.
}
procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  if (Button1.Enabled) then
    Memo2.Lines.Add('Now that the dataset is open, record information is available.')
  else
    Memo2.Lines.Add('Now that the dataset is closed, record information is not available.');
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

Opening and Closing Datasets

39.1.17.6.7 TDataSet.AfterPost Event

Occurs after an application writes the active record to the database or change log and returns to browse state.

Pascal

```
property AfterPost: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterPost;
```

Description

Write an AfterPost event handler to take specific action immediately after an application posts a change to the active record. AfterPost is called after a modification or insertion is made to a record.

Delphi Examples:

```
{
```

```
This example updates the form's status bar with a message
when an AfterPost event occurs.
}
procedure TForm1.ClientDataSet1AfterPost(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before posting a record');
end;
```

See Also

BeforePost (see page 7052)

Post (see page 6977)

39.1.17.6.8 TDataSet.AfterRefresh Event

Occurs after an application refreshes the data in the dataset.

Pascal

```
property AfterRefresh: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterRefresh;
```

Description

Write an AfterRefresh event handler to take specific action immediately after an application has updated the records in the dataset. AfterRefresh is generated by calls to the Refresh (see page 6991) method.

See Also

BeforeRefresh (see page 7052)

Refresh (see page 6991)

39.1.17.6.9 TDataSet.AfterScroll Event

Occurs after an application scrolls from one record to another.

Pascal

```
property AfterScroll: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterScroll;
```

Description

Write an AfterScroll event handler to take specific action immediately after an application scrolls to another record as a result of a call to the First (see page 6942), Last (see page 6968), MoveBy (see page 6971), Next (see page 6973), Prior (see page 6979), FindKey, FindFirst (see page 6939), FindNext (see page 6940), FindLast (see page 6940), FindPrior (see page 6941), and Locate (see page 6970) methods. AfterScroll is called after all other events triggered by these methods and any other methods that switch from record to record in the dataset.

See Also

BeforeScroll (see page 7053)

First (see page 6942)

Last (see page 6968)

MoveBy (see page 6971)

Next (see page 6973)

Prior (see page 6979)

Navigating Datasets

39.1.17.6.10 TDataSet.BeforeCancel Event

Occurs before an application executes a request to cancel changes to the active record.

Pascal

```
property BeforeCancel: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeCancel;
```

Description

Write a BeforeCancel event to take specific action before an application carries out a request to cancel changes. BeforeCancel is called by the Cancel (see page 6916) method before it cancels a dataset operation such as Edit (see page 6932), Insert (see page 6959), or Delete (see page 6924).

An application might use the BeforeCancel event to record a user's changes in an undo buffer.

See Also

AfterCancel (see page 7038)

Delete (see page 6924)

Edit (see page 6932)

Insert (see page 6959)

39.1.17.6.11 TDataSet.BeforeClose Event

Occurs immediately before the dataset closes.

Pascal

```
property BeforeClose: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeClose;
```

Description

Write a BeforeClose event to take specific action before an application closes a dataset. Calling Close (see page 6920) or setting the Active (see page 7004) property to false results in a call to the BeforeClose event handler.

See Also

Active (see page 7004)

AfterClose (see page 7040)

Close (see page 6920)

Opening and Closing Datasets

Posting Data

39.1.17.6.12 TDataSet.BeforeDelete Event

Occurs before an application attempts to delete the active record.

Pascal

```
property BeforeDelete: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeDelete;
```

Description

Write a BeforeDelete event handler to take specific action before an application deletes the active record. BeforeDelete is called by Delete (see page 6924) before it actually deletes a record.

In Delphi, making use of this event an application might, for example, display a dialog box asking for confirmation before deleting the record. On denial of confirmation, the application could abort the deletion by calling the Abort procedure.

See Also

AfterDelete (see page 7041)

Delete (see page 6924)

Abort (see page 22786)

39.1.17.6.13 TDataSet.BeforeEdit Event

Occurs before an application enters edit mode for the active record.

Pascal

```
property BeforeEdit: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeEdit;
```

Description

Write a BeforeEdit event handler to take specific action before an application enables editing of the active record. For example, an application that keeps a log of database edits could use the BeforeEdit event to record the edit request, time, and user before entering edit state.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;
```

```
procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
```

See Also

State (see page 7036)

AfterEdit (see page 7044)

Edit (see page 6932)

39.1.17.6.14 TDataSet.BeforeInsert Event

Occurs before an application enters insert mode.

Pascal

```
property BeforeInsert: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeInsert;
```

Description

Write a BeforeInsert event handler to take specific action before an application inserts or appends a new record. The Insert (see page 6959) or Append (see page 6910) method generates a BeforeInsert method before it sets the dataset into dsInsert state.

Delphi Examples:

```
{
This example updates a memo with a message when an
AfterInsert event or a BeforeInsert event occurs.
}
procedure TForm1.ClientDataSet1AfterInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After inserting a record');
end;

procedure TForm1.ClientDataSet1BeforeInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before inserting a record');
end;
{
This example uses the BeforeInsert event to do data
validation. If the StrToInt function raises an exception,
the edit control’s contents are set to a valid value so
that the assignment to the INTEGER field in the dataset
will succeed.  Continuing after the exception causes a
'0' to be placed in the PORTA field.
DataSet design:
This example requires a ClientDataSet, a DBGrid, a
DataSource and a DBNavigator.  Name the ClientDataSet CDS.
Set the DataSet property in the DataSource to CDS and name
that DataSource DS.  Set the DataSource in the DBNavigator
to DS the DataSource in the DBGrid to DS.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
```

```
  attribute name of HOST with an attribute type of string and
  an attribute name of PORTA with an attribute type of integer.
  Add DB, DBCtrls, Grids, DBGrids and DBClient to the uses clause.
  }
  {$IFNDEF UNICODE}
  uses SwSystem;
  {$ENDIF}

  procedure TForm1.Button3Click(Sender: TObject);
  begin
    CDS.Insert;
    CDS.FieldByName('PORTA').AsInteger := StrToInt(Edit1.Text);
    CDS.Post;
  end;

  procedure TForm1.CDSBeforeInsert(DataSet: TDataSet);
  begin
    try
    { Make sure edit field can be converted to integer --
     this will raise an exception if it can't }
      StrToInt(Edit1.Text);
    except
      Edit1.Text := '0';
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
  {$IFDEF UNICODE}
    CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
  {$ELSE}
    CDS.LoadFromFile(gsAppPath + 'CDS.XML');
  {$ENDIF}
  end;
```

See Also

State (see page 7036)

AfterInsert (see page 7044)

Append (see page 6910)

Insert (see page 6959)

39.1.17.6.15 TDataSet.BeforeOpen Event

Occurs before an application executes a request to open a dataset.

Pascal

```
property BeforeOpen: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeOpen;
```

Description

Write a BeforeOpen event handler to take specific action before an application opens a dataset for viewing or editing. BeforeOpen is triggered when an application sets the Active (see page 7004) property to true for a dataset or an application calls Open (see page 6976).

See Also

Active (see page 7004)

AfterOpen (see page 7045)

Open (see page 6976)

Opening and Closing Datasets

39.1.17.6.16 TDataSet.BeforePost Event

Occurs before an application posts changes for the active record to the database or change log.

Pascal

```
property BeforePost: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforePost;
```

Description

Write a BeforePost event handler to take specific action before an application posts dataset changes. BeforePost is triggered when an application calls the Post (see page 6977) method. Post (see page 6977) checks to make sure all required fields are present, then calls BeforePost before posting the record.

An application might use BeforePost to perform validity checks on data changes before committing them. If it encountered a validity problem, it could call Abort to cancel the Post (see page 6977) operation (Delphi) or throw an exception (C++).

Delphi Examples:

```
{
This example checks for a valid entry in a TDBEdit control
and calls the Abort procedure if the control is empty; Abort
cancels the post before it happens.
}
procedure TForm1.ClientDataSet1BeforePost(DataSet: TDataSet);
begin
  if DBEdit1.Text = '' then
    Abort;
  DataSet.Fields[2].AsString := DBEdit1.Text;
end;
```

See Also

AfterPost (see page 7046)

Post (see page 6977)

Abort (see page 22786)

Working with Field Component Methods at Runtime

39.1.17.6.17 TDataSet.BeforeRefresh Event

Occurs immediately before an application refreshes the data in the dataset.

Pascal

```
property BeforeRefresh: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeRefresh;
```

Description

Write a BeforeRefresh event handler to take specific action immediately before an application updates the records in the dataset.

BeforeRefresh is generated by calls to the Refresh (see page 6991) method.

See Also

AfterRefresh (see page 7047)

Refresh (see page 6991)

39.1.17.6.18 TDataSet.BeforeScroll Event

Occurs before an application scrolls from one record to another.

Pascal

```
property BeforeScroll: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeScroll;
```

Description

Write a BeforeScroll event handler to take specific action immediately before an application scrolls to another record as a result of a call to the First (see page 6942), Last (see page 6968), MoveBy (see page 6971), Next (see page 6973), Prior (see page 6979), FindKey, FindFirst (see page 6939), FindNext (see page 6940), FindLast (see page 6940), FindPrior (see page 6941), and Locate (see page 6970) methods. BeforeScroll is called before all other events triggered by these methods and any other methods that switch from record to record in the dataset.

See Also

AfterScroll (see page 7047)

First (see page 6942)

Last (see page 6968)

MoveBy (see page 6971)

Next (see page 6973)

Prior (see page 6979)

Navigating Datasets

39.1.17.6.19 TDataSet.OnCalcFields Event

Occurs when an application recalculates calculated fields.

Pascal

```
property OnCalcFields: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent OnCalcFields;
```

Description

Write an OnCalcFields event handler to take specific action when an application recalculates calculated fields. A calculated field is one that derives its value from the values in one or more fields in the dataset, sometimes with additional processing.

OnCalcFields is triggered when:

A dataset is opened.

A dataset is put into dsEdit state.

A record is retrieved from a database.

When the AutoCalcFields (see page 7006) property is true, OnCalcFields is also triggered when:

Focus moves from one visual control to another, or from one column to another is a data-aware grid control and modifications were made to the record.

Note: When the AutoCalcFields (see page 7006) property is true, an OnCalcFields event handler should not modify the dataset (or a linked dataset if it is part of a master-detail relationship), because such modifications retrigger the OnCalcField event, leading to infinite recursion.

If an application permits users to change data, OnCalcFields is frequently triggered. To reduce the frequency with which OnCalcFields occurs, set AutoCalcFields (see page 7006) to false.

Warning: When the dataset is the master table of a master-detail relationship, OnCalcFields occurs before detail sets have been synchronized with the master table.

See Also

Active (see page 7004)

AutoCalcFields (see page 7006)

Open (see page 6976)

Post (see page 6977)

Calculating Fields

Using Internally Calculated Fields in Client Datasets

Defining a Calculated Field

39.1.17.6.20 TDataSet.OnDeleteError Event

Occurs when an application attempts to delete a record and an exception is raised.

Pascal

```
property OnDeleteError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnDeleteError;
```

Description

Write an OnDeleteError event handler to handle exceptions that occur when an attempt to delete a record fails.

See Also

OnEditError (see page 7054)

OnPostError (see page 7056)

Delete (see page 6924)

39.1.17.6.21 TDataSet.OnEditError Event

Occurs when an application attempts to modify or insert a record and an exception is raised.

Pascal

```
property OnEditError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnEditError;
```

Description

Write an OnEditError event handler to handle exceptions that occur when an attempt to edit a record fails.

See Also

OnDeleteError (see page 7054)

OnPostError (see page 7056)

Edit (see page 6932)

Insert (see page 6959)

39.1.17.6.22 TDataSet.OnFilterRecord Event

Occurs each time a different record in the dataset becomes the active record and filtering is enabled.

Pascal

```
property OnFilterRecord: TFilterRecordEvent;
```

C++

```
__property TFilterRecordEvent OnFilterRecord;
```

Description

Write an OnFilterRecord event handler to specify for each record in a dataset whether it should be visible to the application. To indicate that a record passes the filter condition, the OnFilterRecord event handler must set the Accept parameter to true. To exclude a record, set the Accept parameter to false. Most TDataSet (see page 6894) descendants (such as ADO datasets or BDE-based datasets) initialize Accept to true before calling the OnFilterRecord event handler.

Warning: Do not supply an OnFilterRecord event handler to a unidirectional dataset. Unidirectional datasets do not support filters, and assigning an OnFilterRecord event handler causes the dataset to raise an exception.

Filtering is enabled if the Filtered (see page 7027) property is true. When an application is processing a filter, the State (see page 7036) property for the dataset is dsFilter.

Use an OnFilterRecord event handler to filter records using a criterion that can't be implemented using the Filter (see page 7026) property. For example, using the Filter (see page 7026) property, field comparisons are not supported against local tables (Paradox, dBASE, Access, FoxPro), but an OnFilterRecord event handler can implement any criterion at all.

Tip: Be sure that any interactions between the Filter (see page 7026) property and the OnFilterRecord event handler do not result in an empty filter set when they are used simultaneously in an application.

See Also

Filter (see page 7026)

Filtered (see page 7027)

State (see page 7036)

Creating Filters

Navigating Records in a Filtered Dataset

Displaying and Editing a Subset of Data Using Filters

Writing an OnFilterRecord Event Handler

39.1.17.6.23 TDataSet.OnNewRecord Event

Occurs when an application inserts or appends a new dataset record.

Pascal

```
property OnNewRecord: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent OnNewRecord;
```

Description

Write an OnNewRecord event handler to take specific actions as an application inserts or appends a new record. OnNewRecord is called as part of the insert or append process. An application might use the OnNewRecord event to set initial values for a record or as a way of implementing cascading insertions in related datasets.

See Also

AfterInsert (see page 7044)

BeforeInsert (see page 7050)

39.1.17.6.24 TDataSet.OnPostError Event

Occurs when an application attempts to modify or insert a record and an exception is raised.

Pascal

```
property OnPostError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnPostError;
```

Description

Write an OnPostError event handler to handle exceptions that occur when an attempt to post a record fails.

See Also

OnDeleteError (see page 7054)

OnEditError (see page 7054)

Post (see page 6977)

39.1.18 TDataSetDesigner Class

TDataSetDesigner is the base class for all dataset designers.

Class Hierarchy

Pascal

```
TDataSetDesigner = class(TObject);
```

C++

```
class TDataSetDesigner : public TObject;
```

File

DB

Description

Use TDataSetDesigner when defining a design-time editor, such as the Fields editor, that enables a developer to specify the fields that belong to a dataset at design time. The dataset designer is specified as the designer property of a dataset that uses it to enable design-time specification of its structure.

See Also

Tdataset

RegisterFields

39.1.18.1 TDataSetDesigner Members

The following tables list the members exposed by TDataSetDesigner.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDesign (see page 7059)	Ensures that the dataset is not active while design changes are made.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 7058)	Creates and initializes an instance of TDataSetDesigner (see page 7056).
	DataEvent (see page 7059)	Provides the interface for a method that can respond to data events.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 7058)	Disposes of an instance of TDataSetDesigner (see page 7056).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndDesign (see page 7059)	Reactivates the dataset if it was active when designing began.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	DataSet (see page 7060)	Provides a reference to the dataset currently being designed.

39.1.18.2 TDataSetDesigner.Create Constructor

Creates and initializes an instance of TDataSetDesigner (see page 7056).

Pascal

```
constructor Create(DataSet: TDataSet);
```

C++

```
__fastcall TDataSetDesigner(TDataSet DataSet);
```

Description

Call Create from the component editor of a specialized dataset to create an instance of the dataset designer. Create initializes the DataSet (see page 7060) property of the dataset designer and the Designer property of the dataset.

See Also

TComponentEditor (see page 10927)

DataSet (see page 7060)

Designer (see page 7015)

Destroy (see page 7058)

39.1.18.3 TDataSetDesigner.Destroy Destructor

Disposes of an instance of TDataSetDesigner (see page 7056).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataSetDesigner();
```

Description

Do not call the Destroy method directly. Instead, when freeing the dataset designer from a component editor, use the Free method. Free checks that the dataset designer reference is not nil, and only then calls Destroy.

Destroy sets the Designer property of the associated dataset to nil (Delphi) or NULL (C++) before destroying the instance of TDataSetDesigner (see page 7056).

See Also

Free (see page 22300)

TComponentEditor (see page 10927)

Create (see page 7058)

39.1.18.4 TDataSetDesigner Methods

The methods of the TDataSetDesigner class are listed here.

Public Methods

	Name	Description
	BeginDesign (see page 7059)	Ensures that the dataset is not active while design changes are made.
	DataEvent (see page 7059)	Provides the interface for a method that can respond to data events.
	EndDesign (see page 7059)	Reactivates the dataset if it was active when designing began.

39.1.18.4.1 TDataSetDesigner.BeginDesign Method

Ensures that the dataset is not active while design changes are made.

Pascal

```
procedure BeginDesign;
```

C++

```
__fastcall BeginDesign();
```

Description

BeginDesign is called before changing the structure of the associated dataset. BeginDesign deactivates the dataset and disables any associated controls until the EndDesign (see page 7059) method is called.

See Also

Active (see page 7004)

EndDesign (see page 7059)

DataSet (see page 7060)

39.1.18.4.2 TDataSetDesigner.DataEvent Method

Provides the interface for a method that can respond to data events.

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); virtual;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

Call DataEvent to pass information about data events to the dataset designer. The Event parameter specifies the type of event that is occurring. Use the Info parameter to specify additional information about the event. The value of the Info parameter depends on the type of data event.

The DataEvent method for TDataSetDesigner (see page 7056) does nothing when informed of a data event. Override this method to allow the data set designer to respond to different types of events.

39.1.18.4.3 TDataSetDesigner.EndDesign Method

Reactivates the dataset if it was active when designing began.

Pascal

```
procedure EndDesign;
```

C++

```
__fastcall EndDesign();
```

Description

Call EndDesign when changes to the dataset are complete. EndDesign re-enables all controls that use the dataset and resets the Active property of the dataset to the value it help when BeginDesign (see page 7059) was called.

See Also

Active (see page 7004)

BeginDesign (see page 7059)

DataSet (see page 7060)

39.1.18.5 TDataSetDesigner Properties

The properties of the TDataSetDesigner class are listed here.

Public Properties

	Name	Description
R	DataSet (see page 7060)	Provides a reference to the dataset currently being designed.

39.1.18.5.1 TDataSetDesigner.DataSet Property

Provides a reference to the dataset currently being designed.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Use DataSet to access the dataset, if any, that is being designed. When the user specifies changes in the dataset designer, the changes can be made to the dataset specified by the DataSet property.

See Also

TDataSet (see page 6894)

39.1.19 TDataSetField Class

TDataSetField provides access to nested datasets.

Class Hierarchy

Pascal

```
TDataSetField = class(TObjectField);
```

C++

```
class TDataSetField : public TObjectField;
```

File

DB

Description

TDataSetField represents a nested dataset field in a database. This nested dataset can result from an object relational database (such as the nested datasets in Oracle 8 databases) or from a provider that packages data for the master table of a master/detail relationship.

TDataSetField introduces a new property NestedDataSet (see page 7070) for referencing nested datasets. It also introduces the Fields (see page 7384) property for accessing the fields in the nested dataset. When assigning data to a data set field, use the DataSetField property of a dataset component that is assigned as the value of the dataset field.

See Also

TDataSet (see page 6894)

Working with DataSet Fields

Working with Reference Fields

39.1.19.1 TDataSetField Members

The following tables list the members exposed by TDataSetField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7069)	This is Bind, a member of class TDataSetField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CheckTypeSize (see page 7380)	This is CheckTypeSize, a member of class TObjectField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.

	DefineProperties (see page 7380)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
	FreeBuffers (see page 7380)	This is FreeBuffers, a member of class TObjectField.
	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
	GetAsString (see page 7381)	This is GetAsString, a member of class TObjectField.
	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
	GetAsVariant (see page 7381)	This is GetAsVariant, a member of class TObjectField.
	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
	GetCanModify (see page 7069)	This is GetCanModify, a member of class TDataSetField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
	GetDataSize (see page 7133)	This is GetDataSize, a member of class TField.
	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
	GetDefaultWidth (see page 7381)	This is GetDefaultWidth, a member of class TObjectField.
	GetFieldCount (see page 7381)	This is GetFieldCount, a member of class TObjectField.
	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
	GetFields (see page 7069)	This is GetFields, a member of class TDataSetField.
	GetFieldValue (see page 7382)	This is GetFieldValue, a member of class TObjectField.
	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetHasConstraints (see page 7382)	This is GetHasConstraints, a member of class TObjectField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetSize (see page 7135)	This is GetSize, a member of class TField.
	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.

	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 7382)	This is SetChildOrder, a member of class TObjectField.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataSet (see page 7383)	This is SetDataSet, a member of class TObjectField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetFieldKind (see page 7383)	This is SetFieldKind, a member of class TObjectField.
	SetFieldValue (see page 7383)	This is SetFieldValue, a member of class TObjectField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetParentField (see page 7383)	This is SetParentField, a member of class TObjectField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetUnNamed (see page 7383)	This is SetUnNamed, a member of class TObjectField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetVarValue (see page 7384)	This is SetVarValue, a member of class TObjectField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 7068)	Copies the Value property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 7126)	Sets the value of the field to NULL.
V	Create (see page 7067)	Creates and initializes a TDataSetField (see page 7060) instance.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 7067)	Destroys an instance of TObjectField.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetChildren (see page 7381)	This is GetChildren, a member of class TObjectField.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.

	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldCount (see page 7384)	Indicates the number of child fields that comprise the object field.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	Fields (see page 7384)	Specifies the TFields (see page 7211) object that contains an array of child fields.
	FieldValues (see page 7385)	Provides access to the values for all child fields in the object field.

R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
R	NestedDataSet (see page 7070)	Indicates the dataset that is nested in the dataset field.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
R	UnNamed (see page 7386)	Indicates whether an object field in a nested table has a name associated with it.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	IncludeObjectField (see page 7069)	Indicates whether this field can be represented as a persistent field in the nested dataset. Reserved for future use.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.

	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectType (see page 7385)	Specifies the classification of the field object in Oracle.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.19.2 TDataSetField.Create Constructor

Creates and initializes a TDataSetField (see page 7060) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDataSetField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TDataSetField (see page 7060). Instead, the field components are created automatically, as persistent field components defined in the Fields (see page 7384) editor at design time or as dynamic field components created automatically by the dataset.

Create sets the DataType (see page 7159) property to ftDataSet. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TDataSetField (see page 7060). After instantiating a TDataSetField (see page 7060), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TDataSetField (see page 7060) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Specify the dataset that contains the dataset field by setting its DataSet (see page 7157) property.

39.1.19.3 TDataSetField.Destroy Destructor

Destroys an instance of TObjectField.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataSetField();
```

Description

Do not call Destroy directly in an application. The destructor is called automatically by the dataset that owns the object field component, and applications never need to call it explicitly.

If an application creates a descendant of TObjectField without an owner, it should call Free instead of Destroy. Free checks that the field reference is not nil, and only then calls Destroy.

Destroy closes the dataset, deletes the instance of TObjectField from the dataset, and calls the inherited destructor.

See Also

Free (see page 22300)

39.1.19.4 TDataSetField Methods

The methods of the TDataSetField class are listed here.

Protected Methods

	Name	Description
	Bind (see page 7069)	This is Bind, a member of class TDataSetField.
	GetCanModify (see page 7069)	This is GetCanModify, a member of class TDataSetField.
	GetFields (see page 7069)	This is GetFields, a member of class TDataSetField.

Public Methods

	Name	Description
	Assign (see page 7068)	Copies the Value property from another field component or assigns another object to the field component.

39.1.19.4.1 TDataSetField.Assign Method

Copies the Value property from another field component or assigns another object to the field component.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to copy the Value property from one field to another. The fields must have compatible data types.

When Source is another field object, Assign calls the AssignValue method, using the Source field's Value property. Calling Assign with the Source parameter set to nil (Delphi) or NULL (C++) assigns a blank value to the field component. Calling Assign with any other object type calls the inherited method, which allows assignment from objects that implement a TField object in their AssignTo method.

See Also

AssignValue (see page 7124)

Clear (see page 7126)

DataType (see page 7159)

AssignTo (see page 2931)

Value (see page 7180)

39.1.19.4.2 TDataSetField.Bind Method

Pascal

```
procedure Bind(Binding: Boolean); override;
```

C++

```
virtual __fastcall Bind(Boolean Binding);
```

Description

This is Bind, a member of class TDataSetField.

39.1.19.4.3 TDataSetField.GetCanModify Method

Pascal

```
function GetCanModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetCanModify();
```

Description

This is GetCanModify, a member of class TDataSetField.

39.1.19.4.4 TDataSetField.GetFields Method

Pascal

```
function GetFields: TFields; override;
```

C++

```
virtual __fastcall TFields GetFields();
```

Description

This is GetFields, a member of class TDataSetField.

39.1.19.5 TDataSetField Properties

The properties of the TDataSetField class are listed here.

Public Properties

	Name	Description
R	NestedDataSet (see page 7070)	Indicates the dataset that is nested in the dataset field.

Published Properties

	Name	Description
	IncludeObjectField (see page 7069)	Indicates whether this field can be represented as a persistent field in the nested dataset. Reserved for future use.

39.1.19.5.1 TDataSetField.IncludeObjectField Property

Indicates whether this field can be represented as a persistent field in the nested dataset. Reserved for future use.

Pascal

```
property IncludeObjectField: Boolean;
```

C++

```
__property Boolean IncludeObjectField;
```

Description

The IncludeObjectField property is not currently implemented.

In BDE-enabled datasets, set this property to true to allow the nested dataset that is the value of this field to access this parent dataset field. When this property is true, a persistent field can be created for this dataset field in the detail dataset using the Fields (see page 7384) editor. The name of this dataset field is then displayed above the child fields in a grid associated with the nested dataset.

The default value is false.

See Also

NestedDataSet (see page 7070)

ParentField (see page 7176)

DataSetField (see page 7013)

39.1.19.5.2 TDataSetField.NestedDataSet Property

Indicates the dataset that is nested in the dataset field.

Pascal

```
property NestedDataSet: TDataSet;
```

C++

```
__property TDataSet NestedDataSet;
```

Description

Read NestedDataSet to access the nested dataset of the dataset field.

See Also

DataSetField (see page 7013)

Working with DataSet Fields

39.1.20 TDataSource Class

TDataSource provides an interface between a dataset component and data-aware controls on a form.

Class Hierarchy

Pascal

```
TDataSource = class(TComponent);
```

C++

```
class TDataSource : public TComponent;
```

File

DB

Description

Use TDataSource to

provide a conduit between a dataset and data-aware controls on a form that enable display, navigation, and editing of the data underlying the dataset.

link two datasets in a master/detail relationship.

All datasets must be associated with a data source component if their data is to be displayed and manipulated in data-aware controls. Similarly, each data-aware control needs to be associated with a data source component in order for the control to receive and manipulate data.

Data source components also link datasets in master-detail relationships.

Delphi Examples:

```
{
This example requires two ClientDataSets, two DBGrids, two
DataSources and two DBNavigators.  Name the two
ClientDataSets CDS and CDS2. Set the DataSet property in the
first DataSource to CDS and name that DataSource DS.  Set the
DataSet property in the second DataSource to CDS2 and name
that DataSource DS2.  Set the DataSource in the first
DBNavigator to DS and the DataSource in the second DBNavigator
to DS2.  Set the DataSource in the first DBGrid to DS and the
DataSource in the second DBGrid to DS2.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
attribute name of HOST with an attribute type of string and
an attribute name of PORTA with an attribute type of integer.
Add DB, DBCtrls, Grids, DBGrids, DBClient and SwSystem to the
uses clause.  "LoadFormFile" to start with the file, or
"CreateDataSet" to start from scratch.  You must "CloseDataSet"
after a "LoadFromFile" before you can do another "CreateDataSet".
}
{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button1Click(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.SaveToFile(GetCurrentDir + '\CDS.XML', dfXML);
{$ELSE}
  CDS.SaveToFile(gsAppPath + 'CDS.XML', dfXML);
{$ENDIF}
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  CDS.CreateDataSet;
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  CDS2.Data := CDS.Data;
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  CDS.Close;
end;
```

VCL Overview

39.1.20.1 TDataSource Members

The following tables list the members exposed by TDataSource.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	DataLinks (see page 7078)	This is DataLinks, a member of class TDataSource.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 7075)	Creates an instance of a TDataSource (see page 7070) component.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 7075)	Destroys the instance of a data source component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.

V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 7076)	Puts the associated dataset into edit mode, if possible.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 7076)	Checks whether a data source is linked to a specified dataset.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.

R	State (see page 7080)	Reads the current state of the dataset component associated with a data source.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnDataChange (see page 7080)	Occurs when the data in a record has changed, either due to field edits or moving the cursor to a new record.
	OnStateChange (see page 7082)	Occurs when the state of a data source component's dataset changes.
	OnUpdateData (see page 7082)	Occurs when the data in the current record is about to be updated.

Published Properties

	Name	Description
	AutoEdit (see page 7077)	Determines if a data source component automatically calls a dataset's Edit (see page 7076) method when a data-aware control associated with the data source receives focus.
	DataSet (see page 7078)	Specifies the dataset for which the data source component serves as a conduit to data-aware controls or other datasets.
	Enabled (see page 7079)	Determines if the data-aware controls associated with the data source component display data.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

39.1.20.2 TDataSource.Create Constructor

Creates an instance of a TDataSource (see page 7070) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDataSource(TComponent * AOwner);
```

Description

Call Create to instantiate a TDataSource (see page 7070) component at runtime. Data source components added to a form or data module at design time are automatically created.

Create instantiates a data link list, and sets the Enabled (see page 7079) and AutoEdit (see page 7077) properties of the component to true.

See Also

AutoEdit (see page 7077)

Enabled (see page 7079)

Destroy (see page 7075)

39.1.20.3 TDataSource.Destroy Destructor

Destroys the instance of a data source component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataSource();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the data source reference is not nil before calling Destroy.

Destroy sets OnStateChange (see page 7082) to nil (Delphi) or NULL (C++), sets the dataset for the component to nil (Delphi) or NULL (C++), and frees the data link list before calling the inherited destructor for the component.

See Also

Create (see page 7075)

DataSet (see page 7078)

OnStateChange (see page 7082)

Create (see page 7075)

Free (see page 22300)

39.1.20.4 TDataSource Methods

The methods of the TDataSource class are listed here.

Public Methods

	Name	Description
	Edit (see page 7076)	Puts the associated dataset into edit mode, if possible.
	IsLinkedTo (see page 7076)	Checks whether a data source is linked to a specified dataset.

39.1.20.4.1 TDataSource.Edit Method

Puts the associated dataset into edit mode, if possible.

Pascal

```
procedure Edit;
```

C++

```
__fastcall Edit();
```

Description

Call Edit to enable a data source component to control a user's ability to edit a dataset associated with the data source. Edit checks that the AutoEdit (see page 7077) property of the data source is true and that its State (see page 7080) property is dsBrowse before calling the dataset's Edit method. Checking these properties before calling the dataset's Edit method ensures that the dataset is in a state that supports editing, and that the data source allows editing as well.

See Also

AutoEdit (see page 7077)

State (see page 7080)

Edit (see page 6932)

39.1.20.4.2 TDataSource.IsLinkedTo Method

Checks whether a data source is linked to a specified dataset.

Pascal

```
function IsLinkedTo(DataSet: TDataSet): Boolean;
```

C++

```
__fastcall Boolean IsLinkedTo(TDataSet DataSet);
```

Description

Call IsLinkedTo to verify that a data source is linked to a specific dataset. DataSet (see page 7078) is the name of the dataset to which the data source should be linked.

If the data source already uses the specified dataset (or its parent dataset if the specified dataset is nested in another dataset), IsLinkedTo returns true. If the data source does not use the specified dataset IsLinkedTo returns false.

Note: IsLinkedTo is a low-level method mainly of interest to component developers who need to detect circular data references. Otherwise IsLinkedTo should not be called directly.

See Also

DataSet (see page 7078)

IsLinkedTo (see page 6967)

39.1.20.5 TDataSource Properties

The properties of the TDataSource class are listed here.

Protected Properties

	Name	Description
R	DataLinks (see page 7078)	This is DataLinks, a member of class TDataSource.

Public Properties

	Name	Description
R	State (see page 7080)	Reads the current state of the dataset component associated with a data source.

Published Properties

	Name	Description
	AutoEdit (see page 7077)	Determines if a data source component automatically calls a dataset's Edit (see page 7076) method when a data-aware control associated with the data source receives focus.
	DataSet (see page 7078)	Specifies the dataset for which the data source component serves as a conduit to data-aware controls or other datasets.
	Enabled (see page 7079)	Determines if the data-aware controls associated with the data source component display data.

39.1.20.5.1 TDataSource.AutoEdit Property

Determines if a data source component automatically calls a dataset's Edit (see page 7076) method when a data-aware control associated with the data source receives focus.

Pascal

```
property AutoEdit: Boolean;
```

C++

```
__property Boolean AutoEdit;
```

Description

AutoEdit is true by default. If AutoEdit is true, then when a user attempts to modify the data displayed by the control the data source calls the underlying dataset's Edit (see page 7076) method.

Set AutoEdit to false to protect data from unintentional modification. Even if AutoEdit is false, an application can explicitly call a dataset's Edit (see page 7076) method to permit data modification.

See Also

DataSet (see page 7078)

Enabled (see page 7079)

OnDataChange (see page 7080)

OnStateChange (see page 7082)

Edit (see page 7076)

Edit (see page 6932)

Enabling Editing in Controls On User Entry

39.1.20.5.2 TDataSource.DataLinks Property

Pascal

```
property DataLinks: TList;
```

C++

```
__property TList DataLinks;
```

Description

This is DataLinks, a member of class TDataSource.

39.1.20.5.3 TDataSource.DataSet Property

Specifies the dataset for which the data source component serves as a conduit to data-aware controls or other datasets.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Set DataSet to the name of an existing dataset component either at design time, or at runtime. By changing the value of DataSet at runtime an application can effectively use the same data-aware controls to display and edit data in different datasets.

DataSource.DataSet := ClientDataSet1;

DataSource->DataSet = ClientDataSet1;

Note: To link a dataset that resides in a data module to a form at design-time, choose File | Use unit (Delphi) or File | Include unit header (C++).

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

AutoEdit (see page 7077)

Enabled (see page 7079)

Associating a Data Control with a Dataset

39.1.20.5.4 TDataSource.Enabled Property

Determines if the data-aware controls associated with the data source component display data.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to control whether data-aware controls connected to a data source display data. If Enabled is true (the default), data are displayed. If Enabled is false, all controls associated with the data source are blank.

Note: While an application can set Enabled to false to blank out data-aware controls during processing of multiple records, a better choice is to use the TDataSet (see page 6894) EnableControls and DisableControls methods. Using these methods prevents the controls from blanking out during processing.

See Also

State (see page 7080)

DisableControls (see page 6925)

EnableControls (see page 6934)

Editing Data in a Control

Enabling and Disabling the Data Source

39.1.20.5.5 TDataSource.State Property

Reads the current state of the dataset component associated with a data source.

Pascal

```
property State: TDataSetState;
```

C++

```
__property TDataSetState State;
```

Description

Examine State to determine the current state of the dataset associated with a data source component. The state of a dataset indicates the action, if any, taking place against the dataset.

The possible values of State correspond to the values for a dataset's State property and are identical to them except that when Enabled (see page 7079) is false or DataSet (see page 7078) is unassigned, State is dsInactive regardless of the actual state of the dataset.

See Also

DataSet (see page 7078)

Enabled (see page 7079)

Edit (see page 7076)

State (see page 7036)

OnCalcFields (see page 7053)

OnFilterRecord (see page 7055)

SetRange (see page 10209)

39.1.20.6 TDataSource Events

The events of the TDataSource class are listed here.

Published Events

	Name	Description
	OnDataChange (see page 7080)	Occurs when the data in a record has changed, either due to field edits or moving the cursor to a new record.
	OnStateChange (see page 7082)	Occurs when the state of a data source component's dataset changes.
	OnUpdateData (see page 7082)	Occurs when the data in the current record is about to be updated.

39.1.20.6.1 TDataSource.OnDataChange Event

Occurs when the data in a record has changed, either due to field edits or moving the cursor to a new record.

Pascal

```
property OnDataChange: TDataChangeEvent;
```

C++

```
__property TDataChangeEvent OnDataChange;
```

Description

Write an OnDataChange event handler to take specific actions when a field in the current record has been edited and the

application moves to another field, or when the current record in the associated dataset changes. OnDataChange is especially useful in applications that must synchronize data display in controls that are not data-aware. This event is typically used to make sure the control reflects the current field values in the dataset, because it is triggered by all changes.

Methods that can trigger this event include the Next or Prior methods for the dataset. Data-aware controls notify a data source of a data change when:

Scrolling to a new record.

Modifications to a field's data.

Delphi Examples:

```
{
This example uses a button to copy the value of a field in
the previous record into the corresponding field in the
current record.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   SavePlace: TBookmark;
   PrevValue: Variant;
begin
   with Customers do
   begin
    { get a bookmark so that we can return to the same record }
    SavePlace := GetBookmark;
    try
      { move to prior record}
      FindPrior;
      { get the value }
      PrevValue := Fields[1].Value;
      {Move back to the bookmark
      this may not be the next record anymore
      if something else is changing the dataset asynchronously }
      GotoBookmark(SavePlace);
      { Set the value }
      Edit;
      Fields[1].Value := PrevValue;
      { Free the bookmark }
    finally
      FreeBookmark(SavePlace);
    end;
  end;
end;

{
To ensure that the button is disabled when there is no
previous record, the OnDataChange event of the DataSource
detects when the user moves to the beginning of file (BOF
property becomes true), and disables the button.  Detection
occurs on scrolling and editing, not selection with the mouse.
}
procedure TForm1.DS2DataChange(Sender: TObject; Field: TField);
begin
  if Customers.Bof then
    Button1.Enabled := False
  else
    Button1.Enabled := True;
end;

Responding to Changes Mediated by the Data Source

Displaying

39.1.20.6.2 TDataSource.OnStateChange Event

Occurs when the state of a data source component's dataset changes.

Pascal

```
property OnStateChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStateChange;
```

Description

Write an OnStateChange event handler to take specific actions when the State (see page 7080) property changes for a dataset associated with a data source component.

During the course of a normal connection to a database, a dataset's state changes frequently. For example, each time a user starts editing a field in a data-aware control the dataset's State (see page 7080) property is changed from dsBrowse to dsEdit if the State (see page 7080) is not already dsEdit. An OnStateChange event handler can respond to changes in state by taking actions such as disabling or enabling menu items or buttons.

Displaying

39.1.20.6.3 TDataSource.OnUpdateData Event

Occurs when the data in the current record is about to be updated.

Pascal

```
property OnUpdateData: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnUpdateData;
```

Description

Write an OnUpdateData event handler to take specific actions prior to posting data changes to the database. If an application posts changes to the database and an OnUpdateData event handler exists, the handler is called before the dataset's Post method is executed. An OnUpdateData event handler might be useful for performing additional data processing or validation before posting.

39.1.21 TDateField Class

TDateField represents a date field in a dataset.

Class Hierarchy

Pascal

```
TDateField = class(TDateTimeField);
```

C++

```
class TDateField : public TDateTimeField;
```

File

DB

Description

TDateField encapsulates the fundamental behavior common to Date fields. Date fields contain date values (without any time value), which they manage using the TDateTime type (Delphi) or class (C++).

If you use the Fields editor at design time to create a persistent field component for the date field, you can access it by name at runtime. When using dynamic field components, you can access the TDateField instance using the dataset's Fields property or FieldByName method.

39.1.21.1 TDateField Members

The following tables list the members exposed by TDateField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7098)	This is CopyData, a member of class TDateTimeField.
V	CopyData (see page 7127)	This is CopyData, a member of class TField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7098)	This is GetAsDateTime, a member of class TDateTimeField.
V	GetAsDateTime (see page 7129)	This is GetAsDateTime, a member of class TField.
V	GetAsFloat (see page 7099)	This is GetAsFloat, a member of class TDateTimeField.
V	GetAsFloat (see page 7129)	This is GetAsFloat, a member of class TField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7099)	This is GetAsString, a member of class TDateTimeField.
V	GetAsString (see page 7130)	This is GetAsString, a member of class TField.
V	GetAsVariant (see page 7099)	This is GetAsVariant, a member of class TDateTimeField.
V	GetAsVariant (see page 7130)	This is GetAsVariant, a member of class TField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7090)	This is GetDataSize, a member of class TDateField.
V	GetDefaultWidth (see page 7100)	This is GetDefaultWidth, a member of class TDateTimeField.
V	GetDefaultWidth (see page 7133)	This is GetDefaultWidth, a member of class TField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 7100)	This is GetText, a member of class TDateTimeField.

	GetText (see page 7135)	This is GetText, a member of class TField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7100)	This is SetAsDateTime, a member of class TDateTimeField.
	SetAsDateTime (see page 7139)	This is SetAsDateTime, a member of class TField.
	SetAsFloat (see page 7100)	This is SetAsFloat, a member of class TDateTimeField.
	SetAsFloat (see page 7140)	This is SetAsFloat, a member of class TField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7100)	This is SetAsString, a member of class TDateTimeField.
	SetAsString (see page 7140)	This is SetAsString, a member of class TField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 7101)	This is SetVarValue, a member of class TDateTimeField.
	SetVarValue (see page 7144)	This is SetVarValue, a member of class TField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.

	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.
	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 7126)	Sets the value of the field to NULL.
	Create (see page 7089)	Creates an instance of TDateField (see page 7083).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.

	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetData (see page 7141)	Assigns unformatted data to the field.
V	SetFieldType (see page 7142)	Provides the interface for a method that can set the DataType (see page 7159) for the field.
V	SetParentComponent (see page 7143)	This is SetParentComponent, a member of class TField.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	Validate (see page 7144)	Generates an OnValidate (see page 7183) event.

Public Properties

	Name	Description
	AsBCD (see page 7147)	Represents the field's value as a TBcd value.
	AsBoolean (see page 7147)	Represents the field's value as a boolean value.
	AsCurrency (see page 7148)	Represents the field's value as a Currency value.
	AsDateTime (see page 7148)	Represents the field's value as a TDateTime value.
	AsFloat (see page 7149)	Represents the field's value as a double value.
	AsInteger (see page 7149)	Represents the field's value as a 32-bit integer.
	AsSQLTimeStamp (see page 7150)	Represents the field's value as a TSQLTimeStamp.
	AsString (see page 7151)	Represents the field's value as a string (Delphi) or an AnsiString (C++).
	AsVariant (see page 7152)	Represents the Value (see page 7180) of the field as a Variant.
	AsWideString (see page 7152)	This is AsWideString, a member of class TField.
	AttributeSet (see page 7153)	Specifies the name of an attribute set in the data dictionary to apply to the field component.
	Calculated (see page 7154)	Determines whether the value of the field is calculated by the OnCalcFields event handler of its dataset.
R	CanModify (see page 7154)	Specifies whether a field can be modified.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.

R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurValue (see page 7155)	Represents the current value of the field component including changes made by other users of the database.
	DataSet (see page 7157)	Identifies the dataset to which a field component belongs.
R	DataSize (see page 7157)	Indicates the amount of memory needed to store a field component's value.
R	DataType (see page 7159)	Identifies the data type of the field component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DisplayName (see page 7160)	Represents the name of the field for display purposes.
R	DisplayText (see page 7162)	Represents the field's value as it is displayed in a data-aware control.
	EditMask (see page 7163)	Contains a mask that restricts the data that can be entered into a data field.
R	EditMaskPtr (see page 7163)	Provides read-only access to the EditMask (see page 7163) property.
R	FieldNo (see page 7166)	Indicates the ordinal position of the field's column in the underlying table or query result.
R	FullName (see page 7166)	Indicates the field name qualified by the full name of the parent field, if any.
R	IsIndexField (see page 7168)	Indicates whether a field is an index field.
R	IsNull (see page 7169)	Indicates whether the field has a value assigned to it.
	Lookup (see page 7170)	Determines whether the field is specified as a lookup field.
R	LookupList (see page 7172)	Indicates a cache of values from the LookupDataSet (see page 7171) indexed by a set of values from the KeyFields (see page 7169) property.
	NewValue (see page 7174)	Represents the current value of the field component including pending cached updates.
R	Offset (see page 7175)	Indicates the number of bytes added to the end of the current record buffer in the dataset for storing cached values (for calculated fields or BLOB fields).
R	OldValue (see page 7175)	Represents the original value of the field (as a Variant).
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	ParentField (see page 7176)	Specifies the TObjectField (see page 7372) object from which this field is derived.
	Size (see page 7178)	Indicates the size used in the definition of the physical database field for data types that support different sizes.
	Text (see page 7179)	Contains the string to display in a data-aware control when the field is in edit mode.
	ValidChars (see page 7179)	Specifies the characters that can be included in the text representation of the field's value.
	Value (see page 7103)	Represents the value of the date in the date-time field.
	Value (see page 7180)	Represents the data in a field component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnChange (see page 7181)	Occurs immediately after the data in the field is written to the record buffer.
	OnGetText (see page 7182)	Occurs when the DisplayText (see page 7162) or Text (see page 7179) properties of the field are referenced.
	OnSetText (see page 7182)	Occurs when the Text (see page 7179) property is assigned a value.
	OnValidate (see page 7183)	Occurs just before the data is written to the record buffer.

Published Properties

	Name	Description
	Alignment (see page 7146)	Determines how the field's data is displayed within a data-aware control.
	AutoGenerateValue (see page 7153)	Indicates whether the field values can be generated by the server rather than entered by the user.
	ConstraintErrorMessage (see page 7155)	Specifies a customized error message that appears when the user tries to set a value that violates the data constraints of the field.
	CustomConstraint (see page 7156)	Specifies an SQL string the enforces any application-specific constraints on the field's value.
	DefaultExpression (see page 7159)	Specifies an SQL expression that is assigned to the field if the user does not provide a value.

	DisplayFormat (see page 7101)	Controls (see page 5711) the formatting of the date-time field for display purposes.
	DisplayLabel (see page 7160)	Contains the text to display in the corresponding column heading of a data grid.
	DisplayWidth (see page 7162)	Specifies the number of characters that should be used to display a field's value by a cooperating data-aware control.
	EditMask (see page 7102)	Contains a mask that restricts the data that can be entered into a data field.
	FieldKind (see page 7164)	Indicates whether a field represents a column in a dataset, a calculated field, or a lookup field.
	FieldName (see page 7164)	Indicates the name of the physical column in the underlying table or query result to which a field component is bound.
R	HasConstraints (see page 7167)	Indicates whether field values are constrained.
	ImportedConstraint (see page 7167)	Represents an SQL clause that enforces constraints stored on the server.
	Index (see page 7168)	Specifies the field component's index in the Fields property of the dataset.
	KeyFields (see page 7169)	Identifies the field or fields in the dataset that must be matched in a lookup dataset when doing a lookup.
	LookupCache (see page 7170)	Determines whether the values of a lookup field are cached or looked up dynamically every time the current record in the dataset changes.
	LookupDataSet (see page 7171)	Identifies the dataset used to look up field values.
	LookupKeyFields (see page 7172)	Identifies the field or fields in the lookup dataset to match when doing a lookup.
	LookupResultField (see page 7173)	Identifies the field from the lookup dataset whose value becomes the Value (see page 7180) property of the field component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Origin (see page 7176)	Indicates the name of the field in its original database table.
	ProviderFlags (see page 7176)	Specifies how a provider uses the field value when applying updates.
	ReadOnly (see page 7177)	Determines whether the field can be modified.
	Required (see page 7177)	Specifies whether a nonblank value for a field is required.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 7181)	Determines whether the field appears in a data grid.

39.1.21.2 TDateField.Create Constructor

Creates an instance of TDateField (see page 7083).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDateField(TComponent * AOwner);
```

Description

Most applications do not explicitly create instances of TDateField (see page 7083). Instead, the field components are created automatically, as persistent field components defined in the Fields editor at design time or as dynamic field components created automatically by the dataset.

Create sets the DataType (see page 7159) property to ftDate. The AOwner parameter specifies the component, typically a dataset, that becomes the new field's Owner. The Owner is responsible for freeing the component.

In the rare cases when you must create a persistent field component at runtime, call Create to create and initialize an instance of TDateField (see page 7083). After instantiating a TDateField (see page 7083), associate it with a specific field by setting its FieldName (see page 7164) property to the name of the field. Give the TDateField (see page 7083) a unique identifier in the Name property. Establish where the field appears in the collection of fields by providing an ordinal number in the Index (see page 7168) property. Associate the TDateField (see page 7083) with a dataset component by setting its DataSet (see page 7157) property.

The example below creates a TDateField (see page 7083) object for a field named LastContact accessed through a TClientDataSet named ClientDataSet1.

```
var
  T: TDateField;
begin
  ClientDataSet1.Close;
  T := TDateField.Create(ClientDataSet1);
  T.FieldName := 'LastContact';
  T.Name := ClientDataSet1.Name + T.FieldName;
  T.Index := ClientDataSet1.FieldCount;
  T.DataSet := ClientDataSet1;
  T.DisplayFormat := 'mm/dd/yyyy';
  ClientDataSet1.FieldDefs.UpDate;
  ClientDataSet1.Open;
end;
ClientDataSet1->Close();
TDateField *T = new TDateField(ClientDataSet1);
T->FieldName = "LastContact";
T->Name = ClientDataSet1->Name + T->FieldName;
T->Index = ClientDataSet1->FieldCount;
T->DataSet = ClientDataSet1;
T->DisplayFormat = "mm//dd//yyyy";
ClientDataSet1->FieldDefs->UpDate();
ClientDataSet1->Open();
```

39.1.21.3 TDateField Methods

The methods of the TDateField class are listed here.

Protected Methods

	Name	Description
	GetDataSize (see page 7090)	This is GetDataSize, a member of class TDateField.

39.1.21.3.1 TDateField.GetDataSize Method

Pascal

```
function GetDataSize: Integer; override;
```

C++

```
virtual __fastcall int GetDataSize();
```

Description

This is GetDataSize, a member of class TDateField.

39.1.22 TDateTimeField Class

TDateTimeField represents a date-time field in a dataset.

Class Hierarchy

Pascal

```
TDateTimeField = class(TField);
```

C++

```
class TDateTimeField : public TField;
```

File

DB

Description

TDateTimeField encapsulates the fundamental behavior common to Date-time fields. Date-time fields contain combined date and time information, sometimes called timestamps. TDateTimeField introduces new properties to convert between date-time values and other data types, and to format the value of a date-time field for display.

Note: Date-time values accessed through dbExpress use TSQLTimeStampField (see page 7469) instead of TDateTimeField

If you use the Fields editor at design time to create a persistent field component for the date-time field, you can access it by name at runtime. When using dynamic field components, you can access the TDateTimeField instance using the dataset's Fields property or FieldByName method.

39.1.22.1 TDateTimeField Members

The following tables list the members exposed by TDateTimeField.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AccessError (see page 7124)	This is AccessError, a member of class TField.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Bind (see page 7126)	This is Bind, a member of class TField.
V	Change (see page 7126)	This is Change, a member of class TField.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	CheckInactive (see page 7126)	This is CheckInactive, a member of class TField.
V	CheckTypeSize (see page 7126)	This is CheckTypeSize, a member of class TField.
V	CopyData (see page 7098)	This is CopyData, a member of class TDateTimeField.
	DataChanged (see page 7127)	This is DataChanged, a member of class TField.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 7127)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	FreeBuffers (see page 7128)	This is FreeBuffers, a member of class TField.
V	GetAsBCD (see page 7128)	This is GetAsBCD, a member of class TField.
V	GetAsBoolean (see page 7129)	This is GetAsBoolean, a member of class TField.
V	GetAsByteArray (see page 7129)	This is GetAsByteArray, a member of class TField.
V	GetAsCurrency (see page 7129)	This is GetAsCurrency, a member of class TField.
V	GetAsDateTime (see page 7098)	This is GetAsDateTime, a member of class TDateTimeField.
V	GetAsFloat (see page 7099)	This is GetAsFloat, a member of class TDateTimeField.
V	GetAsInteger (see page 7130)	This is GetAsInteger, a member of class TField.
V	GetAsSQLTimeStamp (see page 7130)	This is GetAsSQLTimeStamp, a member of class TField.
V	GetAsString (see page 7099)	This is GetAsString, a member of class TDateTimeField.
V	GetAsVariant (see page 7099)	This is GetAsVariant, a member of class TDateTimeField.
V	GetAsWideString (see page 7131)	This is GetAsWideString, a member of class TField.
V	GetCanModify (see page 7131)	This is GetCanModify, a member of class TField.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClassDesc (see page 7131)	This is GetClassDesc, a member of class TField.
V	GetDataSize (see page 7099)	This is GetDataSize, a member of class TDateTimeField.
V	GetDefaultWidth (see page 7100)	This is GetDefaultWidth, a member of class TDateTimeField.
V	GetFieldNo (see page 7134)	This is GetFieldNo, a member of class TField.
V	GetHasConstraints (see page 7134)	This is GetHasConstraints, a member of class TField.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetIsNull (see page 7134)	This is GetIsNull, a member of class TField.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSize (see page 7135)	This is GetSize, a member of class TField.
V	GetText (see page 7100)	This is GetText, a member of class TDateTimeField.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
V	GetWideText (see page 7135)	This is GetWideText, a member of class TField.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.

	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 7137)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PropertyChanged (see page 7138)	This is PropertyChanged, a member of class TField.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 7138)	This is ReadState, a member of class TField.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAsBCD (see page 7139)	This is SetAsBCD, a member of class TField.
	SetAsBoolean (see page 7139)	This is SetAsBoolean, a member of class TField.
	SetAsByteArray (see page 7139)	This is SetAsByteArray, a member of class TField.
	SetAsCurrency (see page 7139)	This is SetAsCurrency, a member of class TField.
	SetAsDateTime (see page 7100)	This is SetAsDateTime, a member of class TDateTimeField.
	SetAsFloat (see page 7100)	This is SetAsFloat, a member of class TDateTimeField.
	SetAsInteger (see page 7140)	This is SetAsInteger, a member of class TField.
	SetAsSQLTimeStamp (see page 7140)	This is SetAsSQLTimeStamp, a member of class TField.
	SetAsString (see page 7100)	This is SetAsString, a member of class TDateTimeField.
	SetAsVariant (see page 7141)	This is SetAsVariant, a member of class TField.
	SetAsWideString (see page 7141)	This is SetAsWideString, a member of class TField.
	SetAutoGenerateValue (see page 7141)	This is SetAutoGenerateValue, a member of class TField.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 7142)	This is SetDataSet, a member of class TField.
	SetDataType (see page 7142)	This is SetDataType, a member of class TField.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldKind (see page 7142)	This is SetFieldKind, a member of class TField.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentField (see page 7143)	This is SetParentField, a member of class TField.
	SetSize (see page 7143)	This is SetSize, a member of class TField.
	SetText (see page 7144)	This is SetText, a member of class TField.
	SetVarValue (see page 7101)	This is SetVarValue, a member of class TDateTimeField.
	SetWideText (see page 7144)	This is SetWideText, a member of class TField.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 7124)	Copies the Value (see page 7180) property from another field component or assigns another object to the field component.

	AssignValue (see page 7124)	Sets the field value using one of the AsInteger (see page 7149), AsBoolean (see page 7147), AsString (see page 7151) or AsFloat (see page 7149) properties.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 7126)	Sets the value of the field to NULL.
V	Create (see page 7097)	Creates and initializes a TDateTimeField (see page 7090) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 7122)	Destroys an instance of TField (see page 7115).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FocusControl (see page 7128)	Forces a form's focus to the first data-aware component associated with the field object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetData (see page 7131)	Returns the unformatted data for the field.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 7134)	Returns the component which directs the loading and saving of the field.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 7135)	Returns true, indicating that field components act as part of a larger composite.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsBlob (see page 7136)	Indicates whether the field represents the data in a binary large object (BLOB) field.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
V	IsValidChar (see page 7136)	Indicates whether a particular character is valid for the field.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RefreshLookupList (see page 7138)	Loads LookupList (see page 7172) with all the values for LookupResultField (see page 7173) that match distinct values of LookupKeyFields (see page 7172).
