	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.
	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.
	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.

	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.
	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Menu (see page 14045)	Specifies the form's main menu.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.

	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.
	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.
	WindowState (see page 14063)	Represents how the form appears on the screen.

48.1.1.2 TDbEngineErrorDlg Fields

The fields of the TDbEngineErrorDlg class are listed here.

Public Fields

	Name	Description
	BackBtn (see page 9564)	This is BackBtn, a member of class TDbEngineErrorDlg.
	BasicPanel (see page 9564)	This is BasicPanel, a member of class TDbEngineErrorDlg.
	BDELabel (see page 9564)	This is BDELabel, a member of class TDbEngineErrorDlg.
	ButtonPanel (see page 9564)	This is ButtonPanel, a member of class TDbEngineErrorDlg.
	DbCatSub (see page 9564)	This is DbCatSub, a member of class TDbEngineErrorDlg.
	DbMessageText (see page 9565)	This is DbMessageText, a member of class TDbEngineErrorDlg.
	DbResult (see page 9565)	This is DbResult, a member of class TDbEngineErrorDlg.
	DetailsBtn (see page 9565)	This is DetailsBtn, a member of class TDbEngineErrorDlg.
	DetailsPanel (see page 9565)	This is DetailsPanel, a member of class TDbEngineErrorDlg.
	ErrorText (see page 9566)	This is ErrorText, a member of class TDbEngineErrorDlg.
	IconImage (see page 9566)	This is IconImage, a member of class TDbEngineErrorDlg.
	IconPanel (see page 9566)	This is IconPanel, a member of class TDbEngineErrorDlg.
	NativeLabel (see page 9566)	This is NativeLabel, a member of class TDbEngineErrorDlg.
	NativeResult (see page 9566)	This is NativeResult, a member of class TDbEngineErrorDlg.
	NextBtn (see page 9567)	This is NextBtn, a member of class TDbEngineErrorDlg.
	OKBtn (see page 9567)	This is OKBtn, a member of class TDbEngineErrorDlg.
	RightPanel (see page 9567)	This is RightPanel, a member of class TDbEngineErrorDlg.
	TopPanel (see page 9567)	This is TopPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.1 TDbEngineErrorDlg.BackBtn Field

Pascal

```
BackBtn: TButton;
```

C++

```
TButton BackBtn;
```

Description

This is BackBtn, a member of class TDbEngineErrorDlg.

48.1.1.2.2 TDbEngineErrorDlg.BasicPanel Field

Pascal

```
BasicPanel: TPanel;
```

C++

```
TPanel BasicPanel;
```

Description

This is BasicPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.3 TDbEngineErrorDlg.BDELabel Field

Pascal

```
BDELabel: TLabel;
```

C++

```
TLabel BDELabel;
```

Description

This is BDELabel, a member of class TDbEngineErrorDlg.

48.1.1.2.4 TDbEngineErrorDlg.ButtonPanel Field

Pascal

```
ButtonPanel: TPanel;
```

C++

```
TPanel ButtonPanel;
```

Description

This is ButtonPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.5 TDbEngineErrorDlg.DbCatSub Field

Pascal

```
DbCatSub: TEdit;
```

C++

```
TEdit DbCatSub;
```

Description

This is DbCatSub, a member of class TDbEngineErrorDlg.

48.1.1.2.6 TDbEngineErrorDlg.DbMessageText Field

Pascal

```
DbMessageText: TMemo;
```

C++

```
TMemo DbMessageText;
```

Description

This is DbMessageText, a member of class TDbEngineErrorDlg.

48.1.1.2.7 TDbEngineErrorDlg.DbResult Field

Pascal

```
DbResult: TEdit;
```

C++

```
TEdit DbResult;
```

Description

This is DbResult, a member of class TDbEngineErrorDlg.

48.1.1.2.8 TDbEngineErrorDlg.DetailsBtn Field

Pascal

```
DetailsBtn: TButton;
```

C++

```
TButton DetailsBtn;
```

Description

This is DetailsBtn, a member of class TDbEngineErrorDlg.

48.1.1.2.9 TDbEngineErrorDlg.DetailsPanel Field

Pascal

```
DetailsPanel: TPanel;
```

C++

```
TPanel DetailsPanel;
```

Description

This is DetailsPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.10 TDbEngineErrorDlg.ErrorText Field

Pascal

```
ErrorText: TLabel;
```

C++

```
TLabel ErrorText;
```

Description

This is ErrorText, a member of class TDbEngineErrorDlg.

48.1.1.2.11 TDbEngineErrorDlg.IconImage Field

Pascal

```
IconImage: TImage;
```

C++

```
TImage IconImage;
```

Description

This is IconImage, a member of class TDbEngineErrorDlg.

48.1.1.2.12 TDbEngineErrorDlg.IconPanel Field

Pascal

```
IconPanel: TPanel;
```

C++

```
TPanel IconPanel;
```

Description

This is IconPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.13 TDbEngineErrorDlg.NativeLabel Field

Pascal

```
NativeLabel: TLabel;
```

C++

```
TLabel NativeLabel;
```

Description

This is NativeLabel, a member of class TDbEngineErrorDlg.

48.1.1.2.14 TDbEngineErrorDlg.NativeResult Field

Pascal

```
NativeResult: TEdit;
```

C++

```
TEdit NativeResult;
```

Description

This is NativeResult, a member of class TDbEngineErrorDlg.

48.1.1.2.15 TDbEngineErrorDlg.NextBtn Field

Pascal

```
NextBtn: TButton;
```

C++

```
TButton NextBtn;
```

Description

This is NextBtn, a member of class TDbEngineErrorDlg.

48.1.1.2.16 TDbEngineErrorDlg.OKBtn Field

Pascal

```
OKBtn: TButton;
```

C++

```
TButton OKBtn;
```

Description

This is OKBtn, a member of class TDbEngineErrorDlg.

48.1.1.2.17 TDbEngineErrorDlg.RightPanel Field

Pascal

```
RightPanel: TPanel;
```

C++

```
TPanel RightPanel;
```

Description

This is RightPanel, a member of class TDbEngineErrorDlg.

48.1.1.2.18 TDbEngineErrorDlg.TopPanel Field

Pascal

```
TopPanel: TPanel;
```

C++

```
TPanel TopPanel;
```

Description

This is TopPanel, a member of class TDbEngineErrorDlg.

48.1.1.3 TDbEngineErrorDlg Methods

The methods of the TDbEngineErrorDlg class are listed here.

Public Methods

	Name	Description
	BackClick (see page 9568)	Displays the previous exception.
	DetailsBtnClick (see page 9568)	Displays or hides the detail context information for an exception.
	FormCreate (see page 9568)	Initializes the dialog when it is first created.
	FormDestroy (see page 9569)	This is FormDestroy, a member of class TDbEngineErrorDlg.
	FormShow (see page 9569)	Displays the text for the current exception and its details.
	HookExceptions (see page 9569)	Enables the TDbEngineErrorDlg (see page 9546) instance, replacing the standard exception message at runtime.
	NextClick (see page 9570)	Displays the next exception.
	ShowException (see page 9570)	Displays an EDBEngineError exception in the TDbEngineErrorDlg (see page 9546).

48.1.1.3.1 TDbEngineErrorDlg.BackClick Method

Displays the previous exception.

Pascal

```
procedure BackClick(Sender: TObject);
```

C++

```
__fastcall BackClick(TObject * Sender);
```

Description

Call BackClick to simulate clicking the Back button in the dialog. BackClick displays information about the previous exception in the stack of exceptions shown in the dialog.

See Also

NextClick (see page 9570)

DetailsBtnClick (see page 9568)

48.1.1.3.2 TDbEngineErrorDlg.DetailsBtnClick Method

Displays or hides the detail context information for an exception.

Pascal

```
procedure DetailsBtnClick(Sender: TObject);
```

C++

```
__fastcall DetailsBtnClick(TObject * Sender);
```

Description

Call DetailsBtnClick to simulate clicking the Details button in the dialog. If the detail context information is showing, DetailsBtnClick hides it. If the detail information is not showing, DetailsBtnClick displays it..

See Also

NextClick (see page 9570)

BackClick (see page 9568)

48.1.1.3.3 TDbEngineErrorDlg.FormCreate Method

Initializes the dialog when it is first created.

Pascal

```
procedure FormCreate(Sender: TObject);
```

C++

```
__fastcall FormCreate(TObject * Sender);
```

Description

Applications should not call FormCreate. It initializes the detail window so that the Details button works correctly.

See Also

formdestroy (see page 9569)

FormShow (see page 9569)

DetailsBtnClick (see page 9568)

48.1.1.3.4 TDbEngineErrorDlg.FormDestroy Method

Pascal

```
procedure FormDestroy(Sender: TObject);
```

C++

```
__fastcall FormDestroy(TObject * Sender);
```

Description

This is FormDestroy, a member of class TDbEngineErrorDlg.

48.1.1.3.5 TDbEngineErrorDlg.FormShow Method

Displays the text for the current exception and its details.

Pascal

```
procedure FormShow(Sender: TObject);
```

C++

```
__fastcall FormShow(TObject * Sender);
```

Description

Applications should not call FormShow. It is called automatically when the dialog becomes visible. FormShow sets the text for the current exception and, if detail information is showing, displays its details.

See Also

FormCreate (see page 9568)

OnException (see page 13728)

DetailsBtnClick (see page 9568)

48.1.1.3.6 TDbEngineErrorDlg.HookExceptions Method

Enables the TDbEngineErrorDlg (see page 9546) instance, replacing the standard exception message at runtime.

Pascal

```
procedure HookExceptions;
```

C++

```
__fastcall HookExceptions();
```

Description

To display all unhandled EDBEngineError exceptions in a TDbEngineErrorDlg (see page 9546) (rather than the standard message box), create a TDbEngineErrorDlg (see page 9546) and call HookExceptions to enable it:

```
TDbEngineErrorDlg.Create(Application).HookExceptions;
TDbEngineErrorDlg *pDBEDlg = new TDbEngineErrorDlg (Application);
pDBEDlg->HookExceptions();
```

If you include this code in an application's project file, in an OnCreate event handler, or the constructor for the project's main form, the TDbEngineErrorDlg (see page 9546) will trap and display unhandled EDBEngineError exceptions at runtime.

See Also

EDbEngineError

ShowException (see page 9570)

48.1.1.3.7 TDbEngineErrorDlg.NextClick Method

Displays the next exception.

Pascal

```
procedure NextClick(Sender: TObject);
```

C++

```
__fastcall NextClick(TObject * Sender);
```

Description

Call NextClick to simulate clicking the Next button in the dialog. NextClick displays information about the next exception in the stack of exceptions shown in the dialog.

See Also

BackClick (see page 9568)

DetailsBtnClick (see page 9568)

48.1.1.3.8 TDbEngineErrorDlg.ShowException Method

Displays an EDBEngineError exception in the TDbEngineErrorDlg (see page 9546).

Pascal

```
function ShowException(Error: EDbEngineError): TModalResult;
```

C++

```
__fastcall TModalResult ShowException(EDbEngineError Error);
```

Description

Call ShowException in an EDBEngineError exception handler to display the exception in a TDbEngineErrorDlg (see page 9546). You can create the TDbEngineErrorDlg (see page 9546) in the exception handler itself, or in the initialization section of your application.

See Also

EDbEngineError

ModalResult (see page 13924)

HookExceptions (see page 9569)

48.1.1.4 TDbEngineErrorDlg Properties

The properties of the TDbEngineErrorDlg class are listed here.

Public Properties

	Name	Description
	DbException (see page 9571)	Holds an instance of EDBEngineError.

48.1.1.4.1 TDbEngineErrorDlg.DbException Property

Holds an instance of EDBEngineError.

Pascal

```
property DbException: EDbEngineError;
```

C++

```
__property EDbEngineError DbException;
```

Description

DBException is the EDBEngineError instance that causes the error dialog to appear.

48.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
DbEngineErrorDlg (see page 9572)	This is variable DbExcept.DbEngineErrorDlg.

48.2.1 DbExcept.DbEngineErrorDlg Variable

Pascal

```
DbEngineErrorDlg: TDbEngineErrorDlg;
```

C++

```
TDbEngineErrorDlg DbEngineErrorDlg;
```

File

DbExcept

Description

This is variable DbExcept.DbEngineErrorDlg.

49 DBGrids Namespace

This is namespace DBGrids.

Topics

Name	Description
Classes (see page 9575)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 9765)	The following table lists structs, records, enums in this documentation.
Types (see page 9769)	The following table lists types in this documentation.
Constants (see page 9772)	The following table lists constants in this documentation.

Classes

	Name	Description
	TBookmarkList (see page 9575)	TBookmarkList is a collection of bookmarks that identify a set of records in a dataset.
	TColumn (see page 9583)	TColumn represents a column in a data grid (TDBGrid (see page 9668)).
	TColumnTitle (see page 9601)	TColumnTitle represents the title of a data-grid column (TColumn (see page 9583)).
	TCustomDBGrid (see page 9608)	TCustomDBGrid is the base class for grid controls that display the records from a dataset in a tabular format.
	TDBGrid (see page 9668)	TDBGrid displays and manipulates records from a dataset in a tabular grid.
	TDBGridColumns (see page 9746)	TDBGridColumns represents a container for TColumn (see page 9583) objects.
	TGridDataLink (see page 9754)	TGridDataLink helps manage the link to a data source and maintain the field mapping for a TCustomDBGrid (see page 9608) object.

Constants

Name	Description
cm_DeferLayout (see page 9772)	This is constant DBGrids.cm_DeferLayout.
ColumnTitleValues (see page 9772)	This is constant DBGrids.ColumnTitleValues.
IndicatorWidth (see page 9772)	This is constant DBGrids.IndicatorWidth.

Structs, Records, Enums

	Name	Description
	TColumnButtonStyle (see page 9765)	TColumnButtonStyle indicates whether and how the user can select values for a column from a list.
	TColumnValue (see page 9766)	TColumnValue and TColumnValues (see page 9769) indicate which properties on the column of a DB (see page 6725) grid are persistent.

	TDBGridColumnsState (see page 9767)	TDBGridColumnsState indicates whether the columns in a DB (see page 6725) grid dynamically reflect dataset fields.
	TDBGridOption (see page 9767)	TDBGridOption and TDBGridOptions (see page 9770) indicate display and behavioral property of a DB (see page 6725) grid.

Types

Name	Description
TColumnClass (see page 9769)	TColumnClass defines the metaclass for TColumn (see page 9583).
TColumnValues (see page 9769)	This is type DBGrids.TColumnValues.
TDBGridClickEvent (see page 9770)	This is type DBGrids.TDBGridClickEvent.
TDBGridOptions (see page 9770)	This is type DBGrids.TDBGridOptions.
TDrawColumnCellEvent (see page 9770)	This is type DBGrids.TDrawColumnCellEvent.
TDrawDataCellEvent (see page 9771)	This is type DBGrids.TDrawDataCellEvent.

49.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TBookmarkList (see page 9575)	TBookmarkList is a collection of bookmarks that identify a set of records in a dataset.
	TColumn (see page 9583)	TColumn represents a column in a data grid (TDBGrid (see page 9668)).
	TColumnTitle (see page 9601)	TColumnTitle represents the title of a data-grid column (TColumn (see page 9583)).
	TCustomDBGrid (see page 9608)	TCustomDBGrid is the base class for grid controls that display the records from a dataset in a tabular format.
	TDBGrid (see page 9668)	TDBGrid displays and manipulates records from a dataset in a tabular grid.
	TDBGridColumns (see page 9746)	TDBGridColumns represents a container for TColumn (see page 9583) objects.
	TGridDataLink (see page 9754)	TGridDataLink helps manage the link to a data source and maintain the field mapping for a TCustomDBGrid (see page 9608) object.

49.1.1 TBookmarkList Class

TBookmarkList is a collection of bookmarks that identify a set of records in a dataset.

Class Hierarchy

DBGrids.TBookmarkList

Pascal

```
TBookmarkList = class;
```

C++

```
class TBookmarkList;
```

File

DBGrids

Description

Use TBookmarkList to manage a set of bookmarks when working with the records in a dataset. Each bookmark identifies a particular record in the dataset, and can be identified by a string.

See Also

TCustomDBGrid (see page 9608)

49.1.1.1 TBookmarkList Members

The following tables list the members exposed by TBookmarkList.

Protected Methods

	Name	Description
	Compare (see page 9578)	This is Compare, a member of class TBookmarkList.
	CurrentRow (see page 9578)	This is CurrentRow, a member of class TBookmarkList.
	LinkActive (see page 9579)	This is LinkActive, a member of class TBookmarkList.

Public Methods

	Name	Description
	Clear (see page 9577)	Deletes all bookmarks from the list.
	Create (see page 9576)	Creates an instance of TBookmarkList (see page 9575) and associates it with a DBGrid.
	Delete (see page 9578)	Deletes all the records specified by the bookmarks in the list from the dataset of the associated DBGrid.
V	Destroy (see page 9576)	Destroys an instance of TBookmarkList (see page 9575).
	Find (see page 9578)	Indicates whether a specified bookmark string is contained in the bookmark list.
	IndexOf (see page 9579)	Returns the index of a bookmark string in the Items (see page 9581) property array.
	Refresh (see page 9580)	Removes all invalid bookmarks from the Items (see page 9581) property array.

Public Properties

	Name	Description
R	Count (see page 9580)	Indicates the number of bookmarks in the bookmark list.
	CurrentRowSelected (see page 9581)	Indicates whether the Bookmark property of the associated DBGrid's dataset is in the Items (see page 9581) array.
R	Items (see page 9581)	Provides indexed access to the bookmarks for marked records in the dataset.

49.1.1.2 TBookmarkList.Create Constructor

Creates an instance of TBookmarkList (see page 9575) and associates it with a DBGrid.

Pascal

```
constructor Create(AGrid: TCustomDBGrid);
```

C++

```
__fastcall TBookmarkList(TCustomDBGrid AGrid);
```

Description

Applications do not need to call create to instantiate the bookmark list used by DBGrids (see page 9573) to implement their SelectedRows property. DBGrids (see page 9573) call Create from their constructor to create this bookmark list. Component writers that implement additional properties for descendants of TCustomDBGrid (see page 9608) can create additional bookmark list objects to represent other sets of records in the dataset.

See Also

TCustomDBGrid (see page 9608)

49.1.1.3 TBookmarkList.Destroy Destructor

Destroys an instance of TBookmarkList (see page 9575).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBookmarkList();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TBookmarkList (see page 9575) object is not nil, and only then calls Destroy.

Destroy frees the memory used to store the Items (see page 9581) property array.

See Also

Free (see page 22300)

Items (see page 9581)

delete

49.1.1.4 TBookmarkList Methods

The methods of the TBookmarkList class are listed here.

Protected Methods

	Name	Description
	Compare (see page 9578)	This is Compare, a member of class TBookmarkList.
	CurrentRow (see page 9578)	This is CurrentRow, a member of class TBookmarkList.
	LinkActive (see page 9579)	This is LinkActive, a member of class TBookmarkList.

Public Methods

	Name	Description
	Clear (see page 9577)	Deletes all bookmarks from the list.
	Delete (see page 9578)	Deletes all the records specified by the bookmarks in the list from the dataset of the associated DBGrid.
	Find (see page 9578)	Indicates whether a specified bookmark string is contained in the bookmark list.
	IndexOf (see page 9579)	Returns the index of a bookmark string in the Items (see page 9581) property array.
	Refresh (see page 9580)	Removes all invalid bookmarks from the Items (see page 9581) property array.

49.1.1.4.1 TBookmarkList.Clear Method

Deletes all bookmarks from the list.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the Items (see page 9581) array and set the Count (see page 9580) property to 0 when all rows of the associated DBGrid are deselected. Calling Clear invalidates the associated DBGrid so that the selected rows that were referenced by the bookmarks in the bookmark list can be repainted.

Note: Clear removes the bookmarks from the bookmark list to reflect the fact that the corresponding rows are not selected. To delete the rows from the dataset rather than just deselecting them, call the Delete (see page 9578) method instead.

See Also

Items (see page 9581)

Delete (see page 9578)

Refresh (see page 9580)

Count (see page 9580)

49.1.1.4.2 TBookmarkList.Compare Method

Pascal

```
function Compare(const Item1: TBookmarkStr; const Item2: TBookmarkStr): Integer;
```

C++

```
__fastcall int Compare(const TBookmarkStr Item1, const TBookmarkStr Item2);
```

Description

This is Compare, a member of class TBookmarkList.

49.1.1.4.3 TBookmarkList.CurrentRow Method

Pascal

```
function CurrentRow: TBookmarkStr;
```

C++

```
__fastcall TBookmarkStr CurrentRow();
```

Description

This is CurrentRow, a member of class TBookmarkList.

49.1.1.4.4 TBookmarkList.Delete Method

Deletes all the records specified by the bookmarks in the list from the dataset of the associated DBGrid.

Pascal

```
procedure Delete;
```

C++

```
__fastcall Delete();
```

Description

Call Delete to delete the set of records represented by the bookmark list from the dataset of the associated DBGrid. To remove all the bookmarks from the list without changing the dataset, use the Clear (see page 9577) method instead.

See Also

Clear (see page 9577)

Items (see page 9581)

49.1.1.4.5 TBookmarkList.Find Method

Indicates whether a specified bookmark string is contained in the bookmark list.

Pascal

```
function Find(const Item: TBookmarkStr; var Index: Integer): Boolean;
```

C++

```
__fastcall Boolean Find(const TBookmarkStr Item, int Index);
```

Description

Call Find to determine whether the string specified by the Item parameter is one of the bookmark strings in the Items (see page 9581) property array. Find returns true if the bookmark list contains the bookmark string, false otherwise. If Find returns true, the index of the bookmark string is returned as the value of the Index parameter.

Note: The index of a specific bookmark string can also be obtained by using the IndexOf (see page 9579) method. Unlike the IndexOf (see page 9579) method, which returns a value of -1 if the bookmark string is not in the Items (see page 9581) array, Find does not change the value of the Index parameter if the bookmark string can't be found. Use Find when a default value should be changed only if the bookmark is not in the list.

See Also

Items (see page 9581)

IndexOf (see page 9579)

49.1.1.4.6 TBookmarkList.IndexOf Method

Returns the index of a bookmark string in the Items (see page 9581) property array.

Pascal

```
function IndexOf(const Item: TBookmarkStr): Integer;
```

C++

```
__fastcall int IndexOf(const TBookmarkStr Item);
```

Description

Call IndexOf to get the index for a bookmark string in the Items (see page 9581) array. The first item in the array has index 0, the second item has index 1, and so on. If an item is not in the list, IndexOf returns -1.

See Also

Find (see page 9578)

Items (see page 9581)

49.1.1.4.7 TBookmarkList.LinkActive Method

Pascal

```
procedure LinkActive(Value: Boolean);
```

C++

```
__fastcall LinkActive(Boolean Value);
```

Description

This is LinkActive, a member of class TBookmarkList.

49.1.1.4.8 TBookmarkList.Refresh Method

Removes all invalid bookmarks from the Items (see page 9581) property array.

Pascal

```
function Refresh: Boolean;
```

C++

```
__fastcall Boolean Refresh();
```

Description

Bookmarks in the bookmark list are not automatically deleted when records in the dataset are deleted. As a result, some bookmarks in the Items (see page 9581) array may become invalid. Call Refresh to ensure that every bookmark in the bookmark list is valid. Refresh attempts to locate every record in the dataset that corresponds to a bookmark in the Items (see page 9581) property array. All bookmarks that do not correspond to records in the dataset are removed.

If any of the bookmarks in the list are invalid, Refresh returns true, and invalidates the DBGrid so that it will repaint, reflecting the removal of all invalid records. If all bookmarks in the list are still valid, Refresh returns false.

See Also

Items (see page 9581)

49.1.1.5 TBookmarkList Properties

The properties of the TBookmarkList class are listed here.

Public Properties

	Name	Description
R	Count (see page 9580)	Indicates the number of bookmarks in the bookmark list.
	CurrentRowSelected (see page 9581)	Indicates whether the Bookmark property of the associated DBGrid's dataset is in the Items (see page 9581) array.
R	Items (see page 9581)	Provides indexed access to the bookmarks for marked records in the dataset.

49.1.1.5.1 TBookmarkList.Count Property

Indicates the number of bookmarks in the bookmark list.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read Count to determine the number of entries in the Items (see page 9581) array. Use Count as an upper limit when iterating over the strings in the Items (see page 9581) array.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

Items (see page 9581)

49.1.1.5.2 TBookmarkList.CurrentRowSelected Property

Indicates whether the Bookmark property of the associated DBGrid's dataset is in the Items (see page 9581) array.

Pascal

```
property CurrentRowSelected: Boolean;
```

C++

```
__property Boolean CurrentRowSelected;
```

Description

Read CurrentRowSelected to determine whether the Bookmark property of the associated DBGrid's dataset specifies a bookmark string in the Items (see page 9581) property array. CurrentRowSelected is true when the bookmark string is included, false when it is not. The Bookmark property of the dataset indicates the current record in the dataset.

Set CurrentRowSelected to specify whether the Bookmark string of the associated DBGrid's dataset should be included in the bookmark list. Setting CurrentRowSelected to true adds the Bookmark property of the dataset to the Items (see page 9581) array if it is not already there. Setting CurrentRowSelected to false removes the Bookmark of the dataset from the Items (see page 9581) array if it is there. If the Bookmark property of the dataset is an empty string (no bookmark), setting CurrentRowSelected does nothing.

Note: Trying to read or write CurrentRowSelected when the dataset is not active will raise an EInvalidGridOperation exception.

See Also

Bookmark (see page 7009)

Items (see page 9581)

49.1.1.5.3 TBookmarkList.Items Property

Provides indexed access to the bookmarks for marked records in the dataset.

Pascal

```
property Items [Index: Integer]: TBookmarkStr;
```

C++

```
__property TBookmarkStr Items[int Index];
```

Description

Use Items to obtain a bookmark string from the set maintained by the TBookmarkList (see page 9575) object. Each bookmark string represents a single record in the dataset of the associated DBGrid. Bookmark strings can be compared with other bookmark strings to determine relative position within the database, and used to position the dataset on an arbitrary record. The Index parameter indicates the index of the bookmark, where 0 is the index of the first bookmark, 1 is the index of the second bookmark, and so on.

Use Items with the Count (see page 9580) property to iterate through all of the bookmarks in the list.

Note: Bookmarks in the bookmark list are not automatically deleted when records in the dataset are deleted. As a result, some bookmarks in the Items array may become invalid. Call the Refresh (see page 9580) method to delete invalid bookmarks from the Items array.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

Refresh (see page 9580)

operator_sb

49.1.2 TColumn Class

TColumn represents a column in a data grid (TDBGrid (see page 9668)).

Class Hierarchy

Pascal

```
TColumn = class(TCollectionItem);
```

C++

```
class TColumn : public TCollectionItem;
```

File

DBGrids

Description

Each TDBGrid (see page 9668) uses a TDBGridColumns (see page 9746) to maintain a collection of TColumn objects. Each TColumn object represents the visual characteristics and data binding of a column in the grid.

See Also

TCollection (see page 2731)

TCollectionItem (see page 2755)

TDBGridColumns (see page 9746)

TDBGrid (see page 9668)

49.1.2.1 TColumn Members

The following tables list the members exposed by TColumn.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	CreateTitle (see page 9587)	This is CreateTitle, a member of class TColumn.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetDisplayName (see page 9590)	Returns the name of the collection item as it appears in the collection editor.
	GetGrid (see page 9590)	This is GetGrid, a member of class TColumn.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	RefreshDefaultFont (see page 9591)	This is RefreshDefaultFont, a member of class TColumn.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 9591)	Moves the collection item to a specified position in the parent collection.

Protected Properties

	Name	Description
	IsStored (see page 9598)	This is IsStored, a member of class TColumn.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 9586)	Copies the contents of the source column to a new column.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 9585)	Creates and initializes a data-grid column.
	DefaultAlignment (see page 9587)	Returns the default alignment for the column.
	DefaultColor (see page 9587)	Returns the default background color for the column.
	DefaultFont (see page 9588)	Returns the default font for data displayed in the column.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefaultImeMode (see page 9588)	Describes the default behavior of the Input Method Editor (IME).
	DefaultImeName (see page 9588)	Returns the name of the default Input Method Editor (IME).
	DefaultReadOnly (see page 9589)	Returns the default ReadOnly (see page 9599) setting for the column.
	DefaultWidth (see page 9589)	Returns the default width for the column.
	Depth (see page 9590)	Returns the position of the column in relation to any parent columns. A column with no parent column returns 0.
V	Destroy (see page 9585)	Destroys the column and frees its memory.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	RestoreDefaults (see page 9591)	Restores the column's default settings.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	AssignedValues (see page 9593)	Indicates which TColumn (see page 9583) and TColumnTitle (see page 9601) properties have been set.
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	Expandable (see page 9594)	Specifies whether the column can be expanded to show any child field columns.
	Field (see page 9595)	Indicates the TField instance represented by the column.

R	Grid (see page 9596)	Indicates the grid that contains the column.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).
R	ParentColumn (see page 9598)	Refers to the TColumn (see page 9583) object that owns the column.
R	Showing (see page 9599)	Indicates whether the column is showing.

Published Properties

	Name	Description
	Alignment (see page 9592)	Specifies how text is aligned within the column.
	ButtonStyle (see page 9593)	Determines whether and how the user can select values for the column from a list.
	Color (see page 9594)	Specifies the background color for the column.
	DropDownRows (see page 9594)	Specifies the number of lines displayed in the column's drop-down list.
	Expanded (see page 9595)	Specifies whether the column is expanded.
	FieldName (see page 9595)	Indicates the name of the field represented by the column.
	Font (see page 9596)	Controls (see page 5711) the font in which the column displays its data.
	ImeMode (see page 9597)	Determines the behavior of the input method editor (IME) when the column is edited.
	ImeName (see page 9597)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	PickList (see page 9598)	Lists values that the user can select for the column.
	PopupMenu (see page 9599)	Identifies the pop-up menu associated with the column.
	ReadOnly (see page 9599)	Determines whether data displayed in the column is editable.
	Title (see page 9600)	Indicates the TColumn (see page 9583) Title that represents the column's title.
	Visible (see page 9600)	Specifies whether the column is visible in the grid.
	Width (see page 9600)	The width of the column.

49.1.2.2 TColumn.Create Constructor

Creates and initializes a data-grid column.

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TColumn(TCollection Collection);
```

Description

Call Create to instantiate a TColumn (see page 9583) object. Create should take a TDBGridColumns (see page 9746) instance as its argument. It creates a data-grid column along with its title (TColumnTitle (see page 9601)) and font (TFont).

See Also

Title (see page 9600)

Font (see page 9596)

Create (see page 9603)

Create (see page 14499)

TDBGridColumns (see page 9746)

49.1.2.3 TColumn.Destroy Destructor

Destroys the column and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TColumn();
```

Description

Destroy eliminates the TColumn (see page 9583) instance along with its title (TColumnTitle (see page 9601)), font (TFont), and pick list (TStrings).

See Also

Title (see page 9600)

Font (see page 9596)

PickList (see page 9598)

Free (see page 22300)

49.1.2.4 TColumn Methods

The methods of the TColumn class are listed here.

Protected Methods

	Name	Description
	CreateTitle (see page 9587)	This is CreateTitle, a member of class TColumn.
	GetDisplayName (see page 9590)	Returns the name of the collection item as it appears in the collection editor.
	GetGrid (see page 9590)	This is GetGrid, a member of class TColumn.
	RefreshDefaultFont (see page 9591)	This is RefreshDefaultFont, a member of class TColumn.
	SetIndex (see page 9591)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	Assign (see page 9586)	Copies the contents of the source column to a new column.
	DefaultAlignment (see page 9587)	Returns the default alignment for the column.
	DefaultColor (see page 9587)	Returns the default background color for the column.
	DefaultFont (see page 9588)	Returns the default font for data displayed in the column.
	DefaultImeMode (see page 9588)	Describes the default behavior of the Input Method Editor (IME).
	DefaultImeName (see page 9588)	Returns the name of the default Input Method Editor (IME).
	DefaultReadOnly (see page 9589)	Returns the default ReadOnly (see page 9599) setting for the column.
	DefaultWidth (see page 9589)	Returns the default width for the column.
	Depth (see page 9590)	Returns the position of the column in relation to any parent columns. A column with no parent column returns 0.
	RestoreDefaults (see page 9591)	Restores the column's default settings.

49.1.2.4.1 TColumn.Assign Method

Copies the contents of the source column to a new column.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign creates a new column with the same FieldName (see page 9595), Title (see page 9600), DropDownRows (see page 9594), ButtonStyle (see page 9593), and PickList (see page 9598) values as the source object. Color (see page 9594), Width (see page 9600), Font (see page 9596), Alignment (see page 9592), and ReadOnly (see page 9599) are also copied if AssignedValues (see page 9593) indicates that they have been changed.

See Also

Assign (see page 2930)

AssignedValues (see page 9593)

49.1.2.4.2 TColumn.CreateTitle Method

Pascal

```
function CreateTitle: TColumnTitle; virtual;
```

C++

```
virtual __fastcall TColumnTitle CreateTitle();
```

Description

This is CreateTitle, a member of class TColumn.

49.1.2.4.3 TColumn.DefaultAlignment Method

Returns the default alignment for the column.

Pascal

```
function DefaultAlignment: TAlignment;
```

C++

```
__fastcall TAlignment DefaultAlignment();
```

Description

Use DefaultAlignment to determine the alignment of the data in the column when the Alignment (see page 9592) property has not been explicitly set. DefaultAlignment returns the Alignment (see page 9592) property of the TField associated with the column. If the column has no dataset field associated with it, DefaultAlignment returns taLeftJustify.

See Also

Alignment (see page 9592)

Field (see page 9595)

Alignment (see page 7146)

49.1.2.4.4 TColumn.DefaultColor Method

Returns the default background color for the column.

Pascal

```
function DefaultColor: TColor;
```

C++

```
__fastcall TColor DefaultColor();
```

Description

Use Default color to determine the color of the column when the Color (see page 9594) property is not explicitly set. DefaultColor returns the Color (see page 9594) of the data grid to which the column belongs. If the column has no associated data grid, DefaultColor returns clWindow.

See Also

Color (see page 9594)

Color (see page 5812)

49.1.2.4.5 TColumn.DefaultFont Method

Returns the default font for data displayed in the column.

Pascal

```
function DefaultFont: TFont;
```

C++

```
__fastcall TFont DefaultFont();
```

Description

DefaultFont returns the Font (see page 9596) of the data grid to which the column belongs. If the column has no associated data grid, DefaultFont returns the current value of the column's Font (see page 9596) property.

See Also

Font (see page 9596)

Font (see page 5823)

49.1.2.4.6 TColumn.DefaultImeMode Method

Describes the default behavior of the Input Method Editor (IME).

Pascal

```
function DefaultImeMode: TImeMode;
```

C++

```
__fastcall TImeMode DefaultImeMode();
```

Description

DefaultImeMode returns the ImeMode (see page 9597) property of the data grid to which the column belongs. If the column has no associated data grid, DefaultImeMode returns the current value of the column's ImeMode (see page 9597) property.

See Also

ImeMode (see page 9597)

ImeMode (see page 6207)

49.1.2.4.7 TColumn.DefaultImeName Method

Returns the name of the default Input Method Editor (IME).

Pascal

```
function DefaultImeName: TImeName;
```

C++

```
__fastcall TImeName DefaultImeName();
```

Description

DefaultImeName returns the ImeName (see page 9597) property of the data grid to which the column belongs. If the column has no associated data grid, DefaultImeName returns the current value of the column's ImeName (see page 9597) property.

See Also

ImeName (see page 9597)

ImeName (see page 6208)

49.1.2.4.8 TColumn.DefaultReadOnly Method

Returns the default ReadOnly (see page 9599) setting for the column.

Pascal

```
function DefaultReadOnly: Boolean;
```

C++

```
__fastcall Boolean DefaultReadOnly();
```

Description

Reflects the ReadOnly (see page 9599) state of the grid and the grid's dataset and field.

See Also

ReadOnly (see page 9599)

49.1.2.4.9 TColumn.DefaultWidth Method

Returns the default width for the column.

Pascal

```
function DefaultWidth: Integer;
```

C++

```
__fastcall int DefaultWidth();
```

Description

The value of DefaultWidth is determined as follows:

If the column has no data grid associated with it, DefaultWidth returns 64.

If the column has an associated data grid but the Field (see page 9595) property is empty, DefaultWidth returns data grid's protected DefaultColWidth property. Usually, this value is 64.

If the column has an associated data field, DefaultWidth is calculated from the TField object's DisplayWidth property using the column's font.

If the dgTitles flag is set in the data grid's Options property, DefaultWidth is increased (as necessary) to accommodate the column's title caption.

See Also

Width (see page 9600)

Field (see page 9595)

TField (see page 7115)

DisplayWidth (see page 7162)

TDBGrid (see page 9668)

Options (see page 9659)

Title (see page 9600)

Caption (see page 9607)

49.1.2.4.10 TColumn.Depth Method

Returns the position of the column in relation to any parent columns. A column with no parent column returns 0.

Pascal

```
function Depth: Integer;
```

C++

```
__fastcall int Depth();
```

Description

If a column does not have any parent columns, Depth returns 0. Columns with parent columns return a number equal to the number of parents it has. For example, a parentless ADT field called Date has a Depth of 0. Its three child fields, Month, Day, and Year, each have a Depth of 1.

See Also

ParentColumn (see page 9598)

49.1.2.4.11 TColumn.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName (see page 2761)

GetNamePath (see page 2759)

49.1.2.4.12 TColumn.GetGrid Method

Pascal

```
function GetGrid: TCustomDBGrid;
```

C++

```
__fastcall TCustomDBGrid GetGrid();
```

Description

This is GetGrid, a member of class TColumn.

49.1.2.4.13 TColumn.RefreshDefaultFont Method

Pascal

```
procedure RefreshDefaultFont;
```

C++

```
__fastcall RefreshDefaultFont();
```

Description

This is RefreshDefaultFont, a member of class TColumn.

49.1.2.4.14 TColumn.RestoreDefaults Method

Restores the column's default settings.

Pascal

```
procedure RestoreDefaults; virtual;
```

C++

```
virtual __fastcall RestoreDefaults();
```

Description

RestoreDefaults reinitializes the AssignedValues (see page 9593), ButtonStyle (see page 9593), Font (see page 9596), and PickList (see page 9598) properties, freeing the pick list (TStrings) object if there is one. It also calls the RestoreDefaults method in the column's title (TColumnTitle (see page 9601)) to restore the default properties of the column title.

See Also

AssignedValues (see page 9593)

ButtonStyle (see page 9593)

Font (see page 9596)

PickList (see page 9598)

RestoreDefaults (see page 9606)

Restoring Default Values to a Column

49.1.2.4.15 TColumn.SetIndex Method

Moves the collection item to a specified position in the parent collection.

Pascal

```
procedure SetIndex(Value: Integer); override;
```

C++

```
virtual __fastcall SetIndex(int Value);
```

Description

SetIndex is the protected write implementation of the Index property. The Value parameter specifies the new (0-based) position

for the item in its parent collection.

See Also

Index (see page 2762)

49.1.2.5 TColumn Properties

The properties of the TColumn class are listed here.

Protected Properties

	Name	Description
	IsStored (see page 9598)	This is IsStored, a member of class TColumn.

Public Properties

	Name	Description
R	AssignedValues (see page 9593)	Indicates which TColumn (see page 9583) and TColumnTitle (see page 9601) properties have been set.
R	Expandable (see page 9594)	Specifies whether the column can be expanded to show any child field columns.
	Field (see page 9595)	Indicates the TField instance represented by the column.
R	Grid (see page 9596)	Indicates the grid that contains the column.
R	ParentColumn (see page 9598)	Refers to the TColumn (see page 9583) object that owns the column.
R	Showing (see page 9599)	Indicates whether the column is showing.

Published Properties

	Name	Description
	Alignment (see page 9592)	Specifies how text is aligned within the column.
	ButtonStyle (see page 9593)	Determines whether and how the user can select values for the column from a list.
	Color (see page 9594)	Specifies the background color for the column.
	DropDownRows (see page 9594)	Specifies the number of lines displayed in the column's drop-down list.
	Expanded (see page 9595)	Specifies whether the column is expanded.
	FieldName (see page 9595)	Indicates the name of the field represented by the column.
	Font (see page 9596)	Controls (see page 5711) the font in which the column displays its data.
	ImeMode (see page 9597)	Determines the behavior of the input method editor (IME) when the column is edited.
	ImeName (see page 9597)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	PickList (see page 9598)	Lists values that the user can select for the column.
	PopupMenu (see page 9599)	Identifies the pop-up menu associated with the column.
	ReadOnly (see page 9599)	Determines whether data displayed in the column is editable.
	Title (see page 9600)	Indicates the TColumn (see page 9583) Title that represents the column's title.
	Visible (see page 9600)	Specifies whether the column is visible in the grid.
	Width (see page 9600)	The width of the column.

49.1.2.5.1 TColumn.Alignment Property

Specifies how text is aligned within the column.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to specify whether values should be left-justified, right-justified, or centered in the column.

See Also

State (see page 9753)

Alignment (see page 9606)

49.1.2.5.2 TColumn.AssignedValues Property

Indicates which TColumn (see page 9583) and TColumnTitle (see page 9601) properties have been set.

Pascal

```
property AssignedValues: TColumnValues;
```

C++

```
__property TColumnValues AssignedValues;
```

Description

For example, if the AssignedValues property contains cvColor, and cvTitleCaption, then the column's font and title caption have been changed and no longer track with changes made to their default source.

Many column properties obtain their values from external sources, such as properties of the associated TField objects. The column will reflect changes made to the property's default source until a value is assigned to the column property. After assignment, the column property is independent of its default source.

See Also

Title (see page 9600)

TColumnTitle (see page 9601)

RestoreDefaults (see page 9591)

Restoring Default Values to a Column

49.1.2.5.3 TColumn.ButtonStyle Property

Determines whether and how the user can select values for the column from a list.

Pascal

```
property ButtonStyle: TColumnButtonStyle;
```

C++

```
__property TColumnButtonStyle ButtonStyle;
```

Description

The ButtonStyle property determines how users can edit the data of a data-grid column.

See Also

PickList (see page 9598)

DropDownRows (see page 9594)

OnEditButtonClick (see page 9668)

Defining a Lookup List Column

49.1.2.5.4 TColumn.Color Property

Specifies the background color for the column.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

The Color property determines the background color of the data-grid column. You can set Color to one of the constants defined in the Graphics (see page 14387) unit (such as clBlue), or to an explicit RGB integer value.

49.1.2.5.5 TColumn.DropDownRows Property

Specifies the number of lines displayed in the column's drop-down list.

Pascal

```
property DropDownRows: Cardinal;
```

C++

```
__property unsigned DropDownRows;
```

Description

DropDownRows determines the number of lines of text displayed in the drop-down list associated with the column. This property is used only if ButtonStyle (see page 9593) is set to cbsAuto and the column has a lookup field or pick list associated with it.

See Also

ButtonStyle (see page 9593)

PickList (see page 9598)

TDBLookupComboBox (see page 8963)

Defining a Lookup List Column

49.1.2.5.6 TColumn.Expandable Property

Specifies whether the column can be expanded to show any child field columns.

Pascal

```
property Expandable: Boolean;
```

C++

```
__property Boolean Expandable;
```

Description

Expandable will be false if the represented field is not an ADT, array, or reference field.

See Also

Depth (see page 9590)

Expanded (see page 9595)

ObjectView (see page 7031)

49.1.2.5.7 TColumn.Expanded Property

Specifies whether the column is expanded.

Pascal

```
property Expanded: Boolean;
```

C++

```
__property Boolean Expanded;
```

Description

Expanded only applies to columns that represent fields that are TObjectField descendants. When a column is expanded, a column appears for each child field of the object field. These child field columns each have a column title and appear under the column title of the parent object field. When Expanded is false, child field values are summarized in a comma-delimited string in the object field's column, and cannot be edited.

Object fields can also be expanded and contracted at runtime through the UI by clicking on the triangle that appears next to its name in the column title.

See Also

Expandable (see page 9594)

ObjectView (see page 7031)

49.1.2.5.8 TColumn.Field Property

Indicates the TField instance represented by the column.

Pascal

```
property Field: TField;
```

C++

```
__property TField Field;
```

Description

Field points to the TField object that corresponds to the dataset field displayed in the column. The value of Field will be nil (Delphi) or NULL (C++), if the column does not correspond to a field in the dataset (for example, a calculated field).

See Also

FieldName (see page 9595)

Fields (see page 9657)

Creating a Customized Grid

49.1.2.5.9 TColumn.FieldName Property

Indicates the name of the field represented by the column.

Pascal

```
property FieldName: WideString;
```

C++

```
__property BSTR FieldName;
```

Description

Setting FieldName changes the Field (see page 9595) property so that it points to the dataset field with the same name. If the dataset does not have a field with the same name, Field (see page 9595) is set to nil (Delphi), or NULL (C++).

See Also

Field (see page 9595)

Title (see page 9600)

Caption (see page 9607)

Creating a Customized Grid

Creating Persistent Columns

Defining a Lookup List Column

49.1.2.5.10 TColumn.Font Property

Controls (see page 5711) the font in which the column displays its data.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

The Font property points to a TFont object that determines typographic attributes of text displayed in the column.

See Also

Font (see page 5823)

Font (see page 9608)

Using a Grid Control in Its Default State

49.1.2.5.11 TColumn.Grid Property

Indicates the grid that contains the column.

Pascal

```
property Grid: TCustomDBGrid;
```

C++

```
__property TCustomDBGrid Grid;
```

Description

Use the Grid property to access the grid that contains the column.

See Also

TDBGrid (see page 9668)

49.1.2.5.12 TColumn.ImeMode Property

Determines the behavior of the input method editor (IME) when the column is edited.

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes when the user is editing the column. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows the type of conversion performed by the IME to be tailored to the input expected for the column. For example, a column that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

See Also

DefaultImeMode (see page 9588)

ImeName (see page 9597)

49.1.2.5.13 TColumn.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes when the user is editing the column. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

See Also

DefaultImeName (see page 9588)

ImeMode (see page 9597)

DefaultIme (see page 14216)

Imes (see page 14227)

49.1.2.5.14 TColumn.IsStored Property

Pascal

```
property IsStored: Boolean;
```

C++

```
__property Boolean IsStored;
```

Description

This is IsStored, a member of class TColumn.

49.1.2.5.15 TColumn.ParentColumn Property

Refers to the TColumn (see page 9583) object that owns the column.

Pascal

```
property ParentColumn: TColumn;
```

C++

```
__property TColumn ParentColumn;
```

Description

If the column represents a child field, ParentColumn refers to the column of the object field that parents the child field.

See Also

Expanded (see page 9595)

49.1.2.5.16 TColumn.PickList Property

Lists values that the user can select for the column.

Pascal

```
property PickList: TStrings;
```

C++

```
__property TStrings PickList;
```

Description

The PickList property points to a TStrings object. If ButtonStyle (see page 9593) is cbsAuto, these strings appear in the drop-down list associated with the column.

See Also

TStrings (see page 3029)

ButtonStyle (see page 9593)

DropDownRows (see page 9594)

PopupMenu (see page 9599)

Defining a Lookup List Column

49.1.2.5.17 TColumn.PopupMenu Property

Identifies the pop-up menu associated with the column.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign (see page 9586) a value to PopupMenu to make a pop-up menu appear when the user clicks the right mouse button on the column. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method.

See Also

PickList (see page 9598)

AutoPopup (see page 16178)

49.1.2.5.18 TColumn.ReadOnly Property

Determines whether data displayed in the column is editable.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Data displayed in the column cannot be changed by the user at runtime if ReadOnly is set to true. If ReadOnly is set to false (and the data grid's Options property includes the dgEditing flag), users can edit data directly from the grid.

See Also

Options (see page 9659)

49.1.2.5.19 TColumn.Showing Property

Indicates whether the column is showing.

Pascal

```
property Showing: Boolean;
```

C++

```
__property Boolean Showing;
```

Description

Showing will return true if Visible (see page 9600) is true and Expanded (see page 9595) is false, and if the field represented is the child of an object field, if the parent column is expanded.

See Also

Visible (see page 9600)

Expanded (see page 9595)

49.1.2.5.20 TColumn.Title Property

Indicates the TColumn (see page 9583) Title that represents the column's title.

Pascal

```
property Title: TColumnTitle;
```

C++

```
__property TColumnTitle Title;
```

Description

The Title property points to a TColumn (see page 9583) Title object that determines attributes of the column's title. If FieldName (see page 9595) is set, the value of FieldName (see page 9595) becomes the default column title (the Caption property of the TColumn (see page 9583) Title object).

The column title appears at runtime only if the dgTitles flag is set in the data grid's Options property.

See Also

TColumnTitle (see page 9601)

Caption (see page 9607)

FieldName (see page 9595)

Options (see page 9659)

Creating Persistent Columns

49.1.2.5.21 TColumn.Visible Property

Specifies whether the column is visible in the grid.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

To hide a column in the grid, set Visible to false. If Visible is true, and the field's Visible property is true, the column will appear in the grid. This property only determines whether the column is allowed to be drawn/shown. The Showing (see page 9599) property reflects the actual display ability of the column based on additional factors.

See Also

Showing (see page 9599)

Expanded (see page 9595)

49.1.2.5.22 TColumn.Width Property

The width of the column.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

The Width property determines the width of the column, in pixels. If the dgColumnResize flag is set in the data grid's Options property, users can resize the column at runtime.

See Also

Options (see page 9659)

Using a Grid Control in Its Default State

49.1.3 TColumnTitle Class

TColumnTitle represents the title of a data-grid column (TColumn (see page 9583)).

Class Hierarchy

Pascal

```
TColumnTitle = class(TPersistent);
```

C++

```
class TColumnTitle : public TPersistent;
```

File

DBGrids

Description

TDBGrid (see page 9668) uses a TDBGridColumns (see page 9746) to maintain a collection of TColumn (see page 9583) objects. Each TColumn (see page 9583) has an associated TColumnTitle that holds information about its title. The TColumnTitle instance is stored in the column's Title property.

See Also

TDBGrid (see page 9668)

TDBGridColumns (see page 9746)

TColumn (see page 9583)

TColumn (see page 9583)

TColumn (see page 9583)

49.1.3.1 TColumnTitle Members

The following tables list the members exposed by TColumnTitle.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.

	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	RefreshDefaultFont (see page 9606)	This is RefreshDefaultFont, a member of class TColumnTitle.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 9604)	Copies the contents of the source column title to a new column title.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 9603)	Creates and initializes a column title.
	DefaultAlignment (see page 9604)	Returns the default alignment of the column title.
	DefaultCaption (see page 9604)	Returns the default caption of the column title.
	DefaultColor (see page 9605)	Returns the default background color for the column title.
	DefaultFont (see page 9605)	Returns the default font for the column title.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 9603)	Destroys the column and frees its memory.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RestoreDefaults (see page 9606)	Restores the column title's default settings.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Column (see page 9607)	Specifies the TColumn (see page 9583) object that is associated with the column title.

Published Properties

	Name	Description
	Alignment (see page 9606)	Specifies how text is aligned within the column title.
	Caption (see page 9607)	Specifies the text that appears at the top of the column.
	Color (see page 9607)	Specifies the background color for the column title.

	Font (see page 9608)	Controls (see page 5711) the font in which the column title displays its caption.

49.1.3.2 TColumnTitle.Create Constructor

Creates and initializes a column title.

Pascal

```
constructor Create(Column: TColumn);
```

C++

```
__fastcall TColumnTitle(TColumn Column);
```

Description

Call Create to instantiate an instance of TColumnTitle (see page 9601). Create takes a TColumn (see page 9583) instance as its argument.

Most applications need not create column title instances, as these are instantiated by the associated column.

See Also

TColumn (see page 9583)

49.1.3.3 TColumnTitle.Destroy Destructor

Destroys the column and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TColumnTitle();
```

Description

Destroy eliminates the TColumnTitle (see page 9601) instance along with its associated font (TFont).

See Also

Font (see page 9608)

TFont (see page 14497)

Free (see page 22300)

49.1.3.4 TColumnTitle Methods

The methods of the TColumnTitle class are listed here.

Protected Methods

	Name	Description
	RefreshDefaultFont (see page 9606)	This is RefreshDefaultFont, a member of class TColumnTitle.

Public Methods

	Name	Description
	Assign (see page 9604)	Copies the contents of the source column title to a new column title.
	DefaultAlignment (see page 9604)	Returns the default alignment of the column title.

	DefaultCaption (see page 9604)	Returns the default caption of the column title.
	DefaultColor (see page 9605)	Returns the default background color for the column title.
	DefaultFont (see page 9605)	Returns the default font for the column title.
V	RestoreDefaults (see page 9606)	Restores the column title's default settings.

49.1.3.4.1 TColumnTitle.Assign Method

Copies the contents of the source column title to a new column title.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the Alignment (see page 9606), Color (see page 9607), Caption (see page 9607), and Font (see page 9608) values of the source object if it is another column title. Otherwise, it calls the inherited method, which allows properties to be copied from any object that implements its AssignTo method with a target of TColumn (see page 9583).

See Also

Assign (see page 2930)

49.1.3.4.2 TColumnTitle.DefaultAlignment Method

Returns the default alignment of the column title.

Pascal

```
function DefaultAlignment: TAlignment;
```

C++

```
__fastcall TAlignment DefaultAlignment();
```

Description

DefaultAlignment returns the alignment for the column that should be used if the Alignment (see page 9606) property is not explicitly set. The DefaultAlignment property for TColumnTitle (see page 9601) always returns taLeftJustify. Descendants of TColumnTitle (see page 9601) can override this to compute the default alignment in an appropriate way.

See Also

Alignment (see page 9606)

49.1.3.4.3 TColumnTitle.DefaultCaption Method

Returns the default caption of the column title.

Pascal

```
function DefaultCaption: string;
```

C++

```
__fastcall AnsiString DefaultCaption();
```

Description

DefaultCaption returns the DisplayLabel of the TField object associated with the column. If there is no dataset field associated with the column (that is, if the column's Field property is empty), it returns the column's FieldName.

See Also

Caption (see page 9607)

DisplayName (see page 7160)

Field (see page 9595)

FieldName (see page 9595)

49.1.3.4.4 TColumnTitle.DefaultColor Method

Returns the default background color for the column title.

Pascal

```
function DefaultColor: TColor;
```

C++

```
__fastcall TColor DefaultColor();
```

Description

Use DefaultColor to determine the background color of the column title if the Color (see page 9607) property is not explicitly set. DefaultColor returns the FixedColor of the data grid to which the column belongs. If the column has no associated data grid, DefaultColor returns clBtnFace.

See Also

Color (see page 9607)

FixedColor (see page 14848)

49.1.3.4.5 TColumnTitle.DefaultFont Method

Returns the default font for the column title.

Pascal

```
function DefaultFont: TFont;
```

C++

```
__fastcall TFont DefaultFont();
```

Description

Use DefaultColor (see page 9605) to determine the font of the column title if the Font (see page 9608) property is not explicitly set. DefaultFont returns the TitleFont of the data grid to which the column belongs. If the column has no associated data grid, DefaultFont returns the current value of the associated column's Font (see page 9608) property.

See Also

Font (see page 9608)

TitleFont (see page 9663)

Font (see page 9596)

49.1.3.4.6 TColumnTitle.RefreshDefaultFont Method

Pascal

```
procedure RefreshDefaultFont;
```

C++

```
__fastcall RefreshDefaultFont();
```

Description

This is RefreshDefaultFont, a member of class TColumnTitle.

49.1.3.4.7 TColumnTitle.RestoreDefaults Method

Restores the column title's default settings.

Pascal

```
procedure RestoreDefaults; virtual;
```

C++

```
virtual __fastcall RestoreDefaults();
```

Description

RestoreDefaults reinitializes the Caption (see page 9607) and Font (see page 9608) properties.

See Also

AssignedValues (see page 9593)

RestoreDefaults (see page 9591)

49.1.3.5 TColumnTitle Properties

The properties of the TColumnTitle class are listed here.

Public Properties

	Name	Description
R	Column (see page 9607)	Specifies the TColumn (see page 9583) object that is associated with the column title.

Published Properties

	Name	Description
	Alignment (see page 9606)	Specifies how text is aligned within the column title.
	Caption (see page 9607)	Specifies the text that appears at the top of the column.
	Color (see page 9607)	Specifies the background color for the column title.
	Font (see page 9608)	Controls (see page 5711) the font in which the column title displays its caption.

49.1.3.5.1 TColumnTitle.Alignment Property

Specifies how text is aligned within the column title.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to specify whether the column title is left-justified, right-justified, or centered.

See Also

Caption (see page 9607)

49.1.3.5.2 TColumnTitle.Caption Property

Specifies the text that appears at the top of the column.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

Description

The Caption property contains a text string that identifies the column. If the dgTitles flag is set in the data grid's Options property, the title appears on the form at runtime.

If the FieldName property is set in TColumn (see page 9583), the Caption default value comes from the DisplayLabel property of the Field object, which itself defaults to FieldName.

See Also

Options (see page 9659)

Title (see page 9600)

FieldName (see page 9595)

49.1.3.5.3 TColumnTitle.Color Property

Specifies the background color for the column title.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

The Color property determines the background color of the column title. You can set Color to one of the constants defined in the Graphics (see page 14387) unit (such as clBlue), or to an explicit RGB integer value. The default value is the grid's FixedColor property.

49.1.3.5.4 TColumnTitle.Column Property

Specifies the TColumn (see page 9583) object that is associated with the column title.

Pascal

```
property Column: TColumn;
```

C++

```
__property TColumn Column;
```

Description

Use Column to determine the column associated with the column title.

See Also

Title (see page 9600)

49.1.3.5.5 TColumnTitle.Font Property

Controls (see page 5711) the font in which the column title displays its caption.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

The Font property points to a TFont object that determines typographic attributes of text displayed in the column title. The default value is the grid's TitleFont property.

See Also

Font (see page 9596)

49.1.4 TCustomDBGrid Class

TCustomDBGrid is the base class for grid controls that display the records from a dataset in a tabular format.

Class Hierarchy

Pascal

```
TCustomDBGrid = class(TCustomGrid);
```

C++

```
class TCustomDBGrid : public TCustomGrid;
```

File

DBGrids

Description

TCustomDBGrid introduces new properties, events, and methods to expand the capabilities of TCustomGrid for displaying the fields from a dataset. At runtime, users can manipulate TCustomDBGrid objects using the TDBNavigator object.

Do not create instances of TCustomDBGrid. Use TCustomDBGrid as a base class when declaring grid objects that display information from datasets. Properties and methods of TCustomDBGrid provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TDBGrid (see page 9668)

TDataSet (see page 6894)

TDBNavigator (see page 9230)

49.1.4.1 TCustomDBGrid Members

The following tables list the members exposed by TCustomDBGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCellClick (see page 9664)	Occurs when the user releases the mouse in one of the cells of the grid.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnColEnter (see page 9665)	Occurs when focus moves to a new cell in the grid.
	OnColExit (see page 9665)	Occurs just before a cell in the grid loses input focus.
	OnColumnMoved (see page 9666)	Occurs when the user moves a column using the mouse.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDrawColumnCell (see page 9666)	Occurs when the grid needs to paint a cell.
	OnDrawDataCell (see page 9667)	Occurs when the grid needs to paint a cell if the State property of Columns (see page 9653) is csDefault.
	OnEditButtonClick (see page 9668)	Occurs when the user presses the ellipsis button in a grid column.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.

	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTitleClick (see page 9668)	Occurs when the user releases the mouse in one of the column headers.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAcquireFocus (see page 9623)	This is FAcquireFocus, a member of class TCustomDBGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	FUpdateFields (see page 9623)	This is FUpdateFields, a member of class TCustomDBGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AcquireLayoutLock (see page 9625)	Calls BeginLayout (see page 9626) if the table is not currently being reformatted.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BeginColumnDrag (see page 9625)	Starts the dragging of a column in the grid.
	BeginLayout (see page 9626)	Increments the LayoutLock (see page 9659) property when the column bindings or fields in the dataset change.

	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BeginUpdate (see page 9627)	Increments the UpdateLock (see page 9664) property when the data in the grid changes.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 9627)	Determines the appearance of the mouse cursor during resizing.
	CalcTitleRect (see page 9627)	This is CalcTitleRect, a member of class TCustomDBGrid.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CancelLayout (see page 9628)	Decrements the LayoutLock (see page 9659) property.
V	CanEditAcceptKey (see page 9628)	Indicates whether the Key parameter can be entered into the current cell.
V	CanEditModify (see page 9629)	Indicates whether the current column of the grid can be edited.
V	CanEditShow (see page 9629)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellClick (see page 9629)	Generates an OnCellClick (see page 9664) event.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
V	CheckColumnDrag (see page 9630)	Validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
	ColEnter (see page 9630)	Generates an OnColEnter (see page 9665) event.
	ColExit (see page 9630)	Generates an OnColExit (see page 9665) event.
	ColumnAtDepth (see page 9631)	Returns the column object associated with nth parent field of the given column.
V	ColumnMoved (see page 9631)	Generates an OnColumnMoved (see page 9666) event.
V	ColWidthsChanged (see page 9631)	Updates the column widths in the Columns (see page 9653) property when the user resizes the columns.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateColumns (see page 9632)	Creates the TDBGridColumns (see page 9746) object that stores the column descriptors for the grid.
	CreateDataLink (see page 9632)	Creates the data link that the grid uses to manage the connection to its data source.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateEditor (see page 9632)	Creates the inplace editor that allows the cells of the grid to be edited.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 9633)	Creates the window used to display the data-aware grid.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.

	DataToRawColumn (see page 9633)	Converts a column index in the Columns (see page 9653) property to the index of the corresponding column in the visual display.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DeferLayout (see page 9635)	Decrements the LayoutLock (see page 9659) property and posts a message to the grid to trigger a new layout sequence at a more appropriate time.
V	DefineFieldMap (see page 9636)	Builds the Fields (see page 9657) array from the Columns (see page 9653) property and the data source.
V	DefineProperties (see page 9636)	Defines a savable version of the Columns (see page 9653) property when necessary.
V	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
V	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
V	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
V	DoMouseWheelDown (see page 9636)	Performs tasks when the mouse wheel is rotated downward.
V	DoMouseWheelUp (see page 9637)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
V	DrawCell (see page 9637)	Draws the cell specified by the ACol and ARow parameters.
	DrawColumnCell (see page 9638)	Generates an OnDrawColumnCell (see page 9666) event.
	DrawDataCell (see page 9638)	Generates an OnDrawDataCell (see page 9667) event.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EditButtonClick (see page 9638)	Generates an OnEditButtonClick (see page 9668) event.
V	EndColumnDrag (see page 9639)	Ends the dragging of a column in the grid.
	EndLayout (see page 9639)	Decrements the LayoutLock (see page 9659) property and recomputes the Columns (see page 9653) property if LayoutLock (see page 9659) reaches 0.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EndUpdate (see page 9640)	Decrements the UpdateLock (see page 9664) property.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.

	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetColField (see page 9640)	Returns the field component that represents the binding of a specified column.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEditLimit (see page 9641)	Limits the number of characters that can be typed into cells representing string fields.
V	GetEditMask (see page 9641)	Returns the input mask associated with the field for the selected cell.
V	GetEditStyle (see page 9642)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
V	GetEditText (see page 9642)	Returns the value of the indicated cell formatted for editing.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFieldValue (see page 9643)	Returns the value of the indicated cell formatted for display.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
V	HighlightCell (see page 9643)	Indicates whether a specified cell should be highlighted when it is drawn.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.

	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	InvalidateTitles (see page 9644)	Invalidates the column titles so that they will be repainted.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
V	KeyDown (see page 9644)	Provides special processing when the user presses down on a key.
V	KeyPress (see page 9645)	Responds when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	LayoutChanged (see page 9645)	Recomputes the Columns (see page 9653) property.
V	LinkActive (see page 9646)	Recomputes the Columns (see page 9653) property and the vertical scroll bar of the grid.
V	Loaded (see page 9646)	Sets up the Columns (see page 9653) property once the data grid and all its child components are loaded.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 9647)	Provides special processing when the user clicks on the mouse.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
V	MouseUp (see page 9647)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 9647)	Responds to notifications that components are about to be destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	RawToDataColumn (see page 9648)	Converts the index of a column in the visual display to the corresponding index in the Columns (see page 9653) property.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.

	RowHeightsChanged (see page 14837)	Responds when the row heights change.
	RowMoved (see page 14837)	Provides the interface for a method that responds when the position of a row changes.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
V	Scroll (see page 9648)	Updates the image of the grid to reflect a new record position.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
V	SetColumnAttributes (see page 9649)	This is SetColumnAttributes, a member of class TCustomDBGrid.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEditText (see page 9649)	Updates the edited version of the current cell's data.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	StoreColumns (see page 9650)	Indicates whether the columns of the grid are stored when the grid is saved, or whether they are generated dynamically.
V	TimedScroll (see page 9650)	Moves the current record in response to the user dragging the mouse outside of the data cells.
	TitleClick (see page 9651)	Generates an OnTitleClick (see page 9668) event.
V	TopLeftChanged (see page 9651)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.

V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
V	UpdateScrollBar (see page 9652)	This is UpdateScrollBar, a member of class TCustomDBGrid.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	UseRightToLeftAlignmentForField (see page 9652)	Indicates whether the alignment of a specified field should be changed from left-aligned to right-aligned.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 14843)	Determines whether a single line border is drawn around the grid.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	Color (see page 5812)	Specifies the background color of the control.
	Color (see page 14844)	Specifies the background color of the control.
	Columns (see page 9653)	Describes the display attributes and field bindings of the columns.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
R	DataLink (see page 9654)	Helps the data-aware grid manage its link to the data source and respond to data events.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 9655)	Indicates whether the cells in the data-aware grid are drawn automatically.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	FixedColor (see page 14848)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
R	IndicatorOffset (see page 9658)	Indicates the index of the first column in the grid that contains data.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	LayoutLock (see page 9659)	Counts the number of times BeginLayout (see page 9626) has been called without an EndLayout (see page 9639) or CancelLayout (see page 9628) call.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	Options (see page 9659)	Specifies various display and behavioral properties of the data-aware grid.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 9660)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 9660)	Indicates whether the grid is used for display only, or whether the user can edit data using the grid.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
R	SelectedRows (see page 9662)	Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.
	TitleFont (see page 9663)	Describes the font used to draw the column titles in the grid.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
R	UpdateLock (see page 9664)	Counts the number of times BeginUpdate (see page 9627) is called without a corresponding call to EndUpdate (see page 9640).
R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 9622)	Creates and initializes an instance of TCustomDBGrid (see page 9608).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultDrawColumnCell (see page 9634)	Draws the text in a column cell.
	DefaultDrawDataCell (see page 9634)	Draws the text in a column cell.
V	DefaultHandler (see page 9635)	Displays the popup menu when a column is right-clicked.
V	Destroy (see page 9622)	Destroys an instance of TCustomDBGrid (see page 9608).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
V	ExecuteAction (see page 9640)	Executes an action with the DB (see page 6725) grid as its target.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.

	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	ShowPopupEditor (see page 9649)	Displays the nested dataset associated with Column in a new window.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
V	UpdateAction (see page 9651)	Updates an action to reflect the current state of the grid.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
	ValidFieldIndex (see page 9652)	Indicates whether an index into the columns array refers to a valid field in the dataset.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.

	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DataSource (see page 9655)	Identifies the link to the dataset where the data-aware grid finds its data.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditorMode (see page 9656)	Determines whether the current cell can be edited.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	FieldCount (see page 9656)	Specifies the number of fields (columns) displayed in the grid.
R	Fields (see page 9657)	Provides indexed access to the field components that correspond to the columns.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelectedField (see page 9661)	Specifies the field component for the currently selected cell in the grid.
	SelectedIndex (see page 9661)	Specifies the index of the currently selected column in the Columns (see page 9653) array.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.

	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

49.1.4.2 TCustomDBGrid.Create Constructor

Creates and initializes an instance of TCustomDBGrid (see page 9608).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomDBGrid(TComponent * AOwner);
```

Description

Call Create to instantiate a data-aware grid at runtime. Grids (see page 14765) placed on a form at design time are created automatically.

Pass a single Component as a parameter to provide the grid with an Owner that is responsible for freeing the grid.

See Also

DefaultDrawing (see page 9655)

Options (see page 9659)

ParentColor (see page 5834)

Color (see page 5812)

Create (see page 14813)

49.1.4.3 TCustomDBGrid.Destroy Destructor

Destroys an instance of TCustomDBGrid (see page 9608).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomDBGrid();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the data-aware grid is not nil, and only then calls Destroy. Destroy frees all the helper objects used by the grid.

See Also

Free (see page 22300)

Create (see page 9622)

49.1.4.4 TCustomDBGrid Fields

The fields of the TCustomDBGrid class are listed here.

Protected Fields

	Name	Description
	FAcquireFocus (see page 9623)	This is FAcquireFocus, a member of class TCustomDBGrid.
	FUpdateFields (see page 9623)	This is FUpdateFields, a member of class TCustomDBGrid.

49.1.4.4.1 TCustomDBGrid.FAcquireFocus Field

Pascal

```
FAcquireFocus: Boolean;
```

C++

```
Boolean FAcquireFocus;
```

Description

This is FAcquireFocus, a member of class TCustomDBGrid.

49.1.4.4.2 TCustomDBGrid.FUpdateFields Field

Pascal

```
FUpdateFields: Boolean;
```

C++

```
Boolean FUpdateFields;
```

Description

This is FUpdateFields, a member of class TCustomDBGrid.

49.1.4.5 TCustomDBGrid Methods

The methods of the TCustomDBGrid class are listed here.

Protected Methods

	Name	Description
	AcquireLayoutLock (see page 9625)	Calls BeginLayout (see page 9626) if the table is not currently being reformatted.
	BeginColumnDrag (see page 9625)	Starts the dragging of a column in the grid.
	BeginLayout (see page 9626)	Increments the LayoutLock (see page 9659) property when the column bindings or fields in the dataset change.

	BeginUpdate (see page 9627)	Increments the UpdateLock (see page 9664) property when the data in the grid changes.
V	CalcSizingState (see page 9627)	Determines the appearance of the mouse cursor during resizing.
	CalcTitleRect (see page 9627)	This is CalcTitleRect, a member of class TCustomDBGrid.
	CancelLayout (see page 9628)	Decrements the LayoutLock (see page 9659) property.
V	CanEditAcceptKey (see page 9628)	Indicates whether the Key parameter can be entered into the current cell.
V	CanEditModify (see page 9629)	Indicates whether the current column of the grid can be edited.
V	CanEditShow (see page 9629)	Indicates whether the inplace edit control can be created to allow editing.
	CellClick (see page 9629)	Generates an OnCellClick (see page 9664) event.
V	CheckColumnDrag (see page 9630)	Validates whether the column currently selected for dragging can be dropped at the current location.
	ColEnter (see page 9630)	Generates an OnColEnter (see page 9665) event.
	ColExit (see page 9630)	Generates an OnColExit (see page 9665) event.
	ColumnAtDepth (see page 9631)	Returns the column object associated with nth parent field of the given column.
V	ColumnMoved (see page 9631)	Generates an OnColumnMoved (see page 9666) event.
V	ColWidthsChanged (see page 9631)	Updates the column widths in the Columns (see page 9653) property when the user resizes the columns.
	CreateColumns (see page 9632)	Creates the TDBGridColumns (see page 9746) object that stores the column descriptors for the grid.
	CreateDataLink (see page 9632)	Creates the data link that the grid uses to manage the connection to its data source.
V	CreateEditor (see page 9632)	Creates the inplace editor that allows the cells of the grid to be edited.
V	CreateWnd (see page 9633)	Creates the window used to display the data-aware grid.
	DataToRawColumn (see page 9633)	Converts a column index in the Columns (see page 9653) property to the index of the corresponding column in the visual display.
	DeferLayout (see page 9635)	Decrements the LayoutLock (see page 9659) property and posts a message to the grid to trigger a new layout sequence at a more appropriate time.
V	DefineFieldMap (see page 9636)	Builds the Fields (see page 9657) array from the Columns (see page 9653) property and the data source.
V	DefineProperties (see page 9636)	Defines a savable version of the Columns (see page 9653) property when necessary.
V	DoMouseWheelDown (see page 9636)	Performs tasks when the mouse wheel is rotated downward.
V	DoMouseWheelUp (see page 9637)	Performs tasks when the mouse wheel is rotated upward.
V	DrawCell (see page 9637)	Draws the cell specified by the ACol and ARow parameters.
	DrawColumnCell (see page 9638)	Generates an OnDrawColumnCell (see page 9666) event.
	DrawDataCell (see page 9638)	Generates an OnDrawDataCell (see page 9667) event.
	EditButtonClick (see page 9638)	Generates an OnEditButtonClick (see page 9668) event.
V	EndColumnDrag (see page 9639)	Ends the dragging of a column in the grid.
	EndLayout (see page 9639)	Decrements the LayoutLock (see page 9659) property and recomputes the Columns (see page 9653) property if LayoutLock (see page 9659) reaches 0.
	EndUpdate (see page 9640)	Decrements the UpdateLock (see page 9664) property.
	GetColField (see page 9640)	Returns the field component that represents the binding of a specified column.
V	GetEditLimit (see page 9641)	Limits the number of characters that can be typed into cells representing string fields.
V	GetEditMask (see page 9641)	Returns the input mask associated with the field for the selected cell.
V	GetEditStyle (see page 9642)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
V	GetEditText (see page 9642)	Returns the value of the indicated cell formatted for editing.
	GetFieldValue (see page 9643)	Returns the value of the indicated cell formatted for display.
V	HighlightCell (see page 9643)	Indicates whether a specified cell should be highlighted when it is drawn.
	InvalidateTitles (see page 9644)	Invalidates the column titles so that they will be repainted.
V	KeyDown (see page 9644)	Provides special processing when the user presses down on a key.
V	KeyPress (see page 9645)	Responds when the user presses a key.
V	LayoutChanged (see page 9645)	Recomputes the Columns (see page 9653) property.
V	LinkActive (see page 9646)	Recomputes the Columns (see page 9653) property and the vertical scroll bar of the grid.
V	Loaded (see page 9646)	Sets up the Columns (see page 9653) property once the data grid and all its child components are loaded.
V	MouseDown (see page 9647)	Provides special processing when the user clicks on the mouse.

	MouseUp (see page 9647)	Provides special processing when the user releases the mouse button.
	Notification (see page 9647)	Responds to notifications that components are about to be destroyed.
	RawToDataColumn (see page 9648)	Converts the index of a column in the visual display to the corresponding index in the Columns (see page 9653) property.
	Scroll (see page 9648)	Updates the image of the grid to reflect a new record position.
	SetColumnAttributes (see page 9649)	This is SetColumnAttributes, a member of class TCustomDBGrid.
	SetEditText (see page 9649)	Updates the edited version of the current cell's data.
	StoreColumns (see page 9650)	Indicates whether the columns of the grid are stored when the grid is saved, or whether they are generated dynamically.
	TimedScroll (see page 9650)	Moves the current record in response to the user dragging the mouse outside of the data cells.
	TitleClick (see page 9651)	Generates an OnTitleClick (see page 9668) event.
	TopLeftChanged (see page 9651)	Updates the position of the inplace editor when the grid scrolls.
	UpdateScrollBar (see page 9652)	This is UpdateScrollBar, a member of class TCustomDBGrid.
	UseRightToLeftAlignmentForField (see page 9652)	Indicates whether the alignment of a specified field should be changed from left-aligned to right-aligned.

Public Methods

	Name	Description
	DefaultDrawColumnCell (see page 9634)	Draws the text in a column cell.
	DefaultDrawDataCell (see page 9634)	Draws the text in a column cell.
	DefaultHandler (see page 9635)	Displays the popup menu when a column is right-clicked.
	ExecuteAction (see page 9640)	Executes an action with the DB (see page 6725) grid as its target.
	ShowPopupEditor (see page 9649)	Displays the nested dataset associated with Column in a new window.
	UpdateAction (see page 9651)	Updates an action to reflect the current state of the grid.
	ValidFieldIndex (see page 9652)	Indicates whether an index into the columns array refers to a valid field in the dataset.

49.1.4.5.1 TCustomDBGrid.AcquireLayoutLock Method

Calls BeginLayout (see page 9626) if the table is not currently being reformatted.

Pascal

```
function AcquireLayoutLock: Boolean;
```

C++

```
__fastcall Boolean AcquireLayoutLock();
```

Description

Applications cannot call this protected method. AcquireLayoutLock is called before recomputing Columns (see page 9653) when the fields in the dataset change or when the Columns (see page 9653) property changes. AcquireLayoutLock returns true if the table is not already being laid out, to indicate that the computation of Columns (see page 9653) should proceed. AcquireLayoutLock prevents the computation of Columns (see page 9653) from looping endlessly because of the changes that must occur during the computation.

See Also

BeginLayout (see page 9626)

Columns (see page 9653)

LayoutChanged (see page 9645)

49.1.4.5.2 TCustomDBGrid.BeginColumnDrag Method

Starts the dragging of a column in the grid.

Pascal

```
function BeginColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt:
TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean BeginColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

BeginColumnDrag is called automatically when the user clicks a column to initiate a drag operation.

Origin is the column number of the column to move. When BeginColumnDrag is called, this is the column under the mouse. BeginColumnDrag may adjust this value to take into account non-scrolling columns.

Destination is the current destination of the column. On both entry and exit, this is the same as Origin, because the column has not yet moved.

MousePt is the coordinates of the mouse at the point when the button was clicked.

BeginColumnDrag returns true if the grid permits the column to be moved, false if the column move should be aborted.

See Also

BeginRowDrag (see page 14817)

EndColumnDrag (see page 9639)

49.1.4.5.3 TCustomDBGrid.BeginLayout Method

Increments the LayoutLock (see page 9659) property when the column bindings or fields in the dataset change.

Pascal

```
procedure BeginLayout;
```

C++

```
__fastcall BeginLayout();
```

Description

Applications cannot call this protected method. Data-aware grids call BeginLayout internally before making changes to the Columns (see page 9653) property or any of the individual TColumn (see page 9583) objects in Columns (see page 9653). Once the change is complete, the data-aware grid calls EndLayout (see page 9639). If the response to the change must be canceled or postponed, the grid calls CancelLayout (see page 9628).

Each call to BeginLayout increments the LayoutLock (see page 9659) property. Each call to EndLayout (see page 9639) or CancelLayout (see page 9628) decrements the LayoutLock (see page 9659) property. If LayoutLock (see page 9659) returns to 0 in a call to EndLayout (see page 9639), the Fields (see page 9657) property is updated to match both the bindings of the Columns (see page 9653) property and the fields available in the dataset. The Columns (see page 9653) property is then updated in turn to match the Fields (see page 9657) property. This ensures that the Columns (see page 9653) property matches both the specified column bindings and the fields available in the dataset.

See Also

AcquireLayoutLock (see page 9625)

CancelLayout (see page 9628)

Columns (see page 9653)

DeferLayout (see page 9635)

DefineFieldMap (see page 9636)

EndLayout (see page 9639)

Fields (see page 9657)

LayoutLock (see page 9659)

49.1.4.5.4 TCustomDBGrid.BeginUpdate Method

Increments the UpdateLock (see page 9664) property when the data in the grid changes.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

Applications cannot call this protected method. Data-aware grids call BeginUpdate internally before making changes that affect the data that is drawn in the grid. Once the change is complete, the data-aware grid calls EndUpdate (see page 9640), which decrements the UpdateLock (see page 9664) property.

While UpdateLock (see page 9664) is greater than 0, the grid does not repaint its cells. BeginUpdate and EndUpdate (see page 9640) prevent the grid from flickering when the grid is resized or the user scrolls through the data.

See Also

EndUpdate (see page 9640)

UpdateLock (see page 9664)

49.1.4.5.5 TCustomDBGrid.CalcSizingState Method

Determines the appearance of the mouse cursor during resizing.

Pascal

```
procedure CalcSizingState(X: Integer; Y: Integer; var State: TGridState; var Index: Longint;
var SizingPos: Integer; var SizingOfs: Integer; var FixedInfo: TGridDrawInfo); override;
```

C++

```
virtual __fastcall CalcSizingState(int X, int Y, TGridState State, Longint Index, int
SizingPos, int SizingOfs, TGridDrawInfo FixedInfo);
```

Description

Use CalcSizingState to determine if the mouse cursor should be changed to a resize or drag cursor based on where the mouse is in the grid. For example, cursor over a grid line, in the fixed cell region, and column resize is enabled = resize cursor.

See Also

CalcFixedInfo (see page 14818)

49.1.4.5.6 TCustomDBGrid.CalcTitleRect Method

Pascal

```
function CalcTitleRect(Col: TColumn; ARow: Integer; var MasterCol: TColumn): TRect;
```

C++

```
__fastcall TRect CalcTitleRect(TColumn Col, int ARow, TColumn MasterCol);
```

Description

This is CalcTitleRect, a member of class TCustomDBGrid.

49.1.4.5.7 TCustomDBGrid.CancelLayout Method

Decrements the LayoutLock (see page 9659) property.

Pascal

```
procedure CancelLayout;
```

C++

```
__fastcall CancelLayout();
```

Description

Applications cannot call this protected method. Data-aware grids call CancelLayout internally when postponing the recomputation of Columns (see page 9653).

Each call to BeginLayout (see page 9626) increments the LayoutLock (see page 9659) property. Each call to EndLayout (see page 9639) or CancelLayout decrements the LayoutLock (see page 9659) property. If LayoutLock (see page 9659) returns to 0 in a call to CancelLayout, the Columns (see page 9653) property is not updated. CancelLayout is called from the DeferLayout (see page 9635) method to decrement the LayoutLock (see page 9659) and prevent the recomputation of Columns (see page 9653) until a more appropriate time.

See Also

BeginLayout (see page 9626)

Columns (see page 9653)

DeferLayout (see page 9635)

EndLayout (see page 9639)

LayoutLock (see page 9659)

49.1.4.5.8 TCustomDBGrid.CanEditAcceptKey Method

Indicates whether the Key parameter can be entered into the current cell.

Pascal

```
function CanEditAcceptKey(Key: Char): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanEditAcceptKey(Char Key);
```

Description

Data-aware grids use CanEditAcceptKey internally to determine whether keys typed by the user are valid for the field represented by the current cell. CanEditAcceptKey calls the IsValidChar method of the field component associated with the column that has input focus.

CanEditAcceptKey provides a crude validation of keyboard input. More refined validation is provided when the value in the cell is written to the record in the dataset, or by an edit mask.

See Also

GetColField (see page 9640)

GetEditMask (see page 9641)

IsValidChar (see page 7136)

49.1.4.5.9 TCustomDBGrid.CanEditModify Method

Indicates whether the current column of the grid can be edited.

Pascal

```
function CanEditModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean CanEditModify();
```

Description

Data-aware grids use CanEditModify internally to determine whether to allow the user to edit the current cell. CanEditModify returns true if the field in the current column can be edited. CanEditModify returns false if the field cannot be edited. If the dataset is not in edit mode, CanEditModify will attempt to put it in edit mode.

Note: CanEditModify returns false when the current field is a binary large object (BLOB) field. BLOB fields can only be edited through the clipboard or by streaming.

See Also

ReadOnly (see page 9660)

ReadOnly (see page 9599)

CanModify (see page 7154)

49.1.4.5.10 TCustomDBGrid.CanEditShow Method

Indicates whether the inplace edit control can be created to allow editing.

Pascal

```
function CanEditShow: Boolean; override;
```

C++

```
virtual __fastcall Boolean CanEditShow();
```

Description

TCustomDBGrid (see page 9608) overrides the inherited method to prevent the inplace edit control from coming up while the layout of the grid is being recomputed.

Grid controls call CanEditShow internally before creating the editor for a cell. CanEditShow is called after the grid has determined that the field can be edited by calling CanEditModify (see page 9629).

See Also

CanEditModify (see page 9629)

CanEditShow (see page 14820)

49.1.4.5.11 TCustomDBGrid.CellClick Method

Generates an OnCellClick (see page 9664) event.

Pascal

```
procedure CellClick(Column: TColumn); dynamic;
```

C++

```
__fastcall CellClick(TColumn Column);
```

Description

Applications cannot directly call CellClick. It is exposed as a protected method so that descendants can call the OnCellClick (see page 9664) event handler in response to other events or override the response when the user releases the mouse in a cell of the grid.

See Also

OnCellClick (see page 9664)

49.1.4.5.12 TCustomDBGrid.CheckColumnDrag Method

Validates whether the column currently selected for dragging can be dropped at the current location.

Pascal

```
function CheckColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt:
TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean CheckColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Use CheckColumnDrag to validate that the column currently selected for dragging can be dropped at the current location. CheckColumnDrag can change the Origin (the column being dragged) and/or the Destination (the drop target), as needed, to keep the grid's columns in order.

See Also

BeginColumnDrag (see page 14817)

EndColumnDrag (see page 14827)

49.1.4.5.13 TCustomDBGrid.ColEnter Method

Generates an OnColEnter (see page 9665) event.

Pascal

```
procedure ColEnter; dynamic;
```

C++

```
__fastcall ColEnter();
```

Description

Applications cannot directly call ColEnter. It is exposed as a protected method so that descendants can call the OnCellEnter event handler in response to other events or override the response when a cell in the grid is selected.

See Also

OnColEnter (see page 9665)

49.1.4.5.14 TCustomDBGrid.ColExit Method

Generates an OnColExit (see page 9665) event.

Pascal

```
procedure ColExit; dynamic;
```

C++

```
__fastcall ColExit();
```

Description

Applications cannot directly call ColExit. It is exposed as a protected method so that descendants can call the OnColExit (see page 9665) event handler in response to other events or override the response when a cell in the grid loses focus.

See Also

OnColExit (see page 9665)

49.1.4.5.15 TCustomDBGrid.ColumnAtDepth Method

Returns the column object associated with nth parent field of the given column.

Pascal

```
function ColumnAtDepth(Col: TColumn; ADepth: Integer): TColumn;
```

C++

```
__fastcall TColumn ColumnAtDepth(TColumn Col, int ADepth);
```

Description

ColumnAtDepth is used to calculate MasterCol used in the CalcTitleRec method.

See Also

CalcTitleRec

49.1.4.5.16 TCustomDBGrid.ColumnMoved Method

Generates an OnColumnMoved (see page 9666) event.

Pascal

```
procedure ColumnMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall ColumnMoved(Longint FromIndex, Longint ToIndex);
```

Description

Applications cannot directly call ColumnMoved. It is exposed as a protected method so that descendants can call the OnColumnMoved (see page 9666) event handler in response to other events or override the response after a column in the grid is moved.

See Also

OnColumnMoved (see page 9666)

49.1.4.5.17 TCustomDBGrid.ColWidthsChanged Method

Updates the column widths in the Columns (see page 9653) property when the user resizes the columns.

Pascal

```
procedure ColWidthsChanged; override;
```

C++

```
virtual __fastcall ColWidthsChanged();
```

Description

Applications cannot directly call ColWidthsChanged. It is called automatically when the user resizes the columns in the grid. ColWidthsChanged overrides the inherited method to update the column widths in the Columns (see page 9653) property.

See Also

Columns (see page 9653)

Width (see page 9600)

49.1.4.5.18 TCustomDBGrid.CreateColumns Method

Creates the TDBGridColumns (see page 9746) object that stores the column descriptors for the grid.

Pascal

```
function CreateColumns: TDBGridColumns; dynamic;
```

C++

```
__fastcall TDBGridColumns CreateColumns();
```

Description

Applications cannot call CreateColumns. It is exposed as a protected method so that component writers can substitute a descendant of TDBGridColumns (see page 9746) to manage the column descriptors of a data-aware grid.

See Also

Columns (see page 9653)

49.1.4.5.19 TCustomDBGrid.CreateDataLink Method

Creates the data link that the grid uses to manage the connection to its data source.

Pascal

```
function CreateDataLink: TGridDataLink; dynamic;
```

C++

```
__fastcall TGridDataLink CreateDataLink();
```

Description

TCustomDBGrid (see page 9608) calls CreateDataLink from its constructor to create the data link that manages the connection to a data source. Descendant classes can override this method to create a different TGridDataLink (see page 9754) descendant.

See Also

DataSource (see page 9655)

49.1.4.5.20 TCustomDBGrid.CreateEditor Method

Creates the inplace editor that allows the cells of the grid to be edited.

Pascal

```
function CreateEditor: TInplaceEdit; override;
```

C++

```
virtual __fastcall TInplaceEdit CreateEditor();
```

Description

CreateEditor overrides the inherited method to create a data-aware descendant of TInplaceEdit.

See Also

TInplaceEdit (see page 14938)

49.1.4.5.21 TCustomDBGrid.CreateWnd Method

Creates the window used to display the data-aware grid.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The Windows control for the grid can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. TCustomDBGrid (see page 9608) calls CreateWnd to create this Windows control when necessary.

CreateWnd overrides the inherited method to set up the relationship between the visual display and the data source after the window is created.

See Also

CreateWnd (see page 6137)

49.1.4.5.22 TCustomDBGrid.DataToRawColumn Method

Converts a column index in the Columns (see page 9653) property to the index of the corresponding column in the visual display.

Pascal

```
function DataToRawColumn(ACol: Integer): Integer;
```

C++

```
__fastcall int DataToRawColumn(int ACol);
```

Description

Applications cannot call this protected method. It is used internally to allow the data-aware grid to adjust to the presence or absence of the column that contains the row indicator.

See Also

Columns (see page 9653)

IndicatorOffset (see page 9658)

RawToDataColumn (see page 9648)

49.1.4.5.23 TCustomDBGrid.DefaultDrawColumnCell Method

Draws the text in a column cell.

Pascal

```
procedure DefaultDrawColumnCell(const Rect: TRect; DataCol: Integer; Column: TColumn; State:
TGridDrawState);
```

C++

```
__fastcall DefaultDrawColumnCell(const TRect Rect, int DataCol, TColumn Column, TGridDrawState
State);
```

Description

Call DefaultDrawColumnCell from an OnDrawColumnCell (see page 9666) event handler to lookup up the text representation of a field and write it to the cell. DefaultDrawColumnCell does exactly what the grid does when the DefaultDrawing (see page 9655) property is true, except it never draws a focus rectangle on selected cells.

The Rect parameter is the position of the cell on the canvas. The DataCol parameter is the index of the column in the Columns (see page 9653) array. The Column parameter is the TColumn (see page 9583) object that describes the display attributes and field binding for the cell. The State parameter indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (non-data) cell such as a column header.

See Also

Columns (see page 9653)

DefaultDrawing (see page 9655)

OnDrawColumnCell (see page 9666)

49.1.4.5.24 TCustomDBGrid.DefaultDrawDataCell Method

Draws the text in a column cell.

Pascal

```
procedure DefaultDrawDataCell(const Rect: TRect; Field: TField; State: TGridDrawState);
```

C++

```
__fastcall DefaultDrawDataCell(const TRect Rect, TField Field, TGridDrawState State);
```

Description

Call DefaultDrawDataCell from an OnDrawDataCell (see page 9667) event handler to lookup up the text representation of a field and write it to the cell. Unlike what the grid draws when the DefaultDrawing (see page 9655) property is true, DefaultDrawDataCell gets the alignment for the text from the field component rather than the column descriptor, and it never draws a focus rectangle on selected cells.

The Rect parameter gives the position of the cell on the canvas. The Field parameter gives the field component that provides the data and alignment for the cell. The State parameter indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (non-data) cell such as a column header.

See Also

DefaultDrawing (see page 9655)

OnDrawDataCell (see page 9667)

49.1.4.5.25 TCustomDBGrid.DefaultHandler Method

Displays the popup menu when a column is right-clicked.

Pascal

```
procedure DefaultHandler(var Msg); override;
```

C++

```
virtual __fastcall DefaultHandler( Msg);
```

Description

DefaultHandler is the last method to receive Windows messages that are sent to the grid. After calling the inherited method and allowing it to process the message, DefaultHandler checks if the Msg parameter indicates the right mouse button was released over a column with a popup menu. If the column has a popup menu with its AutoPopup property set to true, DefaultHandler displays the popup menu.

When overriding DefaultHandler, be sure to call the inherited method for all unhandled messages.

See Also

PopupMenu (see page 9599)

AutoPopup (see page 16178)

DefaultHandler (see page 6139)

49.1.4.5.26 TCustomDBGrid.DeferLayout Method

Decrements the LayoutLock (see page 9659) property and posts a message to the grid to trigger a new layout sequence at a more appropriate time.

Pascal

```
procedure DeferLayout;
```

C++

```
__fastcall DeferLayout();
```

Description

Applications cannot call this protected method. Data-aware grids call DeferLayout internally to postpone the recomputation of the Columns (see page 9653) property after the dataset changes when it is inappropriate to recompute columns immediately.

DeferLayout calls CancelLayout (see page 9628) to decrement the LayoutLock (see page 9659) property, which was incremented in response to the change in the dataset. It then posts a message to the grid, which triggers another layout attempt at a later point in time. When the message is received, the grid calls BeginLayout (see page 9626) and then either EndLayout (see page 9639) or DeferLayout, depending on whether it is an appropriate time to proceed with the computation of Columns (see page 9653).

See Also

BeginLayout (see page 9626)

CancelLayout (see page 9628)

Columns (see page 9653)

EndLayout (see page 9639)

LayoutLock (see page 9659)

49.1.4.5.27 TCustomDBGrid.DefineFieldMap Method

Builds the Fields (see page 9657) array from the Columns (see page 9653) property and the data source.

Pascal

```
procedure DefineFieldMap; virtual;
```

C++

```
virtual __fastcall DefineFieldMap();
```

Description

Applications cannot call this protected method. DefineFieldMap rebuilds the Fields (see page 9657) array to reflect the fields from the data source that correspond to the columns in the Columns (see page 9653) property. After calling DefineFieldMap, the Columns (see page 9653) property should be updated to use the field components in the Fields (see page 9657) array. This ensures that the Columns (see page 9653) property reflects any changes imposed by the dataset.

See Also

Columns (see page 9653)

EndLayout (see page 9639)

Fields (see page 9657)

49.1.4.5.28 TCustomDBGrid.DefineProperties Method

Defines a savable version of the Columns (see page 9653) property when necessary.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties overrides the inherited method to load and save the Columns (see page 9653) property if the columns have been customized.

See Also

Columns (see page 9653)

DefineProperties (see page 2931)

49.1.4.5.29 TCustomDBGrid.DoMouseWheelDown Method

Performs tasks when the mouse wheel is rotated downward.

Pascal

```
function DoMouseWheelDown(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelDown(TShiftState Shift, TPoint MousePos);
```

Description

Override DoMouseWheelDown to perform tasks when the mouse wheel is rotated downward.

DoMouseWheelDown returns false if the control's parent should handle the message.

In TCustomGrid, DoMouseWheelDown increments the current row and returns true.

See Also

DoMouseWheelUp (see page 14826)

Row (see page 14854)

49.1.4.5.30 TCustomDBGrid.DoMouseWheelUp Method

Performs tasks when the mouse wheel is rotated upward.

Pascal

```
function DoMouseWheelUp(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelUp(TShiftState Shift, TPoint MousePos);
```

Description

Override DoMouseWheelUp to perform tasks when the mouse wheel is rotated downward.

DoMouseWheelUp should return false if the control's parent should handle the message.

In TCustomGrid, DoMouseWheelUp decrements the current row and returns true.

See Also

DoMouseWheelDown (see page 14825)

Row (see page 14854)

49.1.4.5.31 TCustomDBGrid.DrawCell Method

Draws the cell specified by the ACol and ARow parameters.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell overrides the inherited method to use the Columns (see page 9653) property when drawing cells in the grid.

DrawCell sets up the font and brush and paints the background of the cell. If the DefaultDrawing (see page 9655) property is true, DrawCell fetches the data for the cell and writes it to the position described by the ARect parameter. Whether DefaultDrawing (see page 9655) is true or false, DrawCell generates the OnDrawDataCell (see page 9667) and OnDrawColumnCell (see page 9666) events. Finally, if DefaultDrawing (see page 9655) is true and either the cell has focus or the cell is selected and Options (see page 9659) includes dgAlwaysShowSelection, DrawCell draws a focus rectangle around the cell.

See Also

Columns (see page 9653)

DefaultDrawing (see page 9655)

OnDrawColumnCell (see page 9666)

OnDrawDataCell (see page 9667)

Options (see page 9659)

49.1.4.5.32 TCustomDBGrid.DrawColumnCell Method

Generates an OnDrawColumnCell (see page 9666) event.

Pascal

```
procedure DrawColumnCell(const Rect: TRect; DataCol: Integer; Column: TColumn; State:
TGridDrawState); dynamic;
```

C++

```
__fastcall DrawColumnCell(const TRect Rect, int DataCol, TColumn Column, TGridDrawState State);
```

Description

Applications cannot call DrawColumnCell directly. It is exposed as a protected method so that descendants can call the OnDrawColumnCell (see page 9666) event handler or override the method to block the event.

See Also

OnDrawColumnCell (see page 9666)

49.1.4.5.33 TCustomDBGrid.DrawDataCell Method

Generates an OnDrawDataCell (see page 9667) event.

Pascal

```
procedure DrawDataCell(const Rect: TRect; Field: TField; State: TGridDrawState); dynamic;
```

C++

```
__fastcall DrawDataCell(const TRect Rect, TField Field, TGridDrawState State);
```

Description

Applications cannot call DrawDataCell directly. It is exposed as a protected method so that descendants can call the OnDrawDataCell (see page 9667) event handler or override the method to block the event.

See Also

OnDrawDataCell (see page 9667)

49.1.4.5.34 TCustomDBGrid.EditButtonClick Method

Generates an OnEditButtonClick (see page 9668) event.

Pascal

```
procedure EditButtonClick; dynamic;
```

C++

```
__fastcall EditButtonClick();
```

Description

Applications cannot call EditButtonClick directly. It is exposed as a protected method so that descendants can call the OnEditButtonClick (see page 9668) event handler or override the method to block the event.

See Also

OnEditButtonClick (see page 9668)

49.1.4.5.35 TCustomDBGrid.EndColumnDrag Method

Ends the dragging of a column in the grid.

Pascal

```
function EndColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt: TPoint):
Boolean; override;
```

C++

```
virtual __fastcall Boolean EndColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Call EndColumnDrag to end a drag operation. EndColumnDrag enables the grid to control where the column can be dropped. It is exposed as a protected method so that descendants of TCustomDBGrid (see page 9608) can customize column dragging in a grid.

See Also

BeginColumnDrag (see page 9625)

49.1.4.5.36 TCustomDBGrid.EndLayout Method

Decrements the LayoutLock (see page 9659) property and recomputes the Columns (see page 9653) property if LayoutLock (see page 9659) reaches 0.

Pascal

```
procedure EndLayout;
```

C++

```
__fastcall EndLayout();
```

Description

Applications cannot call this protected method. Data-aware grids call EndLayout internally after changes to the Columns (see page 9653) property or the dataset. EndLayout decrements the LayoutLock (see page 9659) property which was previously incremented by BeginLayout (see page 9626) before the Columns (see page 9653) property was changed or when notification of the change to the dataset was received.

If LayoutLock (see page 9659) returns to 0, EndLayout updates the Fields (see page 9657) property to match both the bindings of the Columns (see page 9653) property and the fields available in the dataset. The Columns (see page 9653) property is then updated in turn to match the Fields (see page 9657) property. This ensures that the Columns (see page 9653) property matches both the specified column bindings and the fields available in the dataset.

See Also

BeginLayout (see page 9626)

Columns (see page 9653)

DefineFieldMap (see page 9636)

Fields (see page 9657)

LayoutLock (see page 9659)

49.1.4.5.37 TCustomDBGrid.EndUpdate Method

Decrements the UpdateLock (see page 9664) property.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Applications cannot call this protected method. Data-aware grids call EndUpdate internally after making changes that affect the data that is drawn in the grid. EndUpdate returns the UpdateLock (see page 9664) to the state it was in before the BeginUpdate (see page 9627) method was called at the start of the changes.

While UpdateLock (see page 9664) is greater than 0, the grid does not repaint its cells. When UpdateLock (see page 9664) returns to 0, painting is reenabled. BeginUpdate (see page 9627) and EndUpdate prevent the grid from flickering when the grid is resized or the user scrolls through the data.

See Also

BeginUpdate (see page 9627)

UpdateLock (see page 9664)

49.1.4.5.38 TCustomDBGrid.ExecuteAction Method

Executes an action with the DB (see page 6725) grid as its target.

Pascal

```
function ExecuteAction(Action: TBasicAction): Boolean; override;
```

C++

```
virtual __fastcall Boolean ExecuteAction(TBasicAction Action);
```

Description

ExecuteAction is called automatically when the user invokes an action with the DB (see page 6725) grid as its target. The Action parameter specifies the action that was invoked. ExecuteAction returns a boolean value indicating whether the action was successfully executed.

ExecuteAction first calls the inherited method, which checks whether the action knows how to execute with the grid as a target. If this does not successfully dispatch the action, ExecuteAction attempts to invoke the action with the grid's associated dataset as a target.

See Also

Execute (see page 2712)

DataSource (see page 9655)

49.1.4.5.39 TCustomDBGrid.GetColField Method

Returns the field component that represents the binding of a specified column.

Pascal

```
function GetColField(DataCol: Integer): TField;
```

C++

```
__fastcall TField GetColField(int DataCol);
```

Description

Call GetColField to obtain the field component for a column in the data-aware grid. The DataCol parameter is the index of the column in the Columns (see page 9653) property, where 0 is the first column, 1 is the second column, and so on.

Unlike the Fields (see page 9657) property, GetColField will return field components for columns that do not represent fields in the dataset, such as calculated fields. GetColField will return nil (Delphi) or NULL (C++) if no field is associated with the column or if the dataset is not active.

See Also

Columns (see page 9653)

Fields (see page 9657)

49.1.4.5.40 TCustomDBGrid.GetEditLimit Method

Limits the number of characters that can be typed into cells representing string fields.

Pascal

```
function GetEditLimit: Integer; override;
```

C++

```
virtual __fastcall int GetEditLimit();
```

Description

GetEditLimit is called by the inplace editor to determine what limit, if any, should be placed on the number of characters a user can type into a cell. GetEditLimit sets no limits except when the selected cell represents a string field.

See Also

CreateEditor (see page 9632)

49.1.4.5.41 TCustomDBGrid.GetEditMask Method

Returns the input mask associated with the field for the selected cell.

Pascal

```
function GetEditMask(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditMask(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditMask to obtain any input mask associated with the field binding of the indicated cell. GetEditMask returns the EditMask property of the field component from the Columns (see page 9653) array.

The ACol and ARow parameters indicate the index of the row and column of the cell in the grid. The ACol parameter is not the same as the index of the column in the Columns (see page 9653) array if the Options (see page 9659) property includes dgIndicator.

See Also

Columns (see page 9653)

Options (see page 9659)

RawToDataColumn (see page 9648)

EditMask (see page 7163)

49.1.4.5.42 TCustomDBGrid.GetEditStyle Method

Indicates whether a specified cell has an ellipsis button or drop-down arrow.

Pascal

```
function GetEditStyle(ACol: Longint; ARow: Longint): TEditStyle; override;
```

C++

```
virtual __fastcall TEditStyle GetEditStyle(Longint ACol, Longint ARow);
```

Description

GetEditStyle indicates whether the specified cell can only be edited directly (esSimple), whether it has an ellipsis button that users can click to launch an editor for modifying field values (esEllipsis), or whether it has a drop-down arrow that users can click to display a pick list of possible values (esPickList).

ACol is the column that contains the cell. ARow is the row that contains the cell.

In TCustomDBGrid (see page 9608), GetEditStyle checks the properties of the column object that corresponds to ACol.

If the column has a ButtonStyle of cbsEllipsis or if it has a ButtonStyle of cbsAuto and it represents a dataset or reference field, then GetEditStyle returns esEllipsis.

If the column has a ButtonStyle of cbsAuto, is not read-only, and either has a pick list or represents a lookup field, then GetEditStyle returns esPickList.

If the column has a ButtonStyle of cbsNone or neither of the two previous conditions are met, then GetEditStyle returns esSimple.

See Also

ButtonStyle (see page 9593)

FieldName (see page 9595)

ReadOnly (see page 9599)

Columns (see page 9653)

PickList (see page 9598)

49.1.4.5.43 TCustomDBGrid.GetEditText Method

Returns the value of the indicated cell formatted for editing.

Pascal

```
function GetEditText(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditText(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditText to obtain the text for the indicated cell. GetEditText locates the field component for the cell from the Columns (see page 9653) array and returns its value formatted for editing.

The ACol and ARow parameters indicate the index of the row and column of the cell in the grid. The ACol parameter is the "raw" column index, which is not the same as the index of the column in the Columns (see page 9653) array if the Options (see

page 9659) property includes dgIndicator.

Note: The string returned by GetEditText may differ from the string returned by the GetFieldValue (see page 9643) method if the field formats its value differently for editing and display.

See Also

Columns (see page 9653)

Options (see page 9659)

RawToDataColumn (see page 9648)

EditMask (see page 7163)

49.1.4.5.44 TCustomDBGrid.GetFieldValue Method

Returns the value of the indicated cell formatted for display.

Pascal

```
function GetFieldValue(ACol: Integer): string;
```

C++

```
__fastcall AnsiString GetFieldValue(int ACol);
```

Description

The DefaultDrawColumnCell (see page 9634) method calls GetFieldValue to obtain the text that should be displayed in a cell. Applications do not call this protected method.

The ACol parameter is the index of the column in the columns array. If the Options (see page 9659) property includes dgIndicator, this is not the same as the index of the column in the physical display.

See Also

Columns (see page 9653)

Options

DisplayText (see page 7162)

DefaultDrawColumnCell (see page 9634)

49.1.4.5.45 TCustomDBGrid.HighlightCell Method

Indicates whether a specified cell should be highlighted when it is drawn.

Pascal

```
function HighlightCell(DataCol: Integer; DataRow: Integer; const Value: string; AState:
TGridDrawState): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean HighlightCell(int DataCol, int DataRow, const AnsiString Value,
TGridDrawState AState);
```

Description

Applications cannot call this protected method. It is called internally by the DrawCell (see page 9637) method to determine whether the cell specified by the DataCol and DataRow parameters should be highlighted. HighlightCell returns true if the cell has focus, the cell is selected and Options (see page 9659) includes dgAlwaysShowSelection, or the cell is in a selected row and Options (see page 9659) includes dgRowSelect.

See Also

DrawCell (see page 9637)

Options (see page 9659)

49.1.4.5.46 TCustomDBGrid.InvalidateTitles Method

Invalidates the column titles so that they will be repainted.

Pascal

```
procedure InvalidateTitles;
```

C++

```
__fastcall InvalidateTitles();
```

Description

Call InvalidateTitles to cause the column titles to be repainted.

49.1.4.5.47 TCustomDBGrid.KeyDown Method

Provides special processing when the user presses down on a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

Applications cannot call KeyDown. It is called automatically when the user presses a key, before the KeyPress (see page 9645) method is called.

KeyDown generates an OnKeyDown event and then responds to the following keystrokes:

Keystroke	Response
UpArrow	Move to the previous row. If Options (see page 9659) includes dgRowSelect, select it.
Ctrl+UpArrow	Move to the first row in the grid. Deselect any selected rows.
DownArrow	Move to the next row. If Options (see page 9659) includes dgRowSelect, select it.
Ctrl+DownArrow	Move to the last row in the grid. Deselect any selected rows.
PageUp	Move up by the number of records shown in the grid. Deselect any selected rows.
Ctrl+PageUp	Move to the first row in the grid. Deselect any selected rows.
PageDown	Move down by the number of records shown in the grid. Deselect any selected rows.
LeftArrow	Move left one column. If Options (see page 9659) includes dgRowSelect, move to the previous row without selecting it.
Ctrl+LeftArrow	Move to the first column in the current row.
RightArrow	Move right one column. If Options (see page 9659) includes dgRowSelect, move to the next row without selecting it.
Ctrl+RightArrow	Move to the last column in the current row.

Home	Move to the first column of the current row. If Options (see page 9659) includes dgRowSelect or the grid has only one column, move to the first record in the dataset. Deselect any selected rows.
Ctrl+Home	Move to the first record in the dataset. Deselect any selected rows.
End	Move to the last column of the current row. If Options (see page 9659) includes dgRowSelect or the grid has only one column, move to the last record in the dataset. Deselect any selected rows.
Ctrl+End	Move to the last record in the dataset. Deselect any selected rows.
Tab	Move to the next cell in the grid.
Shift+Tab	Move to the previous cell in the grid.
Ctrl+Delete	Delete the current selection.
Insert	Insert a new row above the current one, and move to it. Deselect any selected rows.
Escape	Cancel any unposted edits. Deselect any selected rows.
F2	Put the grid in edit mode.

See Also

KeyPress (see page 9645)

Options (see page 9659)

OnKeyDown

49.1.4.5.48 TCustomDBGrid.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

When the user presses a key, first the KeyDown (see page 9644) method is called, then the KeyPress method, and finally the KeyUp method when the user releases the key. KeyPress overrides the inherited method to write edits to the dataset when the user presses Return.

See Also

KeyDown (see page 9644)

KeyPress (see page 14833)

KeyUp (see page 6164)

49.1.4.5.49 TCustomDBGrid.LayoutChanged Method

Recomputes the Columns (see page 9653) property.

Pascal

```
procedure LayoutChanged; virtual;
```

C++

```
virtual __fastcall LayoutChanged();
```

Description

Applications cannot call this protected method. It is called automatically in response to changes the affect the layout of the columns. These include

Changes to the fields in the dataset.

Changes in the Options (see page 9659) property that affect the layout.

Changes to the TitleFont (see page 9663) property.

LayoutChanged calls AcquireLayoutLock (see page 9625) to initiate the changes to Columns (see page 9653). If AcquireLayoutLock (see page 9625) does not indicate that the call to LayoutChanged is recursive, LayoutChanged calls EndLayout (see page 9639) to perform the actual computation.

See Also

AcquireLayoutLock (see page 9625)

Columns (see page 9653)

EndLayout (see page 9639)

Options (see page 9659)

TitleFont (see page 9663)

49.1.4.5.50 TCustomDBGrid.LinkActive Method

Recomputes the Columns (see page 9653) property and the vertical scroll bar of the grid.

Pascal

```
procedure LinkActive(Value: Boolean); virtual;
```

C++

```
virtual __fastcall LinkActive(Boolean Value);
```

Description

Applications cannot call this protected method. It is called automatically when the dataset is opened. LinkActive calls LayoutChanged (see page 9645) to recompute the Columns (see page 9653) property, and adjusts the vertical scroll bar for the data in the dataset.

See Also

Columns (see page 9653)

LayoutChanged (see page 9645)

49.1.4.5.51 TCustomDBGrid.Loaded Method

Sets up the Columns (see page 9653) property once the data grid and all its child components are loaded.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Applications cannot call this protected method. Loaded overrides the inherited method to lay out the grid once all of its parts

have been loaded.

See Also

Columns (see page 9653)

49.1.4.5.52 TCustomDBGrid.MouseDown Method

Provides special processing when the user clicks on the mouse.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseDown is called automatically when the user presses the mouse button. If the mouse is pressed in the row or column resize region of the grid, MouseDown posts any pending edits and calls the inherited method to handle the resize. When Options (see page 9659) includes dgRowSelect, MouseDown selects the row that received the click, or toggles its selection state if the Ctrl key is pressed. If the mouse is clicked in a data cell, MouseDown tries to put the grid into edit mode.

See Also

MouseUp (see page 9647)

Options (see page 9659)

MouseDown (see page 14834)

49.1.4.5.53 TCustomDBGrid.MouseUp Method

Provides special processing when the user releases the mouse button.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseUp is called automatically when the user releases the mouse button. After calling the inherited method, MouseUp locates the cell that was under the mouse when it was released. MouseUp generates an OnTitleClick (see page 9668) or OnCellClick (see page 9664) event, depending on the location of the mouse.

See Also

OnCellClick (see page 9664)

OnTitleClick (see page 9668)

MouseUp (see page 14835)

49.1.4.5.54 TCustomDBGrid.Notification Method

Responds to notifications that components are about to be destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

After calling the inherited method, Notification

Checks if the pop-up menu for any of its columns is going away, and if so, resets the PopupMenu property of the column object.

Checks if the data source is going away, and if so, sets the DataSource (see page 9655) property to nil (Delphi) or NULL (C++).

Checks if any of the field components associated with its columns is going away, and if so, removes the column from the layout.

See Also

Columns (see page 9653)

DataSource (see page 9655)

PopupMenu (see page 9599)

49.1.4.5.55 TCustomDBGrid.RawToDataColumn Method

Converts the index of a column in the visual display to the corresponding index in the Columns (see page 9653) property.

Pascal

```
function RawToDataColumn(ACol: Integer): Integer;
```

C++

```
__fastcall int RawToDataColumn(int ACol);
```

Description

Applications cannot call this protected method. It is used internally to allow the data-aware grid to adjust to the presence or absence of the column that contains the row indicator.

See Also

Columns (see page 9653)

DataToRawColumn (see page 9633)

IndicatorOffset (see page 9658)

49.1.4.5.56 TCustomDBGrid.Scroll Method

Updates the image of the grid to reflect a new record position.

Pascal

```
procedure Scroll(Distance: Integer); virtual;
```

C++

```
virtual __fastcall Scroll(int Distance);
```

Description

Scroll is called in response to changes in the current record in the dataset. Scroll updates the image in the grid, scrolling the data if necessary.

See Also

TimedScroll (see page 9650)

49.1.4.5.57 TCustomDBGrid.SetColumnAttributes Method

Pascal

```
procedure SetColumnAttributes; virtual;
```

C++

```
virtual __fastcall SetColumnAttributes();
```

Description

This is SetColumnAttributes, a member of class TCustomDBGrid.

49.1.4.5.58 TCustomDBGrid.SetEditText Method

Updates the edited version of the current cell's data.

Pascal

```
procedure SetEditText(ACol: Longint; ARow: Longint; const Value: string); override;
```

C++

```
virtual __fastcall SetEditText(Longint ACol, Longint ARow, const AnsiString Value);
```

Description

The inplace editor calls SetEditText so that the grid can store the new value for the current cell. The grid stores this value until the user moves to a new cell or presses Escape. If the user moves to a new cell, this value is written to the record in the database. If the user presses Escape, the value is discarded.

See Also

GetEditText (see page 9642)

49.1.4.5.59 TCustomDBGrid.ShowPopupEditor Method

Displays the nested dataset associated with Column in a new window.

Pascal

```
procedure ShowPopupEditor(Column: TColumn; X: Integer = Low(Integer); Y: Integer =
Low(Integer)); dynamic;
```

C++

```
__fastcall ShowPopupEditor(TColumn Column, int X = Low(Integer), int Y = Low(Integer));
```

Description

Call ShowPopupEditor to display a nested dataset or ADT in a new grid in a new window. Column is the column that is representing the dataset or reference field of the dataset.

For example, if the seventh column in the grid represents a dataset field, the following code displays the dataset associated with that field for the current record.

```
DBGrid1.ShowPopupEditor(DBGrid1.Columns[7]);
DBGrid1->ShowPopupEditor(DBGrid1->Columns->Items[7]);
```

ShowPopupEditor expects the TColumn (see page 9583) object field type passed to be ftDataSet.

When the ellipsis button in the grid cell of a nested dataset or reference field is clicked, EditButtonClick (see page 9638) is called. If the grid's OnEditButtonClick (see page 9668) event has an event handler, that event is fired and ShowPopupEditor is not called. If the event handler is not assigned, ShowPopupEditor is called.

The X and Y parameters are screen coordinates to position the popup editor form. The default behavior is to position the form below the cell in the grid.

See Also

TDataSetField (see page 7060)

TReferenceField (see page 7452)

OnEditButtonClick (see page 9668)

EditButtonClick (see page 9638)

Working with DataSet Fields

Working with Reference Fields

49.1.4.5.60 TCustomDBGrid.StoreColumns Method

Indicates whether the columns of the grid are stored when the grid is saved, or whether they are generated dynamically.

Pascal

```
function StoreColumns: Boolean;
```

C++

```
__fastcall Boolean StoreColumns();
```

Description

StoreColumns causes the Columns (see page 9653) property to be stored only when the Columns (see page 9653) property has a State property of csCustomized. The State property for Columns (see page 9653) indicates whether the columns are generated automatically from the fields in the dataset, or if they are specified programmatically or by the Columns (see page 9653) editor.

See Also

Columns (see page 9653)

State (see page 9753)

49.1.4.5.61 TCustomDBGrid.TimedScroll Method

Moves the current record in response to the user dragging the mouse outside of the data cells.

Pascal

```
procedure TimedScroll(Direction: TGridScrollDirection); override;
```

C++

```
virtual __fastcall TimedScroll(TGridScrollDirection Direction);
```

Description

If the Direction parameter includes sdUp, TimedScroll moves the dataset to the first visible record in the grid. If the Direction parameter includes sdDown, TimedScroll moves the dataset to the last visible record in the grid. After adjusting the current record, TimedScroll calls the inherited method to update the image.

See Also

TimedScroll (see page 14840)

49.1.4.5.62 TCustomDBGrid.TitleClick Method

Generates an OnTitleClick (see page 9668) event.

Pascal

```
procedure TitleClick(Column: TColumn); dynamic;
```

C++

```
__fastcall TitleClick(TColumn Column);
```

Description

Applications cannot call TitleClick directly. It is exposed as a protected method so that descendants can call the OnTitleClick (see page 9668) event handler or override the method to block the event.

See Also

OnTitleClick (see page 9668)

49.1.4.5.63 TCustomDBGrid.TopLeftChanged Method

Updates the position of the inplace editor when the grid scrolls.

Pascal

```
procedure TopLeftChanged; override;
```

C++

```
virtual __fastcall TopLeftChanged();
```

Description

TopLeftChanged is called whenever the LeftCol or TopRow property changes. InvalidateTitles (see page 9644) and the inherited method TopLeftChanged method are called.

See Also

TopLeftChanged (see page 14841)

InvalidateTitles (see page 9644)

49.1.4.5.64 TCustomDBGrid.UpdateAction Method

Updates an action to reflect the current state of the grid.

Pascal

```
function UpdateAction(Action: TBasicAction): Boolean; override;
```

C++

```
virtual __fastcall Boolean UpdateAction(TBasicAction Action);
```

Description

UpdateAction is called automatically when the application is idle allow the grid to set action properties to reflect the current state of the grid. The Action parameter is the action to be updated. UpdateAction returns a boolean that indicates whether the action was updated by the grid.

As implemented in TCustomDBGrid (see page 9608), UpdateAction checks whether the action relies on the state of the associated dataset, and if so, updates the action accordingly.

See Also

UpdateAction (see page 6887)

DataSource (see page 9655)

Update (see page 2714)

49.1.4.5.65 TCustomDBGrid.UpdateScrollBar Method

Pascal

```
procedure UpdateScrollBar; virtual;
```

C++

```
virtual __fastcall UpdateScrollBar();
```

Description

This is UpdateScrollBar, a member of class TCustomDBGrid.

49.1.4.5.66 TCustomDBGrid.UseRightToLeftAlignmentForField Method

Indicates whether the alignment of a specified field should be changed from left-aligned to right-aligned.

Pascal

```
function UseRightToLeftAlignmentForField(const AField: TField; Alignment: TAlignment): Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftAlignmentForField(const TField AField, TAlignment Alignment);
```

Description

UseRightToLeftAlignmentForField is called internally when drawing field values to determine whether the Alignment of AField should be changed from left-aligned to right-aligned. This method lets the data-aware grid honor the current setting of the BiDiMode property. UseRightToLeftAlignment returns true if the application is running in a mideast locale (where alignment should be reversed), the field contains text (as opposed to numeric or date/time values), and the specified alignment is not taCenter.

See Also

IsRightToLeft (see page 5770)

FieldKind (see page 7164)

BiDiMode (see page 5803)

49.1.4.5.67 TCustomDBGrid.ValidFieldIndex Method

Indicates whether an index into the columns array refers to a valid field in the dataset.

Pascal

```
function ValidFieldIndex(FieldIndex: Integer): Boolean;
```

C++

```
__fastcall Boolean ValidFieldIndex(int FieldIndex);
```

Description

Call ValidFieldIndex to determine whether a column displays data from a field in the dataset. ValidFieldIndex returns true if the column is associated with a database field. ValidFieldIndex returns false if the column is a calculated field or if the field for the column is undefined.

See Also

Columns (see page 9653)

Fields (see page 9657)

GetColField (see page 9640)

49.1.4.6 TCustomDBGrid Properties

The properties of the TCustomDBGrid class are listed here.

Protected Properties

	Name	Description
	Columns (see page 9653)	Describes the display attributes and field bindings of the columns.
R	DataLink (see page 9654)	Helps the data-aware grid manage its link to the data source and respond to data events.
	DefaultDrawing (see page 9655)	Indicates whether the cells in the data-aware grid are drawn automatically.
R	IndicatorOffset (see page 9658)	Indicates the index of the first column in the grid that contains data.
R	LayoutLock (see page 9659)	Counts the number of times BeginLayout (see page 9626) has been called without an EndLayout (see page 9639) or CancelLayout (see page 9628) call.
	Options (see page 9659)	Specifies various display and behavioral properties of the data-aware grid.
	ParentColor (see page 9660)	Determines where a control looks for its color information.
	ReadOnly (see page 9660)	Indicates whether the grid is used for display only, or whether the user can edit data using the grid.
R	SelectedRows (see page 9662)	Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.
	TitleFont (see page 9663)	Describes the font used to draw the column titles in the grid.
R	UpdateLock (see page 9664)	Counts the number of times BeginUpdate (see page 9627) is called without a corresponding call to EndUpdate (see page 9640).

Public Properties

	Name	Description
	DataSource (see page 9655)	Identifies the link to the dataset where the data-aware grid finds its data.
	EditorMode (see page 9656)	Determines whether the current cell can be edited.
R	FieldCount (see page 9656)	Specifies the number of fields (columns) displayed in the grid.
R	Fields (see page 9657)	Provides indexed access to the field components that correspond to the columns.
	SelectedField (see page 9661)	Specifies the field component for the currently selected cell in the grid.
	SelectedIndex (see page 9661)	Specifies the index of the currently selected column in the Columns (see page 9653) array.

49.1.4.6.1 TCustomDBGrid.Columns Property

Describes the display attributes and field bindings of the columns.

Pascal

```
property Columns: TDBGridColumns;
```

C++

```
__property TDBGridColumns Columns;
```

Description

Use Columns to read or set the field bindings and display attributes of the columns in the data-aware grid. The Columns property is an indexed collection of TColumn (see page 9583) objects. Use the properties of the TColumn (see page 9583) objects to specify the display attributes or field bindings of individual columns in the grid. The field binding of a column designates a field within the dataset specified by the DataSource (see page 9655) property.

Columns can be set at design time through the Columns editor, or programmatically at runtime.

See Also

CreateColumns (see page 9632)

Fields (see page 9657)

IndicatorOffset (see page 9658)

setcolumnattributes (see page 9649)

StoreColumns (see page 9650)

TDBGridColumns (see page 9746)

TColumn (see page 9583)

Creating Persistent Columns

Viewing and Editing Data with TDBGrid

49.1.4.6.2 TCustomDBGrid.DataLink Property

Helps the data-aware grid manage its link to the data source and respond to data events.

Pascal

```
property DataLink: TGridDataLink;
```

C++

```
__property TGridDataLink DataLink;
```

Description

Applications should not need to use the DataLink property. It is exposed as a protected property so that component writers can use descendants of TGridDataLink (see page 9754) to respond to additional data events.

DataLink helps TCustomDBGrid (see page 9608) to

Resolve the field bindings specified by Columns (see page 9653) with the fields in the dataset.

Respond to changes in the values of fields.

Respond to changes in record currency.

Respond to changes in the editing state of the dataset.

Keep track of unposted edits and discard or post them as appropriate.

See Also

Columns (see page 9653)

DataSource (see page 9655)

Fields (see page 9657)

TGridDataLink (see page 9754)

49.1.4.6.3 TCustomDBGrid.DataSource Property

Identifies the link to the dataset where the data-aware grid finds its data.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Set DataSource to the TDataSource object that links to the dataset where the data-aware grid should fetch its data. DataSource allows the data-aware grid to read from, write to, and navigate around the dataset.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

Making the Table a Detail of Another Dataset

49.1.4.6.4 TCustomDBGrid.DefaultDrawing Property

Indicates whether the cells in the data-aware grid are drawn automatically.

Pascal

```
property DefaultDrawing: Boolean;
```

C++

```
__property Boolean DefaultDrawing;
```

Description

Set DefaultDrawing to true to allow the data-aware grid to draw the data in the cells of the grid automatically. Set DefaultDrawing to false to turn off the default drawing when providing customized painting in an OnDrawColumnCell (see page 9666) event handler or an OnDrawDataCell (see page 9667) event handler.

When DefaultDrawing is true, the data-aware grid fetches the data for each cell from the appropriate entry in the Fields (see page 9657) array, and writes it to the cell. It then draws the focus rectangle if the cell has focus, or if the cell is selected and the Options (see page 9659) property includes dgAlwaysShowSelection.

When DefaultDrawing is false, the data-aware grid draws the appropriate background color on the cell and sets up the brush and font described by the appropriate TColumn (see page 9583) object. However, the value of the field is not written to the cell, and no focus rectangle is drawn.

Controlling Grid Drawing

49.1.4.6.5 TCustomDBGrid.EditorMode Property

Determines whether the current cell can be edited.

Pascal

```
property EditorMode: Boolean;
```

C++

```
__property Boolean EditorMode;
```

Description

Set EditorMode to true, at runtime, to put the grid in edit mode. When EditorMode is true, the user can edit cells in the grid. When the user presses F2, EditorMode is set to true. When the user presses Enter, the value of EditorMode is toggled.

Note: EditorMode has no effect if the Options property does not include goEditing or if the Options property includes goAlwaysShowEditor.

See Also

HideEditor (see page 14830)

Options (see page 14853)

ShowEditor (see page 14839)

49.1.4.6.6 TCustomDBGrid.FieldCount Property

Specifies the number of fields (columns) displayed in the grid.

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

Use FieldCount to iterate through all the field components indexed by the Fields (see page 9657) property. FieldCount may differ from the number of fields in the underlying dataset because the grid may contain calculated fields, and not all fields in the dataset are necessarily shown in the grid. Individual fields are removed and calculated fields are added using the Columns (see page 9653) editor at design time.

FieldCount is the same as the number of columns at runtime. At design time, the grid may contain empty columns.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

Columns (see page 9653)

Fields (see page 9657)

Creating a Customized Grid

49.1.4.6.7 TCustomDBGrid.Fields Property

Provides indexed access to the field components that correspond to the columns.

Pascal

```
property Fields [FieldIndex: Integer]: TField;
```

C++

```
__property TField Fields[int FieldIndex];
```

Description

Use Fields to gain direct access to the field component in the dataset for a particular column in the grid. The field for the first data column is obtained using an Index of 0, the field for the second data column using an Index of 1, and so on. The range for Index is 0... FieldCount (see page 9656) - 1.

The first data column in the grid may not be the same as the first column in the grid. If Options (see page 9659) includes dgIndicator, the first column in the grid is a non-scrolling column that contains the current row indicator.

The individual field components in Fields can be used to obtain information such as the value of the field on the current record, its preferred display width, or the string to draw when displaying or editing the field. Use the field component to write values directly to the dataset without using the editor in the cell.

Note: If the column in the grid represents a calculated field, there is no field component for that column in the dataset. Fields returns nil (Delphi) or NULL (C++) when the Index specifies the column that contains a calculated field. To obtain the field component for a calculated field, use the GetColField (see page 9640) method.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

Columns (see page 9653)

GetColField (see page 9640)

Options (see page 9659)

SelectedField (see page 9661)

TField (see page 7115)

49.1.4.6.8 TCustomDBGrid.IndicatorOffset Property

Indicates the index of the first column in the grid that contains data.

Pascal

```
property IndicatorOffset: Byte;
```

C++

```
__property Byte IndicatorOffset;
```

Description

Use IndicatorOffset to convert between the positions of the columns in the Columns (see page 9653) property and the columns drawn on the data-aware grid. IndicatorOffset is 1 if the Options (see page 9659) property includes dgIndicator, because the first column of the grid is used for the current row indicator. IndicatorOffset is 0 if all columns contain data.

See Also

Columns (see page 9653)

DataToRawColumn (see page 9633)

Options (see page 9659)

RawToDataColumn (see page 9648)

49.1.4.6.9 TCustomDBGrid.LayoutLock Property

Counts the number of times BeginLayout (see page 9626) has been called without an EndLayout (see page 9639) or CancelLayout (see page 9628) call.

Pascal

```
property LayoutLock: Byte;
```

C++

```
__property Byte LayoutLock;
```

Description

Use LayoutLock to determine when the column bindings change. Whenever a column width or binding changes or the fields in the data source change, the BeginLayout (see page 9626) method is called. BeginLayout (see page 9626) increments LayoutLock to keep track of the fact that the column bindings are changing. When changes are complete, the EndLayout (see page 9639) method is called. EndLayout (see page 9639) decrements LayoutLock. When LayoutLock returns to 0, the data-aware grid knows that all changes are complete, and the Fields (see page 9657) and Columns (see page 9653) properties are updated.

See Also

AcquireLayoutLock (see page 9625)

BeginLayout (see page 9626)

CancelLayout (see page 9628)

DeferLayout (see page 9635)

DefineFieldMap (see page 9636)

EndLayout (see page 9639)

49.1.4.6.10 TCustomDBGrid.Options Property

Specifies various display and behavioral properties of the data-aware grid.

Pascal

```
property Options: TDBGridOptions;
```

C++

```
__property TDBGridOptions Options;
```

Description

Set Options to include the desired properties for the data-aware grid.

See Also

ReadOnly (see page 9660)

SelectedIndex (see page 9661)

SelectedRows (see page 9662)

Setting Grid Options

49.1.4.6.11 TCustomDBGrid.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

49.1.4.6.12 TCustomDBGrid.ReadOnly Property

Indicates whether the grid is used for display only, or whether the user can edit data using the grid.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set ReadOnly to true to prevent users from changing the data in the dataset. Set ReadOnly to false to allow users to edit data using the grid.

When ReadOnly is true, users cannot use the Insert key to insert a new row in the grid or use the Down Arrow key to add a row to the end of the grid.

See Also

CanEditModify (see page 9629)

Options (see page 9659)

Editing in the Grid

49.1.4.6.13 TCustomDBGrid.SelectedField Property

Specifies the field component for the currently selected cell in the grid.

Pascal

```
property SelectedField: TField;
```

C++

```
__property TField SelectedField;
```

Description

Set SelectedField to move focus to a particular field in the grid. Read SelectedField to obtain access to the field component for the currently selected cell. If there is not currently selected cell, SelectedField is nil (Delphi) or NULL (C++). For example, when an entire row is selected, SelectedField is nil or NULL.

See Also

Fields (see page 9657)

SelectedIndex (see page 9661)

Creating a Customized Grid

Responding to User Actions at Runtime

49.1.4.6.14 TCustomDBGrid.SelectedIndex Property

Specifies the index of the currently selected column in the Columns (see page 9653) array.

Pascal

```
property SelectedIndex: Integer;
```

C++

```
__property int SelectedIndex;
```

Description

Set SelectedIndex to move focus to a column in the grid that is identified by position. Read SelectedIndex to determine which column in the grid has focus. A value of 0 indicates the first data column, 1 is the second data column, and so on. SelectedIndex is -1 if there is no currently selected column.

If the Options (see page 9659) property includes dgIndicator, the index of the data column given by SelectedIndex will differ from the index of the physical column in the grid.

To access the field component for the selected column, use the SelectedField (see page 9661) property.

C++ Examples:

```
/*
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
```

```
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
*/
void __fastcall TForm1::UpDownClick(TObject *Sender)
{
  CDS2->MoveBy(((TComponent *)Sender)->Tag);
  DBGrid2->SetFocus();
}

void __fastcall TForm1::LeftRightClick(TObject *Sender)
{
  DBGrid2->SelectedIndex = DBGrid2->SelectedIndex + ((TComponent *)Sender)->Tag;
  DBGrid2->SetFocus();
}
```

Delphi Examples:

```
{
The following example enables the user to move the current
selected cell in a db grid.  The Up and Down buttons have
their OnClick events assigned to the UpDownClick procedure.
The Left and Right buttons have their OnClick events
assigned to the LeftRightClick procedure.  The Up and Left
buttons have their Tag property set to -1, while the Down
and Right buttons have their Tag property set to 1.  MoveBy
does not move the cell in the db grid, it only moves the
selection.  The data set is not edited.  Notice that the
Up button and the Down button are separate TButtons, not
one TUpDown.  The tags must be set different.
}
procedure TForm1.UpDownClick(Sender: TObject);
begin
  CDS.MoveBy(TComponent(Sender).Tag);
  DBGrid1.SetFocus;
end;

procedure TForm1.LeftRightClick(Sender: TObject);
begin
  DBGrid1.SelectedIndex := DBGrid1.SelectedIndex + TComponent(Sender).Tag;
  DBGrid1.SetFocus;
end;
```

See Also

Columns (see page 9653)

Options (see page 9659)

SelectedField (see page 9661)

Creating a Customized Grid

49.1.4.6.15 TCustomDBGrid.SelectedRows Property

Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.

Pascal

```
property SelectedRows: TBookmarkList;
```

C++

```
__property TBookmarkList SelectedRows;
```

Description

Use the properties and methods of the TBookmarkList (see page 9575) object returned by SelectedRows to

Determine the number of rows in the grid that are selected.

Determine whether the current record in the dataset is selected.

Determine whether a particular record in the dataset is selected.

Delete all selected rows from the dataset.

SelectedRows is only meaningful when the Options (see page 9659) property includes dgRowSelect and dgMultiSelect.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

Options (see page 9659)

TBookmarkList (see page 9575)

49.1.4.6.16 TCustomDBGrid.TitleFont Property

Describes the font used to draw the column titles in the grid.

Pascal

```
property TitleFont: TFont;
```

C++

```
__property TFont TitleFont;
```

Description

Set TitleFont to change the font used to draw the column headings. TitleFont is only meaningful if the Options (see page 9659) property includes dgTitles.

See Also

Options (see page 9659)

TFont (see page 14497)

49.1.4.6.17 TCustomDBGrid.UpdateLock Property

Counts the number of times BeginUpdate (see page 9627) is called without a corresponding call to EndUpdate (see page 9640).

Pascal

```
property UpdateLock: Byte;
```

C++

```
__property Byte UpdateLock;
```

Description

UpdateLock prevents the grid from repainting while the data in the grid changes. Whenever a change is made that affects the data that is drawn in the grid, the BeginUpdate (see page 9627) method is called. BeginUpdate (see page 9627) increments UpdateLock to keep track of the fact that the contents of the grid are changing. When changes are complete, the EndUpdate (see page 9640) method is called. EndUpdate (see page 9640) decrements UpdateLock.

When UpdateLock returns to 0, the data-aware grid can repaint its cells. When UpdateLock is greater than 0, the grid defers repaints. UpdateLock prevents the grid from flickering when the grid is resized or the user scrolls through the data.

See Also

BeginUpdate (see page 9627)

EndUpdate (see page 9640)

LayoutLock (see page 9659)

49.1.4.7 TCustomDBGrid Events

The events of the TCustomDBGrid class are listed here.

Protected Events

	Name	Description
	OnCellClick (see page 9664)	Occurs when the user releases the mouse in one of the cells of the grid.
	OnColEnter (see page 9665)	Occurs when focus moves to a new cell in the grid.
	OnColExit (see page 9665)	Occurs just before a cell in the grid loses input focus.
	OnColumnMoved (see page 9666)	Occurs when the user moves a column using the mouse.
	OnDrawColumnCell (see page 9666)	Occurs when the grid needs to paint a cell.
	OnDrawDataCell (see page 9667)	Occurs when the grid needs to paint a cell if the State property of Columns (see page 9653) is csDefault.
	OnEditButtonClick (see page 9668)	Occurs when the user presses the ellipsis button in a grid column.
	OnTitleClick (see page 9668)	Occurs when the user releases the mouse in one of the column headers.

49.1.4.7.1 TCustomDBGrid.OnCellClick Event

Occurs when the user releases the mouse in one of the cells of the grid.

Pascal

```
property OnCellClick: TDBGridClickEvent;
```

C++

```
__property TDBGridClickEvent OnCellClick;
```

Description

Write an OnCellClick event handler to take specific action when the user clicks in one of the cells of the data-aware grid.

OnCellClick occurs when the user releases the mouse. To take action when the user clicks down on the mouse, use the OnColEnter (see page 9665) event.

OnCellClick will not occur when the mouse is released at the end of resizing a row or column, or when the cell is being edited.

See Also

Columns (see page 9653)

OnColEnter (see page 9665)

OnTitleClick (see page 9668)

TColumn (see page 9583)

49.1.4.7.2 TCustomDBGrid.OnColEnter Event

Occurs when focus moves to a new cell in the grid.

Pascal

```
property OnColEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnColEnter;
```

Description

Write an OnColEnter event handler to take specific action when a new cell has just been selected. Focus moves to a cell when

The user navigates to the cell using the keyboard. For example, when the user uses the Tab key, or the Home key.

The user clicks the mouse button down in the cell.

The SelectedField (see page 9661) or SelectedIndex (see page 9661) property is set.

Read the SelectedField (see page 9661) or SelectedIndex (see page 9661) property to determine which cell was just entered.

See Also

OnCellClick (see page 9664)

OnColExit (see page 9665)

SelectedField (see page 9661)

SelectedIndex (see page 9661)

49.1.4.7.3 TCustomDBGrid.OnColExit Event

Occurs just before a cell in the grid loses input focus.

Pascal

```
property OnColExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnColExit;
```

Description

Write an OnColExit event handler to take specific action when a cell is about to lose focus. For example, use OnColExit to post edits to the underlying dataset when the user leaves a cell, rather than waiting for the user to leave the record.

A cell loses focus when

The user navigates out of the cell using the keyboard. For example, when the user presses the Tab key or the Home key.

The user clicks the mouse button down in another cell.

The SelectedField (see page 9661) or SelectedIndex (see page 9661) property is set.

When the selected cell in the data-aware grid changes, first the OnColExit event occurs. Then the values of SelectedField (see page 9661) and SelectedIndex (see page 9661) are updated. Finally the OnColEnter (see page 9665) event occurs. Thus, in an OnColExit event handler, the SelectedField (see page 9661) or SelectedIndex (see page 9661) property can be used to determine which column is about to lose focus.

See Also

OnColEnter (see page 9665)

SelectedField (see page 9661)

SelectedIndex (see page 9661)

49.1.4.7.4 TCustomDBGrid.OnColumnMoved Event

Occurs when the user moves a column using the mouse.

Pascal

```
property OnColumnMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnColumnMoved;
```

Description

Write an OnColumnMoved event handler to take specific action just after a column in the grid has been moved.

OnColumnMoved can only occur when the Options (see page 9659) property includes dgColumnResize.

See Also

Columns (see page 9653)

Options (see page 9659)

49.1.4.7.5 TCustomDBGrid.OnDrawColumnCell Event

Occurs when the grid needs to paint a cell.

Pascal

```
property OnDrawColumnCell: TDrawColumnCellEvent;
```

C++

```
__property TDrawColumnCellEvent OnDrawColumnCell;
```

Description

Write an OnDrawColumnCell event handler to provide customized drawing for the data in the cells of the grid. Draw on the cell using the methods of the Canvas property.

An OnDrawColumnCell event handler can call the DefaultDrawColumnCell (see page 9634) method to instruct the data-aware grid to write the data value in the cell. The OnDrawColumnCell event handler can augment the DefaultDrawColumnCell (see page 9634) method to provide visual indications of selection and focus.

If DefaultDrawing (see page 9655) is true, the data will already be drawn in the cell before the OnDrawColumnCell event, and the grid draws a focus rectangle around selected cells after the OnDrawColumnCell event.

Note: If the Columns (see page 9653) property has a State property of csDefault, the OnDrawDataCell (see page 9667) event occurs before the OnDrawColumnCell. The OnDrawDataCell (see page 9667) event is obsolete, and only included for backward compatibility. Do not set both an OnDrawDataCell (see page 9667) event handler and an OnDrawColumnCell event handler.

See Also

DefaultDrawColumnCell (see page 9634)

DefaultDrawing (see page 9655)

DrawCell (see page 9637)

OnDrawDataCell (see page 9667)

Canvas (see page 5921)

State (see page 9753)

Controlling Grid Drawing

49.1.4.7.6 TCustomDBGrid.OnDrawDataCell Event

Occurs when the grid needs to paint a cell if the State property of Columns (see page 9653) is csDefault.

Pascal

```
property OnDrawDataCell: TDrawDataCellEvent;
```

C++

```
__property TDrawDataCellEvent OnDrawDataCell;
```

Description

Do not write an OnDrawDataCell event handler. OnDrawDataCell is obsolete and included for backward compatibility. Instead, write an OnDrawColumnCell (see page 9666) event handler.

See Also

DefaultDrawDataCell (see page 9634)

DefaultDrawing (see page 9655)

OnDrawColumnCell (see page 9666)

State (see page 9753)

49.1.4.7.7 TCustomDBGrid.OnEditButtonClick Event

Occurs when the user presses the ellipsis button in a grid column.

Pascal

```
property OnEditButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEditButtonClick;
```

Description

Write an OnEditButtonClick event handler to bring up an appropriate list or dialog when the user presses the ellipsis button in a grid cell. The OnEditButtonClick event handler can set the value of the field based on the user response to the list or dialog. Use the SelectedField (see page 9661) property to access the TField component whose value should be set.

See Also

OnCellClick (see page 9664)

SelectedField (see page 9661)

TField (see page 7115)

Putting a Button in a Column

49.1.4.7.8 TCustomDBGrid.OnTitleClick Event

Occurs when the user releases the mouse in one of the column headers.

Pascal

```
property OnTitleClick: TDBGridClickEvent;
```

C++

```
__property TDBGridClickEvent OnTitleClick;
```

Description

Write an OnTitleClick event handler to take specific action when the user clicks in one of the column headers. The Column parameter is the TColumn (see page 9583) object that corresponds to the column where the mouse was when the user released the left mouse button.

See Also

Columns (see page 9653)

OnCellClick (see page 9664)

TColumn (see page 9583)

49.1.5 TDBGrid Class

TDBGrid displays and manipulates records from a dataset in a tabular grid.

Class Hierarchy

Pascal

```
TDBGrid = class(TCustomDBGrid);
```

C++

```
class TDBGrid : public TCustomDBGrid;
```

File

DBGrids

Description

Put a TDBGrid object on a form to display and edit the records from a database table or query. Applications can use the data grid to insert, delete, or edit data in the database, or simply to display it.

At runtime, users can use the database navigator (TDBNavigator) to move through data in the grid, and to insert, delete, and edit the data. Edits that are made in the data grid are not posted to the underlying dataset until the user moves to a different record or closes the application.

TDBGrid implements the generic behavior introduced in TCustomDBGrid (see page 9608). TDBGrid publishes many of the properties inherited from TCustomDBGrid (see page 9608), but does not introduce any new behavior.

Delphi Examples:

```
{
This example requires two ClientDataSets, two DBGrids, two
DataSources and two DBNavigators.  Name the two
ClientDataSets CDS and CDS2. Set the DataSet property in the
first DataSource to CDS and name that DataSource DS.  Set the
DataSet property in the second DataSource to CDS2 and name
that DataSource DS2.  Set the DataSource in the first
DBNavigator to DS and the DataSource in the second DBNavigator
to DS2.  Set the DataSource in the first DBGrid to DS and the
DataSource in the second DBGrid to DS2.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
attribute name of HOST with an attribute type of string and
an attribute name of PORTA with an attribute type of integer.
Add DB, DBCtrls, Grids, DBGrids, DBClient and SwSystem to the
uses clause.  "LoadFormFile" to start with the file, or
"CreateDataSet" to start from scratch.  You must "CloseDataSet"
after a "LoadFromFile" before you can do another "CreateDataSet".
}
{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button1Click(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
```

```
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.SaveToFile(GetCurrentDir + '\CDS.XML', dfXML);
{$ELSE}
  CDS.SaveToFile(gsAppPath + 'CDS.XML', dfXML);
{$ENDIF}
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  CDS.CreateDataSet;
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  CDS2.Data := CDS.Data;
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  CDS.Close;
end;
```

Grids

49.1.5.1 TDBGrid Members

The following tables list the members exposed by TDBGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.

	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAcquireFocus (see page 9623)	This is FAcquireFocus, a member of class TCustomDBGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	FUpdateFields (see page 9623)	This is FUpdateFields, a member of class TCustomDBGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AcquireLayoutLock (see page 9625)	Calls BeginLayout (see page 9626) if the table is not currently being reformatted.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 9625)	Starts the dragging of a column in the grid.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.

	BeginLayout (see page 9626)	Increments the LayoutLock (see page 9659) property when the column bindings or fields in the dataset change.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BeginUpdate (see page 9627)	Increments the UpdateLock (see page 9664) property when the data in the grid changes.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
	CalcSizingState (see page 9627)	Determines the appearance of the mouse cursor during resizing.
	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
	CalcTitleRect (see page 9627)	This is CalcTitleRect, a member of class TCustomDBGrid.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CancelLayout (see page 9628)	Decrements the LayoutLock (see page 9659) property.
	CanEditAcceptKey (see page 9628)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 9629)	Indicates whether the current column of the grid can be edited.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.
	CanEditShow (see page 9629)	Indicates whether the inplace edit control can be created to allow editing.
	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellClick (see page 9629)	Generates an OnCellClick (see page 9664) event.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 9630)	Validates whether the column currently selected for dragging can be dropped at the current location.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
	ColEnter (see page 9630)	Generates an OnColEnter (see page 9665) event.
	ColExit (see page 9630)	Generates an OnColExit (see page 9665) event.
	ColumnAtDepth (see page 9631)	Returns the column object associated with nth parent field of the given column.
	ColumnMoved (see page 9631)	Generates an OnColumnMoved (see page 9666) event.
	ColumnMoved (see page 14822)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 9631)	Updates the column widths in the Columns (see page 9653) property when the user resizes the columns.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateColumns (see page 9632)	Creates the TDBGridColumns (see page 9746) object that stores the column descriptors for the grid.
	CreateDataLink (see page 9632)	Creates the data link that the grid uses to manage the connection to its data source.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.

	CreateEditor (see page 9632)	Creates the inplace editor that allows the cells of the grid to be edited.
	CreateEditor (see page 14823)	Creates the inplace editor control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 9633)	Creates the window used to display the data-aware grid.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DataToRawColumn (see page 9633)	Converts a column index in the Columns (see page 9653) property to the index of the corresponding column in the visual display.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DeferLayout (see page 9635)	Decrements the LayoutLock (see page 9659) property and posts a message to the grid to trigger a new layout sequence at a more appropriate time.
	DefineFieldMap (see page 9636)	Builds the Fields (see page 9657) array from the Columns (see page 9653) property and the data source.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 9636)	Defines a savable version of the Columns (see page 9653) property when necessary.
	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.

	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
V	DoMouseWheelDown (see page 9636)	Performs tasks when the mouse wheel is rotated downward.
V	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
V	DoMouseWheelUp (see page 9637)	Performs tasks when the mouse wheel is rotated upward.
V	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
V	DrawCell (see page 9637)	Draws the cell specified by the ACol and ARow parameters.
A	DrawCell (see page 14826)	Provides the prototype for a method that draws the contents of a cell in the grid.
	DrawColumnCell (see page 9638)	Generates an OnDrawColumnCell (see page 9666) event.
	DrawDataCell (see page 9638)	Generates an OnDrawDataCell (see page 9667) event.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EditButtonClick (see page 9638)	Generates an OnEditButtonClick (see page 9668) event.
V	EndColumnDrag (see page 9639)	Ends the dragging of a column in the grid.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndLayout (see page 9639)	Decrements the LayoutLock (see page 9659) property and recomputes the Columns (see page 9653) property if LayoutLock (see page 9659) reaches 0.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EndUpdate (see page 9640)	Decrements the UpdateLock (see page 9664) property.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetColField (see page 9640)	Returns the field component that represents the binding of a specified column.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEditLimit (see page 9641)	Limits the number of characters that can be typed into cells representing string fields.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
V	GetEditMask (see page 9641)	Returns the input mask associated with the field for the selected cell.
	GetEditMask (see page 14828)	Provides the interface for a method that returns an input mask for the specified cell.
V	GetEditStyle (see page 9642)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.

	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
V	GetEditText (see page 9642)	Returns the value of the indicated cell formatted for editing.
	GetEditText (see page 14829)	Returns the value of the indicated cell formatted for editing.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFieldValue (see page 9643)	Returns the value of the indicated cell formatted for display.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
V	HighlightCell (see page 9643)	Indicates whether a specified cell should be highlighted when it is drawn.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	InvalidateTitles (see page 9644)	Invalidates the column titles so that they will be repainted.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
V	KeyDown (see page 9644)	Provides special processing when the user presses down on a key.
V	KeyDown (see page 14833)	Provides special processing when the user presses a key.
	KeyPress (see page 6163)	Respond to keyboard input.
V	KeyPress (see page 9645)	Responds when the user presses a key.
V	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	LayoutChanged (see page 9645)	Recomputes the Columns (see page 9653) property.
V	LinkActive (see page 9646)	Recomputes the Columns (see page 9653) property and the vertical scroll bar of the grid.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 9646)	Sets up the Columns (see page 9653) property once the data grid and all its child components are loaded.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.

	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
V	MouseDown (see page 9647)	Provides special processing when the user clicks on the mouse.
V	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	MouseUp (see page 9647)	Provides special processing when the user releases the mouse button.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 9647)	Responds to notifications that components are about to be destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	RawToDataColumn (see page 9648)	Converts the index of a column in the visual display to the corresponding index in the Columns (see page 9653) property.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
	RowMoved (see page 14837)	Provides the interface for a method that responds when the position of a row changes.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
V	Scroll (see page 9648)	Updates the image of the grid to reflect a new record position.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.

	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
V	SetColumnAttributes (see page 9649)	This is SetColumnAttributes, a member of class TCustomDBGrid.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEditText (see page 9649)	Updates the edited version of the current cell's data.
	SetEditText (see page 14839)	Provides the interface for a method that updates the text associated with a cell.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	StoreColumns (see page 9650)	Indicates whether the columns of the grid are stored when the grid is saved, or whether they are generated dynamically.
V	TimedScroll (see page 9650)	Moves the current record in response to the user dragging the mouse outside of the data cells.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TitleClick (see page 9651)	Generates an OnTitleClick (see page 9668) event.
V	TopLeftChanged (see page 9651)	Updates the position of the inplace editor when the grid scrolls.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
V	UpdateScrollBar (see page 9652)	This is UpdateScrollBar, a member of class TCustomDBGrid.

	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	UseRightToLeftAlignmentForField (see page 9652)	Indicates whether the alignment of a specified field should be changed from left-aligned to right-aligned.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
R	DataLink (see page 9654)	Helps the data-aware grid manage its link to the data source and respond to data events.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
R	IndicatorOffset (see page 9658)	Indicates the index of the first column in the grid that contains data.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	LayoutLock (see page 9659)	Counts the number of times BeginLayout (see page 9626) has been called without an EndLayout (see page 9639) or CancelLayout (see page 9628) call.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.

	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
R	UpdateLock (see page 9664)	Counts the number of times BeginUpdate (see page 9627) is called without a corresponding call to EndUpdate (see page 9640).
R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 5918)	Creates an instance of TCustomControl (see page 5908).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 9622)	Creates and initializes an instance of TCustomDBGrid (see page 9608).
V	Create (see page 14813)	Creates an instance of TCustomGrid (see page 14800).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultDrawColumnCell (see page 9634)	Draws the text in a column cell.
	DefaultDrawDataCell (see page 9634)	Draws the text in a column cell.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.

	DefaultHandler (see page 9635)	Displays the popup menu when a column is right-clicked.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 9622)	Destroys an instance of TCustomDBGrid (see page 9608).
	Destroy (see page 14813)	Destroys an instance of TCustomGrid (see page 14800).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	ExecuteAction (see page 9640)	Executes an action with the DB (see page 6725) grid as its target.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.

	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.

	Show (see page 5788)	Makes a control visible.
	ShowPopupEditor (see page 9649)	Displays the nested dataset associated with Column in a new window.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
V	UpdateAction (see page 9651)	Updates an action to reflect the current state of the grid.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
	ValidFieldIndex (see page 9652)	Indicates whether an index into the columns array refers to a valid field in the dataset.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 9690)	Specifies the TCanvas object that presents a drawing surface for the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditorMode (see page 9656)	Determines whether the current cell can be edited.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	FieldCount (see page 9656)	Specifies the number of fields (columns) displayed in the grid.
R	Fields (see page 9657)	Provides indexed access to the field components that correspond to the columns.
R	Floating (see page 5823)	Indicates whether the control is floating.

	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelectedField (see page 9661)	Specifies the field component for the currently selected cell in the grid.
	SelectedIndex (see page 9661)	Specifies the index of the currently selected column in the Columns (see page 9653) array.
	SelectedRows (see page 9709)	Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnCellClick (see page 9715)	Occurs when the user releases the mouse in one of the cells of the grid.
	OnColEnter (see page 9716)	Occurs when focus moves to a new cell in the grid.
	OnColExit (see page 9716)	Occurs just before a cell in the grid loses input focus.
	OnColumnMoved (see page 9717)	Occurs when the user moves a column using the mouse.
	OnDblClick (see page 9717)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 9717)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 9720)	Occurs when the user drags an object over a control.
	OnDrawColumnCell (see page 9722)	Occurs when the grid needs to paint a cell.
	OnDrawDataCell (see page 9723)	Occurs when the grid needs to paint a cell if the State property of Columns is csDefault.
	OnEditButtonClick (see page 9723)	Occurs when the user presses the ellipsis button in a grid column.
	OnEndDock (see page 9724)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 9724)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 9725)	Occurs when a control receives the input focus.
	OnExit (see page 9728)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 9729)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 9732)	Occurs when a key is pressed.
	OnKeyUp (see page 9733)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 9735)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 9736)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 9738)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 9738)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 9738)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 9741)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 9743)	Occurs when the mouse wheel is rotated.

	OnMouseWheelDown (see page 9743)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 9744)	Occurs when the mouse wheel is rotated upward.
	OnStartDock (see page 9744)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 9745)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTitleClick (see page 9745)	Occurs when the user releases the mouse in one of the column headers.

Published Properties

	Name	Description
	Align (see page 9686)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 9689)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 9690)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 9690)	Determines whether a single line border is drawn around the grid.
	Color (see page 9692)	Specifies the background color of the control.
	Columns (see page 9693)	Describes the display attributes and field bindings of the columns.
	Constraints (see page 9694)	Specifies the size constraints for the control.
	Ctl3D (see page 9694)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DataSource (see page 9695)	Identifies the link to the dataset where the data-aware grid finds its data.
	DefaultDrawing (see page 9696)	Indicates whether the cells in the data-aware grid are drawn automatically.
	DragCursor (see page 9696)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 9697)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 9697)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 9699)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 9699)	Specifies the background color of the fixed rows and columns in the grid.
	Font (see page 9699)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 9700)	Determines the behavior of the input method editor (IME).
	ImeName (see page 9701)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 9702)	Specifies various display and behavioral properties of the data-aware grid.
	ParentBiDiMode (see page 9702)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 9702)	Determines where a control looks for its color information.
	ParentCtl3D (see page 9703)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 9703)	Determines where a control looks for its font information.
	ParentShowHint (see page 9704)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 9704)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 9709)	Indicates whether the grid is used for display only, or whether the user can edit data using the grid.
	ShowHint (see page 9710)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 9712)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 9712)	Determines if the user can tab to a control.

	Tag (see page 2808)	Stores an integer value as part of a component.
	TitleFont (see page 9713)	Describes the font used to draw the column titles in the grid.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 9713)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

49.1.5.2 TDBGrid Properties

The properties of the TDBGrid class are listed here.

Public Properties

	Name	Description
	Canvas (see page 9690)	Specifies the TCanvas object that presents a drawing surface for the control.
	SelectedRows (see page 9709)	Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.

Published Properties

	Name	Description
	Align (see page 9686)	Determines how the control aligns within its container (parent control).
	Anchors (see page 9689)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 9690)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 9690)	Determines whether a single line border is drawn around the grid.
	Color (see page 9692)	Specifies the background color of the control.
	Columns (see page 9693)	Describes the display attributes and field bindings of the columns.
	Constraints (see page 9694)	Specifies the size constraints for the control.
	Ctl3D (see page 9694)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DataSource (see page 9695)	Identifies the link to the dataset where the data-aware grid finds its data.
	DefaultDrawing (see page 9696)	Indicates whether the cells in the data-aware grid are drawn automatically.
	DragCursor (see page 9696)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 9697)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 9697)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 9699)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 9699)	Specifies the background color of the fixed rows and columns in the grid.
	Font (see page 9699)	Controls the attributes of text written on or in the control.
	ImeMode (see page 9700)	Determines the behavior of the input method editor (IME).
	ImeName (see page 9701)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Options (see page 9702)	Specifies various display and behavioral properties of the data-aware grid.
	ParentBiDiMode (see page 9702)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 9702)	Determines where a control looks for its color information.
	ParentCtl3D (see page 9703)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 9703)	Determines where a control looks for its font information.
	ParentShowHint (see page 9704)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 9704)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 9709)	Indicates whether the grid is used for display only, or whether the user can edit data using the grid.
	ShowHint (see page 9710)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 9712)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 9712)	Determines if the user can tab to a control.
	TitleFont (see page 9713)	Describes the font used to draw the column titles in the grid.
	Visible (see page 9713)	Determines whether the component appears onscreen.

49.1.5.2.1 TDBGrid.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

Anchors (see page 5802)

49.1.5.2.2 TDBGrid.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent (see page 5832)

Align (see page 5798)

49.1.5.2.3 TDBGrid.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

49.1.5.2.4 TDBGrid.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

49.1.5.2.5 TDBGrid.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = (TStringGrid *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
```

```
  component to draw the contents of each cell in a draw grid.
  It draws a focus rectangle around the cell that has focus.
  goDrawFocusSelect in the DrawGrid Options parameter must be
  True to set focus on a cell.  The ImageList Draw method must
  be called after DrawFocusRect. The OnSelectCell event handler
  must implemented to return true.
  }
  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clWhite;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
  {
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  }
    if (ListBox1.Items.Objects[Index] is TStringGrid) then
    begin
      myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
      with myStringGrid.ClientRect do
      begin // make sure we are using the TControl's canvas and not the form's!
        myStringGrid.Canvas.MoveTo(Left, Top);
        myStringGrid.Canvas.LineTo(Right, Bottom);
      end;
    myStringGrid:= nil;
    end;
```

Paint (see page 5920)

49.1.5.2.6 TDBGrid.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the

Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor (see page 5834)

49.1.5.2.7 TDBGrid.Columns Property

Describes the display attributes and field bindings of the columns.

Pascal

```
property Columns: TDBGridColumns;
```

C++

```
__property TDBGridColumns Columns;
```

Description

Use Columns to read or set the field bindings and display attributes of the columns in the data-aware grid. The Columns property is an indexed collection of TColumn objects. Use the properties of the TColumn objects to specify the display attributes or field bindings of individual columns in the grid. The field binding of a column designates a field within the dataset specified by the DataSource property.

Columns can be set at design time through the Columns editor, or programmatically at runtime.

Creating Persistent Columns

Viewing and Editing Data with TDBGrid

49.1.5.2.8 TDBGrid.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

49.1.5.2.9 TDBGrid.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception

of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

49.1.5.2.10 TDBGrid.DataSource Property

Identifies the link to the dataset where the data-aware grid finds its data.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Set DataSource to the TDataSource object that links to the dataset where the data-aware grid should fetch its data. DataSource allows the data-aware grid to read from, write to, and navigate around the dataset.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

Making the Table a Detail of Another Dataset

49.1.5.2.11 TDBGrid.DefaultDrawing Property

Indicates whether the cells in the data-aware grid are drawn automatically.

Pascal

```
property DefaultDrawing: Boolean;
```

C++

```
__property Boolean DefaultDrawing;__property Boolean DefaultDrawing;
```

Description

Set DefaultDrawing to true to allow the data-aware grid to draw the data in the cells of the grid automatically. Set DefaultDrawing to false to turn off the default drawing when providing customized painting in an OnDrawColumnCell event handler or an OnDrawDataCell event handler.

When DefaultDrawing is true, the data-aware grid fetches the data for each cell from the appropriate entry in the Fields array, and writes it to the cell. It then draws the focus rectangle if the cell has focus, or if the cell is selected and the Options property includes dgAlwaysShowSelection.

When DefaultDrawing is false, the data-aware grid draws the appropriate background color on the cell and sets up the brush and font described by the appropriate TColumn object. However, the value of the field is not written to the cell, and no focus rectangle is drawn.

Controlling Grid Drawing

49.1.5.2.12 TDBGrid.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

49.1.5.2.13 TDBGrid.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

49.1.5.2.14 TDBGrid.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
```

```
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

49.1.5.2.15 TDBGrid.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

Enabling Mouse

49.1.5.2.16 TDBGrid.FixedColor Property

Specifies the background color of the fixed rows and columns in the grid.

Pascal

```
property FixedColor: TColor;
```

C++

```
__property TColor FixedColor;
```

Description

Set FixedColor to specify the color for the nonscrolling cells in the grid. The scrolling region of the grid is drawn using the Color property.

See Also

Color (see page 5812)

FixedCols (see page 14848)

FixedRows (see page 14849)

49.1.5.2.17 TDBGrid.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

49.1.5.2.18 TDBGrid.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

49.1.5.2.19 TDBGrid.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

DefaultIme (see page 14216)

Imes (see page 14227)

49.1.5.2.20 TDBGrid.Options Property

Specifies various display and behavioral properties of the data-aware grid.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TDBGridOptions Options;__property TGridOptions Options;
```

Description

Set Options to include the desired properties for the data-aware grid.

See Also

ReadOnly (see page 9660)

SelectedIndex (see page 9661)

SelectedRows (see page 9662)

Setting Grid Options

49.1.5.2.21 TDBGrid.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

49.1.5.2.22 TDBGrid.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

49.1.5.2.23 TDBGrid.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

49.1.5.2.24 TDBGrid.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint (see page 5835)

49.1.5.2.25 TDBGrid.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

49.1.5.2.26 TDBGrid.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
```

```
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}
```

```
void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
```

```
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

49.1.5.2.27 TDBGrid.ReadOnly Property

Indicates whether the grid is used for display only, or whether the user can edit data using the grid.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set ReadOnly to true to prevent users from changing the data in the dataset. Set ReadOnly to false to allow users to edit data using the grid.

When ReadOnly is true, users cannot use the Insert key to insert a new row in the grid or use the Down Arrow key to add a row to the end of the grid.

See Also

CanEditModify (see page 9629)

Options (see page 9659)

Editing in the Grid

49.1.5.2.28 TDBGrid.SelectedRows Property

Specifies a set of bookmarks for all the records in the dataset that correspond to rows selected in the grid.

Pascal

```
property SelectedRows: TBookmarkList;
```

C++

```
__property TBookmarkList SelectedRows;
```

Description

Use the properties and methods of the TBookmarkList object returned by SelectedRows to

Determine the number of rows in the grid that are selected.

Determine whether the current record in the dataset is selected.

Determine whether a particular record in the dataset is selected.

Delete all selected rows from the dataset.

SelectedRows is only meaningful when the Options property includes dgRowSelect and dgMultiSelect.

Delphi Examples:

```
{
The following example copies the selected rows in a db grid
to a list box.  Set the db grid Options dgRowSelect,
dgAlwaysShowSelection and dgMultiSelect to True.  Make a
multiple selecton using the CNTL key.  This example requires
a TDataSet associated with a TDataSource and a TDBGrid.}
procedure TForm1.Button2Click(Sender: TObject);
var
  i, j: Integer;
  s: string;
begin
  if DBGrid2.SelectedRows.Count>0 then
    with DBGrid2.DataSource.DataSet do
      for i:=0 to DBGrid2.SelectedRows.Count-1 do
      begin
        GotoBookmark(pointer(DBGrid2.SelectedRows.Items[i]));
        for j := 0 to FieldCount-1 do
        begin
          if (j>0) then s:=s+', ';
          s:=s+Fields[j].AsString;
        end;
        Listbox1.Items.Add(s);
        s:= '';
      end;
end;
```

See Also

Options (see page 9659)

TBookmarkList (see page 9575)

49.1.5.2.29 TDBGrid.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

ShowHint (see page 13721)

Displaying Fly-over Help

49.1.5.2.30 TDBGrid.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

49.1.5.2.31 TDBGrid.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

49.1.5.2.32 TDBGrid.TitleFont Property

Describes the font used to draw the column titles in the grid.

Pascal

```
property TitleFont: TFont;
```

C++

```
__property TFont TitleFont;
```

Description

Set TitleFont to change the font used to draw the column headings. TitleFont is only meaningful if the Options property includes dgTitles.

See Also

Options (see page 9659)

TFont (see page 14497)

49.1.5.2.33 TDBGrid.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

49.1.5.3 TDBGrid Events

The events of the TDBGrid class are listed here.

Published Events

	Name	Description
	OnCellClick (see page 9715)	Occurs when the user releases the mouse in one of the cells of the grid.
	OnColEnter (see page 9716)	Occurs when focus moves to a new cell in the grid.
	OnColExit (see page 9716)	Occurs just before a cell in the grid loses input focus.
	OnColumnMoved (see page 9717)	Occurs when the user moves a column using the mouse.
	OnDblClick (see page 9717)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 9717)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 9720)	Occurs when the user drags an object over a control.
	OnDrawColumnCell (see page 9722)	Occurs when the grid needs to paint a cell.
	OnDrawDataCell (see page 9723)	Occurs when the grid needs to paint a cell if the State property of Columns is csDefault.
	OnEditButtonClick (see page 9723)	Occurs when the user presses the ellipsis button in a grid column.
	OnEndDock (see page 9724)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 9724)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 9725)	Occurs when a control receives the input focus.
	OnExit (see page 9728)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 9729)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 9732)	Occurs when a key is pressed.
	OnKeyUp (see page 9733)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 9735)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 9736)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 9738)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 9738)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 9738)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 9741)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 9743)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 9743)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 9744)	Occurs when the mouse wheel is rotated upward.
	OnStartDock (see page 9744)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 9745)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTitleClick (see page 9745)	Occurs when the user releases the mouse in one of the column headers.

49.1.5.3.1 TDBGrid.OnCellClick Event

Occurs when the user releases the mouse in one of the cells of the grid.

Pascal

```
property OnCellClick: TDBGridClickEvent;
```

C++

```
__property TDBGridClickEvent OnCellClick;
```

Description

Write an OnCellClick event handler to take specific action when the user clicks in one of the cells of the data-aware grid.

OnCellClick occurs when the user releases the mouse. To take action when the user clicks down on the mouse, use the OnColEnter event.

OnCellClick will not occur when the mouse is released at the end of resizing a row or column, or when the cell is being edited.

See Also

Columns (see page 9653)

OnColEnter (see page 9665)

OnTitleClick (see page 9668)

TColumn (see page 9583)

49.1.5.3.2 TDBGrid.OnColEnter Event

Occurs when focus moves to a new cell in the grid.

Pascal

```
property OnColEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnColEnter;
```

Description

Write an OnColEnter event handler to take specific action when a new cell has just been selected. Focus moves to a cell when

The user navigates to the cell using the keyboard. For example, when the user uses the Tab key, or the Home key.

The user clicks the mouse button down in the cell.

The SelectedField or SelectedIndex property is set.

Read the SelectedField or SelectedIndex property to determine which cell was just entered.

49.1.5.3.3 TDBGrid.OnColExit Event

Occurs just before a cell in the grid loses input focus.

Pascal

```
property OnColExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnColExit;
```

Description

Write an OnColExit event handler to take specific action when a cell is about to lose focus. For example, use OnColExit to post edits to the underlying dataset when the user leaves a cell, rather than waiting for the user to leave the record.

A cell loses focus when

The user navigates out of the cell using the keyboard. For example, when the user presses the Tab key or the Home key.

The user clicks the mouse button down in another cell.

The SelectedField or SelectedIndex property is set.

When the selected cell in the data-aware grid changes, first the OnColExit event occurs. Then the values of SelectedField and SelectedIndex are updated. Finally the OnColEnter event occurs. Thus, in an OnColExit event handler, the SelectedField or SelectedIndex property can be used to determine which column is about to lose focus.

OnColEnter (see page 9665)

SelectedField (see page 9661)

SelectedIndex (see page 9661)

49.1.5.3.4 TDBGrid.OnColumnMoved Event

Occurs when the user moves a column using the mouse.

Pascal

```
property OnColumnMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnColumnMoved;
```

Description

Write an OnColumnMoved event handler to take specific action just after a column in the grid has been moved.

OnColumnMoved can only occur when the Options property includes dgColumnResize.

See Also

Columns (see page 9653)

Options (see page 9659)

49.1.5.3.5 TDBGrid.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

49.1.5.3.6 TDBGrid.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
```

```
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

49.1.5.3.7 TDBGrid.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
```

```
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

49.1.5.3.8 TDBGrid.OnDrawColumnCell Event

Occurs when the grid needs to paint a cell.

Pascal

```
property OnDrawColumnCell: TDrawColumnCellEvent;
```

C++

```
__property TDrawColumnCellEvent OnDrawColumnCell;
```

Description

Write an OnDrawColumnCell event handler to provide customized drawing for the data in the cells of the grid. Draw on the cell using the methods of the Canvas property.

An OnDrawColumnCell event handler can call the DefaultDrawColumnCell method to instruct the data-aware grid to write the data value in the cell. The OnDrawColumnCell event handler can augment the DefaultDrawColumnCell method to provide visual indications of selection and focus.

If DefaultDrawing is true, the data will already be drawn in the cell before the OnDrawColumnCell event, and the grid draws a focus rectangle around selected cells after the OnDrawColumnCell event.

Note: If the Columns property has a State property of csDefault, the OnDrawDataCell event occurs before the OnDrawColumnCell. The OnDrawDataCell event is obsolete, and only included for backward compatibility. Do not set both an

OnDrawDataCell event handler and an OnDrawColumnCell event handler.

Controlling Grid Drawing

49.1.5.3.9 TDBGrid.OnDrawDataCell Event

Occurs when the grid needs to paint a cell if the State property of Columns is csDefault.

Pascal

```
property OnDrawDataCell: TDrawDataCellEvent;
```

C++

```
__property TDrawDataCellEvent OnDrawDataCell;
```

Description

Do not write an OnDrawDataCell event handler. OnDrawDataCell is obsolete and included for backward compatibility. Instead, write an OnDrawColumnCell event handler.

49.1.5.3.10 TDBGrid.OnEditButtonClick Event

Occurs when the user presses the ellipsis button in a grid column.

Pascal

```
property OnEditButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEditButtonClick;
```

Description

Write an OnEditButtonClick event handler to bring up an appropriate list or dialog when the user presses the ellipsis button in a grid cell. The OnEditButtonClick event handler can set the value of the field based on the user response to the list or dialog. Use the SelectedField property to access the TField component whose value should be set.

Putting a Button in a Column

49.1.5.3.11 TDBGrid.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

49.1.5.3.12 TDBGrid.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
```

```
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

49.1.5.3.13 TDBGrid.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
```

```
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

Using a Single Navigator for Multiple Datasets

49.1.5.3.14 TDBGrid.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

OnEnter (see page 6219)

ActiveControl (see page 13896)

49.1.5.3.15 TDBGrid.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the

OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
```

```
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

49.1.5.3.16 TDBGrid.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
```

```
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

49.1.5.3.17 TDBGrid.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
```

```
      else
        ComboBox1->Text = "KeyDown";
      Form1->Refresh();
      Memo1->Lines->Add(ComboBox1->Text);
    }
  }

  void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
  {
    if (Key == VK_F1)
    {
      Form1->Color = FormColor;
      if (ComboBox1->Text == "KeyUp")
        ComboBox1->Text = "KeyUp2";
      else
        ComboBox1->Text = "KeyUp";
      Form1->Refresh();
      Memo1->Lines->Add(ComboBox1->Text);
    }
  }
```

Delphi Examples:

```
  {
  This example changes a form's color to aqua when the user
  presses the F1 key, even when a control on the form has the
  focus. When the user releases the key, the form returns to
  its original color.  Set the KeyPreview on the form to True.
  Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
  event to FormKeyUp.  Set the KeyPreview on the form to True.
  }
  var
    FormColor: TColor;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    KeyPreview := True;
    FormColor := Form1.Color;
  end;

  procedure TForm1.FormKeyDown(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;
      if (ComboBox1.Text = 'KeyDown') then
        ComboBox1.Text := 'KeyDown2'
      else
        ComboBox1.Text := 'KeyDown';
      WriteLn(ComboBox1.Text);
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';

49.1.5.3.18 TDBGrid.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

49.1.5.3.19 TDBGrid.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
```

```
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {

49.1.5.3.20 TDBGrid.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

49.1.5.3.21 TDBGrid.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

49.1.5.3.22 TDBGrid.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
```

```
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
```

```
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

OnMouseMove (see page 5865)

Responding to a Mouse-up Action

49.1.5.3.24 TDBGrid.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

49.1.5.3.25 TDBGrid.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

49.1.5.3.26 TDBGrid.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

49.1.5.3.27 TDBGrid.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

49.1.5.3.28 TDBGrid.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

49.1.5.3.29 TDBGrid.OnTitleClick Event

Occurs when the user releases the mouse in one of the column headers.

Pascal

```
property OnTitleClick: TDBGridClickEvent;
```

C++

```
__property TDBGridClickEvent OnTitleClick;
```

Description

Write an OnTitleClick event handler to take specific action when the user clicks in one of the column headers. The Column parameter is the TColumn object that corresponds to the column where the mouse was when the user released the left mouse button.

49.1.6 TDBGridColumns Class

TDBGridColumns represents a container for TColumn (see page 9583) objects.

Class Hierarchy

Pascal

```
TDBGridColumns = class(TCollection);
```

C++

```
class TDBGridColumns : public TCollection;
```

File

DBGrids

Description

Each TDBGridColumns holds a collection of TColumn (see page 9583) objects in a data grid (TDBGrid (see page 9668)). TDBGridColumns maintains an index of the columns in its Items (see page 9753) array. The Count property contains the number of columns in the collection. At design time, use the data grid's Columns editor to add, remove, or modify columns.

See Also

TCollection (see page 2731)

TCustomDBGrid (see page 9608)

Viewing and Editing Data with TDBGrid

49.1.6.1 TDBGridColumns Members

The following tables list the members exposed by TDBGridColumns.

Protected Methods

	Name	Description
	Added (see page 2736)	Responds when items are added to the collection.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	Deleting (see page 2741)	Responds when items are deleted from the collection.

	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 9749)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 9752)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 9749)	Creates a new TColumn (see page 9583) instance and adds it to the Items (see page 9753) array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 9748)	Creates and initializes a TDBGridColumns (see page 9746) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.

	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadFromFile (see page 9750)	Reads the file specified in FileName and loads the data into the TDBGridColumns (see page 9746) object.
	LoadFromStream (see page 9750)	Reads grid columns data from a stream and stores the contents in the TDBGridColumns (see page 9746) object.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
	RebuildColumns (see page 9750)	Deletes existing columns and generates new columns from the dataset associated with the grid.
	RestoreDefaults (see page 9751)	Restores all columns to their default settings.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 9751)	Saves the TDBGridColumns (see page 9746) object to the file specified in FileName.
	SaveToStream (see page 9751)	Writes a stream with the name passed in Stream with the contents of the TDBGridColumns (see page 9746) object.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	Grid (see page 9752)	Indicates the data-grid control to which the TDBGridColumns (see page 9746) instance belongs.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 9753)	Lists the columns in the collection.
	State (see page 9753)	Determines whether the columns in the data grid are dependent on dataset fields.

49.1.6.2 TDBGridColumns.Create Constructor

Creates and initializes a TDBGridColumns (see page 9746) object.

Pascal

```
constructor Create(Grid: TCustomDBGrid; ColumnClass: TColumnClass);
```

C++

```
__fastcall TDBGridColumns(TCustomDBGrid Grid, TColumnClass ColumnClass);
```

Description

The Create method takes two parameters: a data-grid instance object and TColumn (see page 9583) (or the name of a class derived from TColumn (see page 9583)).

An application should seldom need to call Create directly. Instead, objects that use a TDBGridColumns (see page 9746) object instantiate the object as part of their initialization. An example of such an object is the TDBGrid (see page 9668) and its Columns property.

See Also

TDBGrid (see page 9668)

Columns (see page 9653)

49.1.6.3 TDBGridColumns Methods

The methods of the TDBGridColumns class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 9749)	Returns the owner of an object.
	Update (see page 9752)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 9749)	Creates a new TColumn (see page 9583) instance and adds it to the Items (see page 9753) array.
	LoadFromFile (see page 9750)	Reads the file specified in FileName and loads the data into the TDBGridColumns (see page 9746) object.
	LoadFromStream (see page 9750)	Reads grid columns data from a stream and stores the contents in the TDBGridColumns (see page 9746) object.
	RebuildColumns (see page 9750)	Deletes existing columns and generates new columns from the dataset associated with the grid.
	RestoreDefaults (see page 9751)	Restores all columns to their default settings.
	SaveToFile (see page 9751)	Saves the TDBGridColumns (see page 9746) object to the file specified in FileName.
	SaveToStream (see page 9751)	Writes a stream with the name passed in Stream with the contents of the TDBGridColumns (see page 9746) object.

49.1.6.3.1 TDBGridColumns.Add Method

Creates a new TColumn (see page 9583) instance and adds it to the Items (see page 9753) array.

Pascal

```
function Add: TColumn;
```

C++

```
__fastcall TColumn Add();
```

Description

Add returns the new column. At design time, use the data grid's Columns editor to add columns to the grid.

See Also

Items (see page 9753)

Columns (see page 9653)

49.1.6.3.2 TDBGridColumns.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are

introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

49.1.6.3.3 TDBGridColumns.LoadFromFile Method

Reads the file specified in FileName and loads the data into the TDBGridColumns (see page 9746) object.

Pascal

```
procedure LoadFromFile(const Filename: string);
```

C++

```
__fastcall LoadFromFile(const AnsiString Filename);
```

Description

Use the LoadFromFile method to retrieve grid columns data from a file and load into a TDBGridColumns (see page 9746) object. The file must be created by calling the SaveToFile (see page 9751) method of a TDBGridColumns (see page 9746) object.

See Also

SaveToFile (see page 9751)

49.1.6.3.4 TDBGridColumns.LoadFromStream Method

Reads grid columns data from a stream and stores the contents in the TDBGridColumns (see page 9746) object.

Pascal

```
procedure LoadFromStream(S: TStream);
```

C++

```
__fastcall LoadFromStream(TStream S);
```

Description

Use the LoadFromStream method to read Stream and store the contents in the TDBGridColumns (see page 9746) object. The stream should contain data previously saved using the SaveToStream (see page 9751) method.

See Also

SaveToStream (see page 9751)

49.1.6.3.5 TDBGridColumns.RebuildColumns Method

Deletes existing columns and generates new columns from the dataset associated with the grid.

Pascal

```
procedure RebuildColumns;
```

C++

```
__fastcall RebuildColumns();
```

Description

RebuildColumns initializes the TDBGridColumns (see page 9746) object by deleting all existing columns, then creating new ones from the grid's associated dataset. If the grid is not connected to a dataset, RebuildColumns simply deletes any existing columns.

49.1.6.3.6 TDBGridColumns.RestoreDefaults Method

Restores all columns to their default settings.

Pascal

```
procedure RestoreDefaults;
```

C++

```
__fastcall RestoreDefaults();
```

Description

RestoreDefaults iterates through the Items (see page 9753) array, calling the RestoreDefaults method for each TColumn (see page 9583) object. This method removes all changes made to properties of the TColumn (see page 9583) objects and restores the default settings.

See Also

RestoreDefaults (see page 9591)

49.1.6.3.7 TDBGridColumns.SaveToFile Method

Saves the TDBGridColumns (see page 9746) object to the file specified in FileName.

Pascal

```
procedure SaveToFile(const Filename: string);
```

C++

```
__fastcall SaveToFile(const AnsiString Filename);
```

Description

Use the SaveToFile method to store TDBGridColumns (see page 9746) data to a file.

See Also

LoadFromFile (see page 9750)

49.1.6.3.8 TDBGridColumns.SaveToStream Method

Writes a stream with the name passed in Stream with the contents of the TDBGridColumns (see page 9746) object.

Pascal

```
procedure SaveToStream(S: TStream);
```

C++

```
__fastcall SaveToStream(TStream S);
```

Description

Use the SaveToStream method to stream out TDBGridColumns (see page 9746) data.

See Also

LoadFromStream (see page 9750)

49.1.6.3.9 TDBGridColumns.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

See Also

Changed (see page 2740)

Changed (see page 2758)

49.1.6.4 TDBGridColumns Properties

The properties of the TDBGridColumns class are listed here.

Public Properties

	Name	Description
R	Grid (see page 9752)	Indicates the data-grid control to which the TDBGridColumns (see page 9746) instance belongs.
	Items (see page 9753)	Lists the columns in the collection.
	State (see page 9753)	Determines whether the columns in the data grid are dependent on dataset fields.

49.1.6.4.1 TDBGridColumns.Grid Property

Indicates the data-grid control to which the TDBGridColumns (see page 9746) instance belongs.

Pascal

```
property Grid: TCustomDBGrid;
```

C++

```
__property TCustomDBGrid Grid;
```

Description

The read-only Grid property indicates which data-grid control (TDBGrid (see page 9668)) owns the TDBGridColumns (see page 9746) object.

See Also

Columns (see page 9653)

49.1.6.4.2 TDBGridColumns.Items Property

Lists the columns in the collection.

Pascal

```
property Items [Index: Integer]: TColumn;
```

C++

```
__property TColumn Items[int Index];
```

Description

Use Items to access individual columns. The value of the Index parameter corresponds to the Index property of TColumn (see page 9583). It represents the position of the column in the data grid.

Items is the default property of TDBGridColumns (see page 9746). This means that the property name, Items, can be omitted when referring to columns of the TDBGridColumns (see page 9746) object. Thus, the line

```
FirstCol := DBGrid1.Columns.Items[0];
```

can also be written

```
FirstCol := DBGrid1.Columns[0];
```

See Also

Index (see page 2762)

operator_sb

49.1.6.4.3 TDBGridColumns.State Property

Determines whether the columns in the data grid are dependent on dataset fields.

Pascal

```
property State: TDBGridColumnsState;
```

C++

```
__property TDBGridColumnsState State;
```

Description

If State is set to csDefault, columns in the data grid are generated dynamically from information in the grid's associated dataset. The dataset fields determine the appearance, order, and other properties of the columns. Changes made to the columns are reflected in the dataset fields, and vice versa.

If State is set to csCustomized, many properties of the data-grid columns are independent of the associated dataset. For example, a column's title caption is, by default, the same as the associated field's DisplayLabel property; if State is csCustomized, however, the column title's Caption property and the field's DisplayLabel property can be changed independently. In fact, a customized (or "persistent") column need not be associated with a dataset field at all.

Note: If the Columns editor is used to configure data-grid columns, State is automatically set to csCustomized. Changing the

State property at runtime deletes all existing columns.

Caption (see page 9607)

DisplayLabel (see page 7160)

Creating Persistent Columns

Using a Grid Control in Its Default State

49.1.7 TGridDataLink Class

TGridDataLink helps manage the link to a data source and maintain the field mapping for a TCustomDBGrid (see page 9608) object.

Class Hierarchy

Pascal

```
TGridDataLink = class(TDataLink);
```

C++

```
class TGridDataLink : public TDataLink;
```

File

DBGrids

Description

TGridDataLink is tailored to work with a TCustomDBGrid (see page 9608). It should only be used by the TCustomDBGrid (see page 9608) class.

See Also

TCustomDBGrid (see page 9608)

TDataSet (see page 6894)

TDataSource (see page 7070)

49.1.7.1 TGridDataLink Members

The following tables list the members exposed by TGridDataLink.

Protected Methods

	Name	Description
V	ActiveChanged (see page 9757)	Informs the TCustomDBGrid (see page 9608) of changes in the Active property.
	BuildAggMap (see page 9757)	Reserved for future use.
V	DataSetChanged (see page 9758)	Informs TCustomDBGrid (see page 9608) of changes to the dataset.
V	DataSetScrolled (see page 9758)	Informs the TCustomDBGrid (see page 9608) when the dataset has finished scrolling.
V	EditingChanged (see page 9759)	Informs the TCustomDBGrid (see page 9608) of changes in the editing state of the dataset.
V	FocusControl (see page 9759)	Displays the editor and gives focus to a field control in the TCustomDBGrid (see page 9608) object.
	GetMappedIndex (see page 9760)	GetMappedIndex provides the index of a field component in the dataset that corresponds to an index within the field map.
V	IsAggRow (see page 9760)	Reserved for future use.
V	LayoutChanged (see page 9760)	Informs the grid after the layout of the TCustomDBGrid (see page 9608) has changed in a way that affects the representation of the dataset.
V	RecordChanged (see page 9761)	Informs the grid of changes in the current record or field of the DataSource.
V	UpdateData (see page 9762)	Allows the grid to post changes to the dataset.

Public Methods

	Name	Description
	AddMapping (see page 9757)	Adds a field component to the end of the field map.
	ClearMapping (see page 9758)	Empties the field map and frees any associated memory.
	Create (see page 9755)	Creates an instance of TGridDataLink (see page 9754).
V	Destroy (see page 9756)	Destroys an instance of TGridDataLink (see page 9754).
	Modified (see page 9761)	Tracks changes to the data which have not been written to the current record in the database.
	Reset (see page 9761)	Cancels any pending edits to the dataset that have not been written to the current record in the database.

Public Properties

	Name	Description
R	DefaultFields (see page 9762)	Indicates whether the dataset's underlying field components are generated dynamically when the dataset is opened.
R	FieldCount (see page 9763)	Indicates the number of entries in the field map.
R	Fields (see page 9763)	Lists all the field components contained in the field map.
R	Grid (see page 9764)	Identifies the Grid component that uses this data link to manage its data.
	SparseMap (see page 9764)	Indicates whether the associated grid has customized the field map (which means it may contain undefined fields).

49.1.7.2 TGridDataLink.Create Constructor

Creates an instance of TGridDataLink (see page 9754).

Pascal

```
constructor Create(AGrid: TCustomDBGrid);
```

C++

```
__fastcall TGridDataLink(TCustomDBGrid AGrid);
```

Description

Applications should not call the Create method for a TGridDataLink (see page 9754) directly. The TCustomDBGrid (see page 9608) object that owns a TGridDataLink (see page 9754) calls Create from its own constructor.

See Also

Create (see page 6878)

Destroy (see page 9756)

49.1.7.3 TGridDataLink.Destroy Destructor

Destroys an instance of TGridDataLink (see page 9754).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TGridDataLink();
```

Description

Do not call Destroy directly in an application. The TCustomDBGrid (see page 9608) that owns a TGridDataLink (see page 9754) calls Free from its own destructor to destroy the TGridDataLink (see page 9754) object.

Destroy frees up the memory used by the field map before calling the inherited destructor.

See Also

Free (see page 22300)

Create (see page 9755)

49.1.7.4 TGridDataLink Methods

The methods of the TGridDataLink class are listed here.

Protected Methods

	Name	Description
	ActiveChanged (see page 9757)	Informs the TCustomDBGrid (see page 9608) of changes in the Active property.
	BuildAggMap (see page 9757)	Reserved for future use.
	DataSetChanged (see page 9758)	Informs TCustomDBGrid (see page 9608) of changes to the dataset.
	DataSetScrolled (see page 9758)	Informs the TCustomDBGrid (see page 9608) when the dataset has finished scrolling.
	EditingChanged (see page 9759)	Informs the TCustomDBGrid (see page 9608) of changes in the editing state of the dataset.
	FocusControl (see page 9759)	Displays the editor and gives focus to a field control in the TCustomDBGrid (see page 9608) object.
	GetMappedIndex (see page 9760)	GetMappedIndex provides the index of a field component in the dataset that corresponds to an index within the field map.
	IsAggRow (see page 9760)	Reserved for future use.
	LayoutChanged (see page 9760)	Informs the grid after the layout of the TCustomDBGrid (see page 9608) has changed in a way that affects the representation of the dataset.
	RecordChanged (see page 9761)	Informs the grid of changes in the current record or field of the DataSource.
	UpdateData (see page 9762)	Allows the grid to post changes to the dataset.

Public Methods

	Name	Description
	AddMapping (see page 9757)	Adds a field component to the end of the field map.
	ClearMapping (see page 9758)	Empties the field map and frees any associated memory.

	Modified (see page 9761)	Tracks changes to the data which have not been written to the current record in the database.
	Reset (see page 9761)	Cancels any pending edits to the dataset that have not been written to the current record in the database.

49.1.7.4.1 TGridDataLink.ActiveChanged Method

Informs the TCustomDBGrid (see page 9608) of changes in the Active property.

Pascal

```
procedure ActiveChanged; override;
```

C++

```
virtual __fastcall ActiveChanged();
```

Description

Applications cannot call the ActiveChanged procedure directly. Changes in the Active property trigger this procedure. When the dataset becomes inactive, ActiveChanged makes sure that the grid is not in edit mode. When the dataset becomes active, ActiveChanged makes sure that the grid does not contain references to fields that are no longer in the dataset, and that the grid does is not scrolled inappropriately.

See Also

Active (see page 6888)

TCustomDBGrid (see page 9608)

49.1.7.4.2 TGridDataLink.AddMapping Method

Adds a field component to the end of the field map.

Pascal

```
function AddMapping(const FieldName: string): Boolean;
```

C++

```
__fastcall Boolean AddMapping(const AnsiString FieldName);
```

Description

Applications should not call AddMapping directly, because this would cause the field map to become out of sync with the columns in TCustomDBGrid (see page 9608). TCustomDBGrid (see page 9608) calls AddMapping iteratively to build a field map that corresponds to its columns.

See Also

ClearMapping (see page 9758)

Fields (see page 9763)

49.1.7.4.3 TGridDataLink.BuildAggMap Method

Reserved for future use.

Pascal

```
procedure BuildAggMap;
```

C++

```
__fastcall BuildAggMap();
```

Description

BuildAggMap is not currently used. It is reserved for future support of aggregates in data-aware grids.

See Also

Aggregates (see page 8461)

49.1.7.4.4 TGridDataLink.ClearMapping Method

Empties the field map and frees any associated memory.

Pascal

```
procedure ClearMapping;
```

C++

```
__fastcall ClearMapping();
```

Description

Applications should not call ClearMapping directly, because this would cause the field map to become out of sync with the columns of the TCustomDBGrid (see page 9608). The TCustomDBGrid (see page 9608) calls ClearMapping first, every time it regenerates the field map.

See Also

AddMapping (see page 9757)

49.1.7.4.5 TGridDataLink.DataSetChanged Method

Informs TCustomDBGrid (see page 9608) of changes to the dataset.

Pascal

```
procedure DataSetChanged; override;
```

C++

```
virtual __fastcall DataSetChanged();
```

Description

Applications can not call DataSetChanged directly. Changes to the contents of the dataset trigger this method automatically. DataSetChanged allows the TCustomDBGrid (see page 9608) to keep track of when the contents of the dataset change.

See Also

ActiveChanged (see page 9757)

DataSetScrolled (see page 9758)

TDataSet (see page 6894)

49.1.7.4.6 TGridDataLink.DataSetScrolled Method

Informs the TCustomDBGrid (see page 9608) when the dataset has finished scrolling.

Pascal

```
procedure DataSetScrolled(Distance: Integer); override;
```

C++

```
virtual __fastcall DataSetScrolled(int Distance);
```

Description

Applications cannot call the DataSetScrolled procedure directly. This procedure is called automatically after the dataset for the TCustomDBGrid (see page 9608) scrolls. TGridDataLink (see page 9754) informs the TCustomDBGrid (see page 9608) that a scroll of the dataset has just occurred by calling its Scroll method.

See Also

DataSetChanged (see page 9758)

Scroll (see page 9648)

49.1.7.4.7 TGridDataLink.EditingChanged Method

Informs the TCustomDBGrid (see page 9608) of changes in the editing state of the dataset.

Pascal

```
procedure EditingChanged; override;
```

C++

```
virtual __fastcall EditingChanged();
```

Description

Applications cannot call the EditingChanged procedure directly. Changes in the Editing property trigger this procedure. EditingChanged allows the TCustomDBGrid (see page 9608) to provide visual feedback to the user about the editing state of the dataset.

See Also

Editing (see page 6892)

49.1.7.4.8 TGridDataLink.FocusControl Method

Displays the editor and gives focus to a field control in the TCustomDBGrid (see page 9608) object.

Pascal

```
procedure FocusControl(Field: TFieldRef); override;
```

C++

```
virtual __fastcall FocusControl(TFieldRef Field);
```

Description

Call the FocusControl procedure to bring up the editor for the representation of Field in the TCustomDBGrid (see page 9608). FocusControl selects Field in the TCustomDBGrid (see page 9608), and then tells the TCustomDBGrid (see page 9608) object to bring up the editor.

See Also

TabStop

ShowEditor (see page 14839)

49.1.7.4.9 TGridDataLink.GetMappedIndex Method

GetMappedIndex provides the index of a field component in the dataset that corresponds to an index within the field map.

Pascal

```
function GetMappedIndex(ColIndex: Integer): Integer;
```

C++

```
__fastcall int GetMappedIndex(int ColIndex);
```

Description

Use GetMappedIndex on an index into the field map to get an index into the dataset for the same field component. Both the field map and the dataset are zero-based arrays. If an entry in the field map is an undefined field, GetMappedIndex returns -1.

See Also

Fields (see page 9763)

49.1.7.4.10 TGridDataLink.IsAggRow Method

Reserved for future use.

Pascal

```
function IsAggRow(Value: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsAggRow(int Value);
```

Description

IsAggRow indicates whether the row specified by Value contains aggregate values rather than data. Value is the index of a row in the cache of rows currently displayed.

IsAggRow always returns false because data-aware grids do not currently display aggregate values. This method is reserved for future support of aggregates in data-aware grids.

See Also

Aggregates (see page 8461)

49.1.7.4.11 TGridDataLink.LayoutChanged Method

Informs the grid after the layout of the TCustomDBGrid (see page 9608) has changed in a way that affects the representation of the dataset.

Pascal

```
procedure LayoutChanged; override;
```

C++

```
virtual __fastcall LayoutChanged();
```

Description

Applications cannot call the LayoutChanged method directly. The TCustomDBGrid (see page 9608) that owns the TGridDataLink (see page 9754) calls this method automatically when layout changes affect the representation of the dataset. LayoutChanged allows the TCustomDBGrid (see page 9608) to regenerate its layout by calling its LayoutChanged method.

See Also

DataSetChanged (see page 9758)

LayoutChanged (see page 9645)

49.1.7.4.12 TGridDataLink.Modified Method

Tracks changes to the data which have not been written to the current record in the database.

Pascal

```
procedure Modified;
```

C++

```
__fastcall Modified();
```

Description

Applications should not call Modified directly. Modified is called automatically whenever the TCustomDBGrid (see page 9608) starts editing one of its fields. Modified allows the TGridDataLink (see page 9754) to keep track of whether there are any edits that have not been posted.

See Also

Edit (see page 6882)

Editing (see page 6892)

Reset (see page 9761)

49.1.7.4.13 TGridDataLink.RecordChanged Method

Informs the grid of changes in the current record or field of the DataSource.

Pascal

```
procedure RecordChanged(Field: TField); override;
```

C++

```
virtual __fastcall RecordChanged(TField Field);
```

Description

Applications cannot call RecordChanged directly. It is called automatically when the contents of the current record change. The Field parameter indicates which field in the current record has changed. If Field is nil (Delphi) or NULL (C++), the entire record has changed.

RecordChanged informs TCustomDBGrid (see page 9608) of these changes so that it can update the display of the affected column or columns.

See Also

DataSetChanged (see page 9758)

49.1.7.4.14 TGridDataLink.Reset Method

Cancels any pending edits to the dataset that have not been written to the current record in the database.

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

Reset is triggered by user actions that cancel any pending edits to the dataset.

See Also

Modified (see page 9761)

UpdateData (see page 9762)

49.1.7.4.15 TGridDataLink.UpdateData Method

Allows the grid to post changes to the dataset.

Pascal

```
procedure UpdateData; override;
```

C++

```
virtual __fastcall UpdateData();
```

Description

Applications cannot call the UpdateData procedure directly. It is called automatically when pending changes need to be posted to the dataset. UpdateData tells the TCustomDBGrid (see page 9608) to write any unposted changes to the current field to the underlying Field component.

See Also

DataSetChanged (see page 9758)

Modified (see page 9761)

Reset (see page 9761)

TField (see page 7115)

49.1.7.5 TGridDataLink Properties

The properties of the TGridDataLink class are listed here.

Public Properties

	Name	Description
R	DefaultFields (see page 9762)	Indicates whether the dataset's underlying field components are generated dynamically when the dataset is opened.
R	FieldCount (see page 9763)	Indicates the number of entries in the field map.
R	Fields (see page 9763)	Lists all the field components contained in the field map.
R	Grid (see page 9764)	Identifies the Grid component that uses this data link to manage its data.
	SparseMap (see page 9764)	Indicates whether the associated grid has customized the field map (which means it may contain undefined fields).

49.1.7.5.1 TGridDataLink.DefaultFields Property

Indicates whether the dataset's underlying field components are generated dynamically when the dataset is opened.

Pascal

```
property DefaultFields: Boolean;
```

C++

```
__property Boolean DefaultFields;
```

Description

Read DefaultFields to determine whether or not a dataset uses dynamically generated field components or persistent field components. If DefaultFields is true, the dataset uses dynamically allocated field components. If DefaultFields is false, the dataset uses persistent field components or the custom field mapping contains unmapped fields.

If DefaultFields is false, the TCustomDBGrid (see page 9608) may not show all the fields that are present in the underlying database table.

See Also

SparseMap (see page 9764)

49.1.7.5.2 TGridDataLink.FieldCount Property

Indicates the number of entries in the field map.

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

Read FieldCount to determine the number of entries in the field map. Used with the Fields (see page 9763) property, this is useful for applications that need to iterate over all of the mapped fields.

FieldCount is the same as the number of columns in the TCustomDBGrid (see page 9608). The field map can contain undefined fields, which do not appear in the dataset. Undefined fields in the field map stand in for fields in the columns of the grid that are not in the dataset, such as calculated fields.

See Also

AddMapping (see page 9757)

DataSet (see page 6890)

Fields (see page 9763)

SparseMap (see page 9764)

49.1.7.5.3 TGridDataLink.Fields Property

Lists all the field components contained in the field map.

Pascal

```
property Fields [I: Integer]: TField;
```

C++

```
__property TField Fields[int I];
```

Description

Use Fields to access field components by index number. Fields is a zero-based array. If the SparseMap (see page 9764) property is true, the field map may contain undefined fields. For these entries, Fields returns nil (Delphi) or NULL (C++).

See Also

AddMapping (see page 9757)

FieldCount (see page 9763)

SparseMap (see page 9764)

49.1.7.5.4 TGridDataLink.Grid Property

Identifies the Grid component that uses this data link to manage its data.

Pascal

```
property Grid: TCustomDBGrid;
```

C++

```
__property TCustomDBGrid Grid;
```

Description

Use Grid to access the data-aware grid that owns this data link. The value of Grid is assigned by the TGridDataLink (see page 9754) constructor.

See Also

Create (see page 9755)

49.1.7.5.5 TGridDataLink.SparseMap Property

Indicates whether the associated grid has customized the field map (which means it may contain undefined fields).

Pascal

```
property SparseMap: Boolean;
```

C++

```
__property Boolean SparseMap;
```

Description

Read SparseMap to determine whether the field map is not a simple reflection of the underlying dataset. The TCustomDBGrid (see page 9608) sets SparseMap when it builds the field map. SparseMap is false if the TCustomDBGrid (see page 9608) builds a default field map directly from the dataset. Any changes to the field components associated with each column cause TCustomDBGrid (see page 9608) to change SparseMap to true. When SparseMap is true, the field map may contain undefined fields if the column attributes indicate an invalid field name or an unassigned field component.

See Also

AddMapping (see page 9757)

Fields (see page 9763)

49.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TColumnButtonStyle (see page 9765)	TColumnButtonStyle indicates whether and how the user can select values for a column from a list.
	TColumnValue (see page 9766)	TColumnValue and TColumnValues (see page 9769) indicate which properties on the column of a DB (see page 6725) grid are persistent.
	TDBGridColumnsState (see page 9767)	TDBGridColumnsState indicates whether the columns in a DB (see page 6725) grid dynamically reflect dataset fields.
	TDBGridOption (see page 9767)	TDBGridOption and TDBGridOptions (see page 9770) indicate display and behavioral property of a DB (see page 6725) grid.

49.2.1 DBGrids.TColumnButtonStyle Enumeration

TColumnButtonStyle indicates whether and how the user can select values for a column from a list.

Pascal

```
TColumnButtonStyle = (
  cbsAuto,
  cbsEllipsis,
  cbsNone
);
```

C++

```
enum TColumnButtonStyle {
  cbsAuto,
  cbsEllipsis,
  cbsNone
};
```

File

DBGrids

Description

These are the possible values of TColumnButtonStyle:

Value	Meaning
cbsAuto	If the column is associated with a lookup field or has a value assigned to its PickList property, the grid displays a combo box in the column. The user can choose a value from the drop-down list.
cbsEllipsis	The column displays an ellipsis button that the user can click to choose a value. Clicking the ellipsis button triggers an OnEditButtonClick event.
cbsNone	No combo box or ellipsis button is provided. The user cannot select the column's content from a list.

49.2.2 DBGrids.TColumnValue Enumeration

TColumnValue and TColumnValues (see page 9769) indicate which properties on the column of a DB (see page 6725) grid are persistent.

Pascal

```
TColumnValue = (
  cvColor,
  cvWidth,
  cvFont,
  cvAlignment,
  cvReadOnly,
  cvTitleColor,
  cvTitleCaption,
  cvTitleAlignment,
  cvTitleFont,
  cvImeMode,
  cvImeName
);
```

C++

```
enum TColumnValue {
  cvColor,
  cvWidth,
  cvFont,
  cvAlignment,
  cvReadOnly,
  cvTitleColor,
  cvTitleCaption,
  cvTitleAlignment,
  cvTitleFont,
  cvImeMode,
  cvImeName
};
```

File

DBGrids

Description

TColumnValues (see page 9769) is a set that indicates which properties of a column have been set as persistent properties (overriding the defaults). It can contain zero or more of the following TColumnValue values:

Value	Indicates changes to
cvColor	The column's Color property.
cvWidth	The column's Width property.
cvFont	The column's Font property.
cvAlignment	The column's Alignment property.
cvReadOnly	The column's ReadOnly property.
cvTitleColor	The column title's Color property.
cvTitleCaption	The column title's Caption property.
cvTitleAlignment	The column title's Alignment property.
cvTitleFont	The column title's Font property.

cvImeMode	The column's ImeMode property.
cvImeName	The column's ImeName property.

49.2.3 DBGrids.TDBGridColumnsState Enumeration

TDBGridColumnsState indicates whether the columns in a DB (see page 6725) grid dynamically reflect dataset fields.

Pascal

```
TDBGridColumnsState = (
  csDefault,
  csCustomized
);
```

C++

```
enum TDBGridColumnsState {
  csDefault,
  csCustomized
};
```

File

DBGrids

Description

The following table lists the possible values.

Value	Meaning
csDefault	Columns in the data grid are generated dynamically from information in the grid's associated dataset. The dataset fields determine the appearance, order, and other properties of the columns. Changes made to the columns are reflected in the dataset fields, and vice versa.
csCustomized	Properties of the data-grid columns are independent of the associated dataset.

49.2.4 DBGrids.TDBGridOption Enumeration

TDBGridOption and TDBGridOptions (see page 9770) indicate display and behavioral property of a DB (see page 6725) grid.

Pascal

```
TDBGridOption = (
  dgEditing,
  dgAlwaysShowEditor,
  dgTitles,
  dgIndicator,
  dgColumnResize,
  dgColLines,
  dgRowLines,
  dgTabs,
  dgRowSelect,
  dgAlwaysShowSelection,
  dgConfirmDelete,
  dgCancelOnExit,
  dgMultiSelect
```

```
);
```

C++

```
enum TDBGridOption {
  dgEditing,
  dgAlwaysShowEditor,
  dgTitles,
  dgIndicator,
  dgColumnResize,
  dgColLines,
  dgRowLines,
  dgTabs,
  dgRowSelect,
  dgAlwaysShowSelection,
  dgConfirmDelete,
  dgCancelOnExit,
  dgMultiSelect
};
```

File

DBGrids

Description

TDBGridOptions (see page 9770) is a set drawn from the following TDBGridOption values:

Value	Meaning
dgEditing	The user can edit data using the grid. dgEditing is ignored if Options includes dgRowSelect.
dgAlwaysShowEditor	The grid is always in edit mode. That is, the user does not have to press Enter or F2 before editing the contents of a cell. dgAlwaysShowEditor does nothing unless dgEditing is also included in Options. dgAlwaysShowEditor is ignored if Options includes dgRowSelect.
dgTitles	Titles appear at the top of the columns in the grid.
dgIndicator	A small pointer appears in the first column to indicate which row is current.
dgColumnResize	Columns that are bound to fields can be resized or moved.
dgColLines	Lines appear between columns in the grid.
dgRowLines	Lines appear between the rows of the grid.
dgTabs	The user can navigate through the grid using the Tab and Shift+Tab keys.
dgRowSelect	The user can select an entire row, as well as selecting individual cells. If Options includes dgRowSelect, dgEditing and dgAlwaysShowEditor are ignored.
dgAlwaysShowSelection	The selected cell displays the focus rectangle even when the grid does not have focus.
dgConfirmDelete	A message box appears, asking for confirmation, when the user types Ctrl+Delete to delete a row in the grid.
dgCancelOnExit	When the user exits the grid from an inserted record to which the user made no modifications, the inserted record is not posted to the dataset. This prevents the inadvertent posting of empty records.
dgMultiSelect	More than one row in the grid can be selected at a time.

49.3 Types

The following table lists types in this documentation.

Types

Name	Description
TColumnClass (see page 9769)	TColumnClass defines the metaclass for TColumn (see page 9583).
TColumnValues (see page 9769)	This is type DBGrids.TColumnValues.
TDBGridClickEvent (see page 9770)	This is type DBGrids.TDBGridClickEvent.
TDBGridOptions (see page 9770)	This is type DBGrids.TDBGridOptions.
TDrawColumnCellEvent (see page 9770)	This is type DBGrids.TDrawColumnCellEvent.
TDrawDataCellEvent (see page 9771)	This is type DBGrids.TDrawDataCellEvent.

49.3.1 DBGrids.TColumnClass Type

TColumnClass defines the metaclass for TColumn (see page 9583).

Pascal

```
TColumnClass = class of TColumn;
```

C++

```
TColumn TColumnClass;
```

File

DBGrids

Description

TColumnClass is the metaclass for TColumn (see page 9583). Its value is the class reference for TColumn (see page 9583) or for one of its descendants.

49.3.2 DBGrids.TColumnValues Type

Pascal

```
TColumnValues = set of TColumnValue;
```

C++

```
TColumnValue TColumnValues;
```

File

DBGrids

Description

This is type DBGrids.TColumnValues.

49.3.3 DBGrids.TDBGridClickEvent Type

Pascal

```
TDBGridClickEvent = procedure (Column: TColumn) of object;
```

C++

```
(Column: TColumn) ( TDBGridClickEvent)();
```

File

DBGrids

Description

This is type DBGrids.TDBGridClickEvent.

49.3.4 DBGrids.TDBGridOptions Type

Pascal

```
TDBGridOptions = set of TDBGridOption;
```

C++

```
TDBGridOption TDBGridOptions;
```

File

DBGrids

Description

This is type DBGrids.TDBGridOptions.

49.3.5 DBGrids.TDrawColumnCellEvent Type

Pascal

```
TDrawColumnCellEvent = procedure (Sender: TObject; const Rect: TRect; DataCol: Integer;
Column: TColumn; State: TGridDrawState) of object;
```

C++

```
(Sender: TObject; const Rect: TRect; DataCol: Integer; Column: TColumn; State: TGridDrawState)
( TDrawColumnCellEvent)();
```

File

DBGrids

Description

This is type DBGrids.TDrawColumnCellEvent.

49.3.6 DBGrids.TDrawDataCellEvent Type

Pascal

```
TDrawDataCellEvent = procedure (Sender: TObject; const Rect: TRect; Field: TField; State:
TGridDrawState) of object;
```

C++

```
(Sender: TObject; const Rect: TRect; Field: TField; State: TGridDrawState) (
TDrawDataCellEvent)();
```

File

DBGrids

Description

This is type DBGrids.TDrawDataCellEvent.

49.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
cm_DeferLayout (see page 9772)	This is constant DBGrids.cm_DeferLayout.
ColumnTitleValues (see page 9772)	This is constant DBGrids.ColumnTitleValues.
IndicatorWidth (see page 9772)	This is constant DBGrids.IndicatorWidth.

49.4.1 DBGrids.cm_DeferLayout Constant

Pascal

```
cm_DeferLayout = WM_USER + 100;
```

C++

```
cm_DeferLayout = WM_USER + 100;
```

File

DBGrids

Description

This is constant DBGrids.cm_DeferLayout.

49.4.2 DBGrids.ColumnTitleValues Constant

Pascal

```
ColumnTitleValues = [cvTitleColor..cvTitleFont];
```

C++

```
ColumnTitleValues = [cvTitleColor..cvTitleFont];
```

File

DBGrids

Description

This is constant DBGrids.ColumnTitleValues.

49.4.3 DBGrids.IndicatorWidth Constant

Pascal

```
IndicatorWidth = 11;
```

C++

```
IndicatorWidth = 11;
```

File

DBGrids

Description

This is constant DBGrids.IndicatorWidth.

50 DBLogDlg Namespace

This is namespace DBLogDlg.

Topics

Name	Description
Classes (see page 9776)	The following table lists classes in this documentation.
Functions (see page 9797)	The following table lists functions in this documentation.

Classes

	Name	Description
	TLoginDialog (see page 9776)	TLoginDialog is a login dialog box that can be used to provide login security in an application.

Functions

	Name	Description
	LoginDialog (see page 9797)	Brings up the database Login dialog to allow the user to connect to a database server.
	LoginDialogEx (see page 9798)	Brings up the database Login dialog to allow the user to connect to a database server.
	RemoteLoginDialog (see page 9798)	Brings up the database Login dialog to allow the user to connect to a database server.
	SetCursorType (see page 9799)	This is function DBLogDlg.SetCursorType.

50.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TLoginDialog (see page 9776)	TLoginDialog is a login dialog box that can be used to provide login security in an application.

50.1.1 TLoginDialog Class

TLoginDialog is a login dialog box that can be used to provide login security in an application.

Class Hierarchy

Pascal

```
TLoginDialog = class(TForm);
```

C++

```
class TLoginDialog : public TForm;
```

File

DBLogDlg

Description

Use TLoginDialog to provide login security within an application. Usually a TLoginDialog object is created with the LoginDialogEx (see page 9798) or RemoteLoginDialog (see page 9798) function and is used to provide secure access to local database tables. However, TLoginDialog can also be used as a base object for other types of login dialog boxes.

See Also

LoginDialogEx (see page 9798)

TPasswordDialog (see page 9828)

RemoteLoginDialog (see page 9798)

50.1.1.1 TLoginDialog Members

The following tables list the members exposed by TLoginDialog.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.

	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.

	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.

	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.

	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
V	DoCreate (see page 13873)	Form creation event dispatcher.
V	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
V	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.

	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloating (see page 13877)	Returns the value of the Floating property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.

	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.

V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
V	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.

	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.

	Visible (see page 13940)	Indicates whether the form is visible.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Fields

	Name	Description
	Bevel (see page 9793)	This is Bevel, a member of class TLoginDialog.
	CancelButton (see page 9793)	This is CancelButton, a member of class TLoginDialog.
	DatabaseName (see page 9793)	This is DatabaseName, a member of class TLoginDialog.
	Label1 (see page 9794)	This is Label1, a member of class TLoginDialog.
	Label2 (see page 9794)	This is Label2, a member of class TLoginDialog.
	Label3 (see page 9794)	This is Label3, a member of class TLoginDialog.
	OKButton (see page 9794)	This is OKButton, a member of class TLoginDialog.
	Panel (see page 9794)	This is Panel, a member of class TLoginDialog.
	Panel1 (see page 9795)	This is Panel1, a member of class TLoginDialog.
	Password (see page 9795)	This is Password, a member of class TLoginDialog.
	UserName (see page 9795)	This is UserName, a member of class TLoginDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 13866)	Construction event dispatcher.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	ArrangeIcons (see page 14006)	Arranges the icons of minimized MDI child forms.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 13866)	Destruction event dispatcher.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	Cascade (see page 14007)	Arranges MDI child forms so they overlap.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.

	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 5731)	Creates an instance of TControl (see page 5724).
	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 13861)	Creates and initializes a new TForm (see page 13992) object.
	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 13862)	Removes the form from memory.
	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	FormShow (see page 9795)	Adjusts the contents of the login dialog when it becomes visible.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 14008)	Activates the next child form in the form sequence.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Previous (see page 14009)	Activates the previous MDI child form in the form sequence.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
	Tile (see page 14009)	Arranges MDI child forms so that they are all the same size.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveMDIChild (see page 14013)	Specifies the MDI child that has focus.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.

	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	ClientHandle (see page 14024)	Provides access to the handle of the form's internal MDI client window.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockManager (see page 14029)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	MDIChildCount (see page 14044)	Specifies the number of open MDI child forms.

	MDIChildren (see page 14044)	Provides indexed access to all MDI child forms.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TileMode (see page 14059)	Represents how MDI child forms are arranged when the Tile method is called.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnActivate (see page 14065)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.
	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.
	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.
	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.
	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.

	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Menu (see page 14045)	Specifies the form's main menu.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.
	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.

	WindowState (see page 14063)	Represents how the form appears on the screen.

50.1.1.2 TLoginDialog Fields

The fields of the TLoginDialog class are listed here.

Public Fields

	Name	Description
	Bevel (see page 9793)	This is Bevel, a member of class TLoginDialog.
	CancelButton (see page 9793)	This is CancelButton, a member of class TLoginDialog.
	DatabaseName (see page 9793)	This is DatabaseName, a member of class TLoginDialog.
	Label1 (see page 9794)	This is Label1, a member of class TLoginDialog.
	Label2 (see page 9794)	This is Label2, a member of class TLoginDialog.
	Label3 (see page 9794)	This is Label3, a member of class TLoginDialog.
	OKButton (see page 9794)	This is OKButton, a member of class TLoginDialog.
	Panel (see page 9794)	This is Panel, a member of class TLoginDialog.
	Panel1 (see page 9795)	This is Panel1, a member of class TLoginDialog.
	Password (see page 9795)	This is Password, a member of class TLoginDialog.
	UserName (see page 9795)	This is UserName, a member of class TLoginDialog.

50.1.1.2.1 TLoginDialog.Bevel Field

Pascal

```
Bevel: TBevel;
```

C++

```
TBevel Bevel;
```

Description

This is Bevel, a member of class TLoginDialog.

50.1.1.2.2 TLoginDialog.CancelButton Field

Pascal

```
CancelButton: TButton;
```

C++

```
TButton CancelButton;
```

Description

This is CancelButton, a member of class TLoginDialog.

50.1.1.2.3 TLoginDialog.DatabaseName Field

Pascal

```
DatabaseName: TLabel;
```

C++

```
TLabel DatabaseName;
```

Description

This is DatabaseName, a member of class TLoginDialog.

50.1.1.2.4 TLoginDialog.Label1 Field

Pascal

```
Label1: TLabel;
```

C++

```
TLabel Label1;
```

Description

This is Label1, a member of class TLoginDialog.

50.1.1.2.5 TLoginDialog.Label2 Field

Pascal

```
Label2: TLabel;
```

C++

```
TLabel Label2;
```

Description

This is Label2, a member of class TLoginDialog.

50.1.1.2.6 TLoginDialog.Label3 Field

Pascal

```
Label3: TLabel;
```

C++

```
TLabel Label3;
```

Description

This is Label3, a member of class TLoginDialog.

50.1.1.2.7 TLoginDialog.OKButton Field

Pascal

```
OKButton: TButton;
```

C++

```
TButton OKButton;
```

Description

This is OKButton, a member of class TLoginDialog.

50.1.1.2.8 TLoginDialog.Panel Field

Pascal

```
Panel: TPanel;
```

C++

```
TPanel Panel;
```

Description

This is Panel, a member of class TLoginDialog.

50.1.1.2.9 TLoginDialog.Panel1 Field

Pascal

```
Panel1: TPanel;
```

C++

```
TPanel Panel1;
```

Description

This is Panel1, a member of class TLoginDialog.

50.1.1.2.10 TLoginDialog.Password Field

Pascal

```
Password: TEdit;
```

C++

```
TEdit Password;
```

Description

This is Password, a member of class TLoginDialog.

50.1.1.2.11 TLoginDialog.UserName Field

Pascal

```
UserName: TEdit;
```

C++

```
TEdit UserName;
```

Description

This is UserName, a member of class TLoginDialog.

50.1.1.3 TLoginDialog Methods

The methods of the TLoginDialog class are listed here.

Public Methods

	Name	Description
	FormShow (see page 9795)	Adjusts the contents of the login dialog when it becomes visible.

50.1.1.3.1 TLoginDialog.FormShow Method

Adjusts the contents of the login dialog when it becomes visible.

Pascal

```
procedure FormShow(Sender: TObject);
```

C++

```
__fastcall FormShow(TObject * Sender);
```

Description

FormShow is called automatically just before the login dialog becomes visible. It fixes up the controls in the login dialog so that the text appears properly formatted.

50.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	LoginDialog (see page 9797)	Brings up the database Login dialog to allow the user to connect to a database server.
	LoginDialogEx (see page 9798)	Brings up the database Login dialog to allow the user to connect to a database server.
	RemoteLoginDialog (see page 9798)	Brings up the database Login dialog to allow the user to connect to a database server.
	SetCursorType (see page 9799)	This is function DBLogDlg.SetCursorType.

50.2.1 DBLogDlg.LoginDialog Function

Brings up the database Login dialog to allow the user to connect to a database server.

Pascal

```
function LoginDialog(const ADatabaseName: string; var AUserName: string; var APassword:
string): Boolean;
```

C++

```
Boolean LoginDialog(const AnsiString ADatabaseName, AnsiString AUserName, AnsiString
APassword);
```

File

DBLogDlg

Description

Call LoginDialog to bring up the standard Login dialog box to prompt the user for a valid user name and password. The ADatabaseName parameter specifies the database for which access is being requested. The dialog returns the user name and password as the AUserName and APassword parameters.

Note: When building cross-platform applications in C++, add QDBLogDlg.pas unit (instead of DBLogDlg (see page 9775)) to your project if you want the default Database Login dialog to display at runtime. QDBLogDlg does not need to be included if your C++ application includes a DBGrid component.

LoginDialog returns false if the user cancels out of the dialog. If LoginDialog returns true, the application can attempt to connect to the database server using the supplied user name and password.

Note: If the user should not be permitted to change the user name from within the login dialog, use the LoginDialogEx (see page 9798) function.

See Also

LoginDialogEx

RemoteLoginDialog

50.2.2 DBLogDlg.LoginDialogEx Function

Brings up the database Login dialog to allow the user to connect to a database server.

Pascal

```
function LoginDialogEx(const ADatabaseName: string; var AUserName: string; var APassword:
string; NameReadOnly: Boolean): Boolean;
```

C++

```
Boolean LoginDialogEx(const AnsiString ADatabaseName, AnsiString AUserName, AnsiString
APassword, Boolean NameReadOnly);
```

File

DBLogDlg

Description

Call LoginDialogEx to bring up the standard Login dialog box to prompt the user for a valid user name and password. The ADatabaseName parameter specifies the database for which access is being requested. The NameReadOnly parameter specifies whether the user can change the user name from within the dialog.

The dialog returns the user name and password as the AUserName and APassword parameters.

LoginDialogEx returns falseif the user cancels out of the dialog. If LoginDialogEx returns true, the application can attempt to connect to the database server using the supplied user name and password.

Note: When building cross-platform applications in C++, add QDBLogDlg.pas unit (instead of DBLogDlg (see page 9775)) to your project if you want the default Database Login dialog to display at runtime. QDBLogDlg does not need to be included if your C++ application includes a DBGrid component.

See Also

LoginDialog

PasswordDialog

RemoteLoginDialog

50.2.3 DBLogDlg.RemoteLoginDialog Function

Brings up the database Login dialog to allow the user to connect to a database server.

Pascal

```
function RemoteLoginDialog(var AUserName: string; var APassword: string): Boolean;
```

C++

```
Boolean RemoteLoginDialog(AnsiString AUserName, AnsiString APassword);
```

File

DBLogDlg

Description

Call RemoteLoginDialog to bring up the standard Login dialog box to prompt the user for a valid user name and password.

The dialog returns the user name and password as the AUserName and APassword parameters.

RemotLoginDialog returns false if the user cancels out of the dialog. If RemoteLoginDialog returns true, the application can attempt to connect to the database server using the supplied user name and password.

Note: When building cross-platform applications in C++, add QDBLogDlg.pas unit (instead of DBLogDlg (see page 9775)) to your project if you want the default Database Login dialog to display at runtime. QDBLogDlg does not need to be included if your C++ application includes a DBGrid component.

See Also

LoginDialog

PasswordDialog

LoginDialogEx

50.2.4 DBLogDlg.SetCursorType Function

Pascal

```
procedure SetCursorType(const CurIndex: Integer);
```

C++

```
SetCursorType(const int CurIndex);
```

File

DBLogDlg

Description

This is function DBLogDlg.SetCursorType.

51 DBOleCtl Namespace

This is namespace DBOleCtl.

Topics

Name	Description
Classes (see page 9802)	The following table lists classes in this documentation.

Classes

	Name	Description
	TDataBindings (see page 9802)	TDataBindings holds a group of TDataBindItem (see page 9806) objects.
	TDataBindItem (see page 9806)	TDataBindItem represents a data binding in a data-aware ActiveX control.
	TDBOleControl (see page 9810)	Supports simple data binding for ActiveX controls.

51.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDataBindings (see page 9802)	TDataBindings holds a group of TDataBindItem (see page 9806) objects.
	TDataBindItem (see page 9806)	TDataBindItem represents a data binding in a data-aware ActiveX control.
	TDBOleControl (see page 9810)	Supports simple data binding for ActiveX controls.

51.1.1 TDataBindings Class

TDataBindings holds a group of TDataBindItem (see page 9806) objects.

Class Hierarchy

Pascal

```
TDataBindings = class(TCollection);
```

C++

```
class TDataBindings : public TCollection;
```

File

DBOleCtl

Description

Use TDataBindings to connect the properties of a data-aware ActiveX control to the fields in a dataset. TDataBindings maintains an index of data bindings (TDataBindItem (see page 9806) objects) in its Items (see page 9806) array. The Count property of its ancestor TCollection, contains the number of items in the collection. Use the Add (see page 9804) method to add items to the collection.

Typically, this object is for internal use. Instead, you access an object's data bindings through the DataBindings property of the DBOleControl object.

51.1.1.1 TDataBindings Members

The following tables list the members exposed by TDataBindings.

Protected Methods

	Name	Description
	Added (see page 2736)	Responds when items are added to the collection.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	Deleting (see page 2741)	Responds when items are deleted from the collection.

	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 9804)	Creates a new TDataBindItem (see page 9806) object and adds it to the end of the Items (see page 9806) property array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 9804)	Creates an instance of TDataBindings (see page 9802).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetItemByDispID (see page 9805)	Returns the associated TDataBindItem (see page 9806) property for the specified DispID.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.

	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetOwner (see page 9805)	Returns the owner of an object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	Update (see page 9805)	For internal use.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 9806)	Provides indexed access to the TDataBindItem (see page 9806) objects in the collection.

51.1.1.2 TDataBindings.Create Constructor

Creates an instance of TDataBindings (see page 9802).

Pascal

```
constructor Create(DBOleControl: TDBOleControl);
```

C++

```
__fastcall TDataBindings(TDBOleControl DBOleControl);
```

Description

Applications should not need to call Create directly. The data-aware control object that uses the TDataBindings (see page 9802) collection to represent its data bindings creates the TDataBindings (see page 9802) object from its own constructor.

51.1.1.3 TDataBindings Methods

The methods of the TDataBindings class are listed here.

Public Methods

	Name	Description
	Add (see page 9804)	Creates a new TDataBindItem (see page 9806) object and adds it to the end of the Items (see page 9806) property array.
	GetItemByDispID (see page 9805)	Returns the associated TDataBindItem (see page 9806) property for the specified DispID.
V	GetOwner (see page 9805)	Returns the owner of an object.
V	Update (see page 9805)	For internal use.

51.1.1.3.1 TDataBindings.Add Method

Creates a new TDataBindItem (see page 9806) object and adds it to the end of the Items (see page 9806) property array.

Pascal

```
function Add: TDataBindItem;
```

C++

```
__fastcall TDataBindItem Add();
```

Description

Call Add to add a new TDataBindItem (see page 9806) to the set of data bindings associated with the specified data-aware control. With this method, you must also set the fields within the TDataBindItem (see page 9806) at the same time. These data bindings can be modified programmatically at a later time.

See Also

Add (see page 2736)

51.1.1.3.2 TDataBindings.GetItemByDispID Method

Returns the associated TDataBindItem (see page 9806) property for the specified DispID.

Pascal

```
function GetItemByDispID(ADispID: TDispID): TDataBindItem;
```

C++

```
__fastcall TDataBindItem GetItemByDispID(TDispID ADispID);
```

Description

GetItemByDispID returns the TDataBindItem (see page 9806) property for the specified DispID. It returns nil (Delphi) or NULL (C++) if no TDataBindItem (see page 9806) property exists for the specified DispID.

51.1.1.3.3 TDataBindings.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used to find the owner of a data binding, that is, the data-aware control.

See Also

GetOwner (see page 2932)

51.1.1.3.4 TDataBindings.Update Method

For internal use.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Update refreshes the field definitions in the Items (see page 9806) property array to reflect the current state of the physical fields in the underlying dataset. This is typically for internal use.

51.1.1.4 TDataBindings Properties

The properties of the TDataBindings class are listed here.

Public Properties

	Name	Description
	Items (see page 9806)	Provides indexed access to the TDataBindItem (see page 9806) objects in the collection.

51.1.1.4.1 TDataBindings.Items Property

Provides indexed access to the TDataBindItem (see page 9806) objects in the collection.

Pascal

```
property Items [Index: Integer]: TDataBindItem;
```

C++

```
__property TDataBindItem Items[int Index];
```

Description

Use Items to access the properties of TDataBindItem (see page 9806) objects maintained by TDataBindings (see page 9802).

Note: In Delphi code, Items is the default property of TDataBindings (see page 9802), so the name of the property can be left off when using this property. Thus, the line:

```
FirstDataBinding := DBOleCtl1.DataBindings.Items[0];
```

Note: can be written as:

```
FirstDataBinding := DBOleCtl1.DataBindings[0];
```

See Also

TDBOleControl (see page 9810)

TDataBindItem (see page 9806)

operator_[]

51.1.2 TDataBindItem Class

TDataBindItem represents a data binding in a data-aware ActiveX control.

Class Hierarchy

Pascal

```
TDataBindItem = class(TCollectionItem);
```

C++

```
class TDataBindItem : public TCollectionItem;
```

File

DBOleCtl

Description

The TDataBindItem object stores the association between a property in a data-aware control and a field in the dataset. TDataBindings (see page 9802) holds a collection of data bindings for a particular ActiveX control, which is represented by a TDBOleControl (see page 9810) object.

51.1.2.1 TDataBindItem Members

The following tables list the members exposed by TDataBindItem.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetDisplayName (see page 2758)	Returns the name of the collection item as it appears in the collection editor.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 9808)	Creates an instance of TDataBindItem (see page 9806).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 9808)	Destroys the TDataBindItem (see page 9806) instance and frees its memory.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.

	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

Published Properties

	Name	Description
	DataField (see page 9809)	Represents the name of the field to be bound.
	DispID (see page 9809)	The identifier (DispID) of the data-aware control property to be bound.

51.1.2.2 TDataBindItem.Create Constructor

Creates an instance of TDataBindItem (see page 9806).

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TDataBindItem(TCollection Collection);
```

Description

Do not create an instance of TDataBindItem (see page 9806) directly. Instead, an instance is created when the Add method of the TDataBindings (see page 9802) object is called.

See Also

Add (see page 9804)

51.1.2.3 TDataBindItem.Destroy Destructor

Destroys the TDataBindItem (see page 9806) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataBindItem();
```

Description

Destroy is called indirectly by TCollection's Clear method.

See Also

Free (see page 22300)

51.1.2.4 TDataBindItem Properties

The properties of the TDataBindItem class are listed here.

Published Properties

	Name	Description
	DataField (see page 9809)	Represents the name of the field to be bound.
	DispID (see page 9809)	The identifier (DispID) of the data-aware control property to be bound.

51.1.2.4.1 TDataBindItem.DataField Property

Represents the name of the field to be bound.

Pascal

```
property DataField: string;
```

C++

```
__property AnsiString DataField;
```

Description

DataField relates a property in a data-aware ActiveX control to a specific field in the dataset. The dataset is specified by the DataSource property of TDBOleControl (see page 9810) object.

See Also

DataSource (see page 9825)

TDataBindings (see page 9802)

51.1.2.4.2 TDataBindItem.DispID Property

The identifier (DispID) of the data-aware control property to be bound.

Pascal

```
property DispID: TDispID;
```

C++

```
__property TDispID DispID;
```

Description

Every data-aware property in an ActiveX control has a unique DispID. The collection of databindings is represented by the DataBindings property of TDBOleControl (see page 9810) object.

See Also

DataBindings (see page 9825)

TDataBindings (see page 9802)

51.1.3 TDBOleControl Class

Supports simple data binding for ActiveX controls.

Class Hierarchy

Pascal

```
TDBOleControl = class(TOleControl);
```

C++

```
class TDBOleControl : public TOleControl;
```

File

DBOleCtl

Description

Use TBDOleControl to import ActiveX controls that contain simple bindable properties. With simple data binding, you can hook up properties of ActiveX controls to a data source.

Applications typically do not use TDBOleControl; it is available through the ActiveX control wizard and the ActiveForm wizard. Once you create an ActiveX control using either wizard, a type library is created. Edit the type library binding properties to add simple data binding to your applications.

51.1.3.1 TDBOleControl Members

The following tables list the members exposed by TDBOleControl.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_AddRef (see page 18046)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.

	_Release (see page 18047)	Called when an application releases a component interface.
	_SetColorProp (see page 18047)	This is _SetColorProp, a member of class TOleControl.
	_SetTColorProp (see page 18048)	This is _SetTColorProp, a member of class TOleControl.
	_SetTFontProp (see page 18048)	This is _SetTFontProp, a member of class TOleControl.
	_SetTOleEnumProp (see page 18048)	This is _SetTOleEnumProp, a member of class TOleControl.
	_SetTPictureProp (see page 18048)	This is _SetTPictureProp, a member of class TOleControl.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanInPlaceActivate (see page 18049)	This is CanInPlaceActivate, a member of class TOleControl.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ContextSensitiveHelp (see page 18049)	This is ContextSensitiveHelp, a member of class TOleControl.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CreateWnd (see page 18049)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DeactivateAndUndo (see page 18050)	This is DeactivateAndUndo, a member of class TOleControl.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.

	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 18050)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 18051)	Destroys the window created in the CreateWindowHandle method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DiscardUndoState (see page 18051)	This is DiscardUndoState, a member of class TOleControl.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EnableModeless (see page 18052)	This is EnableModeless, a member of class TOleControl.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorder (see page 18052)	This is GetBorder, a member of class TOleControl.
	GetByteProp (see page 18052)	This is GetByteProp, a member of class TOleControl.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.

	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetColorProp (see page 18053)	This is GetColorProp, a member of class TOleControl.
	GetCompProp (see page 18053)	This is GetCompProp, a member of class TOleControl.
	GetContainer (see page 18053)	This is GetContainer, a member of class TOleControl.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetCurrencyProp (see page 18053)	This is GetCurrencyProp, a member of class TOleControl.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDoubleProp (see page 18053)	This is GetDoubleProp, a member of class TOleControl.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetExtendedControl (see page 18054)	This is GetExtendedControl, a member of class TOleControl.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDispatchProp (see page 18055)	This is GetIDispatchProp, a member of class TOleControl.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIDsOfNames (see page 18055)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIntegerProp (see page 18055)	This is GetIntegerProp, a member of class TOleControl.
	GetIUnknownProp (see page 18055)	This is GetIUnknownProp, a member of class TOleControl.
	GetMoniker (see page 18056)	This is GetMoniker, a member of class TOleControl.
	GetOleBoolProp (see page 18056)	This is GetOleBoolProp, a member of class TOleControl.
	GetOleDateProp (see page 18056)	This is GetOleDateProp, a member of class TOleControl.
	GetOleEnumProp (see page 18057)	This is GetOleEnumProp, a member of class TOleControl.
	GetOleVariantProp (see page 18057)	This is GetOleVariantProp, a member of class TOleControl.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetProperty (see page 18058)	This is GetProperty, a member of class TOleControl.
	GetShortIntProp (see page 18058)	This is GetShortIntProp, a member of class TOleControl.
	GetSingleProp (see page 18058)	This is GetSingleProp, a member of class TOleControl.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetSmallintProp (see page 18058)	This is GetSmallintProp, a member of class TOleControl.
	GetStringProp (see page 18059)	This is GetStringProp, a member of class TOleControl.
	GetTColorProp (see page 18059)	This is GetTColorProp, a member of class TOleControl.
	GetTDateTimeProp (see page 18059)	This is GetTDateTimeProp, a member of class TOleControl.
	GetTFontProp (see page 18059)	This is GetTFontProp, a member of class TOleControl.
	GetTOleEnumProp (see page 18059)	This is GetTOleEnumProp, a member of class TOleControl.
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTPictureProp (see page 18060)	This is GetTPictureProp, a member of class TOleControl.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfo (see page 18060)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetTypeInfoCount (see page 18060)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetVariantProp (see page 18061)	This is GetVariantProp, a member of class TOleControl.
	GetWideStringProp (see page 18061)	This is GetWideStringProp, a member of class TOleControl.
	GetWindowContext (see page 18061)	This is GetWindowContext, a member of class TOleControl.

	GetWordBoolProp (see page 18061)	This is GetWordBoolProp, a member of class TOleControl.
	GetWordProp (see page 18062)	This is GetWordProp, a member of class TOleControl.
A	InitControlData (see page 18062)	This is InitControlData, a member of class TOleControl.
V	InitControlInterface (see page 18062)	This is InitControlInterface, a member of class TOleControl.
	InsertMenus (see page 18062)	This is InsertMenus, a member of class TOleControl.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Invoke (see page 18062)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	InvokeEvent (see page 18063)	This is InvokeEvent, a member of class TOleControl.
	InvokeMethod (see page 18063)	This is InvokeMethod, a member of class TOleControl.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	LockInPlaceActive (see page 18064)	This is LockInPlaceActive, a member of class TOleControl.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 9824)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	OleControlSite_TranslateAccelerator (see page 18064)	This is OleControlSite_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceFrame_GetWindow (see page 18064)	This is OleInPlaceFrame_GetWindow, a member of class TOleControl.
	OleInPlaceFrame_TranslateAccelerator (see page 18065)	This is OleInPlaceFrame_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceSite_GetWindow (see page 18065)	This is OleInPlaceSite_GetWindow, a member of class TOleControl.
V	OnChanged (see page 9824)	This is OnChanged, a member of class TDBOleControl.
	OnControlInfoChanged (see page 18065)	This is OnControlInfoChanged, a member of class TOleControl.
	OnFocus (see page 18066)	This is OnFocus, a member of class TOleControl.
	OnInPlaceActivate (see page 18066)	This is OnInPlaceActivate, a member of class TOleControl.
	OnInPlaceDeactivate (see page 18066)	This is OnInPlaceDeactivate, a member of class TOleControl.
	OnPosRectChange (see page 18066)	This is OnPosRectChange, a member of class TOleControl.
V	OnRequestEdit (see page 9825)	This is OnRequestEdit, a member of class TDBOleControl.
	OnShowWindow (see page 18067)	This is OnShowWindow, a member of class TOleControl.
	OnUIActivate (see page 18067)	This is OnUIActivate, a member of class TOleControl.
	OnUIDeactivate (see page 18067)	This is OnUIDeactivate, a member of class TOleControl.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	PaletteChanged (see page 18067)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PictureChanged (see page 18068)	This is PictureChanged, a member of class TOleControl.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	PostMessageFilter (see page 18068)	This is PostMessageFilter, a member of class TOleControl.

	PreMessageFilter (see page 18069)	This is PreMessageFilter, a member of class TOleControl.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 18069)	Returns a reference to a specified interface if the object supports that interface.
	QueryService (see page 18069)	This is QueryService, a member of class TOleControl.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveMenus (see page 18070)	This is RemoveMenus, a member of class TOleControl.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	RequestBorderSpace (see page 18070)	This is RequestBorderSpace, a member of class TOleControl.
	RequestNewObjectLayout (see page 18070)	This is RequestNewObjectLayout, a member of class TOleControl.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	SaveObject (see page 18070)	This is SaveObject, a member of class TOleControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	Scroll (see page 18070)	This is Scroll, a member of class TOleControl.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetActiveObject (see page 18071)	This is SetActiveObject, a member of class TOleControl.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetBorderSpace (see page 18071)	This is SetBorderSpace, a member of class TOleControl.
	SetByteProp (see page 18071)	This is SetByteProp, a member of class TOleControl.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetColorProp (see page 18072)	This is SetColorProp, a member of class TOleControl.
	SetCompProp (see page 18072)	This is SetCompProp, a member of class TOleControl.
	SetCurrencyProp (see page 18072)	This is SetCurrencyProp, a member of class TOleControl.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDoubleProp (see page 18072)	This is SetDoubleProp, a member of class TOleControl.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIDispatchProp (see page 18073)	This is SetIDispatchProp, a member of class TOleControl.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetIntegerProp (see page 18073)	This is SetIntegerProp, a member of class TOleControl.
	SetIUnknownProp (see page 18073)	This is SetIUnknownProp, a member of class TOleControl.
	SetMenu (see page 18073)	This is SetMenu, a member of class TOleControl.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.

	SetName (see page 5785)	Sets the name of the control.
	SetName (see page 18073)	Sets the name of the control.
	SetOleBoolProp (see page 18074)	This is SetOleBoolProp, a member of class TOleControl.
	SetOleDateProp (see page 18074)	This is SetOleDateProp, a member of class TOleControl.
	SetOleEnumProp (see page 18074)	This is SetOleEnumProp, a member of class TOleControl.
	SetOleVariantProp (see page 18075)	This is SetOleVariantProp, a member of class TOleControl.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParent (see page 18075)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetProperty (see page 18076)	This is SetProperty, a member of class TOleControl.
	SetShortIntProp (see page 18076)	This is SetShortIntProp, a member of class TOleControl.
	SetSingleProp (see page 18076)	This is SetSingleProp, a member of class TOleControl.
	SetSmallintProp (see page 18076)	This is SetSmallintProp, a member of class TOleControl.
	SetStatusText (see page 18077)	This is SetStatusText, a member of class TOleControl.
	SetStringProp (see page 18077)	This is SetStringProp, a member of class TOleControl.
	SetTColorProp (see page 18077)	This is SetTColorProp, a member of class TOleControl.
	SetTDateTimeProp (see page 18077)	This is SetTDateTimeProp, a member of class TOleControl.
	SetTFontProp (see page 18077)	This is SetTFontProp, a member of class TOleControl.
	SetTOleEnumProp (see page 18078)	This is SetTOleEnumProp, a member of class TOleControl.
	SetTPictureProp (see page 18078)	This is SetTPictureProp, a member of class TOleControl.
	SetVariantProp (see page 18078)	This is SetVariantProp, a member of class TOleControl.
	SetWideStringProp (see page 18078)	This is SetWideStringProp, a member of class TOleControl.
	SetWordBoolProp (see page 18079)	This is SetWordBoolProp, a member of class TOleControl.
	SetWordProp (see page 18079)	This is SetWordProp, a member of class TOleControl.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowObject (see page 18079)	This is ShowObject, a member of class TOleControl.
	ShowPropertyFrame (see page 18079)	This is ShowPropertyFrame, a member of class TOleControl.
	StandardEvent (see page 18080)	This is StandardEvent, a member of class TOleControl.
	SuppressException (see page 18080)	This is SuppressException, a member of class TOleControl.
	TransformCoords (see page 18080)	This is TransformCoords, a member of class TOleControl.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.

	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WndProc (see page 18080)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	ControlData (see page 18086)	This is ControlData, a member of class TOleControl.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	ServiceQuery (see page 18087)	This is ServiceQuery, a member of class TOleControl.
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	BrowseProperties (see page 18048)	Notifies the ActiveX control to display its Properties dialog box.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 9823)	Creates an instance of TDBOleControl (see page 9810).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 18050)	Handles all otherwise-unhandled messages.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 9823)	Destroys an instance of TDBOleControl (see page 9810).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DoObjectVerb (see page 18051)	Notifies the ActiveX control to perform one of its actions.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.

	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetEnumPropDesc (see page 18054)	Returns descriptions of the ActiveX control's properties.
	GetHelpContext (see page 18054)	Retrieves the Help context of a member of the ActiveX control.
	GetIDsOfNames (see page 22395)	This is GetIDsOfNames, a member of class IDispatch.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetObjectVerbs (see page 18056)	Retrieves the names of the verbs implemented by the ActiveX control.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetPropDisplayString (see page 18057)	Returns the display string for an interface for the ActiveX control.
	GetPropDisplayStrings (see page 18057)	Returns the display strings for an interface for the ActiveX control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	GetTypeInfo (see page 22395)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 22395)	This is GetTypeInfoCount, a member of class IDispatch.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	Invoke (see page 22395)	This is Invoke, a member of class IDispatch.
	IsCustomProperty (see page 18063)	Indicates whether an interface for the ActiveX control is a custom property.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsPropPageProperty (see page 18064)	Indicates whether an interface for the OCX control is a property page property.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetBounds (see page 18071)	Sets the boundaries of the ActiveX control.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.
	SetPropDisplayString (see page 18075)	Sets the display string for an interface for the ActiveX control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	ShowAboutBox (see page 18079)	Notifies the ActiveX control to display its About box.
	Update (see page 5789)	Processes any pending paint messages immediately.
	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	Anchors (see page 18085)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.

R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
R	DefaultDispatch (see page 18086)	The default dispatch interface.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	OleObject (see page 18086)	The ActiveX control associated with the TOleControl (see page 18030) object.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	PerPropBrowsing (see page 18086)	Provides access to information about the property page properties of the OleControl.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TabStop (see page 18087)	Determines if the user can tab to a control.

	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DataBindings (see page 9825)	Represents the data bindings between ActiveX control properties and fields in a dataset.
	DataSource (see page 9825)	Specifies the link to the dataset where the data-aware ActiveX control finds its data.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

51.1.3.2 TDBOleControl.Create Constructor

Creates an instance of TDBOleControl (see page 9810).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDBOleControl(TComponent * AOwner);
```

Description

Use Create to create a new instance of TDBOleControl (see page 9810) object. Create calls the inherited constructor, then creates and initializes TDataBinding objects.

See Also

Create (see page 18043)

DataBindings (see page 9825)

51.1.3.3 TDBOleControl.Destroy Destructor

Destroys an instance of TDBOleControl (see page 9810).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBOleControl();
```

Description

Do not call Destroy. Instead call Free, which calls Destroy if this TDBOleControl (see page 9810) reference is not nil.

See Also

Free (see page 22300)

51.1.3.4 TDBOleControl Methods

The methods of the TDBOleControl class are listed here.

Protected Methods

	Name	Description
	Notification (see page 9824)	Responds to notifications that components are being created or destroyed.
	OnChanged (see page 9824)	This is OnChanged, a member of class TDBOleControl.
	OnRequestEdit (see page 9825)	This is OnRequestEdit, a member of class TDBOleControl.

51.1.3.4.1 TDBOleControl.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

51.1.3.4.2 TDBOleControl.OnChanged Method

Pascal

```
function OnChanged(dispid: TDispID): HResult; override;
```

C++

```
virtual __fastcall HRESULT OnChanged(TDispID dispid);
```

Description

This is OnChanged, a member of class TDBOleControl.

51.1.3.4.3 TDBOleControl.OnRequestEdit Method

Pascal

```
function OnRequestEdit(dispid: TDispID): HResult; override;
```

C++

```
virtual __fastcall HRESULT OnRequestEdit(TDispID dispid);
```

Description

This is OnRequestEdit, a member of class TDBOleControl.

51.1.3.5 TDBOleControl Properties

The properties of the TDBOleControl class are listed here.

Published Properties

	Name	Description
	DataBindings (see page 9825)	Represents the data bindings between ActiveX control properties and fields in a dataset.
	DataSource (see page 9825)	Specifies the link to the dataset where the data-aware ActiveX control finds its data.

51.1.3.5.1 TDBOleControl.DataBindings Property

Represents the data bindings between ActiveX control properties and fields in a dataset.

Pascal

```
property DataBindings: TDataBindings;
```

C++

```
__property TDataBindings DataBindings;
```

Description

Use DataBindings to read or set the data bindings in a data-aware ActiveX control. DataBindings is a collection of TDataBindItem (see page 9806) objects. Use the properties of the TDataBindings (see page 9802) object to specify the data bindings of individual properties in the data-aware control.

Data bindings are typically set by editing the ActiveX control's type library.

See Also

DataSource (see page 9825)

51.1.3.5.2 TDBOleControl.DataSource Property

Specifies the link to the dataset where the data-aware ActiveX control finds its data.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Set DataSource to the TDataSource object that links to the dataset where the data-aware object should fetch its data. DataSource allows the data-aware control to read from, write to, and navigate around the dataset.

See Also

DataBindings (see page 9825)

52 DBPWDlg Namespace

This is namespace DBPWDlg.

Topics

Name	Description
Classes (see page 9828)	The following table lists classes in this documentation.
Functions (see page 9849)	The following table lists functions in this documentation.

Classes

	Name	Description
	TPasswordDialog (see page 9828)	TPasswordDialog is a dialog box that allows the user to specify passwords for the current BDE session.

Functions

	Name	Description
	PasswordDialog (see page 9849)	Displays a dialog box that prompts the user for the password of a local password-protected table.

52.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TPasswordDialog (see page 9828)	TPasswordDialog is a dialog box that allows the user to specify passwords for the current BDE session.

52.1.1 TPasswordDialog Class

TPasswordDialog is a dialog box that allows the user to specify passwords for the current BDE session.

Class Hierarchy

Pascal

```
TPasswordDialog = class(TForm);
```

C++

```
class TPasswordDialog : public TForm;
```

File

DBPWDlg

Description

Use TPasswordDialog to allow the user to specify passwords for the current session in a BDE-based application. (The current session is represented by a TSession object.) The passwords are used when the application opens a Paradox table that requires a password. If a table requires a password that has not been added to the current session, the user will be prompted for the password.

A TPasswordDialog object is usually created with the PasswordDialog (see page 9849) function. However, TPasswordDialog can also be used as a base object for other types of password dialog boxes.

See Also

PasswordDialog (see page 9849)

TLoginDialog (see page 9776)

TSession (see page 10093)

52.1.1.1 TPasswordDialog Members

The following tables list the members exposed by TPasswordDialog.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.

	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.

	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.

	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloating (see page 13877)	Returns the value of the Floating property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.

	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
V	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
V	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
V	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.

V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParent (see page 13887)	Sets the Parent property.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
V	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.

	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.

	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Fields

	Name	Description
	AddButton (see page 9845)	This is AddButton, a member of class TPasswordDialog.
	CancelButton (see page 9845)	This is CancelButton, a member of class TPasswordDialog.
	Edit (see page 9845)	This is Edit, a member of class TPasswordDialog.
	GroupBox1 (see page 9846)	This is GroupBox1, a member of class TPasswordDialog.
	OKButton (see page 9846)	This is OKButton, a member of class TPasswordDialog.
	RemoveAllButton (see page 9846)	This is RemoveAllButton, a member of class TPasswordDialog.
	RemoveButton (see page 9846)	This is RemoveButton, a member of class TPasswordDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddButtonClick (see page 9847)	Controls (see page 5711) what happens when the Add button is clicked.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	ArrangeIcons (see page 14006)	Arranges the icons of minimized MDI child forms.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	Cascade (see page 14007)	Arranges MDI child forms so they overlap.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.

	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 13861)	Creates and initializes a new TForm (see page 13992) object.
V	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EditChange (see page 9847)	Controls (see page 5711) what happens when the contents of the edit box change.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.

	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 14008)	Activates the next child form in the form sequence.
	OKButtonClick (see page 9848)	Controls (see page 5711) what happens when the OK button is clicked.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Previous (see page 14009)	Activates the previous MDI child form in the form sequence.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.

	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveAllButtonClick (see page 9848)	Removes all passwords from the current session.
	RemoveButtonClick (see page 9848)	Removes the password in the edit box from the current session.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
	Tile (see page 14009)	Arranges MDI child forms so that they are all the same size.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveMDIChild (see page 14013)	Specifies the MDI child that has focus.

	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	ClientHandle (see page 14024)	Provides access to the handle of the form's internal MDI client window.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockManager (see page 14029)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.

R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	MDIChildCount (see page 14044)	Specifies the number of open MDI child forms.
	MDIChildren (see page 14044)	Provides indexed access to all MDI child forms.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TileMode (see page 14059)	Represents how MDI child forms are arranged when the Tile method is called.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnActivate (see page 14065)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.

	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.
	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.
	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.

	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Menu (see page 14045)	Specifies the form's main menu.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.

	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.
	WindowState (see page 14063)	Represents how the form appears on the screen.

52.1.1.2 TPasswordDialog Fields

The fields of the TPasswordDialog class are listed here.

Public Fields

	Name	Description
	AddButton (see page 9845)	This is AddButton, a member of class TPasswordDialog.
	CancelButton (see page 9845)	This is CancelButton, a member of class TPasswordDialog.
	Edit (see page 9845)	This is Edit, a member of class TPasswordDialog.
	GroupBox1 (see page 9846)	This is GroupBox1, a member of class TPasswordDialog.
	OKButton (see page 9846)	This is OKButton, a member of class TPasswordDialog.
	RemoveAllButton (see page 9846)	This is RemoveAllButton, a member of class TPasswordDialog.
	RemoveButton (see page 9846)	This is RemoveButton, a member of class TPasswordDialog.

52.1.1.2.1 TPasswordDialog.AddButton Field

Pascal

```
AddButton: TButton;
```

C++

```
TButton AddButton;
```

Description

This is AddButton, a member of class TPasswordDialog.

52.1.1.2.2 TPasswordDialog.CancelButton Field

Pascal

```
CancelButton: TButton;
```

C++

```
TButton CancelButton;
```

Description

This is CancelButton, a member of class TPasswordDialog.

52.1.1.2.3 TPasswordDialog.Edit Field

Pascal

```
Edit: TEdit;
```

C++

```
TEdit Edit;
```

Description

This is Edit, a member of class TPasswordDialog.

52.1.1.2.4 TPasswordDialog.GroupBox1 Field

Pascal

```
GroupBox1: TGroupBox;
```

C++

```
TGroupBox GroupBox1;
```

Description

This is GroupBox1, a member of class TPasswordDialog.

52.1.1.2.5 TPasswordDialog.OKButton Field

Pascal

```
OKButton: TButton;
```

C++

```
TButton OKButton;
```

Description

This is OKButton, a member of class TPasswordDialog.

52.1.1.2.6 TPasswordDialog.RemoveAllButton Field

Pascal

```
RemoveAllButton: TButton;
```

C++

```
TButton RemoveAllButton;
```

Description

This is RemoveAllButton, a member of class TPasswordDialog.

52.1.1.2.7 TPasswordDialog.RemoveButton Field

Pascal

```
RemoveButton: TButton;
```

C++

```
TButton RemoveButton;
```

Description

This is RemoveButton, a member of class TPasswordDialog.

52.1.1.3 TPasswordDialog Methods

The methods of the TPasswordDialog class are listed here.

Public Methods

	Name	Description
	AddButtonClick (see page 9847)	Controls (see page 5711) what happens when the Add button is clicked.
	EditChange (see page 9847)	Controls (see page 5711) what happens when the contents of the edit box change.
	OKButtonClick (see page 9848)	Controls (see page 5711) what happens when the OK button is clicked.
	RemoveAllButtonClick (see page 9848)	Removes all passwords from the current session.
	RemoveButtonClick (see page 9848)	Removes the password in the edit box from the current session.

52.1.1.3.1 TPasswordDialog.AddButtonClick Method

Controls (see page 5711) what happens when the Add button is clicked.

Pascal

```
procedure AddButtonClick(Sender: TObject);
```

C++

```
__fastcall AddButtonClick(TObject * Sender);
```

Description

AddButtonClick adds the password in the edit box to the current session. Then AddButtonClick clears and sets focus to the edit box.

After the AddButtonClick method is called, the OK Button is enabled, regardless of whether the edit box currently contains a password.

See Also

OKButtonClick (see page 9848)

AddPassword (see page 10102)

52.1.1.3.2 TPasswordDialog.EditChange Method

Controls (see page 5711) what happens when the contents of the edit box change.

Pascal

```
procedure EditChange(Sender: TObject);
```

C++

```
__fastcall EditChange(TObject * Sender);
```

Description

EditChange enables or disables the Add, OK, and Remove buttons according to whether the edit box contains a password. If the edit box contains a password, the buttons are enabled. Otherwise the buttons are disabled.

Note: If the AddButtonClick (see page 9847) method has been called, then the OK button is enabled, regardless of whether the edit box contains a password.

See Also

AddButtonClick (see page 9847)

52.1.1.3.3 TPasswordDialog.OKButtonClick Method

Controls (see page 5711) what happens when the OK button is clicked.

Pascal

```
procedure OKButtonClick(Sender: TObject);
```

C++

```
__fastcall OKButtonClick(TObject * Sender);
```

Description

OKButtonClick adds the password in the edit box to the current session.

See Also

AddPassword (see page 10102)

52.1.1.3.4 TPasswordDialog.RemoveAllButtonClick Method

Removes all passwords from the current session.

Pascal

```
procedure RemoveAllButtonClick(Sender: TObject);
```

C++

```
__fastcall RemoveAllButtonClick(TObject * Sender);
```

Description

RemoveAllButtonClick removes all passwords from the current session. Then RemoveAllButtonClick sets focus to the edit box.

See Also

RemoveButtonClick (see page 9848)

RemoveAllPasswords (see page 10118)

52.1.1.3.5 TPasswordDialog.RemoveButtonClick Method

Removes the password in the edit box from the current session.

Pascal

```
procedure RemoveButtonClick(Sender: TObject);
```

C++

```
__fastcall RemoveButtonClick(TObject * Sender);
```

Description

RemoveButtonClick removes the password in the edit box from the current session. Then RemoveButtonClick clears and sets focus to the edit box.

See Also

RemoveAllButtonClick (see page 9848)

RemovePassword (see page 10118)

52.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	PasswordDialog (see page 9849)	Displays a dialog box that prompts the user for the password of a local password-protected table.

52.2.1 DBPWDlg.PasswordDialog Function

Displays a dialog box that prompts the user for the password of a local password-protected table.

Pascal

```
function PasswordDialog(const ASession: IDBSession): Boolean;
```

C++

```
Boolean PasswordDialog(const IDBSession ASession);
```

File

DBPWDlg

Description

Use PasswordDialog to allow the user to enter a password for a password-protected Paradox or dBase table.

ASession is the interface of a component that represents the session onto which the user logs in. Typically, this is the interface of a TSession component.

If the user clicks OK in the dialog box, PasswordDialog returns true. Otherwise it returns false.

Note: When an application opens a Paradox or dBASE table that requires a password, the user is prompted to enter a password unless the Session already has a valid password for that table.

53 DBTables Namespace

This is namespace DBTables.

Topics

Name	Description
Classes (see page 9854)	The following table lists classes in this documentation.
Functions (see page 10244)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 10251)	The following table lists structs, records, enums in this documentation.
Types (see page 10258)	The following table lists types in this documentation.
Variables (see page 10265)	The following table lists variables in this documentation.
Constants (see page 10267)	The following table lists constants in this documentation.

Classes

	Name	Description
	EDBEngineError (see page 9854)	EDBEngineError is the exception class for Borland (see page 1761) Database Engine errors.
	ENoResultSet (see page 9858)	ENoResultSet is the exception class for unsuccessful attempts to open a dataset query.
	TBatchMove (see page 9858)	TBatchMove performs database operations on groups of records or entire tables.
	TBDECallback (see page 9875)	TBDECallback is a wrapper for a Borland (see page 1761) Database Engine (BDE) callback function.
	TBDEDataSet (see page 9878)	Encapsulates Borland (see page 1761) Database Engine (BDE) functionality for descendant dataset objects.
	TBlobStream (see page 9958)	TBlobStream is a stream object that provides services which allow applications to read from or write to field objects that represent Binary large object (BLOB) fields.
	TDatabase (see page 9964)	TDatabase provides discrete control over a connection to a single database in a BDE-based database application.
	TDataSetUpdateObject (see page 9994)	TDataSetUpdateObject is a base class for update objects used to update otherwise unupdatable queries or stored procedures in applications that cache updates.
	TDBDataSet (see page 10000)	TDBDataSet encapsulates database connectivity for descendant dataset objects.
	TDBError (see page 10029)	TDBError represents Borland (see page 1761) Database Engine errors for the EDBEngineError (see page 9854) exception class.
	TIndexFiles (see page 10033)	This is class DBTables.TIndexFiles.
	TNestedTable (see page 10040)	TNestedTable encapsulates a dataset that is nested as a field within another table.
	TParamList (see page 10056)	TParamList manages a list of session parameters.
	TQuery (see page 10059)	TQuery represents a dataset with a result set that is based on an SQL (see page 10089) statement.

	TSession (see page 10093)	TSession provides global management of a group of database connections in an application.
	TSessionList (see page 10129)	TSessionList manages one or more Borland (see page 1761) Database Engine (BDE) sessions in a database application.
	TSQLUpdateObject (see page 10135)	TSQLUpdateObject is the base class for classes that use an SQL command to apply cached updates on behalf of queries or stored procedures that can't post updates directly.
	TStoredProc (see page 10139)	TStoredProc encapsulates a stored procedure in a BDE-based application.
	TTable (see page 10168)	TTable encapsulates a database table.
	TUpdateSQL (see page 10229)	TUpdateSQL applies cached updates on behalf of queries or stored procedures that can't post updates directly.

Constants

Name	Description
BlobTypeMap (see page 10267)	This is constant DBTables.BlobTypeMap.
cmAll (see page 10268)	This is constant DBTables.cmAll.
cmPersistent (see page 10268)	This is constant DBTables.cmPersistent.
cmSession (see page 10268)	This is constant DBTables.cmSession.
cmVirtual (see page 10269)	This is constant DBTables.cmVirtual.
DataTypeMap (see page 10269)	This is constant DBTables.DataTypeMap.
dbfDatabase (see page 10269)	This is constant DBTables.dbfDatabase.
dbfExecProc (see page 10270)	This is constant DBTables.dbfExecProc.
dbfExecSQL (see page 10270)	This is constant DBTables.dbfExecSQL.
dbfFieldList (see page 10270)	This is constant DBTables.dbfFieldList.
dbfIndexList (see page 10271)	This is constant DBTables.dbfIndexList.
dbfOpened (see page 10271)	This is constant DBTables.dbfOpened.
dbfPrepared (see page 10271)	This is constant DBTables.dbfPrepared.
dbfProcDesc (see page 10272)	This is constant DBTables.dbfProcDesc.
dbfProvider (see page 10272)	This is constant DBTables.dbfProvider.
dbfStoredProc (see page 10272)	This is constant DBTables.dbfStoredProc.
dbfTable (see page 10273)	This is constant DBTables.dbfTable.
FldSubTypeMap (see page 10273)	This is constant DBTables.FldSubTypeMap.
FldTypeMap (see page 10273)	This is constant DBTables.FldTypeMap.
smTraceBufSize (see page 10274)	This is constant DBTables.smTraceBufSize.

Functions

	Name	Description
	AnsiToNative (see page 10244)	Converts a string from the ANSI character set to the character set associated with a given locale.
	AnsiToNativeBuf (see page 10245)	Converts a string from the ANSI character set to the character set associated with a given locale.
	Check (see page 10245)	Determines whether a value returned from the Borland (see page 1761) Database Engine (BDE) represents an error condition.
	DbiError (see page 10246)	Creates and raises an EDBEngineError (see page 9854) exception for an error code returned by the Borland (see page 1761) Database Engine (BDE).
	GetFieldSource (see page 10246)	This is function DBTables.GetFieldSource.
	NativeCompareStr (see page 10246)	Compares strings based on a database locale case sensitively.
	NativeCompareStrBuf (see page 10247)	Compares null-terminated strings based on a database locale case sensitively.
	NativeCompareText (see page 10248)	Compares strings based on a database locale without case sensitivity.
	NativeCompareTextBuf (see page 10248)	Compares null-terminated strings based on a database locale and is not case sensitive.
	NativeToAnsi (see page 10249)	Converts a string from the character set of the given locale to the ANSI character set.
	NativeToAnsiBuf (see page 10249)	Converts a string from the character set of a specified locale into the ANSI character set.
	RegisterBDEInitProc (see page 10250)	This is function DBTables.RegisterBDEInitProc.

Structs, Records, Enums

	Name	Description
	TBatchMode (see page 10251)	TBatchMode indicates the type of batch operation to be performed on a database table.
	TBDEKeyBuffer (see page 10252)	This is record DBTables.TBDEKeyBuffer.
	TBDERecInfo (see page 10252)	This is record DBTables.TBDERecInfo.
	TConfigModes (see page 10253)	This is record DBTables.TConfigModes.
	TDatabaseEvent (see page 10253)	This is record DBTables.TDatabaseEvent.
	TLockType (see page 10254)	Indicates how a Paradox or dBASE table can be locked.
	TParamBindMode (see page 10254)	This is record DBTables.TParamBindMode.
	TRecNoStatus (see page 10255)	This is record DBTables.TRecNoStatus.
	TServerDesc (see page 10255)	This is record DBTables.TServerDesc.
	TTableType (see page 10256)	This is record DBTables.TTableType.
	TTraceFlag (see page 10256)	This is record DBTables.TTraceFlag.
	TTransIsolation (see page 10257)	This is record DBTables.TTransIsolation.

Types

Name	Description
PKeyBuffer (see page 10258)	This is type DBTables.PKeyBuffer.
PRecInfo (see page 10258)	This is type DBTables.PRecInfo.
TBDECallbackEvent (see page 10259)	This is type DBTables.TBDECallbackEvent.
TBDEInitProc (see page 10259)	This is type DBTables.TBDEInitProc.
TBlobDataArray (see page 10259)	This is type DBTables.TBlobDataArray.
TConfigMode (see page 10260)	This is type DBTables.TConfigMode.
TDatabaseLoginEvent (see page 10260)	This is type DBTables.TDatabaseLoginEvent.
TDatabaseNotifyEvent (see page 10260)	This is type DBTables.TDatabaseNotifyEvent.
TDBFlags (see page 10261)	This is type DBTables.TDBFlags.
TFieldDescList (see page 10261)	This is type DBTables.TFieldDescList.
TIndexDescList (see page 10261)	This is type DBTables.TIndexDescList.
TIndexName (see page 10262)	This is type DBTables.TIndexName.
TLocale (see page 10262)	TLocale is the type for the Locale or DBLocale property.
TPasswordEvent (see page 10262)	This is type DBTables.TPasswordEvent.
TServerDescList (see page 10263)	This is type DBTables.TServerDescList.
TSPParamDescList (see page 10263)	This is type DBTables.TSPParamDescList.
TTraceFlags (see page 10263)	TTraceFlags and TTraceFlags indicate the types of messages that pass between an application and the InterBase server.
TValCheckList (see page 10264)	This is type DBTables.TValCheckList.

Variables

Name	Description
GetObjectContextProc (see page 10265)	This is variable DBTables.GetObjectContextProc.
Session (see page 10265)	Maintains database components used by an application.
Sessions (see page 10266)	Provides access to TSessionList (see page 10129) methods and properties.

53.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EDBEngineError (see page 9854)	EDBEngineError is the exception class for Borland (see page 1761) Database Engine errors.
	ENoResultSet (see page 9858)	ENoResultSet is the exception class for unsuccessful attempts to open a dataset query.
	TBatchMove (see page 9858)	TBatchMove performs database operations on groups of records or entire tables.
	TBDECallback (see page 9875)	TBDECallback is a wrapper for a Borland (see page 1761) Database Engine (BDE) callback function.
	TBDEDataSet (see page 9878)	Encapsulates Borland (see page 1761) Database Engine (BDE) functionality for descendant dataset objects.
	TBlobStream (see page 9958)	TBlobStream is a stream object that provides services which allow applications to read from or write to field objects that represent Binary large object (BLOB) fields.
	TDatabase (see page 9964)	TDatabase provides discrete control over a connection to a single database in a BDE-based database application.
	TDataSetUpdateObject (see page 9994)	TDataSetUpdateObject is a base class for update objects used to update otherwise unupdatable queries or stored procedures in applications that cache updates.
	TDBDataSet (see page 10000)	TDBDataSet encapsulates database connectivity for descendant dataset objects.
	TDBError (see page 10029)	TDBError represents Borland (see page 1761) Database Engine errors for the EDBEngineError (see page 9854) exception class.
	TIndexFiles (see page 10033)	This is class DBTables.TIndexFiles.
	TNestedTable (see page 10040)	TNestedTable encapsulates a dataset that is nested as a field within another table.
	TParamList (see page 10056)	TParamList manages a list of session parameters.
	TQuery (see page 10059)	TQuery represents a dataset with a result set that is based on an SQL (see page 10089) statement.
	TSession (see page 10093)	TSession provides global management of a group of database connections in an application.
	TSessionList (see page 10129)	TSessionList manages one or more Borland (see page 1761) Database Engine (BDE) sessions in a database application.
	TSQLUpdateObject (see page 10135)	TSQLUpdateObject is the base class for classes that use an SQL command to apply cached updates on behalf of queries or stored procedures that can't post updates directly.
	TStoredProc (see page 10139)	TStoredProc encapsulates a stored procedure in a BDE-based application.
	TTable (see page 10168)	TTable encapsulates a database table.
	TUpdateSQL (see page 10229)	TUpdateSQL applies cached updates on behalf of queries or stored procedures that can't post updates directly.

53.1.1 EDBEngineError Class

EDBEngineError is the exception class for Borland (see page 1761) Database Engine errors.

Class Hierarchy

System::TObject → SysUtils.Exception → DB.EDatabaseError → DBTables.EDBEngineError

Pascal

```
EDBEngineError = class(EDatabaseError);
```

C++

```
class EDBEngineError : public EDatabaseError;
```

File

DBTables

Description

EDBEngineError is raised whenever a BDE error occurs. Its Errors (see page 9857) property contains TDBError (see page 10029) objects.

When EDBEngineError exceptions are raised at design time, they appear in a special dialog (in Delphi, TDBEngineErrorDlg) that displays the complete stack of BDE errors. At runtime, unhandled EDBEngineError exceptions generate the same message box as other exceptions.

See Also

TDBError (see page 10029)

TDbEngineErrorDlg (see page 9546)

DBIError

53.1.1.1 EDBEngineError Members

The following tables list the members exposed by EDBEngineError.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 9856)	Creates an instance of EDBEngineError (see page 9854) using a specified BDE error code.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 9856)	Disposes of the EDBEngineError (see page 9854) instance and each TDBError (see page 10029) instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	ErrorCount (see page 9857)	Indicates the total number of errors contained in the Errors (see page 9857) property.
R	Errors (see page 9857)	Lists the entire Borland (see page 1761) Database Engine error stack.
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

53.1.1.2 EDBEngineError.Create Constructor

Creates an instance of EDBEngineError (see page 9854) using a specified BDE error code.

Pascal

```
constructor Create(ErrorCode: DBIResult);
```

C++

```
__fastcall EDBEngineError(DBIResult ErrorCode);
```

Description

Create calls the Create method inherited from Exception (using an empty string) to construct an initialized instance of EDBEngineError (see page 9854). It then creates a TDBError (see page 10029) instance for each error in the BDE error stack and builds a single string containing all the error messages. If the BDE is uninitialized when Create is called, the method generates only one generic error message and one TDBError (see page 10029) instance.

See Also

Exception (see page 22750)

Create (see page 22752)

TDBError (see page 10029)

53.1.1.3 EDBEngineError.Destroy Destructor

Disposes of the EDBEngineError (see page 9854) instance and each TDBError (see page 10029) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~EDBEngineError();
```

Description

Destroy first disposes of each TDBError (see page 10029) instance referenced in the Errors (see page 9857) property, then calls the inherited destructor to dispose of the EDBEngineError (see page 9854) instance itself.

See Also

TDBError (see page 10029)

Errors (see page 9857)

Free (see page 22300)

53.1.1.4 EDBEngineError Properties

The properties of the EDBEngineError class are listed here.

Public Properties

	Name	Description
R	ErrorCount (see page 9857)	Indicates the total number of errors contained in the Errors (see page 9857) property.
R	Errors (see page 9857)	Lists the entire Borland (see page 1761) Database Engine error stack.

53.1.1.4.1 EDBEngineError.ErrorCount Property

Indicates the total number of errors contained in the Errors (see page 9857) property.

Pascal

```
property ErrorCount: Integer;
```

C++

```
__property int ErrorCount;
```

Description

Use ErrorCount as an upper bound when iterating through the errors in the error stack.

See Also

Errors (see page 9857)

53.1.1.4.2 EDBEngineError.Errors Property

Lists the entire Borland (see page 1761) Database Engine error stack.

Pascal

```
property Errors [Index: Integer]: TDBError;
```

C++

```
__property TDBError Errors[int Index];
```

Description

Errors is an index of TDBError (see page 10029) objects. The first error has an index value of 0.

See Also

TDBError (see page 10029)

53.1.2 ENoResultSet Class

ENoResultSet is the exception class for unsuccessful attempts to open a dataset query.

Class Hierarchy

Pascal

```
ENoResultSet = class(EDatabaseError);
```

C++

```
class ENoResultSet : public EDatabaseError;
```

File

DBTables

Description

ENoResultSet is raised by TQuery (see page 10059) when an attempt is made to open the query without a SELECT statement.

See Also

TQuery (see page 10059)

TDataSet (see page 6894)

53.1.3 TBatchMove Class

TBatchMove performs database operations on groups of records or entire tables.

Class Hierarchy

Pascal

```
TBatchMove = class(TComponent);
```

C++

```
class TBatchMove : public TComponent;
```

File

DBTables

Description

Use a TBatchMove object to

Add the records in a dataset to a database table.

Delete the records in a dataset from a database table.

Copy a dataset to create a new database table or overwrite an existing table.

Set the Mode (see page 9871) property to specify the desired operation. The Source (see page 9874) and Destination (see page 9868) properties indicate the datasets whose records are added, deleted, or copied. Other properties further specify how to perform the operation and how to handle problems that TBatchMove encounters when performing its operation. Once you have set properties to indicate what you want to do, call the Execute (see page 9863) method to perform the actual operation.

Note: TTable (see page 10168) objects can also perform the same batch operations, but only using the options specified by the default TBatchMove property values.

Tip: Applications can use a TBDECallback (see page 9875) object to further refine the response to problems that arise.

TBDECallback (see page 9875)

TTable (see page 10168)

Creating a Batch Move Component

Using TBatchMove

Handling Batch Move Errors

53.1.3.1 TBatchMove Members

The following tables list the members exposed by TBatchMove.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.

	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 9864)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 9862)	Creates an instance of TBatchMove (see page 9858).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 9863)	Destroys an instance of TBatchMove (see page 9858).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 9863)	Performs the batch operation specified by Mode (see page 9871).
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.

	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ChangedCount (see page 9866)	Indicates the number of records from the Destination (see page 9868) table that are altered as a result of the batch operation.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	KeyViolCount (see page 9869)	Reports the number of records which could not be replaced, added, or deleted from Destination (see page 9868) because of integrity or key violations.
R	MovedCount (see page 9872)	Reports the number of records form the Source (see page 9874) which were applied to the destination.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ProblemCount (see page 9872)	Indicates the number of records which could not be added to Destination (see page 9868) without loss of data due to a field type mismatch.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	AbortOnKeyViol (see page 9865)	Specifies whether the batch operation is terminated immediately when integrity or key violations occur.
	AbortOnProblem (see page 9866)	Specifies whether the batch operation is terminated immediately when it is necessary to truncate data to make it fit in the specified Destination (see page 9868).
	ChangedTableName (see page 9867)	Specifies the name of a local Paradox table that is created to hold copies of all records from the destination table changed by the batch operation.
	CommitCount (see page 9867)	Specifies how many records are batch moved before a commit occurs.
	Destination (see page 9868)	Specifies the TTable (see page 10168) object for the database table that is the destination of the batch operation.
	KeyViolTableName (see page 9869)	Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that cannot participate in the batch operation because of integrity or key violations.
	Mappings (see page 9870)	Specifies the column mappings for a batch operation.
	Mode (see page 9871)	Specifies what the TBatchMove (see page 9858) object does when the Execute (see page 9863) method is called.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ProblemTableName (see page 9873)	Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that contain fields which were trimmed to match the corresponding field type in the Destination (see page 9868) table.
	RecordCount (see page 9873)	Specifies the maximum number of records that are applied to the Destination (see page 9868) when Execute (see page 9863) is called.
	Source (see page 9874)	Specifies the dataset that is the source of the batch operation.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Transliterate (see page 9875)	Specifies whether the data in the Source (see page 9874) records should be converted form the locale of the Source (see page 9874) to the locale of the Destination (see page 9868) when the Execute (see page 9863) method is called.

53.1.3.2 TBatchMove.Create Constructor

Creates an instance of TBatchMove (see page 9858).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBatchMove(TComponent * AOwner);
```

Description

Call Create to create an instance of TBatchMove (see page 9858) for performing a batch operation. Create allocates the memory for the TBatchMove (see page 9858) object and

Sets AbortOnKeyViol (see page 9865) to true.

Sets AbortOnProblem (see page 9866) to true.

Sets Transliterate (see page 9875) to true.

Creates a TStringList object to hold the Mappings (see page 9870).

The property settings made by Create are the values used when a TTable (see page 10168) object performs batch operations using its BatchMove method.

See Also

AbortOnKeyViol (see page 9865)

AbortOnProblem (see page 9866)

Mappings (see page 9870)

Transliterate (see page 9875)

BatchMove (see page 10186)

53.1.3.3 TBatchMove.Destroy Destructor

Destroys an instance of TBatchMove (see page 9858).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBatchMove();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the TBatchMove (see page 9858) object is not nil before calling Destroy.Before calling the inherited destructor, Destroy frees the TStringList object that implements the Mappings (see page 9870) property.

See Also

Free (see page 22300)

Mappings (see page 9870)

53.1.3.4 TBatchMove Methods

The methods of the TBatchMove class are listed here.

Protected Methods

	Name	Description
	Notification (see page 9864)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	Execute (see page 9863)	Performs the batch operation specified by Mode (see page 9871).

53.1.3.4.1 TBatchMove.Execute Method

Performs the batch operation specified by Mode (see page 9871).

Pascal

```
procedure Execute;
```

C++

```
__fastcall Execute();
```

Description

After setting properties to indicate what batch operation should be performed and how, call Execute to perform the operation. As a minimum, the Mode (see page 9871), Source (see page 9874), and Destination (see page 9868) properties must be set.

After calling Execute, the values of the ChangedCount (see page 9866), KeyViolCount (see page 9869), MovedCount (see page 9872), ProblemCount (see page 9872), and RecordCount (see page 9873) properties will become available.

These properties will give an indication of what happened as a result of the call to Execute. Additional information about the batch operation will be available through the creation of a changed table, a keyviol table, and/or a problems table if it was requested.

See Also

ChangedCount (see page 9866)

KeyViolCount (see page 9869)

MovedCount (see page 9872)

ProblemCount (see page 9872)

RecordCount (see page 9873)

Source (see page 9874)

Destination (see page 9868)

Executing a Batch Move

53.1.3.4.2 TBatchMove.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

53.1.3.5 TBatchMove Properties

The properties of the TBatchMove class are listed here.

Public Properties

	Name	Description
R	ChangedCount (see page 9866)	Indicates the number of records from the Destination (see page 9868) table that are altered as a result of the batch operation.
R	KeyViolCount (see page 9869)	Reports the number of records which could not be replaced, added, or deleted from Destination (see page 9868) because of integrity or key violations.
R	MovedCount (see page 9872)	Reports the number of records form the Source (see page 9874) which were applied to the destination.
R	ProblemCount (see page 9872)	Indicates the number of records which could not be added to Destination (see page 9868) without loss of data due to a field type mismatch.

Published Properties

	Name	Description
	AbortOnKeyViol (see page 9865)	Specifies whether the batch operation is terminated immediately when integrity or key violations occur.
	AbortOnProblem (see page 9866)	Specifies whether the batch operation is terminated immediately when it is necessary to truncate data to make it fit in the specified Destination (see page 9868).
	ChangedTableName (see page 9867)	Specifies the name of a local Paradox table that is created to hold copies of all records from the destination table changed by the batch operation.
	CommitCount (see page 9867)	Specifies how many records are batch moved before a commit occurs.
	Destination (see page 9868)	Specifies the TTable (see page 10168) object for the database table that is the destination of the batch operation.
	KeyViolTableName (see page 9869)	Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that cannot participate in the batch operation because of integrity or key violations.
	Mappings (see page 9870)	Specifies the column mappings for a batch operation.
	Mode (see page 9871)	Specifies what the TBatchMove (see page 9858) object does when the Execute (see page 9863) method is called.
	ProblemTableName (see page 9873)	Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that contain fields which were trimmed to match the corresponding field type in the Destination (see page 9868) table.
	RecordCount (see page 9873)	Specifies the maximum number of records that are applied to the Destination (see page 9868) when Execute (see page 9863) is called.
	Source (see page 9874)	Specifies the dataset that is the source of the batch operation.
	Transliterate (see page 9875)	Specifies whether the data in the Source (see page 9874) records should be converted form the locale of the Source (see page 9874) to the locale of the Destination (see page 9868) when the Execute (see page 9863) method is called.

53.1.3.5.1 TBatchMove.AbortOnKeyViol Property

Specifies whether the batch operation is terminated immediately when integrity or key violations occur.

Pascal

```
property AbortOnKeyViol: Boolean;
```

C++

```
__property Boolean AbortOnKeyViol;
```

Description

Set AbortOnKeyViol to true to cancel the batch operation when it causes integrity or key violations in the destination table. Set AbortOnKeyViol to false to cause records that would cause integrity or key violations to be posted to a key violations table instead. Provide a KeyViolTableName (see page 9869) when setting AbortOnKeyViol to false. If there is no KeyViolTableName (see page 9869), AbortOnKeyViol may still be set to false, in which case problem records are counted but not saved in a table.

Key violations occur when appending records to a table that has a primary key. On a table with a primary key, no two records may have the same values on all of the key fields. If a record that is being appended has the same values on all the key fields as

a record in the destination table, it cannot be appended.

Integrity violations occur when deleting, appending or updating records to a table that has a referential integrity specification. A referential integrity specification requires that certain fields in one table must have values that exist in a particular field of another table. If a record that is being added does not match the restrictions imposed by referential integrity, it cannot be added. If deleting record would cause tighter referential integrity restrictions that another table cannot meet, it cannot be deleted.

See Also

KeyViolCount (see page 9869)

KeyViolTableName (see page 9869)

Handling Batch Move Errors

53.1.3.5.2 TBatchMove.AbortOnProblem Property

Specifies whether the batch operation is terminated immediately when it is necessary to truncate data to make it fit in the specified Destination (see page 9868).

Pascal

```
property AbortOnProblem: Boolean;
```

C++

```
__property Boolean AbortOnProblem;
```

Description

Set AbortOnProblem to true to cancel the batch operation when types of the fields in the Source (see page 9874) table records do not match the types of the fields in the Destination (see page 9868) table records. Set AbortOnProblem to false to cause the mismatched fields to be "trimmed". When AbortOnProblem is false, set the ProblemTableName (see page 9873) to have all the untrimmed versions of records that were trimmed saved to a separate table.

Trimming a field means converting its value to a value compatible with the destination field type. For example, if a field in the destination table holds a string of size 10 characters, and the corresponding field in the source table holds a string of size 15 characters, any values from the source table longer than 10 characters must be truncated. Values that cannot be converted will cause TBatchMove (see page 9858) to raise an exception.

Trimming does not occur when the Mode (see page 9871) property is set to batCopy. Trimming fields on a delete operation means that records in the destination table may be deleted that do not exactly match the values from the source table.

Note: To allow trimming on a field by field basis, use a TBDECallback (see page 9875) object.

Mode (see page 9871)

ProblemCount (see page 9872)

ProblemTableName (see page 9873)

TBDECallback (see page 9875)

Handling Batch Move Errors

53.1.3.5.3 TBatchMove.ChangedCount Property

Indicates the number of records from the Destination (see page 9868) table that are altered as a result of the batch operation.

Pascal

```
property ChangedCount: Longint;
```

C++

```
__property Longint ChangedCount;
```

Description

Use ChangedCount to learn the number of records in the Destination (see page 9868) table that are updated if the Mode (see page 9871) is batUpdate or batAppendUpdate, or to learn the number that are deleted if the Mode (see page 9871) is batDelete.

Set the ChangedTableName (see page 9867) property to save the unchanged versions of the altered records to a separate table. ChangedCount is then the number of records in that separate table.

See Also

ChangedTableName (see page 9867)

Destination (see page 9868)

Mode (see page 9871)

53.1.3.5.4 TBatchMove.ChangedTableName Property

Specifies the name of a local Paradox table that is created to hold copies of all records from the destination table changed by the batch operation.

Pascal

```
property ChangedTableName: TFileName;
```

C++

```
__property TFileName ChangedTableName;
```

Description

Set ChangedTableName to create a table that saves all unchanged versions of records that are changed by the batch operation. ChangedTableName must specify the name of a Paradox table. Setting ChangedTableName ensures that no information in the Destination (see page 9868) table gets lost when the records are altered or deleted.

When the Mode (see page 9871) property is batUpdate or batAppendUpdate, the new table will hold all records that were updated. When the Mode (see page 9871) property is batDelete, the new table will hold all records that were deleted.

The ChangedCount (see page 9866) property specifies the number of records in the new table.

See Also

ChangedCount (see page 9866)

Destination (see page 9868)

Mode (see page 9871)

Creating a Batch Move Component

Handling Batch Move Errors

53.1.3.5.5 TBatchMove.CommitCount Property

Specifies how many records are batch moved before a commit occurs.

Pascal

```
property CommitCount: Integer;
```

C++

```
__property int CommitCount;
```

Description

Use CommitCount to chunk batch operations into smaller operations. CommitCount allows an application to accommodate server transaction logs that are not big enough to handle the entire batch. Setting CommitCount to 0 will cause chunking into the number of records that will fit in 32Kb.

Note: If the Execute (see page 9863) method is called within an explicit transaction on the database containing the tables, CommitCount is ignored.

See Also

Execute (see page 9863)

Commit (see page 9971)

StartTransaction (see page 9977)

53.1.3.5.6 TBatchMove.Destination Property

Specifies the TTable (see page 10168) object for the database table that is the destination of the batch operation.

Pascal

```
property Destination: TTable;
```

C++

```
__property TTable Destination;
```

Description

Use Destination to indicate the database table that will be created or altered by the batch operation. The batch operation affects the Destination differently depending on the Mode (see page 9871):

Mode (see page 9871)	Effect on Destination
batAppend	Records are added to the destination table. No pre-existing records are altered. Destination table must already exist.
batUpdate	Records in the destination table with key fields matching the corresponding fields in the source are changed to match the source records. No new records are added. Destination table must already exist and must have an index defined.
batAppendUpdate	Records in the destination table with key fields matching the corresponding fields in the source are changed to match the source. Source (see page 9874) records that do not match key fields are added to the destination table. Destination table must already exist and must have an index defined.
batDelete	Records in the destination table that match the records in the source are deleted. Destination table must already exist and must have an index defined.
batCopy	Destination table is created to match the records in the source. If Destination already exists, it is replaced by the copy of the source.

See Also

Mode (see page 9871)

Source (see page 9874)

Creating a Batch Move Component

53.1.3.5.7 TBatchMove.KeyViolCount Property

Reports the number of records which could not be replaced, added, or deleted from Destination (see page 9868) because of integrity or key violations.

Pascal

```
property KeyViolCount: Longint;
```

C++

```
__property Longint KeyViolCount;
```

Description

Use KeyViolCount to learn the number of records form the Source (see page 9874) table that could not be applied to the Destination (see page 9868) table because of integrity or key violations. To obtain a table of the offending records from the Source (see page 9874) table, specify a KeyViolTableName (see page 9869).

Key violations occur when appending records to a table that has a primary key. On a table with a primary key, no two records may have the same values on all of the key fields. If a record that is being appended has the same values on all the key fields as a record in the destination table, it cannot be appended.

Integrity violations occur when deleting, appending or updating records to a table that has a referential integrity specification. A referential integrity specification requires that certain fields in one table must have values that exist in a particular field of another table. If a record that is being added does not match the restrictions imposed by referential integrity, it cannot be added. If deleting record would cause tighter referential integrity restrictions that another table cannot meet, it cannot be deleted.

Note: If AbortOnKeyViol (see page 9865) is true, KeyViolCount will never be greater than one, because the first violation will cause the batch operation to terminate.

See Also

AbortOnKeyViol (see page 9865)

Destination (see page 9868)

KeyViolTableName (see page 9869)

Mode (see page 9871)

Source (see page 9874)

53.1.3.5.8 TBatchMove.KeyViolTableName Property

Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that cannot participate in the batch operation because of integrity or key violations.

Pascal

```
property KeyViolTableName: TFileName;
```

C++

```
__property TFileName KeyViolTableName;
```

Description

Use KeyViolTableName to obtain a table of records that could not be applied to the Destination (see page 9868) table because of integrity or key violations. KeyViolCount (see page 9869) has the number of records in the table that is created.

Key violations occur when appending records to a table that has a primary key. On a table with a primary key, no two records may have the same values on all of the key fields. If a record that is being appended has the same values on all the key fields as a record in the destination table, it cannot be appended.

Integrity violations occur when deleting, appending or updating records to a table that has a referential integrity specification. A referential integrity specification requires that certain fields in one table must have values that exist in a particular field of another table. If a record that is being added does not match the restrictions imposed by referential integrity, it cannot be added. If deleting record would cause tighter referential integrity restrictions that another table cannot meet, it cannot be deleted.

Note: If AbortOnKeyViol (see page 9865) is true, then there will be at most one record in this table because the operation aborts with that first record.

AbortOnKeyViol (see page 9865)

Destination (see page 9868)

KeyViolCount (see page 9869)

Source (see page 9874)

Creating a Batch Move Component

Handling Batch Move Errors

53.1.3.5.9 TBatchMove.Mappings Property

Specifies the column mappings for a batch operation.

Pascal

```
property Mappings: TStrings;
```

C++

```
__property TStrings Mappings;
```

Description

Set Mappings to specify the correspondence between fields in the Source (see page 9874) and fields in the Destination (see page 9868). By default TBatchMove (see page 9858) matches fields based on their position in the source and destination tables. That is, the first column in the source is matched with the first column in the destination, and so on. Mappings enables an application to override this default.

Mappings is a list of column mappings (one per line) in one of two forms. To map the column ColName in the source table to the column of the same name in the destination table, use:

```
ColName
```

To map the column named SourceColName in the source table to the column named DestColName in the destination table, use:

```
DestColName=SourceColName
```

When adding or appending records, fields in Destination (see page 9868) which have no entry in Mappings will be set to NULL. When copying a dataset, fields in Destination (see page 9868) which have no entry in Mappings will not appear as columns in the copy of the table.

If source and destination column data types are not the same, TBatchMove (see page 9858) can either cancel the batch

operation or perform a "best fit". If AbortOnProblem (see page 9866) is true, type mismatches will terminate the batch move. Otherwise, the field values from the Source (see page 9874) will be converted, if possible, to be compatible with the Destination (see page 9868).

See Also

AbortOnProblem (see page 9866)

Destination (see page 9868)

Mode (see page 9871)

Source (see page 9874)

Creating a Batch Move Component

Mapping Data Types

53.1.3.5.10 TBatchMove.Mode Property

Specifies what the TBatchMove (see page 9858) object does when the Execute (see page 9863) method is called.

Pascal

```
property Mode: TBatchMode;
```

C++

```
__property TBatchMode Mode;
```

Description

Use Mode to indicate whether the TBatchMove (see page 9858) object should add records, replace records, delete records, or copy the Source (see page 9874). These are the possible values for Mode:

Value	Meaning
batAppend	Append the records in the source to the destination table. The destination table must already exist, and the two tables must not have records with duplicate keys. This is the default mode.
batUpdate	Replace records in the destination table with matching records from the source table. The destination table must exist and must have an index defined to match records.
batAppendUpdate	If a matching record exists in the destination table, replace it. Otherwise, append records to the destination table. The destination table must exist and must have an index defined to match records.
batCopy	Create (see page 9862) the destination table based on the structure of the source table. If the destination already exists, the operation will delete it, and replace it with the new copy of the source.
batDelete	Delete records in the destination table that match records in the source table. The destination table must already exist and must have an index defined.

See Also

Destination (see page 9868)

Execute (see page 9863)

Source (see page 9874)

Creating a Batch Move Component

Specifying a Batch Move Mode

53.1.3.5.11 TBatchMove.MovedCount Property

Reports the number of records form the Source (see page 9874) which were applied to the destination.

Pascal

```
property MovedCount: Longint;
```

C++

```
__property Longint MovedCount;
```

Description

Read MovedCount to learn the number of records from the Source (see page 9874) that were read during the Execute (see page 9863) method. The MovedCount value includes any records which caused key or integrity violations, or which were trimmed.

See Also

Execute (see page 9863)

Source (see page 9874)

Executing a Batch Move

53.1.3.5.12 TBatchMove.ProblemCount Property

Indicates the number of records which could not be added to Destination (see page 9868) without loss of data due to a field type mismatch.

Pascal

```
property ProblemCount: Longint;
```

C++

```
__property Longint ProblemCount;
```

Description

Read ProblemCount to learn the number of records from the Source (see page 9874) that had field values which could not be mapped to destination fields without being "trimmed". If a ProblemTableName (see page 9873) is specified, ProblemCount is the number of records in that table.

Trimming a field means converting its value to a value compatible with the destination field type. For example, if a field in the destination table holds a string of size 10 characters, and the corresponding field in the source table holds a string of size 15 characters, any values from the source table longer than 10 characters must be truncated. Values that cannot be converted will cause TBatchMove (see page 9858) to raise an exception.

Trimming does not occur when the Mode (see page 9871) property is set to batCopy. Trimming fields on a delete operation means that records in the destination table may be deleted that do not exactly match the values from the source table.

Note: If AbortOnProblem (see page 9866) is true, then ProblemCount will be at most one, because the operation aborts when the problem occurs.

See Also

AbortOnProblem (see page 9866)

Destination (see page 9868)

Mode (see page 9871)

ProblemTableName (see page 9873)

Source (see page 9874)

Handling Batch Move Errors

53.1.3.5.13 TBatchMove.ProblemTableName Property

Specifies the name of a Paradox table that will be created to contain all records from the Source (see page 9874) that contain fields which were trimmed to match the corresponding field type in the Destination (see page 9868) table.

Pascal

```
property ProblemTableName: TFileName;
```

C++

```
__property TFileName ProblemTableName;
```

Description

Set ProblemTableName to create a table that holds records from the Source (see page 9874) that contain fields that had to be trimmed to be applied to the Destination (see page 9868). ProblemCount (see page 9872) will have the number of records placed in the new table. If ProblemTableName is not specified, the data in the record is still trimmed when applied to the destination table, but there will be no easy way to tell which fields were trimmed.

Trimming a field means converting its value to a value compatible with the destination field type. For example, if a field in the destination table holds a string of size 10 characters, and the corresponding field in the source table holds a string of size 15 characters, any values from the source table longer than 10 characters must be truncated. Values that cannot be converted will cause TBatchMove (see page 9858) to raise an exception.

Trimming does not occur when the Mode (see page 9871) property is set to batCopy. Trimming fields on a delete operation means that records in the destination table may be deleted that do not exactly match the values from the source table.

Note: If AbortOnProblem (see page 9866) is true, then there will be at most one record in this table because the operation aborts with the first record that has a problem.

See Also

AbortOnProblem (see page 9866)

Destination (see page 9868)

Mode (see page 9871)

ProblemCount (see page 9872)

Source (see page 9874)

Creating a Batch Move Component

Handling Batch Move Errors

53.1.3.5.14 TBatchMove.RecordCount Property

Specifies the maximum number of records that are applied to the Destination (see page 9868) when Execute (see page 9863) is called.

Pascal

```
property RecordCount: Longint;
```

C++

```
__property Longint RecordCount;
```

Description

Use RecordCount to limit the number of Source (see page 9874) records that are applied to the Destination (see page 9868). If zero, all records are added, subtracted, or copied, beginning with the first record in Source (see page 9874). If RecordCount is greater than zero, up to RecordCount records are applied to the Destination (see page 9868), starting with the current record in the dataset. If RecordCount exceeds the number of records remaining in Source (see page 9874), no wraparound occurs; the operation is terminated.

See Also

CommitCount (see page 9867)

Destination (see page 9868)

MovedCount (see page 9872)

Source (see page 9874)

Executing a Batch Move

53.1.3.5.15 TBatchMove.Source Property

Specifies the dataset that is the source of the batch operation.

Pascal

```
property Source: TBDEDataSet;
```

C++

```
__property TBDEDataSet Source;
```

Description

Use Source to indicate the dataset that contains the records that will be added to, subtracted from, or copied to the Destination (see page 9868). If Source is a TQuery (see page 10059) component, the query is executed before the move is executed. If a filter is currently in effect on Source, the filter conditions are respected when the batch move executes. The Mode (see page 9871) property indicates how the Source records are applied to the Destination (see page 9868):

Mode (see page 9871)	Effect on Destination (see page 9868)
batAppend	Records are added to the destination table.
batUpdate	Records in the destination table with key fields matching the corresponding fields in the source are changed to match the source records.
batAppendUpdate	Records in the destination table with key fields matching the corresponding fields in the source are changed to match the source. Source records that do not match key fields are added to the destination table.
batDelete	Records in the destination table that match the records in the source are deleted.
batCopy	Destination (see page 9868) table is created to match the records in the source.

See Also

Destination (see page 9868)

Mode (see page 9871)

TQuery (see page 10059)

TDataSet (see page 6894)

TTable (see page 10168)

Creating a Batch Move Component

53.1.3.5.16 TBatchMove.Transliterate Property

Specifies whether the data in the Source (see page 9874) records should be converted form the locale of the Source (see page 9874) to the locale of the Destination (see page 9868) when the Execute (see page 9863) method is called.

Pascal

```
property Transliterate: Boolean;
```

C++

```
__property Boolean Transliterate;
```

Description

Set Transliterate to true when the Source (see page 9874) dataset and the Destination (see page 9868) table use different language drivers and the data may contain extended ascii characters. Set Transliterate to false to avoid the overhead of the character set conversion when both the Source (see page 9874) and the Destination (see page 9868) use the same language driver or the data does not contain extended ascii characters.

See Also

Destination (see page 9868)

Execute (see page 9863)

Source (see page 9874)

Locale (see page 9934)

Creating a Batch Move Component

53.1.4 TBDECallback Class

TBDECallback is a wrapper for a Borland (see page 1761) Database Engine (BDE) callback function.

Class Hierarchy

DBTables.TBDECallback

Pascal

```
TBDECallback = class;
```

C++

```
class TBDECallback;
```

File

DBTables

Description

Use a TBDECallback object to register a callback function with the BDE. Callbacks allow an application to instruct the BDE to

take specific actions in response to events that occur during a BDE function call.

For example, the TBatchMove (see page 9858) object may encounter problems when executing the corresponding BDE batch operation. A callback function can respond to those problems by instructing the BDE to generate a problems table or to trim the data so that the operation succeeds.

To use a TBDECallback object, take the following steps:

1. Create (see page 9876) an instance of TBDECallback to register the callback with the BDE.
2. Call the BDE function in which the pertinent events take place. For example, create an instance of TBatchMove (see page 9858), and call its Execute method.
3. When the BDE function returns, destroy the TBDECallback object to unregister the callback function.

See Also

TBatchMove (see page 9858)

53.1.4.1 TBDECallback Members

The following tables list the members exposed by TBDECallback.

Protected Methods

	Name	Description
	Invoke (see page 9878)	This is Invoke, a member of class TBDECallback.

Public Methods

	Name	Description
	Create (see page 9876)	Creates an instance of TBDECallback (see page 9875) and registers the specified callback with the Borland (see page 1761) Database Engine (BDE).
	Destroy (see page 9877)	Unregisters the callback and destroys an instance of TBDECallback (see page 9875).

53.1.4.2 TBDECallback.Create Constructor

Creates an instance of TBDECallback (see page 9875) and registers the specified callback with the Borland (see page 1761) Database Engine (BDE).

Pascal

```
constructor Create(AOwner: TObject; Handle: hDBICur; CBType: CBType; CBBuf: Pointer;
CBBufSize: Integer; CallbackEvent: TBDECallbackEvent; Chain: Boolean);
```

C++

```
__fastcall TBDECallback(TObject * AOwner, hDBICur Handle, CBType CBType, void * CBBuf, int
CBBufSize, TBDECallbackEvent CallbackEvent, Boolean Chain);
```

Description

Call Create to register a callback with the BDE. Create a TBDECallback (see page 9875) object before calling any BDE function that should use the callback to respond to events.

When the BDE encounters the type of event indicated by the CBType parameter, the function specified by the CallbackEvent parameter is called. The CallbackEvent function receives a pointer to a callback descriptor. The type of the callback descriptor varies depending on the CBType. The Delphi application must allocate the memory for the callback descriptor. A pointer to this memory is passed in as the CBBuf parameter, and its size is given by the CBBufSize parameter.

The Chain parameter indicates whether this callback function should replace any other callbacks of this CBType. When Chain is false, the CallbackEvent function replaces any callbacks registered for the CBType. When Chain is true, the CallbackEvent

function is called in addition to other registered callbacks.

The Handle parameter is an optional parameter indicating the database cursor associated with the BDE function that may generate the callback. Provide a Handle to make the callback specific to function calls for that cursor.

The types of callback descriptors associated with each CBType are given in the following table. For more information, see the BDE documentation.

CBTypeUsagecallback descriptor

CBType	Usage	callback descriptor
cbGENPROGRESS	Respond to information about progress during large batch operations. For example, implement a progress bar or cancel button. Return cbrABORT to cancel, cbrCONTINUE to continue.	CBPROGRESSDesc
cbRESTRUCTURE	Instruct BDE on how to proceed with situations encountered during a table restructure.	Return cbrYES, to proceed with the default handling, cbrNO to proceed without the default behavior, cbrABORT to cancel the restructure.
cbBATCHRESULT	Instruct BDE on how to proceed with situations encountered during a batch operation. Return cbrYES, to proceed with the default handling, cbrNO to proceed without the default behavior, cbrABORT to cancel the batch operation.	RESTCbDesc
cbTABLECHANGED	Respond to notifications that a table has changed. The return value is ignored.	not used
cbCANCELQRY	Return cbrABORT to cancel a long running query, or cbrCONTINUE to keep going. The callback is called periodically during the execution of the query.	not used
cbINPUTREQ	Instruct BDE on how to respond when a file (such as a lookup table) is missing. Indicate the chosen behavior in the CBInputDesc and return cbrCONTINUE.	CBInputDesc
cbDBASELOGIN	Enter a password for an encrypted dBASE table and return cbrCONTINUE.	CBLoginDesc
cbFIELDRECALC	Respond to notifications that fields need to be recalculated. The return value is ignored.	not used
cbTRACE	Respond to trace information about the actions taken by the BDE. The return value is ignored.	TRACEDesc
cbDBLOGIN	Log in to a database server. Return cbrCONTINUE.	not used.
cbDELAYEDUPD	Respond to the notification when cached updates fail to write a modified record to the database. Return cbrABORT to cancel all cached updates, cbrSKIP or cbrCONTINUE to discard the failed update and continue posting records, cbrRETRY to try the failed commit again.	DELAYUPDCbDesc

Note: The VCL uses many BDE callback functions. Calling Create with Chain set to false may disable the expected behavior of some objects.

See Also

Destroy (see page 9877)

53.1.4.3 TBDECallback.Destroy Destructor

Unregisters the callback and destroys an instance of TBDECallback (see page 9875).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBDECallback();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the TBDECallback (see page 9875) object is not nil and only then calls Destroy.

Destroy unregisters the callback before freeing the memory associated with the TBDECallback (see page 9875) object. After unregistering the callback, any previous callback of the same type will be reinstated.

See Also

Create (see page 9876)

Free (see page 22300)

53.1.4.4 TBDECallback Methods

The methods of the TBDECallback class are listed here.

Protected Methods

	Name	Description
	Invoke (see page 9878)	This is Invoke, a member of class TBDECallback.

53.1.4.4.1 TBDECallback.Invoke Method

Pascal

```
function Invoke(CallType: CBType; CBInfo: Pointer): CBRType;
```

C++

```
__fastcall CBRType Invoke(CBType CallType, void * CBInfo);
```

Description

This is Invoke, a member of class TBDECallback.

53.1.5 TBDEDataSet Class

Encapsulates Borland (see page 1761) Database Engine (BDE) functionality for descendant dataset objects.

Class Hierarchy

Pascal

```
TBDEDataSet = class(TDataSet);
```

C++

```
class TBDEDataSet : public TDataSet;
```

File

DBTables

Description

TBDEDataSet is a dataset object that defines BDE functionality for a dataset. Applications never use TBDEDataSet objects directly. Instead they use the descendants of TBDEDataSet and TDBDataSet (see page 10000), such as TQuery (see page 10059), TStoredProc (see page 10139), and TTable (see page 10168), which inherit its database-related properties and methods.

Developers who create custom dataset components that work through the BDE may want to derive them directly from TBDEDataSet to inherit all the functionality of TDataSet and the BDE-related properties and methods of TBDEDataSet. To inherit control over database objects, however, most developers should derive custom dataset components that use the BDE from the immediate descendant of TBDEDataSet, TDBDataSet (see page 10000).

See Also

TDataSet (see page 6894)

TDBDataSet (see page 10000)

TQuery (see page 10059)

TStoredProc (see page 10139)

TTable (see page 10168)

53.1.5.1 TBDEDataSet Members

The following tables list the members exposed by TBDEDataSet.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.

	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
	CreateHandle (see page 9900)	This is CreateHandle, a member of class TBDEDataSet.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.
	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.

	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.

	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 6982)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 6982)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 6985)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 6989)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.

	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.

	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.
	StmtHandle (see page 9935)	Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.

Public Events

	Name	Description
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	Create (see page 9889)	Creates an instance of a TBDEDataSet (see page 9878) component.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
V	Destroy (see page 9890)	Destroys the instance of a dataset component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.

	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	Post (see page 9918)	Writes a modified record to the database.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSEndTransaction (see page 7578)	Ends a transaction that was started by a call to PSStartTransaction (see page 7586).
	PSExecute (see page 7578)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 7579)	Executes a specified SQL command.
	PSGetAttributes (see page 7579)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 7579)	Gets the SQL command to be executed by PSExecute (see page 7578).
	PSGetCommandType (see page 7580)	Gets the command type to be executed by PSExecute (see page 7578).
	PSGetDefaultOrder (see page 7580)	Returns the definition of an index that imposes the default order on the data included in data packets.

	PSGetIndexDefs (see page 7581)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 7581)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetParams (see page 7582)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 7582)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetTableName (see page 7583)	Returns the name of the dataset table that appears in generated SQL statements.
	PSInTransaction (see page 7583)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 7584)	Indicates whether the dataset includes native SQL support.
	PSSetCommandText (see page 7585)	Assigns a specified SQL command to be executed by PSExecute (see page 7578).
	PSSetParams (see page 7586)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 7586)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction (see page 7578).
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
R	AggFields (see page 7006)	Contains any aggregate fields.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.

R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	Handle (see page 9933)	Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	UpdateObject (see page 9936)	Specifies the update object component used to update a read-only result set when cached updates are enabled.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.

	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.5.2 TBDEDataSet.Create Constructor

Creates an instance of a TBDEDataSet (see page 9878) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBDEDataSet(TComponent * AOwner);
```

Description

Call Create to instantiate a dataset component at runtime. Ordinarily applications instantiate TBDEDataSet (see page 9878) descendants, such as TTable (see page 10168), TQuery (see page 10059), or TStoredProc (see page 10139).

Create

Calls its inherited Create method.

Set the Locale (see page 9934) property of the dataset to the locale of the default session.

Sets the CacheBlobs (see page 9932) property to true.

See Also

CacheBlobs (see page 9932)

Destroy (see page 9890)

Locale (see page 9934)

TQuery (see page 10059)

TStoredProc (see page 10139)

TTable (see page 10168)

53.1.5.3 TBDEDataSet.Destroy Destructor

Destroys the instance of a dataset component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBDEDataSet();
```

Description

Do not call Destroy directly in an application. Usually destruction of datasets is handled automatically If an application creates its own instances of a dataset, however, the application should call Free, which checks that the dataset component is not nil before calling Destroy.

Destroy calls its inherited destructor if necessary, frees the resources allocated for the BDE asynchronous callback, and sets the UpdateObject (see page 9936) property for the dataset to nil.

See Also

Create (see page 9889)

UpdateObject (see page 9936)

Free (see page 22300)

53.1.5.4 TBDEDataSet Methods

The methods of the TBDEDataSet class are listed here.

Protected Methods

	Name	Description
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
V	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
V	CreateHandle (see page 9900)	This is CreateHandle, a member of class TBDEDataSet.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
V	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
V	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.

	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.

	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.

Public Methods

	Name	Description
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.

	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	Post (see page 9918)	Writes a modified record to the database.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UpdateStatus (see page 9928)	Reports the update status for the current record.

53.1.5.4.1 TBDEDataSet.ActivateFilters Method

Pascal

```
procedure ActivateFilters;
```

C++

```
__fastcall ActivateFilters();
```

Description

This is ActivateFilters, a member of class TBDEDataSet.

53.1.5.4.2 TBDEDataSet.AddFieldDesc Method

Pascal

```
procedure AddFieldDesc(FieldDescs: TFieldDescList; var DescNo: Integer; var FieldID: Integer;
RequiredFields: TBits; FieldDefs: TFieldDefs);
```

C++

```
__fastcall AddFieldDesc(TFieldDescList FieldDescs, int DescNo, int FieldID, TBits
RequiredFields, TFieldDefs FieldDefs);
```

Description

This is AddFieldDesc, a member of class TBDEDataSet.

53.1.5.4.3 TBDEDataSet.AllocCachedUpdateBuffers Method

Pascal

```
procedure AllocCachedUpdateBuffers(Allocate: Boolean);
```

C++

```
__fastcall AllocCachedUpdateBuffers(Boolean Allocate);
```

Description

This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.

53.1.5.4.4 TBDEDataSet.AllocKeyBuffers Method

Pascal

```
procedure AllocKeyBuffers;
```

C++

```
__fastcall AllocKeyBuffers();
```

Description

This is AllocKeyBuffers, a member of class TBDEDataSet.

53.1.5.4.5 TBDEDataSet.AllocRecordBuffer Method

Pascal

```
function AllocRecordBuffer: PChar; override;
```

C++

```
virtual __fastcall const char * AllocRecordBuffer();
```

Description

This is AllocRecordBuffer, a member of class TBDEDataSet.

53.1.5.4.6 TBDEDataSet.ApplyUpdates Method

Writes a dataset's pending cached updates to the database.

Pascal

```
procedure ApplyUpdates;
```

C++

```
__fastcall ApplyUpdates();
```

Description

Call ApplyUpdates to write a dataset's pending cached updates to a database. This method passes cached data to the database for storage, but the changes are not committed to the database. An application must explicitly call the database component's Commit method to commit the changes to the database if the write is successful, or call the database's Rollback method to undo the changes if there is an error.

Following a successful write to the database, and following a successful call to the database's Commit method, an application should call the CommitUpdates (see page 9897) method to clear the cached update buffer.

Note: The preferred method for updating datasets is to call a database component's ApplyUpdates method rather than to call each individual dataset's ApplyUpdates method. The database component's ApplyUpdates method takes care of committing and rolling back transactions and clearing the cache when the operation is successful.

CachedUpdates (see page 9932)

UpdatesPending (see page 9937)

ApplyUpdates (see page 9970)

Using TTable

Applying BDE-based Cached Updates

Applying Cached Updates with Dataset Component Methods

53.1.5.4.7 TBDEDataSet.BlockReadNext Method

Pascal

```
procedure BlockReadNext; override;
```

C++

```
virtual __fastcall BlockReadNext();
```

Description

This is BlockReadNext, a member of class TBDEDataSet.

53.1.5.4.8 TBDEDataSet.BookmarkValid Method

Tests the validity of a specified bookmark.

Pascal

```
function BookmarkValid(Bookmark: TBookmark): Boolean; override;
```

C++

```
virtual __fastcall Boolean BookmarkValid(TBookmark Bookmark);
```

Description

Call BookmarkValid to determine if a specified bookmark is currently assigned a value. Bookmark specifies the bookmark to test.

BookmarkValid returns true if a bookmark is valid. Otherwise, it returns false.

See Also

CompareBookmarks (see page 9898)

TTable (see page 10168)

53.1.5.4.9 TBDEDataSet.CachedUpdateCallBack Method

Pascal

```
function CachedUpdateCallBack(CBInfo: Pointer): CBRType;
```

C++

```
__fastcall CBRType CachedUpdateCallBack(void * CBInfo);
```

Description

This is CachedUpdateCallBack, a member of class TBDEDataSet.

53.1.5.4.10 TBDEDataSet.Cancel Method

Cancels modifications to the current record if those changes are not yet posted.

Pascal

```
procedure Cancel; override;
```

C++

```
virtual __fastcall Cancel();
```

Description

Call Cancel to undo modifications made to one or more fields belonging to the current record. As long as those changes are not already posted to the database, Cancel returns the record to its previous state, and sets the dataset state to dsBrowse.

Typically Cancel is used to back out of changes in response to user request, or in field validation routines that back out illegal field values. The TDBNavigator object contains a Cancel button that triggers a call to Cancel.

See Also

State (see page 7036)

Post (see page 9918)

TDBNavigator (see page 9230)

53.1.5.4.11 TBDEDataSet.CancelUpdates Method

Clears all pending cached updates from the cache and restores the dataset its prior state.

Pascal

```
procedure CancelUpdates;
```

C++

```
__fastcall CancelUpdates();
```

Description

Call CancelUpdates to clear all pending cached updates from the cache and restore the dataset to the state it was in when the table was opened, cached updates were last enabled, or updates were last successfully applied to the database.

When a dataset is closed, or the CachedUpdates (see page 9932) property is set to false, CancelUpdates is called automatically.

Note: To undo changes to a single record, call RevertRecord (see page 9922).

See Also

CachedUpdates (see page 9932)

State (see page 7036)

ApplyUpdates (see page 9894)

RevertRecord (see page 9922)

UpdatesPending (see page 9937)

Enabling BDE-based Cached Updates

Using the BDE to Cache Updates

53.1.5.4.12 TBDEDataSet.CheckCachedUpdateMode Method

Pascal

```
procedure CheckCachedUpdateMode;
```

C++

```
__fastcall CheckCachedUpdateMode();
```

Description

This is CheckCachedUpdateMode, a member of class TBDEDataSet.

53.1.5.4.13 TBDEDataSet.CheckSetKeyMode Method

Pascal

```
procedure CheckSetKeyMode;
```

C++

```
__fastcall CheckSetKeyMode();
```

Description

This is CheckSetKeyMode, a member of class TBDEDataSet.

53.1.5.4.14 TBDEDataSet.ClearCalcFields Method

Pascal

```
procedure ClearCalcFields(Buffer: PChar); override;
```

C++

```
virtual __fastcall ClearCalcFields(const char * Buffer);
```

Description

This is ClearCalcFields, a member of class TBDEDataSet.

53.1.5.4.15 TBDEDataSet.CloseBlob Method

Pascal

```
procedure CloseBlob(Field: TField); override;
```

C++

```
virtual __fastcall CloseBlob(TField Field);
```

Description

This is CloseBlob, a member of class TBDEDataSet.

53.1.5.4.16 TBDEDataSet.CloseCursor Method

Pascal

```
procedure CloseCursor; override;
```

C++

```
virtual __fastcall CloseCursor();
```

Description

This is CloseCursor, a member of class TBDEDataSet.

53.1.5.4.17 TBDEDataSet.CommitUpdates Method

Clears the cached updates buffer.

Pascal

```
procedure CommitUpdates;
```

C++

```
__fastcall CommitUpdates();
```

Description

Call CommitUpdates to clear the cached updates buffer after both a successful call to ApplyUpdates (see page 9894) and a database component's Commit method. Clearing the cache after applying updates ensures that the cache is empty except for records that could not be processed and were skipped by the OnUpdateRecord (see page 9957) or OnUpdateError (see page 9956) event handlers. An application can attempt to modify the records still in the cache.

Record modifications made after a call to CommitUpdates repopulate the cached update buffer and require a subsequent call to ApplyUpdates (see page 9894) to move them to the database.

Note: Applications that use a database component's ApplyUpdates (see page 9894) method to apply and commit pending updates for all datasets associated with the database component do not need to call CommitUpdates.

See Also

CachedUpdates (see page 9932)

UpdatesPending (see page 9937)

OnUpdateError (see page 9956)

OnUpdateRecord (see page 9957)

ApplyUpdates (see page 9894)

ApplyUpdates (see page 9970)

Using the BDE to Cache Updates

Applying BDE-based Cached Updates

Applying Cached Updates with Dataset Component Methods

53.1.5.4.18 TBDEDataSet.CompareBookmarks Method

Indicates the relationship between two bookmarks.

Pascal

```
function CompareBookmarks(Bookmark1: TBookmark; Bookmark2: TBookmark): Integer; override;
```

C++

```
virtual __fastcall int CompareBookmarks(TBookmark Bookmark1, TBookmark Bookmark2);
```

Description

Call CompareBookmarks to determine if two bookmarks are identical. Bookmark1 and Bookmark2 are the bookmarks to compare.

If the bookmarks differ, CompareBookmarks returns -1 if Bookmark1 is less than Bookmark2, 1 if Bookmark1 is greater than Bookmark2, and 0 if the bookmarks are identical, nil (Delphi), or NULL (C++)

See Also

BookmarkValid (see page 9895)

TTable (see page 10168)

53.1.5.4.19 TBDEDataSet.ConstraintCallBack Method

Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.

Pascal

```
function ConstraintCallBack(Req: DsInfoReq; var ADataSources: DataSources): DBIResult; stdcall;
```

C++

```
__fastcall __stdcall DBIResult ConstraintCallBack(DsInfoReq Req, DataSources ADataSources);
```

Description

Use the address of ConstraintCallBack as a parameter when making direct API calls to Borland (see page 1761) Database Engine (BDE) functions that require a callback to provide information about the constraints on the dataset or its fields.

See Also

DisableConstraints (see page 9902)

EnableConstraints (see page 9902)

53.1.5.4.20 TBDEDataSet.ConstraintsDisabled Method

Indicates whether constraints are enabled for a dataset.

Pascal

```
function ConstraintsDisabled: Boolean;
```

C++

```
__fastcall Boolean ConstraintsDisabled();
```

Description

Call ConstraintsDisabled to determine if constraints are currently disabled for a dataset. If ConstraintsDisabled returns true, constraints are currently disabled. If false, constraints are currently enabled.

See Also

DisableConstraints (see page 9902)

EnableConstraints (see page 9902)

53.1.5.4.21 TBDEDataSet.CreateBlobStream Method

Returns a TStream object for reading or writing the data in a specified blob field.

Pascal

```
function CreateBlobStream(Field: TField; Mode: TBlobStreamMode): TStream; override;
```

C++

```
virtual __fastcall TStream CreateBlobStream(TField Field, TBlobStreamMode Mode);
```

Description

Call CreateBlobStream to obtain a stream for reading data from or writing data to a binary large object (BLOB) field. The Field parameter must specify a TBlobField component from the Fields property array. The Mode parameter specifies whether the stream will be used for reading, writing, or updating the contents of the field.

Blob streams are created in a specific mode for a specific field on a specific record. Applications should create a new blob stream every time the record in the dataset changes rather than reusing an existing blob stream.

Delphi Examples:

```
{
The following example copies the data in the Notes field of
Table1 or SQLDataSet1 to the Remarks field of ClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Stream1: TBlobStream;
  Stream2: TStream;
```

```
    blobType : TBlobType;
  begin
    blobType := Table1Notes.BlobType;
    Stream1 := TBlobStream.Create(Table1Notes, bmRead);
    try
      CDS2.Edit;
      { here's a different way to create a blob stream }
      Stream2 := CDS2.CreateBlobStream(CDS2.FieldByName('Remarks'), bmReadWrite);
      try
        Stream2.CopyFrom(Stream1, Stream1.Size);
  //    CDS2.Post;
  //    CDS2.Active := True;
      finally
        Stream2.Free;
      end;
    finally
      Stream1.Free;
    end;
  end;
```

See Also

Fields (see page 7023)

TBlobStream (see page 9958)

53.1.5.4.22 TBDEDataSet.CreateExprFilter Method

Pascal

```
function CreateExprFilter(const Expr: string; Options: TFilterOptions; Priority: Integer):
HDBIFilter;
```

C++

```
__fastcall HDBIFilter CreateExprFilter(const AnsiString Expr, TFilterOptions Options, int
Priority);
```

Description

This is CreateExprFilter, a member of class TBDEDataSet.

53.1.5.4.23 TBDEDataSet.CreateFuncFilter Method

Pascal

```
function CreateFuncFilter(FilterFunc: Pointer; Priority: Integer): HDBIFilter;
```

C++

```
__fastcall HDBIFilter CreateFuncFilter(void * FilterFunc, int Priority);
```

Description

This is CreateFuncFilter, a member of class TBDEDataSet.

53.1.5.4.24 TBDEDataSet.CreateHandle Method

Pascal

```
function CreateHandle: HDBICur; virtual;
```

C++

```
virtual __fastcall HDBICur CreateHandle();
```

Description

This is CreateHandle, a member of class TBDEDataSet.

53.1.5.4.25 TBDEDataSet.CreateLookupFilter Method

Pascal

```
function CreateLookupFilter(Fields: TList; const Values: Variant; Options: TLocateOptions;
Priority: Integer): HDBIFilter;
```

C++

```
__fastcall HDBIFilter CreateLookupFilter(TList Fields, const Variant Values, TLocateOptions
Options, int Priority);
```

Description

This is CreateLookupFilter, a member of class TBDEDataSet.

53.1.5.4.26 TBDEDataSet.DataEvent Method

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); override;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

This is DataEvent, a member of class TBDEDataSet.

53.1.5.4.27 TBDEDataSet.DeactivateFilters Method

Pascal

```
procedure DeactivateFilters;
```

C++

```
__fastcall DeactivateFilters();
```

Description

This is DeactivateFilters, a member of class TBDEDataSet.

53.1.5.4.28 TBDEDataSet.DestroyHandle Method

Pascal

```
procedure DestroyHandle; virtual;
```

C++

```
virtual __fastcall DestroyHandle();
```

Description

This is DestroyHandle, a member of class TBDEDataSet.

53.1.5.4.29 TBDEDataSet.DestroyLookupCursor Method

Pascal

```
procedure DestroyLookupCursor; virtual;
```

C++

```
virtual __fastcall DestroyLookupCursor();
```

Description

This is DestroyLookupCursor, a member of class TBDEDataSet.

53.1.5.4.30 TBDEDataSet.DisableConstraints Method

Disables application of server constraints on the dataset.

Pascal

```
procedure DisableConstraints;
```

C++

```
__fastcall DisableConstraints();
```

Description

Call DisableConstraints to prevent, on a temporary basis, application of server constraints replicated to the dataset. For example, when an application iterates through a dataset, it may improve performance to disable constraints temporarily.

Note: Calling DisableConstraints increments a reference count. As long as this reference count is greater than zero, constraints are disabled for the dataset. To prevent accidental disabling of constraints, always group a call to DisableConstraints with a call to EnableConstraints (see page 9902).

See Also

EnableConstraints (see page 9902)

53.1.5.4.31 TBDEDataSet.EnableConstraints Method

Enables application of server constraints against dataset entries.

Pascal

```
procedure EnableConstraints;
```

C++

```
__fastcall EnableConstraints();
```

Description

Call EnableConstraints to turn on application server constraints previously disabled by a call to DisableConstraints (see page 9902).

Note: Calling EnableConstraints decrements a reference count. When this reference count is zero constraints are enabled for the dataset. To prevent accidental disabling of constraints, always follow a call to DisableConstraints (see page 9902) with a matching call to EnableConstraints.

See Also

DisableConstraints (see page 9902)

53.1.5.4.32 TBDEDataSet.FetchAll Method

Retrieves all records from the current cursor position to the end of the file and stores them locally.

Pascal

```
procedure FetchAll;
```

C++

```
__fastcall FetchAll();
```

Description

Call FetchAll to reduce network traffic when using cached updates. FetchAll calls CheckBrowseMode to post any pending changes, and then retrieves all records from the current cursor position to the end of the file, and store them locally.

Ordinarily when cached updates are enabled, a transaction retrieves only as much data as it needs for display purposes. Each new fetch starts a new, read-only transaction. To consolidate transactions and reduce network traffic, an application can call FetchAll to retrieve all data in a single transaction.

Note: Using FetchAll is not always appropriate. For example, when an application accesses a database used by many simultaneous clients and there is a high degree of contention for updating the same records, fetching all records at once may not be advantageous because some fetched records may be changed by other applications. Always weigh the advantages of reduced network traffic against the need for reduced record contention.

See Also

CachedUpdates (see page 9932)

Filter

Filtered

OnFilterRecord (see page 7055)

OnUpdateRecord (see page 9957)

Using the BDE to Cache Updates

53.1.5.4.33 TBDEDataSet.FindRecord Method

Pascal

```
function FindRecord(Restart: Boolean; GoForward: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean FindRecord(Boolean Restart, Boolean GoForward);
```

Description

This is FindRecord, a member of class TBDEDataSet.

53.1.5.4.34 TBDEDataSet.FlushBuffers Method

Posts all changes that have been written to the record buffer.

Pascal

```
procedure FlushBuffers;
```

C++

```
__fastcall FlushBuffers();
```

Description

Call FlushBuffers to cause the dataset to post all pending changes to the database, including any cached updates. Use FlushBuffers instead of CheckBrowseMode if it is important that cached record buffers are posted.

See Also

CheckBrowseMode (see page 6918)

53.1.5.4.35 TBDEDataSet.ForceUpdateCallback Method

Pascal

```
function ForceUpdateCallback: Boolean;
```

C++

```
__fastcall Boolean ForceUpdateCallback();
```

Description

This is ForceUpdateCallback, a member of class TBDEDataSet.

53.1.5.4.36 TBDEDataSet.FreeKeyBuffers Method

Pascal

```
procedure FreeKeyBuffers;
```

C++

```
__fastcall FreeKeyBuffers();
```

Description

This is FreeKeyBuffers, a member of class TBDEDataSet.

53.1.5.4.37 TBDEDataSet.FreeRecordBuffer Method

Pascal

```
procedure FreeRecordBuffer(var Buffer: PChar); override;
```

C++

```
virtual __fastcall FreeRecordBuffer(const char * Buffer);
```

Description

This is FreeRecordBuffer, a member of class TBDEDataSet.

53.1.5.4.38 TBDEDataSet.GetBlobFieldData Method

Reads BLOB data into a buffer.

Pascal

```
function GetBlobFieldData(FieldNo: Integer; var Buffer: TBlobByteData): Integer; override;
```

C++

```
virtual __fastcall int GetBlobFieldData(int FieldNo, TBlobByteData Buffer);
```

Description

GetBlobFieldData reads blob data from the field specified by FieldNo into a Buffer. The buffer is a dynamic array of bytes, so that it can grow to accommodate the size of the BLOB data. GetBlobFieldData returns the size of the buffer.

See Also

BlobFieldCount (see page 7007)

GetFieldData (see page 6952)

FieldNo (see page 7166)

53.1.5.4.39 TBDEDataSet.GetBookmarkData Method

Pascal

```
procedure GetBookmarkData(Buffer: PChar; Data: Pointer); override;
```

C++

```
virtual __fastcall GetBookmarkData(const char * Buffer, void * Data);
```

Description

This is GetBookmarkData, a member of class TBDEDataSet.

53.1.5.4.40 TBDEDataSet.GetBookmarkFlag Method

Pascal

```
function GetBookmarkFlag(Buffer: PChar): TBookmarkFlag; override;
```

C++

```
virtual __fastcall TBookmarkFlag GetBookmarkFlag(const char * Buffer);
```

Description

This is GetBookmarkFlag, a member of class TBDEDataSet.

53.1.5.4.41 TBDEDataSet.GetCanModify Method

Pascal

```
function GetCanModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetCanModify();
```

Description

This is GetCanModify, a member of class TBDEDataSet.

53.1.5.4.42 TBDEDataSet.GetCurrentRecord Method

Retrieves the current record into a buffer.

Pascal

```
function GetCurrentRecord(Buffer: PChar): Boolean; override;
```

C++

```
virtual __fastcall Boolean GetCurrentRecord(const char * Buffer);
```

Description

Most applications should not need to call GetCurrentRecord. TDataSet automatically allocates a buffer for the active record.

Call GetCurrentRecord to copy the current record into a buffer allocated by the application. Buffer must be at least as big as the record size indicated by the RecordSize property.

See Also

RecordSize

ActiveBuffer (see page 6909)

53.1.5.4.43 GetFieldData Method

This is the overview for the GetFieldData method overload.

Overload List

	Name	Description
	TBDEDataSet.GetFieldData (Integer, Pointer) (see page 9906)	Retrieves the current value of a field into a buffer.
	TBDEDataSet.GetFieldData (TField, Pointer) (see page 9906)	Retrieves the current value of a field into a buffer.

53.1.5.4.43.1 TBDEDataSet.GetFieldData Method (Integer, Pointer)

Retrieves the current value of a field into a buffer.

Pascal

```
function GetFieldData(Field: TField; Buffer: Pointer): Boolean; override; overload;
function GetFieldData(FieldNo: Integer; Buffer: Pointer): Boolean; override; overload;
```

C++

```
virtual __fastcall Boolean GetFieldData(TField Field, void * Buffer);
virtual __fastcall Boolean GetFieldData(int FieldNo, void * Buffer);
```

Description

Most applications do not need to call GetFieldData. TField objects call this method to implement their GetData method.

The Field or FieldNo parameter indicates the field whose data should be fetched. Field specifies the component itself, while FieldNo indicates its field number. The Buffer parameter is a memory buffer with sufficient space to accept the value of the field as it exists in the database (unformatted and untranslated). NativeFormat indicates whether the dataset fetches the field in the library's native format for the field type. When NativeFormat is false, the dataset must convert the field value to the native type. This allows the field to handle data from different types of datasets (ADO-based, BDE-based, and so on) in a uniform manner.

GetFieldData returns a value that indicates whether the data was successfully fetched.

GetFieldData returns true if the buffer is successfully filled with the field's data, and false if the data could not be fetched.

See Also

GetBlobFieldData (see page 9904)

FieldNo (see page 7166)

53.1.5.4.44 TBDEDataSet.GetFieldFullName Method

Pascal

```
function GetFieldFullName(Field: TField): string; override;
```

C++

```
virtual __fastcall AnsiString GetFieldFullName(TField Field);
```

Description

This is GetFieldFullName, a member of class TBDEDataSet.

53.1.5.4.45 TBDEDataSet.GetHandle Method

Pascal

```
function GetHandle: HDBICur;
```

C++

```
__fastcall HDBICur GetHandle();
```

Description

This is GetHandle, a member of class TBDEDataSet.

53.1.5.4.46 TBDEDataSet.GetIndexField Method

Pascal

```
function GetIndexField(Index: Integer): TField;
```

C++

```
__fastcall TField GetIndexField(int Index);
```

Description

This is GetIndexField, a member of class TBDEDataSet.

53.1.5.4.47 TBDEDataSet.GetIndexFieldCount Method

Pascal

```
function GetIndexFieldCount: Integer;
```

C++

```
__fastcall int GetIndexFieldCount();
```

Description

This is GetIndexFieldCount, a member of class TBDEDataSet.

53.1.5.4.48 TBDEDataSet.GetIndexInfo Method

Retrieves information about the current index into the index data fields of the dataset.

Pascal

```
procedure GetIndexInfo;
```

C++

```
__fastcall GetIndexInfo();
```

Description

Call GetIndexInfo to update information about the current index. Ordinarily an application does not need to call GetIndexInfo because this routine is used internally to retrieve index information as needed. Some applications, however, may want to ensure that the index information used by the dataset is up-to-date.

GetIndexInfo queries the BDE for index information, including:

Whether the current index is a dBASE expression index.

Whether the index is case insensitive.

The number of fields that make up the key for the index.

The field map for the index.

The size of the index key.

Number of fields and field map are not retrieved if the index is a dBASE expression index.

ExpIndex (see page 9933)

53.1.5.4.49 TBDEDataSet.GetIsIndexField Method

Pascal

```
function GetIsIndexField(Field: TField): Boolean; override;
```

C++

```
virtual __fastcall Boolean GetIsIndexField(TField Field);
```

Description

This is GetIsIndexField, a member of class TBDEDataSet.

53.1.5.4.50 TBDEDataSet.GetKeyBuffer Method

Pascal

```
function GetKeyBuffer(KeyIndex: TKeyIndex): PKeyBuffer;
```

C++

```
__fastcall PKeyBuffer GetKeyBuffer(TKeyIndex KeyIndex);
```

Description

This is GetKeyBuffer, a member of class TBDEDataSet.

53.1.5.4.51 TBDEDataSet.GetKeyExclusive Method

Pascal

```
function GetKeyExclusive: Boolean;
```

C++

```
__fastcall Boolean GetKeyExclusive();
```

Description

This is GetKeyExclusive, a member of class TBDEDataSet.

53.1.5.4.52 TBDEDataSet.GetKeyFieldCount Method

Pascal

```
function GetKeyFieldCount: Integer;
```

C++

```
__fastcall int GetKeyFieldCount();
```

Description

This is GetKeyFieldCount, a member of class TBDEDataSet.

53.1.5.4.53 TBDEDataSet.GetLookupCursor Method

Pascal

```
function GetLookupCursor(const KeyFields: string; CaseInsensitive: Boolean): HDBICur; virtual;
```

C++

```
virtual __fastcall HDBICur GetLookupCursor(const AnsiString KeyFields, Boolean
CaseInsensitive);
```

Description

This is GetLookupCursor, a member of class TBDEDataSet.

53.1.5.4.54 TBDEDataSet.GetObjectTypeNames Method

Pascal

```
procedure GetObjectTypeNames(Fields: TFields);
```

C++

```
__fastcall GetObjectTypeNames(TFields Fields);
```

Description

This is GetObjectTypeNames, a member of class TBDEDataSet.

53.1.5.4.55 TBDEDataSet.GetRecNo Method

Pascal

```
function GetRecNo: Integer; override;
```

C++

```
virtual __fastcall int GetRecNo();
```

Description

This is GetRecNo, a member of class TBDEDataSet.

53.1.5.4.56 TBDEDataSet.GetRecord Method

Pascal

```
function GetRecord(Buffer: PChar; GetMode: TGetMode; DoCheck: Boolean): TGetResult; override;
```

C++

```
virtual __fastcall TGetResult GetRecord(const char * Buffer, TGetMode GetMode, Boolean
DoCheck);
```

Description

This is GetRecord, a member of class TBDEDataSet.

53.1.5.4.57 TBDEDataSet.GetRecordCount Method

Pascal

```
function GetRecordCount: Integer; override;
```

C++

```
virtual __fastcall int GetRecordCount();
```

Description

This is GetRecordCount, a member of class TBDEDataSet.

53.1.5.4.58 TBDEDataSet.GetRecordSize Method

Pascal

```
function GetRecordSize: Word; override;
```

C++

```
virtual __fastcall Word GetRecordSize();
```

Description

This is GetRecordSize, a member of class TBDEDataSet.

53.1.5.4.59 TBDEDataSet.GetStateFieldValue Method

Pascal

```
function GetStateFieldValue(State: TDataSetState; Field: TField): Variant; override;
```

C++

```
virtual __fastcall Variant GetStateFieldValue(TDataSetState State, TField Field);
```

Description

This is GetStateFieldValue, a member of class TBDEDataSet.

53.1.5.4.60 TBDEDataSet.GetUpdateRecordSet Method

Pascal

```
function GetUpdateRecordSet: TUpdateRecordTypes;
```

C++

```
__fastcall TUpdateRecordTypes GetUpdateRecordSet();
```

Description

This is GetUpdateRecordSet, a member of class TBDEDataSet.

53.1.5.4.61 TBDEDataSet.GetUpdatesPending Method

Pascal

```
function GetUpdatesPending: Boolean;
```

C++

```
__fastcall Boolean GetUpdatesPending();
```

Description

This is GetUpdatesPending, a member of class TBDEDataSet.

53.1.5.4.62 TBDEDataSet.InitKeyBuffer Method

Pascal

```
function InitKeyBuffer(Buffer: PKeyBuffer): PKeyBuffer;
```

C++

```
__fastcall PKeyBuffer InitKeyBuffer(PKeyBuffer Buffer);
```

Description

This is InitKeyBuffer, a member of class TBDEDataSet.

53.1.5.4.63 TBDEDataSet.InitRecord Method

Pascal

```
procedure InitRecord(Buffer: PChar); override;
```

C++

```
virtual __fastcall InitRecord(const char * Buffer);
```

Description

This is InitRecord, a member of class TBDEDataSet.

53.1.5.4.64 TBDEDataSet.InternalAddRecord Method

Pascal

```
procedure InternalAddRecord(Buffer: Pointer; Append: Boolean); override;
```

C++

```
virtual __fastcall InternalAddRecord(void * Buffer, Boolean Append);
```

Description

This is InternalAddRecord, a member of class TBDEDataSet.

53.1.5.4.65 TBDEDataSet.InternalCancel Method

Pascal

```
procedure InternalCancel; override;
```

C++

```
virtual __fastcall InternalCancel();
```

Description

This is InternalCancel, a member of class TBDEDataSet.

53.1.5.4.66 TBDEDataSet.InternalClose Method

Pascal

```
procedure InternalClose; override;
```

C++

```
virtual __fastcall InternalClose();
```

Description

This is InternalClose, a member of class TBDEDataSet.

53.1.5.4.67 TBDEDataSet.InternalDelete Method

Pascal

```
procedure InternalDelete; override;
```

C++

```
virtual __fastcall InternalDelete();
```

Description

This is InternalDelete, a member of class TBDEDataSet.

53.1.5.4.68 TBDEDataSet.InternalEdit Method

Pascal

```
procedure InternalEdit; override;
```

C++

```
virtual __fastcall InternalEdit();
```

Description

This is InternalEdit, a member of class TBDEDataSet.

53.1.5.4.69 TBDEDataSet.InternalFirst Method

Pascal

```
procedure InternalFirst; override;
```

C++

```
virtual __fastcall InternalFirst();
```

Description

This is InternalFirst, a member of class TBDEDataSet.

53.1.5.4.70 TBDEDataSet.InternalGotoBookmark Method

Pascal

```
procedure InternalGotoBookmark(Bookmark: TBookmark); override;
```

C++

```
virtual __fastcall InternalGotoBookmark(TBookmark Bookmark);
```

Description

This is InternalGotoBookmark, a member of class TBDEDataSet.

53.1.5.4.71 TBDEDataSet.InternalHandleException Method

Pascal

```
procedure InternalHandleException; override;
```

C++

```
virtual __fastcall InternalHandleException();
```

Description

This is InternalHandleException, a member of class TBDEDataSet.

53.1.5.4.72 TBDEDataSet.InternalInitFieldDefs Method

Pascal

```
procedure InternalInitFieldDefs; override;
```

C++

```
virtual __fastcall InternalInitFieldDefs();
```

Description

This is InternalInitFieldDefs, a member of class TBDEDataSet.

53.1.5.4.73 TBDEDataSet.InternalInitRecord Method

Pascal

```
procedure InternalInitRecord(Buffer: PChar); override;
```

C++

```
virtual __fastcall InternalInitRecord(const char * Buffer);
```

Description

This is InternalInitRecord, a member of class TBDEDataSet.

53.1.5.4.74 TBDEDataSet.InternalInsert Method

Pascal

```
procedure InternalInsert; override;
```

C++

```
virtual __fastcall InternalInsert();
```

Description

This is InternalInsert, a member of class TBDEDataSet.

53.1.5.4.75 TBDEDataSet.InternalLast Method

Pascal

```
procedure InternalLast; override;
```

C++

```
virtual __fastcall InternalLast();
```

Description

This is InternalLast, a member of class TBDEDataSet.

53.1.5.4.76 TBDEDataSet.InternalOpen Method

Pascal

```
procedure InternalOpen; override;
```

C++

```
virtual __fastcall InternalOpen();
```

Description

This is InternalOpen, a member of class TBDEDataSet.

53.1.5.4.77 TBDEDataSet.InternalPost Method

Pascal

```
procedure InternalPost; override;
```

C++

```
virtual __fastcall InternalPost();
```

Description

This is InternalPost, a member of class TBDEDataSet.

53.1.5.4.78 TBDEDataSet.InternalRefresh Method

Pascal

```
procedure InternalRefresh; override;
```

C++

```
virtual __fastcall InternalRefresh();
```

Description

This is InternalRefresh, a member of class TBDEDataSet.

53.1.5.4.79 TBDEDataSet.InternalSetToRecord Method

Pascal

```
procedure InternalSetToRecord(Buffer: PChar); override;
```

C++

```
virtual __fastcall InternalSetToRecord(const char * Buffer);
```

Description

This is InternalSetToRecord, a member of class TBDEDataSet.

53.1.5.4.80 TBDEDataSet.IsCursorOpen Method

Pascal

```
function IsCursorOpen: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsCursorOpen();
```

Description

This is IsCursorOpen, a member of class TBDEDataSet.

53.1.5.4.81 TBDEDataSet.IsSequenced Method

IsSequenced indicates whether sequence numbers are available for database records.

Pascal

```
function IsSequenced: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsSequenced();
```

Description

Call IsSequenced to determine whether database records can be located by sequence numbers. When IsSequenced is true, the dataset can navigate directly to a specific record by setting the RecNo property. If IsSequenced is false, the only way to navigate to a specific record is to start at the beginning and count records.

See Also

RecNo

53.1.5.4.82 TBDEDataSet.Locate Method

Searches the dataset for a specified record and makes that record the current record.

Pascal

```
function Locate(const KeyFields: string; const KeyValues: Variant; Options: TLocateOptions):
Boolean; override;
```

C++

```
virtual __fastcall Boolean Locate(const AnsiString KeyFields, const Variant KeyValues,
TLocateOptions Options);
```

Description

Call Locate to search a dataset for a specific record and position the cursor on it.

KeyFields is a string containing a semicolon-delimited list of field names on which to search.

KeyValues is a variant array containing the values to match in the key fields. If KeyFields lists a single field, KeyValues specifies the value for that field on the desired record. To specify multiple search values, pass a variant array as KeyValues, or construct a variant array on the fly using the VarArrayOf routine. For example:

```
with CustTable do
  Locate('Company;Contact;Phone', VarArrayOf(['Sight Diver', 'P', '408-431-1000']),
[loPartialKey]);
TLocateOptions Opts;
Opts.Clear();
Opts << loPartialKey;
Variant locvalues[2];
locvalues[0] = Variant("Sight Diver");
locvalues[1] = Variant("P");
CustTable->Locate("Company;Contact", VarArrayOf(locvalues, 1), Opts);
```

Options is a set that optionally specifies additional search latitude when searching on string fields. If Options contains the loCaseInsensitive setting, then Locate ignores case when matching fields. If Options contains the loPartialKey setting, then Locate allows partial-string matching on strings in KeyValues. If Options is an empty set, or if the KeyFields property does not include any string fields, Options is ignored.

Locate returns true if it finds a matching record, and makes that record the current one. Otherwise Locate returns false.

Locate uses the fastest possible method to locate matching records. If the search fields in KeyFields are indexed and the index is compatible with the specified search options, Locate uses the index. Otherwise Locate creates a filter for the search.

See Also

FindField (see page 6938)

Lookup (see page 9916)

53.1.5.4.83 TBDEDataSet.LocateRecord Method

Pascal

```
function LocateRecord(const KeyFields: string; const KeyValues: Variant; Options:
TLocateOptions; SyncCursor: Boolean): Boolean;
```

C++

```
__fastcall Boolean LocateRecord(const AnsiString KeyFields, const Variant KeyValues,
TLocateOptions Options, Boolean SyncCursor);
```

Description

This is LocateRecord, a member of class TBDEDataSet.

53.1.5.4.84 TBDEDataSet.Lookup Method

Retrieves field values from a record that matches specified search values.

Pascal

```
function Lookup(const KeyFields: string; const KeyValues: Variant; const ResultFields:
```

```
string): Variant; override;
```

C++

```
virtual __fastcall Variant Lookup(const AnsiString KeyFields, const Variant KeyValues, const
AnsiString ResultFields);
```

Description

Call Lookup to search for a record in the dataset in which specified fields contain specified values and return other field values from the found record. Unlike other dataset search methods, Lookup performs its search without moving the record pointer of the dataset. This is useful when doing data validation on a record's data while the record is still in edit or insert mode.

KeyFields is a string containing the names of the field or fields on which the search is predicated. If the search is based on more than one field, KeyFields is a list of field names delimited with semicolons.

KeyValues is a variant array containing the values to find in the fields specified in KeyFields. To specify multiple search values, pass KeyValues as a variant array as an argument, or construct a variant array on the fly using the VarArrayOf routine. These search values must be specified in the order of the fields in KeyFields to which each corresponds. For instance, the first value is used for the first field in KeyFields, the second value for the second field, and so on.

ResultFields is a string containing the names of the field or fields from which to return values. If values are to be returned from more than one field, ResultFields is a list of field names delimited with semicolons.

Lookup returns a variant array containing the values from the fields specified in ResultFields.

Lookup uses the fastest possible method to locate matching records. If the search fields in KeyFields are indexed, Lookup uses the index. Otherwise Lookup creates a filter for the search.

The example below uses the Lookup method to search the sample Paradox table Customer. The search is based on two fields: Company and State. The search is also based on the following two values in these two fields: "Blue Sports" and "OR". For the search to be successful, there must be a record where the Company field contains the value "Blue Sports" AND the field State contains "OR". If either criteria is not met, the search is unsuccessful (such a record does exist in this table, so the search will be successful). The values of the CustNo and Addr1 fields are returned by the execution of the Lookup method. If the search is unsuccessful, the VarType function applied to the returned variant array returns varNull.

```
procedure TForm1.Button1Click(Sender: TObject);
var
  V: Variant;
  C: Integer;
  A: String;
begin
  V := Table1.Lookup('Company;State',
    VarArrayOf(['Blue Sports', 'OR']),
    'CustNo;Addr1');
if not (VarType(V) in [varNull]) then begin
    C := V[0];
    A := V[1];
    ShowMessage(IntToStr(C) + #10 + A);
end
else
    ShowMessage('Search unsuccessful!');
end;
int C;
AnsiString A;
Variant V;
V = Table1->Lookup("Company;State",
  VarArrayOf(OPENARRAY(Variant, ("Blue Sports","OR"))),
  "CustNo;Addr1");
if !(VarType(V) == varNull)
{
  C = V[0];
  A = V[1];
  ShowMessage(IntToStr(C) + #10 + A);
```

```
}
else
  ShowMessage("Search unsuccessful!");
```

See Also

Locate (see page 9915)

VarArrayOf (see page 23648)

VarArraycreate

53.1.5.4.85 TBDEDataSet.MapsToIndex Method

Pascal

```
function MapsToIndex(Fields: TList; CaseInsensitive: Boolean): Boolean;
```

C++

```
__fastcall Boolean MapsToIndex(TList Fields, Boolean CaseInsensitive);
```

Description

This is MapsToIndex, a member of class TBDEDataSet.

53.1.5.4.86 TBDEDataSet.OpenCursor Method

Pascal

```
procedure OpenCursor(InfoQuery: Boolean); override;
```

C++

```
virtual __fastcall OpenCursor(Boolean InfoQuery);
```

Description

This is OpenCursor, a member of class TBDEDataSet.

53.1.5.4.87 TBDEDataSet.Post Method

Writes a modified record to the database.

Pascal

```
procedure Post; override;
```

C++

```
virtual __fastcall Post();
```

Description

Call Post to write a modified record to the database. Dataset methods that change the dataset state, such as Edit, Insert, or Append, or that move from one record to another, such as First, Last, Next, and Prior automatically call Post.

Delphi Examples:

```
{
This example appends a new record to a table or client
dataset when the user clicks a button. The two fields
Field1 and Field2 are filled from the contents of two edit
controls.  This example requires a populated TTable or
TDataSet with the appropriate field values.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Customers.Append;
  Customers.FieldValues['Field1'] := StrToInt(Edit1.text);
  Customers.FieldValues['Field2'] := Edit2.text;
  Customers.Post;
end;
```

See Also

State (see page 7036)

BeforePost (see page 7052)

Append (see page 6910)

Edit (see page 6932)

First (see page 6942)

Insert (see page 6959)

Last (see page 6968)

Next (see page 6973)

Prior (see page 6979)

Resync (see page 6994)

UpdateRecord (see page 7002)

53.1.5.4.88 TBDEDataSet.PostKeyBuffer Method

Pascal

```
procedure PostKeyBuffer(Commit: Boolean);
```

C++

```
__fastcall PostKeyBuffer(Boolean Commit);
```

Description

This is PostKeyBuffer, a member of class TBDEDataSet.

53.1.5.4.89 TBDEDataSet.PrepareCursor Method

Pascal

```
procedure PrepareCursor; virtual;
```

C++

```
virtual __fastcall PrepareCursor();
```

Description

This is PrepareCursor, a member of class TBDEDataSet.

53.1.5.4.90 TBDEDataSet.ProcessUpdates Method

Pascal

```
function ProcessUpdates(UpdCmd: DBIDelayedUpdCmd): DBIResult;
```

C++

```
__fastcall DBIResult ProcessUpdates(DBIDelayedUpdCmd UpdCmd);
```

Description

This is ProcessUpdates, a member of class TBDEDataSet.

53.1.5.4.91 TBDEDataSet.PSGetUpdateException Method

Generates an EUpdateError object based on another exception object.

Pascal

```
function PSGetUpdateException(E: Exception; Prev: EUpdateError): EUpdateError; override;
```

C++

```
virtual __fastcall EUpdateError PSGetUpdateException(Exception E, EUpdateError Prev);
```

Description

The provider component calls PSGetUpdateException when the exception E occurs while applying updates. This method allows the provider to create a single EUpdateError object that encapsulates all the exceptions that occur in an update operation.

PSGetUpdateError determines the error message, context string, and error code from the exception specified by E and creates a new EUpdateError exception that includes that information as well as the information about a previous error as specified by Prev. The context string and error code for E may be specific to the Exception class associated with the dataset. By default, TDataSet generates an EUpdateError with an error code of 1 and an empty context string.

See Also

Create (see page 6733)

53.1.5.4.92 TBDEDataSet.PSIsSQLSupported Method

Indicates whether the dataset can execute SQL statements.

Pascal

```
function PSIsSQLSupported: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSIsSQLSupported();
```

Description

PSIsSQLSupported indicates whether the provider can call PSExecuteStatement to execute an SQL statement. When PSIsSQLSupported returns false, calling PSExecuteStatement generates an exception. The provider can still work with a dataset that returns false from PSIsSQLSupported, but it must set the ResolveToDataSet property to true, or provide data on a read-only basis.

See Also

PSIsSQLBased (see page 7584)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

53.1.5.4.93 TBDEDataSet.PSReset Method

Resets the dataset so that it is positioned on the first record.

Pascal

```
procedure PSReset; override;
```

C++

```
virtual __fastcall PSReset();
```

Description

The provider calls PSReset to reposition the dataset on the first record before fetching records.

See Also

GetRecords (see page 18468)

AS_GetRecords (see page 16455)

53.1.5.4.94 TBDEDataSet.PSUpdateRecord Method

Applies a single update to the underlying database table or tables.

Pascal

```
function PSUpdateRecord(UpdateKind: TUpdateKind; Delta: TDataSet): Boolean; override;
```

C++

```
virtual __fastcall Boolean PSUpdateRecord(TUpdateKind UpdateKind, TDataSet Delta);
```

Description

Before the provider generates SQL statements to apply an update, it calls PSUpdateRecord to let the dataset apply the update in some other fashion. For example, BDE-enabled datasets generate an OnUpdateRecord to allow the application to apply the update and, if the OnUpdateRecord event handler does not apply the update, uses any associated TUpdateSQL object to apply the update.

UpdateKind indicates whether the update is an insertion (ukInsert), deletion (ukDelete), or modification (ukModify).

Delta is the delta datapacket. The current record represents the record to be updated.

PSUpdateRecord returns true if it updates the record, false otherwise. If PSUpdateRecord returns false, the provider generates dynamic SQL to perform the update and calls PSExecuteStatement.

Note: PSUpdateRecord is only called if the provider's ResolveToDataSet property is false.

See Also

OnUpdateRecord (see page 9957)

TUpdateSQL (see page 10229)

applyupdates (see page 18459)

ResolveToDataSet (see page 18531)

53.1.5.4.95 TBDEDataSet.ResetCursorRange Method

Pascal

```
function ResetCursorRange: Boolean;
```

C++

```
__fastcall Boolean ResetCursorRange();
```

Description

This is ResetCursorRange, a member of class TBDEDataSet.

53.1.5.4.96 TBDEDataSet.RevertRecord Method

Restores the current record in the dataset to an unmodified state when cached updates are enabled.

Pascal

```
procedure RevertRecord;
```

C++

```
__fastcall RevertRecord();
```

Description

Call RevertRecord to undo changes made to the current record when cached updates are enabled.

Note: To undo all changes to all pending updates in the cache, call CancelUpdates (see page 9896).

See Also

CancelUpdates (see page 9896)

Using the BDE to Cache Updates

53.1.5.4.97 TBDEDataSet.SetBlockReadSize Method

Pascal

```
procedure SetBlockReadSize(Value: Integer); override;
```

C++

```
virtual __fastcall SetBlockReadSize(int Value);
```

Description

This is SetBlockReadSize, a member of class TBDEDataSet.

53.1.5.4.98 TBDEDataSet.SetBookmarkData Method

Pascal

```
procedure SetBookmarkData(Buffer: PChar; Data: Pointer); override;
```

C++

```
virtual __fastcall SetBookmarkData(const char * Buffer, void * Data);
```

Description

This is SetBookmarkData, a member of class TBDEDataSet.

53.1.5.4.99 TBDEDataSet.SetBookmarkFlag Method

Pascal

```
procedure SetBookmarkFlag(Buffer: PChar; Value: TBookmarkFlag); override;
```

C++

```
virtual __fastcall SetBookmarkFlag(const char * Buffer, TBookmarkFlag Value);
```

Description

This is SetBookmarkFlag, a member of class TBDEDataSet.

53.1.5.4.100 TBDEDataSet.SetCachedUpdates Method

Pascal

```
procedure SetCachedUpdates(Value: Boolean);
```

C++

```
__fastcall SetCachedUpdates(Boolean Value);
```

Description

This is SetCachedUpdates, a member of class TBDEDataSet.

53.1.5.4.101 TBDEDataSet.SetCursorRange Method

Pascal

```
function SetCursorRange: Boolean;
```

C++

```
__fastcall Boolean SetCursorRange();
```

Description

This is SetCursorRange, a member of class TBDEDataSet.

53.1.5.4.102 TBDEDataSet.SetFieldData Method

Pascal

```
procedure SetFieldData(Field: TField; Buffer: Pointer); override;
```

C++

```
virtual __fastcall SetFieldData(TField Field, void * Buffer);
```

Description

This is SetFieldData, a member of class TBDEDataSet.

53.1.5.4.103 TBDEDataSet.SetFilterData Method

Pascal

```
procedure SetFilterData(const Text: string; Options: TFilterOptions);
```

C++

```
__fastcall SetFilterData(const AnsiString Text, TFilterOptions Options);
```

Description

This is SetFilterData, a member of class TBDEDataSet.

53.1.5.4.104 TBDEDataSet.SetFiltered Method

Pascal

```
procedure SetFiltered(Value: Boolean); override;
```

C++

```
virtual __fastcall SetFiltered(Boolean Value);
```

Description

This is SetFiltered, a member of class TBDEDataSet.

53.1.5.4.105 TBDEDataSet.SetFilterHandle Method

Pascal

```
procedure SetFilterHandle(var Filter: HDBIFilter; Value: HDBIFilter);
```

C++

```
__fastcall SetFilterHandle(HDBIFilter Filter, HDBIFilter Value);
```

Description

This is SetFilterHandle, a member of class TBDEDataSet.

53.1.5.4.106 TBDEDataSet.SetFilterOptions Method

Pascal

```
procedure SetFilterOptions(Value: TFilterOptions); override;
```

C++

```
virtual __fastcall SetFilterOptions(TFilterOptions Value);
```

Description

This is SetFilterOptions, a member of class TBDEDataSet.

53.1.5.4.107 TBDEDataSet.SetFilterText Method

Pascal

```
procedure SetFilterText(const Value: string); override;
```

C++

```
virtual __fastcall SetFilterText(const AnsiString Value);
```

Description

This is SetFilterText, a member of class TBDEDataSet.

53.1.5.4.108 TBDEDataSet.SetIndexField Method

Pascal

```
procedure SetIndexField(Index: Integer; Value: TField);
```

C++

```
__fastcall SetIndexField(int Index, TField Value);
```

Description

This is SetIndexField, a member of class TBDEDataSet.

53.1.5.4.109 TBDEDataSet.SetKeyBuffer Method

Pascal

```
procedure SetKeyBuffer(KeyIndex: TKeyIndex; Clear: Boolean);
```

C++

```
__fastcall SetKeyBuffer(TKeyIndex KeyIndex, Boolean Clear);
```

Description

This is SetKeyBuffer, a member of class TBDEDataSet.

53.1.5.4.110 TBDEDataSet.SetKeyExclusive Method

Pascal

```
procedure SetKeyExclusive(Value: Boolean);
```

C++

```
__fastcall SetKeyExclusive(Boolean Value);
```

Description

This is SetKeyExclusive, a member of class TBDEDataSet.

53.1.5.4.111 TBDEDataSet.SetKeyFieldCount Method

Pascal

```
procedure SetKeyFieldCount(Value: Integer);
```

C++

```
__fastcall SetKeyFieldCount(int Value);
```

Description

This is SetKeyFieldCount, a member of class TBDEDataSet.

53.1.5.4.112 TBDEDataSet.SetKeyFields Method

Pascal

```
procedure SetKeyFields(KeyIndex: TKeyIndex; const Values: array of const);
```

C++

```
__fastcall SetKeyFields(TKeyIndex KeyIndex, const array of const Values);
```

Description

This is SetKeyFields, a member of class TBDEDataSet.

53.1.5.4.113 TBDEDataSet.SetLinkRanges Method

Pascal

```
procedure SetLinkRanges(MasterFields: TList);
```

C++

```
__fastcall SetLinkRanges(TList MasterFields);
```

Description

This is SetLinkRanges, a member of class TBDEDataSet.

53.1.5.4.114 TBDEDataSet.SetLocale Method

Pascal

```
procedure SetLocale(Value: TLocale);
```

C++

```
__fastcall SetLocale(TLocale Value);
```

Description

This is SetLocale, a member of class TBDEDataSet.

53.1.5.4.115 TBDEDataSet.SetOnFilterRecord Method

Pascal

```
procedure SetOnFilterRecord(const Value: TFilterRecordEvent); override;
```

C++

```
virtual __fastcall SetOnFilterRecord(const TFilterRecordEvent Value);
```

Description

This is SetOnFilterRecord, a member of class TBDEDataSet.

53.1.5.4.116 TBDEDataSet.SetOnUpdateError Method

Pascal

```
procedure SetOnUpdateError(UpdateEvent: TUpdateErrorEvent);
```

C++

```
__fastcall SetOnUpdateError(TUpdateErrorEvent UpdateEvent);
```

Description

This is SetOnUpdateError, a member of class TBDEDataSet.

53.1.5.4.117 TBDEDataSet.SetRecNo Method

Pascal

```
procedure SetRecNo(Value: Integer); override;
```

C++

```
virtual __fastcall SetRecNo(int Value);
```

Description

This is SetRecNo, a member of class TBDEDataSet.

53.1.5.4.118 TBDEDataSet.SetStateFieldValue Method

Pascal

```
procedure SetStateFieldValue(State: TDataSetState; Field: TField; const Value: Variant);
override;
```

C++

```
virtual __fastcall SetStateFieldValue(TDataSetState State, TField Field, const Variant Value);
```

Description

This is SetStateFieldValue, a member of class TBDEDataSet.

53.1.5.4.119 TBDEDataSet.SetupCallBack Method

Pascal

```
procedure SetupCallBack(Value: Boolean);
```

C++

```
__fastcall SetupCallBack(Boolean Value);
```

Description

This is SetupCallBack, a member of class TBDEDataSet.

53.1.5.4.120 TBDEDataSet.SetUpdateObject Method

Pascal

```
procedure SetUpdateObject(Value: TDataSetUpdateObject);
```

C++

```
__fastcall SetUpdateObject(TDataSetUpdateObject Value);
```

Description

This is SetUpdateObject, a member of class TBDEDataSet.

53.1.5.4.121 TBDEDataSet.SetUpdateRecordSet Method

Pascal

```
procedure SetUpdateRecordSet(RecordTypes: TUpdateRecordTypes);
```

C++

```
__fastcall SetUpdateRecordSet(TUpdateRecordTypes RecordTypes);
```

Description

This is SetUpdateRecordSet, a member of class TBDEDataSet.

53.1.5.4.122 TBDEDataSet.SwitchToIndex Method

Pascal

```
procedure SwitchToIndex(const IndexName: string; const TagName: string);
```

C++

```
__fastcall SwitchToIndex(const AnsiString IndexName, const AnsiString TagName);
```

Description

This is SwitchToIndex, a member of class TBDEDataSet.

53.1.5.4.123 TBDEDataSet.Translate Method

Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).

Pascal

```
function Translate(Src: PChar; Dest: PChar; ToOem: Boolean): Integer; override;
```

C++

```
virtual __fastcall int Translate(const char * Src, const char * Dest, Boolean ToOem);
```

Description

When the ToOem parameter is true, Translate converts the source string from the ANSI character set to the OEM character set. If ToOem is false, Translate converts the source string from the OEM character set to the Microsoft ANSI character set. By default, BDE datasets work with strings in the OEM character set.

53.1.5.4.124 TBDEDataSet.UpdateCallbackRequired Method

Pascal

```
function UpdateCallbackRequired: Boolean;
```

C++

```
__fastcall Boolean UpdateCallbackRequired();
```

Description

This is UpdateCallbackRequired, a member of class TBDEDataSet.

53.1.5.4.125 TBDEDataSet.UpdateStatus Method

Reports the update status for the current record.

Pascal

```
function UpdateStatus: TUpdateStatus; override;
```

C++

```
virtual __fastcall TUpdateStatus UpdateStatus();
```

Description

Call UpdateStatus to determine the update status for the current record in a dataset when cached updates are enabled. Update status can change frequently as records are edited, inserted, or deleted. UpdateStatus offers a convenient method for applications to assess the current status before undertaking or completing operations that depend on the update status of individual records in the dataset.

Using the BDE to Cache Updates

53.1.5.5 TBDEDataSet Properties

The properties of the TBDEDataSet class are listed here.

Protected Properties

	Name	Description
	StmtHandle (see page 9935)	Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.

Public Properties

	Name	Description
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	Handle (see page 9933)	Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
	UpdateObject (see page 9936)	Specifies the update object component used to update a read-only result set when cached updates are enabled.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.

53.1.5.5.1 TBDEDataSet.Active Property

Specifies whether or not a dataset is open.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Use Active to determine or set whether a dataset is populated with data. When Active is false, the dataset is closed; the dataset cannot read or write data and data-aware controls can not use it to fetch data or post edits. When Active is true, the dataset can be populated with data. It can read data from a database or other source (such as a provider). Depending on the CanModify property, active datasets can post changes.

Setting Active to true:

1. Generates a BeforeOpen event.
2. Sets the dataset state to dsBrowse.
3. Establishes a way to fetch data (typically by opening a cursor).
4. Generates an AfterOpen event.

If an error occurs while opening the dataset, dataset state is set to dsInactive, and any cursor is closed.

Setting Active to false:

1. Triggers a BeforeClose event.
2. Sets the State property to dsInactive.
3. Closes the cursor.
4. Triggers an AfterClose event.

An application must set Active to false before changing other properties that affect the status of a database or the controls that display data in an application.

Note: Calling the Open method sets Active to true; calling the Close method sets Active to false.

Delphi Examples:

```
{
This example requires a database with the following name or
in the form of a *.DB file in the following path.  The table
should be closed when changing the database.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Active := False;
  try
  { First try to use an alias }
    Customers.DatabaseName := 'DBDEMOS';
    Customers.Active := True;
  except
    on EDatabaseError do
    begin
      { If that fails, try to use the drive and directory }
      Customers.TableName := 'Flights';
      Customers.DatabaseName :=
        'c:\Documents and Settings\All Users\Documents\RAD
Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data';
      Customers.Active := True;
    end;
  end;
```

```
end;
```

Fetching the Data

53.1.5.5.2 TBDEDataSet.AutoCalcFields Property

Determines when the OnCalcFields event is triggered and when lookup field values are calculated.

Pascal

```
property AutoCalcFields: Boolean;
```

C++

```
__property Boolean AutoCalcFields;
```

Description

Set AutoCalcFields to control when the OnCalcFields event is triggered to update calculated fields and when lookup fields are calculated.

A calculated field is one that derives its value from the values of one or more fields in the active record, sometimes with additional processing. Lookup fields are fields whose values come from a secondary dataset or lookup cache.

Note: Unidirectional datasets support calculated fields but not unidirectional fields. For unidirectional datasets, OnCalcFields only controls when calculated fields are updated.

When AutoCalcFields is true (the default), Lookup fields are recalculated and OnCalcFields is triggered when:

The dataset is opened.

The dataset is put into dsEdit state.

Focus moves from one visual control to another, or from one column to another in a data-aware grid and modifications have been made to the record.

When AutoCalcFields is false, Lookup fields are recalculated and the OnCalcFields event occurs only when

The dataset is opened.

The dataset is put into dsEdit state.

A record is retrieved from a database.

If an application permits users to change data, OnCalcFields is frequently triggered. In these cases an application may set AutoCalcFields to false to reduce the frequency with which the OnCalcFields event occurs and with which lookup values are fetched.

OnCalcFields (see page 7053)

Calculating Fields

53.1.5.5.3 TBDEDataSet.CacheBlobs Property

Determines whether BLOB fields are cached in memory.

Pascal

```
property CacheBlobs: Boolean;
```

C++

```
__property Boolean CacheBlobs;
```

Description

Use CacheBlobs to specify whether to store BLOB images in memory to improve performance when scrolling through records that display BLOB images. CacheBlobs is true by default, meaning that BLOBs are cached in memory. If an application does not need to display the BLOBs associated with records, then set CacheBlobs to false to conserve system resources.

See Also

TTable (see page 10168)

Caching BLOBs

53.1.5.5.4 TBDEDataSet.CachedUpdates Property

Specifies whether cached updates are enabled for a dataset.

Pascal

```
property CachedUpdates: Boolean;
```

C++

```
__property Boolean CachedUpdates;
```

Description

CachedUpdates enables or disables the use of cached updates for a dataset. If CachedUpdates is true, cached updates are enabled. If CachedUpdates is false, cached updates are disabled.

When cached updates are enabled, updates to a dataset (such as posting changes, inserting new records, or deleting records), are stored in an internal cache on the client machine instead of being written directly to the dataset's underlying database tables. When changes are complete, an application writes all cached changes to the database in the context of a single transaction.

Cached updates are most useful to client applications in two-tiered applications. The main benefits of enabling cached updates are:

Fewer transactions and shorter transaction times.

Minimization of network traffic.

The potential drawbacks of enabling cached updates are:

Other applications can access and change the actual data on the server while users are editing local copies of the data, resulting in an update conflict when cached updates are applied to the database.

Other applications cannot access data changes made by an application until its cached updates are applied to the database.

Note: Instead of using cached updates, applications can obtain the same benefits with greater control by using a client dataset and a provider component.

Note: When cached updates are enabled, data changes are stored in local memory. The storage medium is a Paradox format in-memory table. This has implications for applications run in a network environment in that the NET DIR parameter for the Borland (see page 1761) Database Engine (BDE) driver for Paradox needs to be set -- even though the application may be designed to use other database types. Failure to properly set this parameter can result in an EDBEngineError (see page 9854) exception. There are two ways to set NET DIR. One is through the BDE configuration utility BDE Administrator (described in the BDE Administrator online help). The other way is through the NetFileDir property of TSession (see page 10093).

Enabling BDE-based Cached Updates

Using the BDE to Cache Updates

Using TUpdateSQL to Update a Dataset

53.1.5.5.5 TBDEDataSet.ExpIndex Property

Indicates whether a dataset is using a dBASE expression index.

Pascal

```
property ExpIndex: Boolean;
```

C++

```
__property Boolean ExpIndex;
```

Description

Read ExpIndex to determine if a dataset is using a dBASE expression index. If ExpIndex is true, an expression index is in use; otherwise ExpIndex is false.

53.1.5.5.6 TBDEDataSet.Handle Property

Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.

Pascal

```
property Handle: HDBICur;
```

C++

```
__property HDBICur Handle;
```

Description

Use Handle only to bypass TDataSet methods and call directly into the BDE. Many BDE function calls require a cursor handle parameter. Handle is assigned an initial value when a dataset is opened. If used with a BDE call that changes the current record position, call Resync immediately after returning from the BDE call.

Note: Do not use this property unless an application requires BDE functionality not available through built-in components.

See Also

Locale (see page 9934)

Resync (see page 6994)

53.1.5.5.7 TBDEDataSet.KeySize Property

Specifies the size of the key for the current index of the dataset.

Pascal

```
property KeySize: Word;
```

C++

```
__property Word KeySize;
```

Description

Check (see page 10245) KeySize to determine the size, in bytes, of the key for the current index. KeySize varies depending on the number and type of fields that make up the current index.

See Also

RecordSize (see page 7035)

53.1.5.5.8 TBDEDataSet.Locale Property

Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.

Pascal

```
property Locale: TLocale;
```

C++

```
__property TLocale Locale;
```

Description

Examine Locale to determine the BDE language driver for the dataset. Applications that make direct calls to the BDE API may need to pass Locale information as a function parameter.

Language driver information may also be available as one of the values in the Params property of the database component that owns the dataset.

Note: Do not use this property unless an application requires BDE functionality not available through built-in components.

See Also

Handle (see page 9933)

Locale (see page 9985)

53.1.5.5.9 TBDEDataSet.ObjectView Property

Specifies whether fields are stored hierarchically or flattened out in the Fields property.

Pascal

```
property ObjectView: Boolean;
```

C++

```
__property Boolean ObjectView;
```

Description

ObjectView affects the way the Fields property stores object fields and the way data-aware grids display ADT and array fields.

When ObjectView is true, the fields are stored hierarchically in the Fields property, meaning any child fields of an object field are referenced by the object field and don't appear sequentially after the object field in the TFields:: .Fields array. When ObjectView is false, the fields are stored sequentially in the Fields property, meaning any child fields of an object field are stored after the object field as siblings in the Fields array.

When ObjectView is false, object field types, such as TADTField, are not created. This switch is provided for increased compatibility with older data-aware controls, which may not handle object field types properly. The default is false for TBDEDataSet, and true for TClientDataSet.

Note: If the ObjectView property of the dataset provided to a TClientDataSet is false, then the TClientDataSet's ObjectView property always acts as false, since the data received is already flattened.

Working with Array Fields

53.1.5.5.10 TBDEDataSet.StmtHandle Property

Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.

Pascal

```
property StmtHandle: HDBIStmt;
```

C++

```
__property HDBIStmt StmtHandle;
```

Description

Use StmtHandle for direct calls to the BDE that bypass the methods of this dataset. Some BDE API calls require a statement

handle as a parameter. For example, TBDEDataSet (see page 9878) descendants use StmtHandle when preparing a query or binding parameters.

Typically, applications do not need to access this property. In TBDEDataSet (see page 9878), StmtHandle is protected, and so unavailable to applications. Some descendants make this property public so that you can bypass the dataset methods and make direct calls to the BDE.

Handle (see page 9933)

Prepare (see page 10077)

Prepare (see page 10157)

Params (see page 10087)

Params (see page 10165)

53.1.5.5.11 TBDEDataSet.UpdateObject Property

Specifies the update object component used to update a read-only result set when cached updates are enabled.

Pascal

```
property UpdateObject: TDataSetUpdateObject;
```

C++

```
__property TDataSetUpdateObject UpdateObject;
```

Description

Use UpdateObject to specify the TUpdateObject component to use in an application that must be able to update a read-only result set returned by the Borland (see page 1761) Database Engine (BDE).

The BDE always attempts to provide an updatable, or "live" query result unless an application specifically requests a read-only view of data. In some cases, such as a query made against multiple tables, a live result set cannot be returned. In these cases, UpdateObject can be used to specify a TUpdateSQL (see page 10229) component that performs updates as a separate transaction that is transparent to the application.

Updating a Read-only Result Set

Using TQuery

Using TUpdateSQL to Update a Dataset

53.1.5.5.12 TBDEDataSet.UpdateRecordTypes Property

Specifies the type of records visible in a dataset when cached updates are enabled.

Pascal

```
property UpdateRecordTypes: TUpdateRecordTypes;
```

C++

```
__property TUpdateRecordTypes UpdateRecordTypes;
```

Description

Use UpdateRecordTypes to specify the records that are visible in a dataset when cached updates are enabled. UpdateRecordTypes is a set that can have the following values:

Value	Meaning
rtModified	Modified records are visible.
rtInserted	Inserted records are visible.
rtDeleted	Deleted records are visible.
rtUnmodified	Unmodified records are visible.

By default, a dataset is created with an UpdateRecordTypes set of [rtModified, rtInserted, rtUnmodified], meaning that all existing, edited, or inserted records are visible to the user.

An application that must cycle through a dataset to undelete records may change UpdateRecordTypes as part of an undelete method, so that deleted records are "visible" long enough to restore them to their previously undeleted conditions.

An application might also use UpdateRecordTypes like a filter to temporarily limit visible records to those added or inserted by the user during the current session.

UpdateStatus (see page 9928)

Using the BDE to Cache Updates

53.1.5.5.13 TBDEDataSet.UpdatesPending Property

Indicates whether the cached updates buffer contains records that are not yet applied.

Pascal

```
property UpdatesPending: Boolean;
```

C++

```
__property Boolean UpdatesPending;
```

Description

Examine UpdatesPending to check the status of the cached updates buffer. If UpdatesPending is true, then there are edited, deleted, or inserted records to apply to the database. If UpdatesPending is false, there are no records in the cache.

53.1.5.6 TBDEDataSet Events

The events of the TBDEDataSet class are listed here.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

53.1.5.6.1 TBDEDataSet.AfterCancel Event

Occurs after an application completes a request to cancel modifications to the active record.

Pascal

```
property AfterCancel: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterCancel;
```

Description

Write an AfterCancel event handler to take specific action after an application cancels changes to the active record. AfterCancel is called by the Cancel method after it updates the current position, releases the lock on the active record if necessary, and sets the dataset state to dsBrowse. If an application requires additional processing before returning control to a user after a Cancel event, code it in the AfterCancel event.

Delphi Examples:

```
{
This example updates the form’s status bar with a message
when an AfterCancel event occurs.  Set the StatusBar
SimplePanel property to True.
}
procedure TForm1.Table1AfterCancel(DataSet: TDataSet);
begin
  StatusBar1.SimpleText := 'Record changes cancelled for ' + DataSet.Name;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Table1.Cancel;
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  Table1.Post
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Name := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
    begin
        Table1.Close;
        Table1.DeleteTable;
    end;
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
```

```
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.AfterCancel:= Table1AfterCancel;
    Table1.Active:= True;
  end;
```

State (see page 7036)

53.1.5.6.2 TBDEDataSet.AfterClose Event

Occurs after an application closes a dataset.

Pascal

```
property AfterClose: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterClose;
```

Description

Write an AfterClose event handler to take specific action immediately after an application closes a dataset. For example, as a security measure, an application might clear a PASSWORD entry from the Params property of a TSQLConnection component when the dataset is closed.

AfterClose is called after a dataset is closed and the dataset state is set to dsInactive.

Delphi Examples:

```
{
This example adds an entry to a memo with a message when an
AfterOpen event or an AfterClose event occurs.  Populate the
ClientDataSet events with CheckButtonActive.
}
procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  if (Button1.Enabled) then
    Memo2.Lines.Add('Now that the dataset is open, record information is available.')
  else
    Memo2.Lines.Add('Now that the dataset is closed, record information is not available.');
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

53.1.5.6.3 TBDEDataSet.AfterDelete Event

Occurs after an application deletes a record.

Pascal

```
property AfterDelete: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterDelete;
```

Description

Write an AfterDelete event handler to take specific action immediately after an application deletes the active record in a dataset. AfterDelete is called by Delete after it deletes the record, sets the dataset state to dsBrowse, and repositions the current record.

C++ Examples:

```
/*
This example displays a message on the form's status bar
indicating the record count after a record is deleted.  Set
the StatusBar SimplePanel property to True.
*/
void __fastcall TForm1::Table1AfterDelete(TDataSet *DataSet)
{
  StatusBar1->SimpleText = Format(
    "There are now %d records in the table",
    ARRAYOFCONST(((int)DataSet->RecordCount)));
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Table1->Delete();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Table1 = new TTable(Form1);
  Table1->Active = false; // The Table component must not be active
  Table1->DatabaseName = "DBDEMOS";
  Table1->TableType = ttParadox;
  Table1->TableName = "CustInfo";
  Table1->Active = False;
  if (!Table1->Exists) // Don't overwrite an existing table
  {
    Table1->Close();
    Table1->DeleteTable();
  }
  // The Table component must not be active
  // First, describe the type of table and give
  // it a name
  // Next, describe the fields in the table
  Table1->FieldDefs->Clear();
  TFieldDef *pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field1";
  pNewDef->DataType = ftInteger;
  pNewDef->Required = true;
  pNewDef = Table1->FieldDefs->AddFieldDef();
  pNewDef->Name = "Field2";
  pNewDef->DataType = ftString;
  pNewDef->Size = 30;
  // Next, describe any indexes
  Table1->IndexDefs->Clear();
```

```
  /* the 1st index has no name because it is a Paradox primary key */
  Table1->IndexDefs->Add("","Field1", TIndexOptions() <<ixPrimary << ixUnique);
  Table1->IndexDefs->Add("Fld2Index","Field2", TIndexOptions() << ixCaseInsensitive);
  // Now that we have specified what we want, create the table
  Table1->CreateTable();
  Table1->Active = True;
  for (int i = 1; i <= 20; i++)
    Table1->AppendRecord(ARRAYOFCONST((i*111, i*222)));
  DS2->DataSet = Table1;
  DBGrid2->DataSource->DataSet = Table1;
  Table1->AfterDelete = Table1AfterDelete;
  Table1->Active = True;
}
```

Delphi Examples:

```
{
This example displays a message on the form's status bar
indicating the record count after a record is deleted.  Set
the StatusBar SimplePanel property to True.
}
procedure TForm1.Table1AfterDelete(DataSet: TDataSet);
begin
  StatusBar1.SimpleText := Format('There are now %d records in the table',
[DataSet.RecordCount]);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Delete;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Name := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
    begin
        Table1.Close;
        Table1.DeleteTable;
    end;
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
```

```
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.AfterDelete:= Table1AfterDelete;
    Table1.Active:= True;
  end;
```

53.1.5.6.4 TBDEDataSet.AfterEdit Event

Occurs after an application starts editing a record.

Pascal

```
property AfterEdit: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterEdit;
```

Description

Write an AfterEdit event handler to take specific action immediately after dataset enters edit mode. AfterEdit is called by Edit after it enables editing of a record, recalculates calculated fields, and calls the data event handler to process a record change.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
```

```
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
```

See Also

BeforeEdit (see page 7049)

Edit (see page 6932)

53.1.5.6.5 TBDEDataSet.AfterInsert Event

Occurs after an application inserts a new record.

Pascal

```
property AfterInsert: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterInsert;
```

Description

Write an AfterInsert event handler to take specific action immediately after an application inserts a record. The Insert and Append methods generate an AfterInsert event after inserting or appending a new record.

Delphi Examples:

```
{
This example updates a memo with a message when an
AfterInsert event or a BeforeInsert event occurs.
}
procedure TForm1.ClientDataSet1AfterInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After inserting a record');
end;

procedure TForm1.ClientDataSet1BeforeInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before inserting a record');
end;
```

See Also

BeforeInsert (see page 7050)

Append (see page 6910)

Insert (see page 6959)

53.1.5.6.6 TBDEDataSet.AfterOpen Event

Occurs after an application completes opening a dataset and before any data access occurs.

Pascal

```
property AfterOpen: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterOpen;
```

Description

Write an AfterOpen event handler to take specific action immediately after an application opens the dataset. AfterOpen is called after the dataset establishes access to its data and the dataset is put into dsBrowse state. For example, an AfterOpen event handler might check an ini file to determine the last record touched in the dataset the previous time the application ran, and position the dataset at that record.

Delphi Examples:

```
{
This example adds an entry to a memo with a message when an
AfterOpen event or an AfterClose event occurs.  Populate the
ClientDataSet events with CheckButtonActive.
}
procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  if (Button1.Enabled) then
    Memo2.Lines.Add('Now that the dataset is open, record information is available.')
  else
    Memo2.Lines.Add('Now that the dataset is closed, record information is not available.');
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
{
The following code fragment illustrates how DataSets and
DataSetCount can be used to ensure that an action is taken
for every open dataset.  Assign CheckButtonActive as the
AfterClose and AfterOpen event handlers for TClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  if not RemoteServer1.Connected then
    RemoteServer1.Connected := True;
  ClientDataSet1.Close;
  with RemoteServer1 do
  begin
    for I := 0 to DataSetCount - 1 do
      DataSets[I].EnableControls;
  end;
  ClientDataSet1.Open;
end;

procedure TForm1.Button3Click(Sender: TObject);
var
  I: Integer;
begin
  ClientDataSet1.Close;
  RemoteServer1.Connected := False;
  with RemoteServer1 do
  begin
```

```
    for I := 0 to DataSetCount - 1 do
      DataSets[I].DisableControls;
  end;
end;

procedure TForm1.CheckButtonActive(DataSet: TDataSet);
begin
  Button1.Enabled := not ClientDataSet1.Active;
  Button2.Enabled := ClientDataSet1.Active;
  Button3.Enabled := ClientDataSet1.Active;
end;
```

See Also

Active (see page 7004)

BeforeOpen (see page 7051)

Open (see page 6976)

Opening and Closing Datasets

53.1.5.6.7 TBDEDataSet.AfterPost Event

Occurs after an application writes the active record to the database or change log and returns to browse state.

Pascal

```
property AfterPost: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterPost;
```

Description

Write an AfterPost event handler to take specific action immediately after an application posts a change to the active record. AfterPost is called after a modification or insertion is made to a record.

Delphi Examples:

```
{
This example updates the form's status bar with a message
when an AfterPost event occurs.
}
procedure TForm1.ClientDataSet1AfterPost(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before posting a record');
end;
```

See Also

BeforePost (see page 7052)

Post (see page 6977)

53.1.5.6.8 TBDEDataSet.AfterRefresh Event

Occurs after an application refreshes the data in the dataset.

Pascal

```
property AfterRefresh: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterRefresh;
```

Description

Write an AfterRefresh event handler to take specific action immediately after an application has updated the records in the dataset. AfterRefresh is generated by calls to the Refresh method.

See Also

BeforeRefresh (see page 7052)

Refresh (see page 6991)

53.1.5.6.9 TBDEDataSet.AfterScroll Event

Occurs after an application scrolls from one record to another.

Pascal

```
property AfterScroll: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent AfterScroll;
```

Description

Write an AfterScroll event handler to take specific action immediately after an application scrolls to another record as a result of a call to the First, Last, MoveBy, Next, Prior, FindKey, FindFirst, FindNext, FindLast, FindPrior, and Locate methods. AfterScroll is called after all other events triggered by these methods and any other methods that switch from record to record in the dataset.

See Also

BeforeScroll (see page 7053)

First (see page 6942)

Last (see page 6968)

MoveBy (see page 6971)

Next (see page 6973)

Prior (see page 6979)

Navigating Datasets

53.1.5.6.10 TBDEDataSet.BeforeCancel Event

Occurs before an application executes a request to cancel changes to the active record.

Pascal

```
property BeforeCancel: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeCancel;
```

Description

Write a BeforeCancel event to take specific action before an application carries out a request to cancel changes. BeforeCancel is called by the Cancel method before it cancels a dataset operation such as Edit, Insert, or Delete.

An application might use the BeforeCancel event to record a user's changes in an undo buffer.

See Also

AfterCancel (see page 7038)

Delete (see page 6924)

Edit (see page 6932)

Insert (see page 6959)

53.1.5.6.11 TBDEDataSet.BeforeClose Event

Occurs immediately before the dataset closes.

Pascal

```
property BeforeClose: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeClose;
```

Description

Write a BeforeClose event to take specific action before an application closes a dataset. Calling Close or setting the Active property to false results in a call to the BeforeClose event handler.

See Also

Active (see page 7004)

AfterClose (see page 7040)

Close (see page 6920)

Opening and Closing Datasets

Posting Data

53.1.5.6.12 TBDEDataSet.BeforeDelete Event

Occurs before an application attempts to delete the active record.

Pascal

```
property BeforeDelete: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeDelete;
```

Description

Write a BeforeDelete event handler to take specific action before an application deletes the active record. BeforeDelete is called by Delete before it actually deletes a record.

In Delphi, making use of this event an application might, for example, display a dialog box asking for confirmation before deleting the record. On denial of confirmation, the application could abort the deletion by calling the Abort procedure.

See Also

AfterDelete (see page 7041)

Delete (see page 6924)

Abort (see page 22786)

53.1.5.6.13 TBDEDataSet.BeforeEdit Event

Occurs before an application enters edit mode for the active record.

Pascal

```
property BeforeEdit: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeEdit;
```

Description

Write a BeforeEdit event handler to take specific action before an application enables editing of the active record. For example, an application that keeps a log of database edits could use the BeforeEdit event to record the edit request, time, and user before entering edit state.

Delphi Examples:

```
{
This example adds an entry to a memo with a message
when an AfterEdit event occurs and when a BeforeEdit event
occurs.  Click on Run SQL to populate the DBGrid.  Then
select a cell to edit and click the Edit current cell
button, or just start editing the cell to invoke the
BeforeEdit and AfterEdit events.
}
procedure TForm1.ClientDataSet1AfterEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.ClientDataSet1BeforeEdit(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before editing record' + IntToStr(DataSet.RecNo));
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  ClientDataSet1.Edit;
end;
```

See Also

State (see page 7036)

AfterEdit (see page 7044)

Edit (see page 6932)

53.1.5.6.14 TBDEDataSet.BeforeInsert Event

Occurs before an application enters insert mode.

Pascal

```
property BeforeInsert: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeInsert;
```

Description

Write a BeforeInsert event handler to take specific action before an application inserts or appends a new record. The Insert or

Append method generates a BeforeInsert method before it sets the dataset into dsInsert state.

Delphi Examples:

```
{
This example updates a memo with a message when an
AfterInsert event or a BeforeInsert event occurs.
}
procedure TForm1.ClientDataSet1AfterInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('After inserting a record');
end;

procedure TForm1.ClientDataSet1BeforeInsert(DataSet: TDataSet);
begin
   Memo2.Lines.Add('Before inserting a record');
end;
{
This example uses the BeforeInsert event to do data
validation. If the StrToInt function raises an exception,
the edit control’s contents are set to a valid value so
that the assignment to the INTEGER field in the dataset
will succeed.  Continuing after the exception causes a
'0' to be placed in the PORTA field.
DataSet design:
This example requires a ClientDataSet, a DBGrid, a
DataSource and a DBNavigator.  Name the ClientDataSet CDS.
Set the DataSet property in the DataSource to CDS and name
that DataSource DS.  Set the DataSource in the DBNavigator
to DS the DataSource in the DBGrid to DS.  Right click on CDS
and select the Fields Editor, then right click on the Field
Editor form and create two fields by selecting "new field".
In the field configuration window, set the name to HOST, the
Component value will automatically be set to CDSHOST.  Set
the filed type to String.  In the field configuration window
for the second field, set the name to PORTA, the Component
value will automatically be set to CDSPORTA.  Set the field
type to Integer.  The file used to load CDS must have an
attribute name of HOST with an attribute type of string and
an attribute name of PORTA with an attribute type of integer.
Add DB, DBCtrls, Grids, DBGrids and DBClient to the uses clause.
}
{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button3Click(Sender: TObject);
begin
  CDS.Insert;
  CDS.FieldByName('PORTA').AsInteger := StrToInt(Edit1.Text);
  CDS.Post;
end;

procedure TForm1.CDSBeforeInsert(DataSet: TDataSet);
begin
  try
  { Make sure edit field can be converted to integer --
   this will raise an exception if it can’t }
    StrToInt(Edit1.Text);
  except
    Edit1.Text := '0';
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;
```

Append (see page 6910)

Insert (see page 6959)

53.1.5.6.15 TBDEDataSet.BeforeOpen Event

Occurs before an application executes a request to open a dataset.

Pascal

```
property BeforeOpen: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeOpen;
```

Description

Write a BeforeOpen event handler to take specific action before an application opens a dataset for viewing or editing. BeforeOpen is triggered when an application sets the Active property to true for a dataset or an application calls Open.

See Also

Active (see page 7004)

AfterOpen (see page 7045)

Open (see page 6976)

Opening and Closing Datasets

53.1.5.6.16 TBDEDataSet.BeforePost Event

Occurs before an application posts changes for the active record to the database or change log.

Pascal

```
property BeforePost: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforePost;
```

Description

Write a BeforePost event handler to take specific action before an application posts dataset changes. BeforePost is triggered when an application calls the Post method. Post checks to make sure all required fields are present, then calls BeforePost before posting the record.

An application might use BeforePost to perform validity checks on data changes before committing them. If it encountered a validity problem, it could call Abort to cancel the Post operation (Delphi) or throw an exception (C++).

Delphi Examples:

```
{
This example checks for a valid entry in a TDBEdit control
and calls the Abort procedure if the control is empty; Abort
cancels the post before it happens.
}
procedure TForm1.ClientDataSet1BeforePost(DataSet: TDataSet);
begin
  if DBEdit1.Text = '' then
    Abort;
  DataSet.Fields[2].AsString := DBEdit1.Text;
end;
```

AfterPost (see page 7046)

Post (see page 6977)

Abort (see page 22786)

Working with Field Component Methods at Runtime

53.1.5.6.17 TBDEDataSet.BeforeRefresh Event

Occurs immediately before an application refreshes the data in the dataset.

Pascal

```
property BeforeRefresh: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeRefresh;
```

Description

Write a BeforeRefresh event handler to take specific action immediately before an application updates the records in the dataset. BeforeRefresh is generated by calls to the Refresh method.

See Also

AfterRefresh (see page 7047)

Refresh (see page 6991)

53.1.5.6.18 TBDEDataSet.BeforeScroll Event

Occurs before an application scrolls from one record to another.

Pascal

```
property BeforeScroll: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent BeforeScroll;
```

Description

Write a BeforeScroll event handler to take specific action immediately before an application scrolls to another record as a result of a call to the First, Last, MoveBy, Next, Prior, FindKey, FindFirst, FindNext, FindLast, FindPrior, and Locate methods. BeforeScroll is called before all other events triggered by these methods and any other methods that switch from record to record in the dataset.

See Also

AfterScroll (see page 7047)

First (see page 6942)

Last (see page 6968)

MoveBy (see page 6971)

Next (see page 6973)

Prior (see page 6979)

Navigating Datasets

53.1.5.6.19 TBDEDataSet.OnCalcFields Event

Occurs when an application recalculates calculated fields.

Pascal

```
property OnCalcFields: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent OnCalcFields;
```

Description

Write an OnCalcFields event handler to take specific action when an application recalculates calculated fields. A calculated field is one that derives its value from the values in one or more fields in the dataset, sometimes with additional processing.

OnCalcFields is triggered when:

A dataset is opened.

A dataset is put into dsEdit state.

A record is retrieved from a database.

When the AutoCalcFields property is true, OnCalcFields is also triggered when:

Focus moves from one visual control to another, or from one column to another is a data-aware grid control and modifications were made to the record.

Note: When the AutoCalcFields property is true, an OnCalcFields event handler should not modify the dataset (or a linked dataset if it is part of a master-detail relationship), because such modifications retrigger the OnCalcField event, leading to infinite recursion.

If an application permits users to change data, OnCalcFields is frequently triggered. To reduce the frequency with which OnCalcFields occurs, set AutoCalcFields to false.

Warning: When the dataset is the master table of a master-detail relationship, OnCalcFields occurs before detail sets have been synchronized with the master table.

Active (see page 7004)

AutoCalcFields (see page 7006)

Open (see page 6976)

Post (see page 6977)

Calculating Fields

Using Internally Calculated Fields in Client Datasets

Defining a Calculated Field

53.1.5.6.20 TBDEDataSet.OnDeleteError Event

Occurs when an application attempts to delete a record and an exception is raised.

Pascal

```
property OnDeleteError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnDeleteError;
```

Description

Write an OnDeleteError event handler to handle exceptions that occur when an attempt to delete a record fails.

See Also

OnEditError (see page 7054)

OnPostError (see page 7056)

Delete (see page 6924)

53.1.5.6.21 TBDEDataSet.OnEditError Event

Occurs when an application attempts to modify or insert a record and an exception is raised.

Pascal

```
property OnEditError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnEditError;
```

Description

Write an OnEditError event handler to handle exceptions that occur when an attempt to edit a record fails.

See Also

OnDeleteError (see page 7054)

OnPostError (see page 7056)

Edit (see page 6932)

Insert (see page 6959)

53.1.5.6.22 TBDEDataSet.OnNewRecord Event

Occurs when an application inserts or appends a new dataset record.

Pascal

```
property OnNewRecord: TDataSetNotifyEvent;
```

C++

```
__property TDataSetNotifyEvent OnNewRecord;
```

Description

Write an OnNewRecord event handler to take specific actions as an application inserts or appends a new record. OnNewRecord

is called as part of the insert or append process. An application might use the OnNewRecord event to set initial values for a record or as a way of implementing cascading insertions in related datasets.

See Also

AfterInsert (see page 7044)

BeforeInsert (see page 7050)

53.1.5.6.23 TBDEDataSet.OnPostError Event

Occurs when an application attempts to modify or insert a record and an exception is raised.

Pascal

```
property OnPostError: TDataSetErrorEvent;
```

C++

```
__property TDataSetErrorEvent OnPostError;
```

Description

Write an OnPostError event handler to handle exceptions that occur when an attempt to post a record fails.

See Also

OnDeleteError (see page 7054)

OnEditError (see page 7054)

Post (see page 6977)

53.1.5.6.24 TBDEDataSet.OnUpdateError Event

Occurs if an exception is generated when cached updates are applied to a database.

Pascal

```
property OnUpdateError: TUpdateErrorEvent;
```

C++

```
__property TUpdateErrorEvent OnUpdateError;
```

Description

Write an OnUpdateError event handler to respond to exceptions generated while applying cached updates to a database.

Because there is a delay between the time a record is first cached and the time cached updates are applied, there is a possibility that another application may change one or more of the same records in the database before the cached changes can be applied. The Borland (see page 1761) Database Engine (BDE) checks for this condition and raises an exception. TBDEDataSet (see page 9878) responds by calling the OnUpdateError event handler if it exists.

DataSet is the name of the dataset to which updates are applied.

E is a pointer to a EDBEngineError (see page 9854) object from which an application can extract an error message and the actual cause of the error condition. The OnUpdateError handler can use this information to determine how to respond to the error condition.

UpdateKind indicates whether the error occurred while inserting, deleting, or modifying a record.

UpdateAction indicates the action to take when the OnUpdateError handler exits. On entry into the handler, UpdateAction is always set to uaFail. If OnUpdateError can handle or correct the error, set UpdateAction to uaRetry before exiting the error handler.

The error handler can use the OldValue and NewValue properties TField to evaluate error conditions and set NewValue to a new value to reapply. In this case, set UpdateAction to uaRetry before exiting.

Note: If a call to ApplyUpdates (see page 9894) raises an exception and ApplyUpdates (see page 9894) is not called within the context of a exception block, an error message is displayed. If an OnUpdateError handler cannot correct the error condition and leaves UpdateAction set to uaFail, the error message is displayed twice. To prevent redisplay, set UpdateAction to uaAbort in the error handler.

Warning: Important:The code in an OnUpdateError handler must not call any methods that make a different record the current one.

Using the BDE to Cache Updates

Handling Cached Update Errors

53.1.5.6.25 TBDEDataSet.OnUpdateRecord Event

Occurs when cached updates are applied to a record.

Pascal

```
property OnUpdateRecord: TUpdateRecordEvent;
```

C++

```
__property TUpdateRecordEvent OnUpdateRecord;
```

Description

Write an OnUpdateRecord event handler to process updates that cannot be handled by a single update component, such as implementation of cascading updates, insertions, or deletions. This handler is also useful for applications that require additional control over parameter substitution in update components.

DataSet is the name of the dataset to which updates are applied.

UpdateKind indicates whether the current update is the insertion of a record, the deletion of a record, or the modification of a record.

UpdateAction indicates the action taken by the OnUpdateRecord handler before it exits. On entry into the handler, UpdateAction is always set to uaFail. If OnUpdateRecord is successful, it should set UpdateAction to uaApplied before exiting.

The code in an OnUpdateRecord handler must not call any methods that make a different record the current one.

Note: As an alternate approach, application can use a client dataset and a provider component to handle cached updates. This alternative provides more support and greater control.

Using Update Objects to Update a Dataset

53.1.6 TBlobStream Class

TBlobStream is a stream object that provides services which allow applications to read from or write to field objects that represent Binary large object (BLOB) fields.

Class Hierarchy

Pascal

```
TBlobStream = class(TStream);
```

C++

```
class TBlobStream : public TStream;
```

File

DBTables

Description

Use TBlobStream to access or modify the value of a BLOB field in a BDE-enabled dataset. TBlob stream works with persistent TBlobField objects (including descendants of TBlobField such as TGraphicField and TMemoField). BLOB fields use BLOB streams to read data from and write data to the dataset.

TBlobStream allows objects that have no specialized knowledge of how data is stored in a BLOB field to read or write such data by employing the uniform stream mechanism.

To use a BLOB stream, create an instance of TBlobStream, use the methods of the stream to read or write the data, and then free the BLOB stream. Do not use the same instance of TBlobStream to access data from more than one record. Instead, create a new TBlobStream object every time you need to read or write BLOB data on a new record.

Specifying the HTML Template

53.1.6.1 TBlobStream Members

The following tables list the members exposed by TBlobStream.

Protected Methods

	Name	Description
	GetSize (see page 2982)	This is GetSize, a member of class TStream.
	SetSize (see page 2989)	This is the overview for the SetSize method overload.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyFrom (see page 2979)	Copies a specified number of bytes from one stream to another.
	Create (see page 9960)	Creates an instance of TBlobStream (see page 9958).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 9961)	Destroys an instance of TBlobStream (see page 9958).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FixupResourceHeader (see page 2981)	Patches the resource header for a resource that has been written to the stream.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Read (see page 9962)	Reads up to Count bytes from the current position in the field's data into Buffer.
	ReadBuffer (see page 2983)	Reads bytes from the stream into Buffer.
	ReadComponent (see page 2983)	Initiates streaming of components and their properties.
	ReadComponentRes (see page 2987)	Reads components and their properties from a stream in a resource file format.
	ReadResHeader (see page 2987)	Reads a resource-file header from the stream.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Seek (see page 9962)	Resets the current position of the TBlobStream (see page 9958) object.
	Seek (see page 2988)	This is the overview for the Seek method overload.
	Truncate (see page 9963)	Discards all data in the BLOB field from the current position on.
	Write (see page 9963)	Writes Count bytes from Buffer to the current position in the field and updates the current position by Count bytes.
	WriteBuffer (see page 2990)	Writes Count bytes from Buffer onto the stream and advances the current position of the stream by Count bytes.
	WriteComponent (see page 2990)	Initiates the writing of components and their properties to a stream.
	WriteComponentRes (see page 2994)	Writes components and their properties to a stream from a resource file format.
	WriteDescendent (see page 2994)	Streams components and their properties in inherited forms.
	WriteDescendentRes (see page 2995)	Streams components and their properties in inherited forms.
	WriteResourceHeader (see page 2995)	Writes a resource-file header to the stream.

Public Properties

	Name	Description
	Position (see page 2996)	Indicates the current offset into the stream for reading and writing.
	Size (see page 2997)	Indicates the size in bytes of the stream.

53.1.6.2 TBlobStream.Create Constructor

Creates an instance of TBlobStream (see page 9958).

Pascal

```
constructor Create(Field: TBlobField; Mode: TBlobStreamMode);
```

C++

```
__fastcall TBlobStream(TBlobField Field, TBlobStreamMode Mode);
```

Description

Call Create to obtain an instance of TBlobStream (see page 9958) for reading from or writing to a specific TBlobField object.

Tip: Different types of dataset use different classes of BLOB streams. It is usually a better idea to call the dataset's CreateBlobStream method than to call the BLOB stream constructor.

Create links the TBlobStream (see page 9958) to the field object specified by the Field parameter. Mode specifies whether the BLOB stream will be used to read data (bmRead), write data (bmWrite) or modify data (bmReadWrite). Mode must be one of the following values:

Value	Meaning
bmRead	The BLOB stream can read data from the field.
bmWrite	The BLOB stream can replace the data in the field.
bmReadWrite	The BLOB stream can modify the data in the field.

Note: : A TBlobStream (see page 9958) object should always be destroyed before navigating to a new record. Create a new instance of TBlobStream (see page 9958) for the new record.

Delphi Examples:

```
{
The following example copies the data in the Notes field of
Table1 or SQLDataSet1 to the Remarks field of ClientDataSet1.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Stream1: TBlobStream;
  Stream2: TStream;
  blobType : TBlobType;
begin
  blobType := Table1Notes.BlobType;
  Stream1 := TBlobStream.Create(Table1Notes, bmRead);
  try
    CDS2.Edit;
    { here's a different way to create a blob stream }
    Stream2 := CDS2.CreateBlobStream(CDS2.FieldByName('Remarks'), bmReadWrite);
    try
      Stream2.CopyFrom(Stream1, Stream1.Size);
//    CDS2.Post;
//    CDS2.Active := True;
    finally
      Stream2.Free;
    end;
  finally
    Stream1.Free;
  end;
end;
```

See Also

TBlobField (see page 6801)

CreateBlobStream (see page 6922)

53.1.6.3 TBlobStream.Destroy Destructor

Destroys an instance of TBlobStream (see page 9958).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBlobStream();
```

Description

Do not call Destroy directly in an application. Instead call Free. Free verifies that the TBlobStream (see page 9958) object is not nil and only then calls Destroy. Destroy the TBlobStream (see page 9958) object when it is no longer needed for reading from or writing to the BLOB field.

Destroy triggers an OnDataChange event if the BLOB stream was used to overwrite or modify the data in the field. Destroy then frees any buffers that were allocated to handle the data.

Note: : A TBlobStream (see page 9958) object should always be destroyed before navigating to a new record. Create (see page 9960) a new instance of TBlobStream (see page 9958) for the new record.

delete

53.1.6.4 TBlobStream Methods

The methods of the TBlobStream class are listed here.

Public Methods

	Name	Description
	Read (see page 9962)	Reads up to Count bytes from the current position in the field's data into Buffer.
	Seek (see page 9962)	Resets the current position of the TBlobStream (see page 9958) object.
	Truncate (see page 9963)	Discards all data in the BLOB field from the current position on.
	Write (see page 9963)	Writes Count bytes from Buffer to the current position in the field and updates the current position by Count bytes.

53.1.6.4.1 TBlobStream.Read Method

Reads up to Count bytes from the current position in the field's data into Buffer.

Pascal

```
function Read(var Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Read( Buffer, Longint Count);
```

Description

Call Read to read data from the BLOB field when the number of bytes in the field's data is not known.

Buffer is the target container for Read and must be of type PChar (Delphi), char * (C++), or equivalent. Buffer must have at least Count bytes allocated to hold the data that was read from the field. Read transfers up to Count bytes from the BLOB data into Buffer, starting in the current position, and then advances the current position by the number of bytes actually transferred. Read returns the number of bytes actually transferred (which may be less than the number requested in Count).

Read checks the Transliterate property of the field, and converts the data into ANSI from the character set specified by the dataset if Transliterate is true.

All the other data-reading methods of a BLOB stream (ReadBuffer, ReadComponent) call Read to do their actual reading.

Note: Do not call Read when the TBlobStream (see page 9958) was created in bmWrite mode.

See Also

Create (see page 9960)

Position (see page 2996)

ReadBuffer (see page 2983)

ReadComponent (see page 2983)

Transliterate (see page 6821)

53.1.6.4.2 TBlobStream.Seek Method

Resets the current position of the TBlobStream (see page 9958) object.

Pascal

```
function Seek(Offset: Longint; Origin: Word): Longint; override;
```

C++

```
virtual __fastcall Longint Seek(Longint Offset, Word Origin);
```

Description

Use Seek to move the current position within the BLOB data by the indicated offset. Seek allows an application to read from or write to a particular location within the BLOB data.

The Origin parameter indicates how to interpret the Offset parameter. Origin should be one of the following values:

Value	Meaning
soFromBeginning	Offset is from the beginning of the BLOB data. Seek moves to the position Offset. Offset must be >= 0.
soFromCurrent	Offset is from the current position in the BLOB data. Seek moves to Position + Offset.
soFromEnd	Offset is from the end of the BLOB data. Offset must be <= 0 to indicate a number of bytes before the end of the BLOB.

Seek returns the new value of the Position property, the new current position in the BLOB data.

See Also

Position (see page 2996)

Read (see page 9962)

Write (see page 9963)

53.1.6.4.3 TBlobStream.Truncate Method

Discards all data in the BLOB field from the current position on.

Pascal

```
procedure Truncate;
```

C++

```
__fastcall Truncate();
```

Description

Use Truncate to limit the size of the BLOB data. Calling Truncate when the current position is 0 will clear the contents of the BLOB field.

Note: Do not call Truncate when the TBlobStream (see page 9958) was created in bmRead mode.

See Also

Create (see page 9960)

Clear (see page 6810)

53.1.6.4.4 TBlobStream.Write Method

Writes Count bytes from Buffer to the current position in the field and updates the current position by Count bytes.

Pascal

```
function Write(const Buffer; Count: Longint): Longint; override;
```

C++

```
virtual __fastcall Longint Write(const  Buffer, Longint Count);
```

Description

Use Write to write Count bytes to the BLOB field, starting at the current position. The Write method for TBlobStream (see page 9958) always writes the entire Count bytes, as BLOB data does not necessarily include a termination character. Thus, Write is equivalent to the WriteBuffer method.

Buffer is the source container for Write and must be of type PChar (Delphi), char * (C++), or equivalent. Write transfers up to Count bytes from Buffer into the BLOB field, starting in the current position, and then advances the current position by the number of bytes actually transferred. Write returns the number of bytes actually transferred (which may be less than the number requested in Count).

Write checks the Transliterate property of the field, and converts the data from ANSI into the character set of the dataset if Transliterate is true.

All the other data-writing methods of a BLOB stream (WriteBuffer, WriteComponent) call Write to do their actual writing.

Note: Do not call Write when the TBlobStream (see page 9958) was created in bmRead mode.

See Also

Create (see page 9960)

Position (see page 2996)

Transliterate (see page 6821)

WriteBuffer (see page 2990)

WriteComponent (see page 2990)

53.1.7 TDatabase Class

TDatabase provides discrete control over a connection to a single database in a BDE-based database application.

Class Hierarchy

Pascal

```
TDatabase = class(TCustomConnection);
```

C++

```
class TDatabase : public TCustomConnection;
```

File

DBTables

Description

Use TDatabase when a BDE-based database application requires any of the following control over a database connection:

Persistent database connections

Customized database server logins

Transaction control

Application-specific BDE aliases

TDatabase is especially important for the control it permits over database transaction processing with the BDE when connected to a remote SQL database server.

Note: Explicit declaration of a TDatabase component for each database connection in an application is optional if the application does not need to explicitly control that connection. If a TDatabase component is not explicitly declared and instantiated for a database connection, a temporary database component with a default set of properties is created for it at runtime.

53.1.7.1 TDatabase Members

The following tables list the members exposed by TDatabase.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoConnect (see page 9972)	Provides the interface for a method that opens a connection.
V	DoDisconnect (see page 9972)	Provides the interface for a method that terminates the connection.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetConnected (see page 9974)	Returns the value of the Connected property.
	GetDataSet (see page 9974)	Returns a dataset, given its index in the DataSets property array.
V	GetDataSetCount (see page 6865)	Returns the value of the DataSetCount (see page 6869) property.

	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 9975)	Initializes the connection component after all objects in the form or data module have been loaded.
	Notification (see page 9976)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RegisterClient (see page 6866)	Registers an object that uses the connection component.
	SendConnectEvent (see page 6867)	Informs all registered clients that use the connection component when a connection is opened or closed.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetConnected (see page 6867)	Changes the value of the Connected (see page 6868) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	UnRegisterClient (see page 6868)	Removes a registered client so that it is no longer associated with the connection component.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	StreamedConnected (see page 6874)	Indicates whether the Connected (see page 6868) property was true when the connection component was loaded from a stream.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	ApplyUpdates (see page 9970)	Posts pending cached updates for specified datasets to the database server.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Close (see page 6863)	Closes the connection.
	CloseDataSets (see page 9971)	Closes all datasets associated with the database component without disconnecting from the database server.
	Commit (see page 9971)	Permanently stores updates, insertions, and deletions of data associated with the current transaction, and ends the current transactions.
V	Create (see page 9969)	Creates an instance of a TDatabase (see page 9964) component.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 9969)	Destroys the instance of a database component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 9973)	Executes an SQL statement.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlushSchemaCache (see page 9973)	Flushes the cached schema information for a table.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFieldNames (see page 9975)	Populates a string list with the names of fields in a table.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetTableNames (see page 9975)	Populates a string list with the names of tables in the database.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Open (see page 6866)	Opens the connection.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.

	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Rollback (see page 9976)	Cancels all updates, insertions, and deletions for the current transaction and ends the transaction.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	StartTransaction (see page 9977)	Begins a new transaction against the database server.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	ValidateName (see page 9977)	Raises an exception if a specified database is already open in the active session.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	DataSetCount (see page 6869)	Indicates the number of datasets associated with the connection component.
R	DataSets (see page 9981)	Provides an indexed array of all active datasets for a database component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	Directory (see page 9981)	Specifies the working directory for a Paradox or dBASE database.
	Handle (see page 9983)	Specifies the Borland (see page 1761) Database Engine (BDE) database handle.
R	InTransaction (see page 9983)	Indicates whether a database transaction is in progress or not.
R	IsSQLBased (see page 9984)	Indicates if a database component is using either the Borland (see page 1761) Database Engine (BDE) SQL Links driver or the BDE ODBC socket.
R	Locale (see page 9985)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the database component.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	Session (see page 9988)	Points to the session component with which this database component is associated.
R	SessionAlias (see page 9988)	Specifies whether a database component is using a session alias.
	Temporary (see page 9989)	Indicates whether a database component is a temporary one, created by the system as needed, or a persistent one explicitly created, managed, and freed within the application.
	TraceFlags (see page 9990)	Specifies the database operations to track with the SQL Monitor at runtime.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterConnect (see page 9992)	Occurs after a connection is established.
	AfterDisconnect (see page 9993)	Occurs after the connection closes.
	BeforeConnect (see page 9993)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 9993)	Occurs immediately before the connection closes.
	OnLogin (see page 9994)	Occurs when an application connects to a database.

Published Properties

	Name	Description
	AliasName (see page 9979)	Specifies the Borland (see page 1761) Database Engine (BDE) alias used by this database connection.
	Connected (see page 9979)	Indicates whether a database connection is active.
	DatabaseName (see page 9980)	Specifies the name of the database to associate with this database component.
	DriverName (see page 9981)	Specifies the name of the BDE driver for the database.

	Exclusive (see page 9982)	Enables an application to gain sole access to a database.
	HandleShared (see page 9983)	Specifies whether to share a database handle.
	KeepConnection (see page 9984)	Specifies whether an application remains connected to a database even if no datasets are open.
	LoginPrompt (see page 9985)	Specifies whether a login dialog appears immediately before opening a new connection.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Params (see page 9986)	Contains database connection parameters for the Borland (see page 1761) Database Engine (BDE) alias associated with the database component.
	ReadOnly (see page 9987)	Specifies that the database connection provides read-only access.
	SessionName (see page 9989)	Identifies the name of the session used by this database component.
	Tag (see page 2808)	Stores an integer value as part of a component.
	TransIsolation (see page 9991)	Specifies the transaction isolation level for transactions managed by the Borland (see page 1761) Database Engine (BDE).

53.1.7.2 TDatabase.Create Constructor

Creates an instance of a TDatabase (see page 9964) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDatabase(TComponent * AOwner);
```

Description

Call Create to instantiate a database component at runtime. An application can create a database component in order to control the component's existence and set its properties and events, or an application can let Delphi create temporary database components as needed at runtime.

AOwner is the component that is responsible for freeing the database instance. It becomes the value of the Owner property.

See Also

Owner (see page 2807)

53.1.7.3 TDatabase.Destroy Destructor

Destroys the instance of a database component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDatabase();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which verifies that the database reference is not nil before calling Destroy

Destroy closes all active datasets and disconnects from the database server, if necessary. It then frees the string resources allocated for the Params (see page 9986) and DataSets (see page 9981) properties before calling its inherited destructor.

See Also

DataSets (see page 9981)

Params (see page 9986)

Create (see page 9969)

Free (see page 22300)

53.1.7.4 TDatabase Methods

The methods of the TDatabase class are listed here.

Protected Methods

	Name	Description
	DoConnect (see page 9972)	Provides the interface for a method that opens a connection.
	DoDisconnect (see page 9972)	Provides the interface for a method that terminates the connection.
	GetConnected (see page 9974)	Returns the value of the Connected property.
	GetDataSet (see page 9974)	Returns a dataset, given its index in the DataSets property array.
	Loaded (see page 9975)	Initializes the connection component after all objects in the form or data module have been loaded.
	Notification (see page 9976)	Forwards notification messages to all owned components.

Public Methods

	Name	Description
	ApplyUpdates (see page 9970)	Posts pending cached updates for specified datasets to the database server.
	CloseDataSets (see page 9971)	Closes all datasets associated with the database component without disconnecting from the database server.
	Commit (see page 9971)	Permanently stores updates, insertions, and deletions of data associated with the current transaction, and ends the current transactions.
	Execute (see page 9973)	Executes an SQL statement.
	FlushSchemaCache (see page 9973)	Flushes the cached schema information for a table.
	GetFieldNames (see page 9975)	Populates a string list with the names of fields in a table.
	GetTableNames (see page 9975)	Populates a string list with the names of tables in the database.
	Rollback (see page 9976)	Cancels all updates, insertions, and deletions for the current transaction and ends the transaction.
	StartTransaction (see page 9977)	Begins a new transaction against the database server.
	ValidateName (see page 9977)	Raises an exception if a specified database is already open in the active session.

53.1.7.4.1 TDatabase.ApplyUpdates Method

Posts pending cached updates for specified datasets to the database server.

Pascal

```
procedure ApplyUpdates(const DataSets: array of TDBDataSet);
```

C++

```
__fastcall ApplyUpdates(const array of TDBDataSet DataSets);
```

Description

Call ApplyUpdates to post pending cached updates for a specific set of open datasets to the database server. ApplyUpdates is only meaningful if the CachedUpdates property of a specified dataset is true.

DataSets (see page 9981) is a list of dataset names specifying the datasets for which to post pending updates. DataSets (see page 9981) need not list every currently open dataset. For each listed dataset ApplyUpdates calls the dataset's ApplyUpdates and CommitUpdates methods to post that dataset's pending cached updates.

Applying updates is a two-phase process that takes place within the context of the database component's transaction control. When an application calls ApplyUpdates, the following events take place:

1A database transaction starts.

2Cached updates are written to the database (Phase 1).

If the database write is successful:

1 Database changes are committed, ending the transaction.

2 Cachedupdates are committed, clearing the internal cache buffer (Phase 2).

If the database write fails database changes are rolled back, ending the transaction.

The two-phased approach allows for effective error recovery, especially when updating multiple and interrelated datasets (for example, the datasets associated with a master/detail form).

See Also

Commit (see page 9971)

Open (see page 6866)

Rollback (see page 9976)

StartTransaction (see page 9977)

CachedUpdates (see page 9932)

ApplyUpdates (see page 9894)

CommitUpdates (see page 9897)

Applying Cached Updates Using a Database

Using the BDE to Cache Updates

53.1.7.4.2 TDatabase.CloseDataSets Method

Closes all datasets associated with the database component without disconnecting from the database server.

Pascal

```
procedure CloseDataSets;
```

C++

```
__fastcall CloseDataSets();
```

Description

Call CloseDataSets to close all active datasets without disconnecting from the database server. Ordinarily, when an application calls Close, all datasets are closed, and the connection to the database server is dropped. Calling CloseDataSets instead of Close ensures that an application can close all active datasets without having to reconnect to the database server at a later time.

See Also

KeepConnection (see page 9984)

Close (see page 6863)

53.1.7.4.3 TDatabase.Commit Method

Permanently stores updates, insertions, and deletions of data associated with the current transaction, and ends the current transactions.

Pascal

```
procedure Commit;
```

C++

```
__fastcall Commit();
```

Description

Call Commit to permanently store to the database server all updates, insertions, and deletions of data associated with the current transaction and then end the transaction. The current transaction is the last transaction started by calling StartTransaction (see page 9977).

Note: Before calling Commit, an application may check the status of the InTransaction (see page 9983) property. If an application calls Commit and there is no current transaction, an exception is raised.

See Also

InTransaction (see page 9983)

Rollback (see page 9976)

StartTransaction (see page 9977)

TransIsolation (see page 9991)

53.1.7.4.4 TDatabase.DoConnect Method

Provides the interface for a method that opens a connection.

Pascal

```
procedure DoConnect; override;
```

C++

```
virtual __fastcall DoConnect();
```

Description

The Connected property uses DoConnect to establish a connection. Descendant classes override the DoConnect method to establish their connection as appropriate. As implemented in TCustomConnection, DoConnect does nothing.

See Also

Connected (see page 6868)

DoDisconnect (see page 6864)

53.1.7.4.5 TDatabase.DoDisconnect Method

Provides the interface for a method that terminates the connection.

Pascal

```
procedure DoDisconnect; override;
```

C++

```
virtual __fastcall DoDisconnect();
```

Description

The Connected property uses DoDisconnect to close a connection. Descendant classes override the DoDisconnect method to drop a connection. As implemented in TCustomConnection, DoDisconnect does nothing.

See Also

Connected (see page 6868)

DoConnect (see page 6864)

53.1.7.4.6 TDatabase.Execute Method

Executes an SQL statement.

Pascal

```
function Execute(const SQL: string; Params: TParams = nil; Cache: Boolean = False; Cursor:
phDBICur = nil): Integer;
```

C++

```
__fastcall int Execute(const AnsiString SQL, TParams Params = nil, Boolean Cache = False,
phDBICur Cursor = nil);
```

Description

Use Execute to execute an SQL statement against the database without the overhead of using a TQuery (see page 10059) object. Execute supports Data Definition Language (DDL) SQL statements and those Data Manipulation Language (DDL) SQL statements that do not return result sets. Examples of DDL statements include: CREATE INDEX, ALTER TABLE, and DROP DOMAIN. The DML statements that perform an action on data but do not return a result set are: INSERT, DELETE, and UPDATE.

SQL is a string value containing the statement to be executed.

Params (see page 9986) is a value of type TParams and lists any parameters used by the SQL statement. Parameter binding is by index only (not by name). The TParam objects in Params (see page 9986) must be in the same order as the the parameters in the SQL statement to which each corresponds. Use the CreateParam method (TParams) to create one TParams object for each parameter in the SQL statement. Use properties and methods of TParam to configure each TParam and to give each a value prior to calling Execute. If the SQL statement does not include any parameters, pass a nil (Delphi) or NULL (C++) value for Params (see page 9986).

Cache specifies whether the prepared SQL statement is cached for reuse within the current transaction. Caching statements can speed their processing if they are used more than once in a transaction.

Cursor allows you to execute a SELECT statement and from it create a Borland (see page 1761) Database Engine (BDE) dataset. If SQL is a SELECT statement, Cursor returns the BDE cursor to the result set. Cursor is a pointer to an already existing BDE cursor. There is currently no provision in the VCL to assign the cursor created by this parameter to a dataset component (like TTable (see page 10168)). This limits its use to cursors subsequently operated on using BDE API code. The result set returned in Cursor is always read-only. If the SQL statement does not return a result set, pass a nil (Delphi) or NULL (C++) value for Cursor.

Execute returns the number of records affected by executing the SQL statement.

See Also

TQuery (see page 10059)

Handle (see page 9933)

53.1.7.4.7 TDatabase.FlushSchemaCache Method

Flushes the cached schema information for a table.

Pascal

```
procedure FlushSchemaCache(const TableName: string);
```

C++

```
__fastcall FlushSchemaCache(const AnsiString TableName);
```

Description

Call FlushSchemaCache if the schema information for an SQL table is changed (for example, because a field, index, or table is added to or dropped from a database).

When an application opens an SQL table, schema information that describes the field names, field types, and index information is stored in memory. If an application changes the schema for an SQL table, it should call FlushSchemaCache to update the schema information in memory.

See Also

Open (see page 6866)

53.1.7.4.8 TDatabase.GetConnected Method

Returns the value of the Connected property.

Pascal

```
function GetConnected: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection, GetConnected always returns false.

See Also

Connected (see page 6868)

SetConnected (see page 6867)

53.1.7.4.9 TDatabase.GetDataSet Method

Returns a dataset, given its index in the DataSets property array.

Pascal

```
function GetDataSet(Index: Integer): TDBDataSet; reintroduce;
```

C++

```
__fastcall TDBDataSet GetDataSet(int Index);
```

Description

GetDataSet is the protected read implementation of the DataSets property.

See Also

DataSets (see page 6870)

53.1.7.4.10 TDatabase.GetFieldNames Method

Populates a string list with the names of fields in a table.

Pascal

```
procedure GetFieldNames(const TableName: string; List: TStrings);
```

C++

```
__fastcall GetFieldNames(const AnsiString TableName, TStrings List);
```

Description

Call GetFieldNames to retrieve a list of fields in a table.

TableName names the table whose field names you want added to the list.

List is a TStrings descendant that receives the field names. Any existing strings are deleted from the list before GetFieldNames adds the names of all the fields in TableName.

For example, the following line fills a list box with the names of all fields in the Employee table:

```
Database1.GetFieldNames('Employee', ListBox1.Items);
Database1->GetFieldNames("Employee", ListBox1->Items);
```

See Also

GetTableNames (see page 9975)

53.1.7.4.11 TDatabase.GetTableNames Method

Populates a string list with the names of tables in the database.

Pascal

```
procedure GetTableNames(List: TStrings; SystemTables: Boolean = False);
```

C++

```
__fastcall GetTableNames(TStrings List, Boolean SystemTables = False);
```

Description

Call GetTableNames to retrieve a list of tables in the associated database.

List is a TStrings descendant that receives the table names. Any existing strings are deleted from the list before GetTableNames adds the names of all tables in the database.

SystemTables specifies whether the list of table names should include only the database's system tables. If SystemTables is true, only the system tables are added to List. If SystemTables is false, the list is filled with ordinary tables.

For example, the following line fills a list box with the names of all tables in the database:

```
Database1.GetTableNames(ListBox1.Items, False);
Database1->GetTableNames(ListBox1->Items, false);
```

See Also

GetFieldNames (see page 9975)

53.1.7.4.12 TDatabase.Loaded Method

Initializes the connection component after all objects in the form or data module have been loaded.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. It is called automatically after the form or data module that contains the connection component has loaded all its owned objects. TCustomConnection overrides the inherited method to establish a connection if the Connected property is true.

See Also

StreamedConnected (see page 6874)

Loaded (see page 2782)

53.1.7.4.13 TDatabase.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

53.1.7.4.14 TDatabase.Rollback Method

Cancels all updates, insertions, and deletions for the current transaction and ends the transaction.

Pascal

```
procedure Rollback;
```

C++

```
__fastcall Rollback();
```

Description

Call Rollback to cancel all updates, insertions, and deletions for the current transaction and to end the transaction. The current transaction is the last transaction started by calling StartTransaction (see page 9977).

Note: Before calling Rollback, an application may check the status of the InTransaction (see page 9983) property. If an application calls Rollback and there is no current transaction, an exception is raised.

See Also

InTransaction (see page 9983)

Commit (see page 9971)

StartTransaction (see page 9977)

TransIsolation (see page 9991)

Connecting to Databases with TDatabase

53.1.7.4.15 TDatabase.StartTransaction Method

Begins a new transaction against the database server.

Pascal

```
procedure StartTransaction;
```

C++

```
__fastcall StartTransaction();
```

Description

Call StartTransaction to begin a new transaction against the database server. Before calling StartTransaction, an application should check the status of the InTransaction (see page 9983) property and adjust the setting of the TransIsolation (see page 9991) property as desired. If InTransaction (see page 9983) is true, indicating that a transaction is already in progress, a subsequent call to StartTransaction without first calling Commit (see page 9971) or Rollback (see page 9976) to end the current transaction raises an exception.

Updates, insertions, and deletions that take place after a call to StartTransaction are held by the server until an application calls Commit (see page 9971) to save the changes or Rollback (see page 9976) is to cancel them.

See Also

InTransaction (see page 9983)

Commit (see page 9971)

Rollback (see page 9976)

TransIsolation (see page 9991)

53.1.7.4.16 TDatabase.ValidateName Method

Raises an exception if a specified database is already open in the active session.

Pascal

```
procedure ValidateName(const Name: string);
```

C++

```
__fastcall ValidateName(const AnsiString Name);
```

Description

Call ValidateName to prevent duplicate access to a database from within a single session. Name is a string containing the name of the database to test. If the database is already open, ValidateName raises the EDatabaseError exception. If the database is not open, the procedure returns, and the application continues processing.

Note: Most applications should not need to call this method directly. It is called automatically each time a database is opened.

See Also

DatabaseName (see page 9980)

Open (see page 6866)

EDatabaseError (see page 6731)

53.1.7.5 TDatabase Properties

The properties of the TDatabase class are listed here.

Public Properties

	Name	Description
R	DataSets (see page 9981)	Provides an indexed array of all active datasets for a database component.
	Directory (see page 9981)	Specifies the working directory for a Paradox or dBASE database.
	Handle (see page 9983)	Specifies the Borland (see page 1761) Database Engine (BDE) database handle.
R	InTransaction (see page 9983)	Indicates whether a database transaction is in progress or not.
R	IsSQLBased (see page 9984)	Indicates if a database component is using either the Borland (see page 1761) Database Engine (BDE) SQL Links driver or the BDE ODBC socket.
R	Locale (see page 9985)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the database component.
R	Session (see page 9988)	Points to the session component with which this database component is associated.
R	SessionAlias (see page 9988)	Specifies whether a database component is using a session alias.
	Temporary (see page 9989)	Indicates whether a database component is a temporary one, created by the system as needed, or a persistent one explicitly created, managed, and freed within the application.
	TraceFlags (see page 9990)	Specifies the database operations to track with the SQL Monitor at runtime.

Published Properties

	Name	Description
	AliasName (see page 9979)	Specifies the Borland (see page 1761) Database Engine (BDE) alias used by this database connection.
	Connected (see page 9979)	Indicates whether a database connection is active.
	DatabaseName (see page 9980)	Specifies the name of the database to associate with this database component.
	DriverName (see page 9981)	Specifies the name of the BDE driver for the database.
	Exclusive (see page 9982)	Enables an application to gain sole access to a database.
	HandleShared (see page 9983)	Specifies whether to share a database handle.
	KeepConnection (see page 9984)	Specifies whether an application remains connected to a database even if no datasets are open.
	LoginPrompt (see page 9985)	Specifies whether a login dialog appears immediately before opening a new connection.
	Params (see page 9986)	Contains database connection parameters for the Borland (see page 1761) Database Engine (BDE) alias associated with the database component.
	ReadOnly (see page 9987)	Specifies that the database connection provides read-only access.
	SessionName (see page 9989)	Identifies the name of the session used by this database component.
	TransIsolation (see page 9991)	Specifies the transaction isolation level for transactions managed by the Borland (see page 1761) Database Engine (BDE).

53.1.7.5.1 TDatabase.AliasName Property

Specifies the Borland (see page 1761) Database Engine (BDE) alias used by this database connection.

Pascal

```
property AliasName: string;
```

C++

```
__property AnsiString AliasName;
```

Description

Use AliasName to specify the name of an existing BDE alias for the database component. A BDE alias contains database configuration information for connection to a specific kind of database, such as InterBase, dBASE, or Paradox. The configuration information associated with a BDE alias differs by database type.

If an application sets AliasName, any value previously assigned to the DriverName (see page 9981) property is cleared because the alias automatically specifies a driver name as one of its parameters. Other alias connection information is stored in the Params (see page 9986) property when AliasName is set.

Note: Attempting to set AliasName when the Connected (see page 9979) property is true raises an exception.

Note: An application can specify the DatabaseName (see page 9980), DriverName (see page 9981), and Params (see page 9986) properties rather than setting AliasName if the desired BDE alias configuration does not already exist. An application can also provide an application-specific "alias" name by setting DatabaseName (see page 9980) when AliasName is already set.

Tip: At design time double-click a TDatabase (see page 9964) component to invoke the Database editor and set the AliasName.

See Also

Connected (see page 9979)

DatabaseName (see page 9980)

DriverName (see page 9981)

Params (see page 9986)

Identifying the Database

53.1.7.5.2 TDatabase.Connected Property

Indicates whether a database connection is active.

Pascal

```
property Connected: Boolean;
```

C++

```
__property Boolean Connected;
```

Description

Set Connected to true to establish a database connection without opening a dataset. Set Connected to false to close a database connection. An application can check Connected to determine the current status of a database connection. If Connected is true,

the database connection is active; if false, and the KeepConnection (see page 9984) property is also false, then the connection is inactive.

Note: Set KeepConnection (see page 9984) to true to avoid having to log in to the server each time a database connection is reopened.

See Also

DataSets (see page 9981)

KeepConnection (see page 9984)

Connecting to Databases with TDatabase

53.1.7.5.3 TDatabase.DatabaseName Property

Specifies the name of the database to associate with this database component.

Pascal

```
property DatabaseName: string;
```

C++

```
__property AnsiString DatabaseName;
```

Description

Use DatabaseName to specify the name of the database to use with a database component. If DatabaseName is the same as an existing Borland (see page 1761) Database Engine (BDE) alias, then the AliasName (see page 9979) and DriverName (see page 9981) properties need not be set. If DatabaseName does not match an existing BDE alias, then either the application must also supply a valid alias in the AliasName (see page 9979) property in addition to the DatabaseName, or it must supply the DriverName (see page 9981) and Params (see page 9986) properties.

DatabaseName can be a fully qualified path name when connecting to a Paradox or dBASE database.

Note: Attempting to set DatabaseName when the Connected (see page 9979) property is true raises an exception.

Tip: At design time double-click a TDatabase (see page 9964) component to invoke the Database editor and set the DatabaseName.

See Also

AliasName (see page 9979)

Connected (see page 9979)

DriverName (see page 9981)

Params (see page 9986)

Identifying the Database

Connecting to Databases with TDatabase

Using TQuery

Using TStoredProc

Using TTable

53.1.7.5.4 TDatabase.DataSets Property

Provides an indexed array of all active datasets for a database component.

Pascal

```
property DataSets [Index: Integer]: TDBDataSet;
```

C++

```
__property TDBDataSet DataSets[int Index];
```

Description

Use DataSets to access active datasets associated with a database component. An active dataset is one that is currently open.

Note: If a TBDEClientDataSet uses the connection component to connect to a database server, DataSets lists the internal dataset that the client dataset creates to access data, not the client dataset itself.

See Also

DataSetCount (see page 6869)

TBDEClientDataSet

53.1.7.5.5 TDatabase.Directory Property

Specifies the working directory for a Paradox or dBASE database.

Pascal

```
property Directory: string;
```

C++

```
__property AnsiString Directory;
```

Description

Use Directory at runtime to change or retrieve the working directory for a Paradox or dBASE database. This is the location these databases use to create temporary tables at runtime.

Ordinarily a directory location is specified in the PATH parameter of the database alias (specified by the AliasName (see page 9979) property). At runtime, however, some applications may need to change the working directory after a database is opened.

To change the value of Directory at runtime, a database must already be open, or an exception is raised. Clearing the current value of Directory sets its value to the original working directory specified when the database was first opened.

Note: Do not use Directory when connected to remote databases. An exception is raised in these circumstances. An exception is also raised if an application accesses Directory when the database is closed.

See Also

AliasName (see page 9979)

DatabaseName (see page 9980)

Open (see page 6866)

53.1.7.5.6 TDatabase.DriverName Property

Specifies the name of the BDE driver for the database.

Pascal

```
property DriverName: string;
```

C++

```
__property AnsiString DriverName;
```

Description

Use DriverName to specify the name of the BDE driver to use for databases connections that do not specify an AliasName (see page 9979), but that do specify a DatabaseName (see page 9980). DriverName must be a valid BDE driver (for instance, STANDARD, ORACLE, SYBASE, or INTERBASE).

Note: If an application sets DriverName, it must also specify connection parameters in the Params (see page 9986) property. Ordinarily the alias specified in the AliasName (see page 9979) property supplies connection parameters, but when DriverName is set, the AliasName (see page 9979) property is automatically cleared to avoid BDE driver name contention.

Attempting to set DriverName when the Connected (see page 9979) property is true raises an exception.

Tip: At design time double-click a TDatabase (see page 9964) component to invoke the Database editor and set the DriverName.

See Also

AliasName (see page 9979)

Connected (see page 9979)

DatabaseName (see page 9980)

Params (see page 9986)

Identifying the Database

53.1.7.5.7 TDatabase.Exclusive Property

Enables an application to gain sole access to a database.

Pascal

```
property Exclusive: Boolean;
```

C++

```
__property Boolean Exclusive;
```

Description

Use Exclusive to prevent other applications from accessing a Paradox or dBASE database while this application is using it. Before opening the database, set Exclusive to true. The default value for Exclusive is false, allowing other applications to use the opened database.

When Exclusive is true and the application successfully opens the database, no other application can access it. If the database for which the application has requested exclusive access is already in use by another application, an exception is raised. To handle such exceptions, write an exception handler. All tables in the database are effectively opened exclusively, as other applications would be prevented from opening the database and the tables would be inaccessible.

A table database must be closed before changing the setting of the Exclusive property. Do not set Exclusive to true at design time if you also intend to set the Connected (see page 9979) property to true at design time. In this case an exception is raised because the database is already in use by the IDE.

Note: An application can attempt to set Exclusive to true for SQL databases, but some SQL servers do not support exclusive database-locking. Others may grant an exclusive read/write lock, but still permit read-only access to other applications. For more

information about exclusive locking of databases for a specific server, see the server's documentation.

See Also

Connected (see page 9979)

53.1.7.5.8 TDatabase.Handle Property

Specifies the Borland (see page 1761) Database Engine (BDE) database handle.

Pascal

```
property Handle: HDBIDB;
```

C++

```
__property HDBIDB Handle;
```

Description

Use Handle only to bypass TDatabase (see page 9964) methods and make direct calls to the directly to the BDE API. Many BDE function calls require a handle parameter. Handle is assigned an initial value when a database is opened.

See Also

IsSQLBased (see page 9984)

Locale (see page 9985)

53.1.7.5.9 TDatabase.HandleShared Property

Specifies whether to share a database handle.

Pascal

```
property HandleShared: Boolean;
```

C++

```
__property Boolean HandleShared;
```

Description

Use HandleShared to indicate that a database component can share its BDE handle in a session component. Set HandleShared to true to avoid namespace conflicts for database components that appear in a remote data module, or that appear in data modules you inherit from the Object Repository.

See Also

Handle (see page 9983)

Using Database Components in Data Modules

53.1.7.5.10 TDatabase.InTransaction Property

Indicates whether a database transaction is in progress or not.

Pascal

```
property InTransaction: Boolean;
```

C++

```
__property Boolean InTransaction;
```

Description

Examine InTransaction at run-time to determine if a database transaction is currently in progress. InTransaction is true if a transaction is in progress, false otherwise.

The value of InTransaction cannot be changed directly. Calling StartTransaction (see page 9977) sets InTransaction to true. Calling Commit (see page 9971) or Rollback (see page 9976) sets InTransaction to false.

See Also

Commit (see page 9971)

Rollback (see page 9976)

StartTransaction (see page 9977)

53.1.7.5.11 TDatabase.IsSQLBased Property

Indicates if a database component is using either the Borland (see page 1761) Database Engine (BDE) SQL Links driver or the BDE ODBC socket.

Pascal

```
property IsSQLBased: Boolean;
```

C++

```
__property Boolean IsSQLBased;
```

Description

Examine IsSQLBased at runtime to determine if a database connection is using a BDE SQL Links driver, the ODBC socket, or the Paradox, dBASE, and ASCII text file STANDARD driver. If IsSQLBased is true, the connection is using an SQL Links driver or is using the ODBC socket to communicate with a third-party ODBC driver. If the connection uses the STANDARD driver, IsSQLBased is false.

See Also

Handle (see page 9983)

Locale (see page 9985)

53.1.7.5.12 TDatabase.KeepConnection Property

Specifies whether an application remains connected to a database even if no datasets are open.

Pascal

```
property KeepConnection: Boolean;
```

C++

```
__property Boolean KeepConnection;
```

Description

Use KeepConnection to specify whether an application remains connected to a database even if no datasets are currently open. When KeepConnection is true (the default) the connection is maintained. For connections to remote database servers, or for applications that frequently open and close datasets, set KeepConnection to true to reduce network traffic, speed up applications, and avoid logging in to the server each time the connection is reestablished.

When KeepConnection is false a connection is dropped when there are no open datasets. Dropping a connection releases system resources allocated to the connection, but if a dataset is later opened that uses the database, the connection must be

reestablished and initialized.

Note: The KeepConnection setting for temporary database components created automatically as needed is determined by the KeepConnections property of TSession (see page 10093).

See Also

Close (see page 6863)

Open (see page 6866)

KeepConnections (see page 10124)

Identifying the Database

53.1.7.5.13 TDatabase.Locale Property

Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the database component.

Pascal

```
property Locale: TLocale;
```

C++

```
__property TLocale Locale;
```

Description

Examine Locale to determine the BDE language driver used by the database component. Applications that make direct calls to the BDE may also need to pass Locale information as an API function parameter.

Language driver information may also be available as one of the values in the Params (see page 9986) property when a database component is using a BDE alias.

See Also

AliasName (see page 9979)

Handle (see page 9983)

IsSQLBased (see page 9984)

Params (see page 9986)

53.1.7.5.14 TDatabase.LoginPrompt Property

Specifies whether a login dialog appears immediately before opening a new connection.

Pascal

```
property LoginPrompt: Boolean;
```

C++

```
__property Boolean LoginPrompt;
```

Description

Set LoginPrompt to true to provide login support when establishing a connection. LoginPrompt controls two things: the occurrence of the OnLogin event, and the appearance of a default login dialog that prompts users for a name and password when you include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi). When the OnLogin event occurs and when the default login dialog appears depend on the type of connection component:

For TDatabase, TIBDatabase, and TSQLConnection, the dialog appears after the BeforeConnect event and before the

AfterConnect event, unless you supply an OnLogin event handler. If there is an OnLogin event handler, that event occurs in place of the login dialog, and there is no need to include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi). If correct values for the user name and password are not supplied in the dialog or by the OnLogin event handler, the connection fails. The OnLogin event does not fire unless LoginPrompt is set to true.

For TADOConnection components, the dialog appears after the OnWillConnect event and before the BeforeConnect event. If there is an OnLogin event handler, that event occurs after the login dialog. If you do not include DBLogDlg.hpp in your unit (C++) or add DBLogDlg to your uses clause (Delphi), the OnLogin event occurs but there is no default login dialog. If correct values for the user name and password are not supplied in the dialog or by the OnLogin event handler, the connection fails. The OnLogin event does not fire unless LoginPrompt is set to true.

For DataSnap SOAP connection components, the dialog appears after the OnGetUsername event and before the BeforeConnect, AfterConnect, and OnLogin events. If the user cancels from the login dialog, no attempt is made to open a connection.

When LoginPrompt is false, the application must supply user name and password values programmatically:

For TDatabase, the user name and password can be supplied as USER NAME and PASSWORD parameters in the Params property.

For TADOConnection, the user name and password can be supplied as the ConnectionString property.

For TSQLConnection, the user name, password, and database can be supplied as UserName, Password, and Database parameters in the Params property, or provided as connection parameters associated with the connection name.

For DataSnap SOAP connection components, there is no built-in use for the user name and password supplied by the login dialog. (The UserName and Password properties of TWebConnection are unrelated).

Warning: Storing hard-coded user name and password entries as property values or in code for an OnLogin event handler can compromise server security.

OnLogin (see page 20259)

OnLogin (see page 9994)

Controlling Server Login

53.1.7.5.15 TDatabase.Params Property

Contains database connection parameters for the Borland (see page 1761) Database Engine (BDE) alias associated with the database component.

Pascal

```
property Params: TStrings;
```

C++

```
__property TStrings Params;
```

Description

Use Params to examine or specify database connection parameters, such as path name, server name, schema-caching size,

language driver, user name, and password. Actual parameters in Params differ depending on the current BDE alias and driver for the database component.

Params is a list of string items, each representing a different database connection parameter. If the AliasName (see page 9979) property specifies a valid BDE alias, then Params automatically contains the parameters defined for that alias. If, instead of providing an alias, an application uses the DriverName (see page 9981) property to provide a local alias, the application must provide Params values directly.

Note: Applications can use Params to override the default settings supplied by a BDE alias.

Tip: At design time double-click a TDatabase (see page 9964) component to invoke the Database editor and set Params.

See Also

AliasName (see page 9979)

DatabaseName (see page 9980)

LoginPrompt (see page 6872)

OnLogin (see page 9994)

Identifying the Database

Setting BDE Alias Parameters

53.1.7.5.16 TDatabase.ReadOnly Property

Specifies that the database connection provides read-only access.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to specify whether the database connection should allow the application to update the tables and other metadata in the database. Set ReadOnly before opening the database.

When ReadOnly is false (the default), the application can modify tables and database metadata (like indexes). When ReadOnly is true, applications can browse tables but cannot update them. The application is also prevented from creating or deleting metadata objects like tables and indexes.

Note: A ReadOnly property value of true should be used when accessing a dBASE or Paradox database on a read-only storage medium, such as a CD.

Note: For SQL databases, if ReadOnly is true, you must also explicitly set the ReadOnly property to true for dataset components like TTable (see page 10168) and TQuery (see page 10059).

See Also

CanModify (see page 7012)

53.1.7.5.17 TDatabase.Session Property

Points to the session component with which this database component is associated.

Pascal

```
property Session: TSession;
```

C++

```
__property TSession Session;
```

Description

Use Session to determine the session component that controls the database component. By default, a database component is associated with the default session component, Session, that is automatically created for all database applications. To assign a database component to a different session in a multi-threaded application, specify the name of a different session component in the SessionName (see page 9989) property.

See Also

SessionAlias (see page 9988)

SessionName (see page 9989)

Associating a Database Component with a Session

Connecting to Databases with TDatabase

53.1.7.5.18 TDatabase.SessionAlias Property

Specifies whether a database component is using a session alias.

Pascal

```
property SessionAlias: Boolean;
```

C++

```
__property Boolean SessionAlias;
```

Description

Examine SessionAlias to see if a database component is using a session alias. If SessionAlias is true, a session alias is in use. If false, a session alias is not in use.

A session alias is automatically created for a database component if it

Uses the DriverName (see page 9981) and Params (see page 9986) properties instead of the AliasName (see page 9979) property, and the Params (see page 9986) property contains any parameters.

Overrides Params (see page 9986) values supplied by a BDE alias in AliasName (see page 9979).

A session alias may also be created if an application permits the user to log into a server using a different user name than the one specified in the Params (see page 9986) property.

A session alias exists only while the application is running. It is not stored in the BDE configuration file, and cannot be accessed from outside the application.

See Also

AliasName (see page 9979)

DriverName (see page 9981)

IsSQLBased (see page 9984)

Params (see page 9986)

Session (see page 9988)

SessionName (see page 9989)

53.1.7.5.19 TDatabase.SessionName Property

Identifies the name of the session used by this database component.

Pascal

```
property SessionName: string;
```

C++

```
__property AnsiString SessionName;
```

Description

Use SessionName to specify the session with which a database component is associated. If SessionName is blank, a database component is automatically associated with the default session, Session (see page 9988).

To associate a database component with a different session in a database application SessionName must matches the SessionName property of an existing session component.

See Also

Session (see page 9988)

SessionAlias (see page 9988)

TSession (see page 10093)

TSessionList (see page 10129)

SessionName (see page 10126)

Associating a Database Component with a Session

53.1.7.5.20 TDatabase.Temporary Property

Indicates whether a database component is a temporary one, created by the system as needed, or a persistent one explicitly created, managed, and freed within the application.

Pascal

```
property Temporary: Boolean;
```

C++

```
__property Boolean Temporary;
```

Description

Examine Temporary to determine if a database component is a temporary one, created by the system as needed, or a persistent one explicitly created, managed, and freed within the application. Temporary is true if the system created the component, false otherwise.

A temporary database component is created when a dataset is opened and the dataset is not already associated with an existing database component. If Temporary remains true, then a temporary database component is freed when the dataset is closed. An application can prevent the destruction of a temporary database component by setting Temporary to false while the dataset is active, but the application is then responsible for closing the database when it is no longer needed.

See Also

Create (see page 9969)

Free (see page 22300)

53.1.7.5.21 TDatabase.TraceFlags Property

Specifies the database operations to track with the SQL Monitor at runtime.

Pascal

```
property TraceFlags: TTraceFlags;
```

C++

```
__property TTraceFlags TraceFlags;
```

Description

Use TraceFlags to specify which database operations the SQL Monitor should track in an application at runtime. TraceFlags is only meaningful for the SQL Monitor, which is provided to enable performance tuning and SQL debugging when working with remote SQL database servers.

Note: Normally trace options are set from the SQL Monitor rather than setting TraceFlags in application code.

The value of a session component's TraceFlags property determines the initial settings of the TraceFlags property for database components associated with the session.

The TTraceFlags (see page 10263) type defines the individual values that can be included in the TraceFlags property. The following table summarizes those values:

Values	Meaning
tfQPrepare	Monitor Prepare statements.
tfQExecute	Monitor ExecSQL statements.
tfError	Monitor server error messages. Such messages may include an error code.
tfStmt	Monitor all SQL statements.
tfConnect	Monitor database connect and disconnect operations, including allocation of connection handles, and freeing connection handles.
tfTransact	Monitor transaction statements, such as StartTransaction (see page 9977), Commit (see page 9971), and Rollback (see page 9976).
tfBlob	Monitor operations on blob data types.
tfMisc	Monitor any statements not covered by other flag options.
tfVendor	Monitor direct API function calls to the database server.
tfDataIn	Monitor data received from a server.
tfDataOut	Monitor data sent to a server.

Because TraceFlags is a set property, an application can specify different combinations of flags to monitor different combinations of statements. For example, the following statement limits monitoring to database connections and SQL statement preparation:

```
TraceFlags := [tfConnect, tfQPrepare];
TraceFlags  << tfConnect << tfQPrepare;
```

See Also

Session (see page 9988)

SessionName (see page 9989)

TraceFlags (see page 10127)

53.1.7.5.22 TDatabase.TransIsolation Property

Specifies the transaction isolation level for transactions managed by the Borland (see page 1761) Database Engine (BDE).

Pascal

```
property TransIsolation: TTransIsolation;
```

C++

```
__property TTransIsolation TransIsolation;
```

Description

Use TransIsolation to specify the transaction isolation level for database transactions managed by the BDE. Transaction isolation level determines how a transaction interacts with other simultaneous transactions when they work with the same tables, and how much a transaction sees of the work performed by other transactions.

Note: Applications that use passthrough SQL for handling transactions must pass a transaction isolation level directly to the database server using the appropriate SQL statement.

TransIsolation can be any one of the three values summarized in the following table:

Isolation level	Meaning
tiDirtyRead	Permits reading of uncommitted changes made to the database by other simultaneous transactions. Uncommitted changes are not permanent, and might be rolled back (undone) at any time. At this level a transaction is least isolated from the effects of other transactions.
tiReadCommitted	Permits reading of committed (permanent) changes made to the database by other simultaneous transactions. This is the default TransIsolation property value.
tiRepeatableRead	Permits a single, one-time reading of the database. The transaction cannot see any subsequent changes made by other simultaneous transactions. This isolation level guarantees that once a transaction reads a record, its view of that record does not change unless it makes a modification to the record itself. At this level, a transaction is most isolated from other transactions.

Different database servers support different levels of transaction isolation. If an application sets TransIsolation to an unsupported level for a remote SQL server, the BDE uses the next highest level supported by that server. The following table summarizes the isolation levels supported by the servers recognized by the BDE:

ServerSpecified LevelActual Level

Server	Specified Level	Actual Level
Oracle	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiReadCommitted | tiReadCommitted | tiRepeatableRead (READONLY)
Sybase, MS-SQL	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiReadCommitted | tiReadCommitted | Not supported
DB2	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiDirtyRead | tiReadCommitted | tiRepeatableRead
Informix	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiDirtyRead | tiReadCommitted | tiRepeatableRead
InterBase	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiReadCommitted | tiReadCommitted | tiRepeatableRead

Paradox, dBASE, Access, FoxPro	tiDirtyRead | tiReadCommitted | tiRepeatableRead	tiDirtyRead | Not supported | Not supported

Note: For local transactions against Paradox and dBASE, TransIsolation must be set to tiDirtyRead. Otherwise, an exception is raised.

If an application uses ODBC to interface with a server, the ODBC driver must also support the isolation level. For more information about supported isolation levels, see the documentation for the ODBC driver in question.

StartTransaction (see page 9977)

53.1.7.6 TDatabase Events

The events of the TDatabase class are listed here.

Published Events

	Name	Description
	AfterConnect (see page 9992)	Occurs after a connection is established.
	AfterDisconnect (see page 9993)	Occurs after the connection closes.
	BeforeConnect (see page 9993)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 9993)	Occurs immediately before the connection closes.
	OnLogin (see page 9994)	Occurs when an application connects to a database.

53.1.7.6.1 TDatabase.AfterConnect Event

Occurs after a connection is established.

Pascal

```
property AfterConnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterConnect;
```

Description

Write an AfterConnect event handler to take application-specific actions immediately after the connection component opens a connection to the remote source of database information.

See Also

BeforeConnect (see page 6875)

Connected (see page 6868)

Connecting to a Database Server

53.1.7.6.2 TDatabase.AfterDisconnect Event

Occurs after the connection closes.

Pascal

```
property AfterDisconnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterDisconnect;
```

Description

Write an AfterDisconnect event handler to take application-specific actions after the connection component drops a connection.

See Also

BeforeDisconnect (see page 6875)

Connected (see page 6868)

Disconnecting from a Database Server

53.1.7.6.3 TDatabase.BeforeConnect Event

Occurs immediately before establishing a connection.

Pascal

```
property BeforeConnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeConnect;
```

Description

Write a BeforeConnect event handler to take application-specific actions before the connection component opens a connection to the remote source of database information.

See Also

AfterConnect (see page 6874)

Connected (see page 6868)

Connecting to a Database Server

53.1.7.6.4 TDatabase.BeforeDisconnect Event

Occurs immediately before the connection closes.

Pascal

```
property BeforeDisconnect: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeDisconnect;
```

Description

Write a BeforeDisconnect event handler to take application-specific actions before dropping a connection.

Delphi Examples:

```
{
This BeforeDisconnect event handler makes sure that the
client dataset has applied all its pending updates before
terminating the connection to the server.
}
procedure TForm1.RemoteServer1BeforeDisconnect(Sender: TObject);
begin
  if (ClientDataSet1.ChangeCount > 0) then
    ClientDataSet1.ApplyUpdates(-1);
end;
```

See Also

AfterDisconnect (see page 6875)

Connected (see page 6868)

Disconnecting from a Database Server

53.1.7.6.5 TDatabase.OnLogin Event

Occurs when an application connects to a database.

Pascal

```
property OnLogin: TDatabaseLoginEvent;
```

C++

```
__property TDatabaseLoginEvent OnLogin;
```

Description

Write an OnLogin event handler to take specific actions when an application attempts to connect to a database. When the LoginPrompt (see page 9985) property is true, a database login is required.

If there is no OnLogin event handler, the current UserName is read from the Params (see page 9986) property, and a standard Login dialog box opens. The dialog prompts for a user name and password combination, and then uses the values entered by the user to set the UserName and PASSWORD values in the Params (see page 9986) property. These values are then passed to the remote server.

Applications that provide alternative OnLogin event handlers must set the UserName and PASSWORD values in LoginParams. LoginParams is a temporary string list and is freed automatically when no longer needed.

Note: The login dialog and OnLogin event only occur when the LoginPrompt (see page 9985) property is true.

53.1.8 TDataSetUpdateObject Class

TDataSetUpdateObject is a base class for update objects used to update otherwise unupdatable queries or stored procedures in applications that cache updates.

Class Hierarchy

Pascal

```
TDataSetUpdateObject = class(TComponent);
```

C++

```
class TDataSetUpdateObject : public TComponent;
```

File

DBTables

Description

Use TDataSetUpdateObject as a base class when creating customized update objects that update BDE datasets.

TUpdateSQL (see page 10229)

53.1.8.1 TDataSetUpdateObject Members

The following tables list the members exposed by TDataSetUpdateObject.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
A	GetDataSet (see page 9998)	GetDataSet returns the value of the DataSet (see page 9999) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.

	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDataSet (see page 9999)	SetDataSet sets the value of the DataSet (see page 9999) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	DataSet (see page 9999)	Specifies the dataset that stores the cached updates to be applied by the update object.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Apply (see page 9998)	Apply applies changes to the dataset specified by the DataSet (see page 9999) property.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.

	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.8.2 TDataSetUpdateObject Methods

The methods of the TDataSetUpdateObject class are listed here.

Protected Methods

	Name	Description
	GetDataSet (see page 9998)	GetDataSet returns the value of the DataSet (see page 9999) property.
	SetDataSet (see page 9999)	SetDataSet sets the value of the DataSet (see page 9999) property.

Public Methods

	Name	Description
	Apply (see page 9998)	Apply applies changes to the dataset specified by the DataSet (see page 9999) property.

53.1.8.2.1 TDataSetUpdateObject.Apply Method

Apply applies changes to the dataset specified by the DataSet (see page 9999) property.

Pascal

```
procedure Apply(UpdateKind: TUpdateKind); virtual; abstract;
```

C++

```
virtual __fastcall Apply(TUpdateKind UpdateKind) = 0;
```

Description

Descendants of TDataSetUpdateObject (see page 9994) implement the Apply method. This method is intended to perform the updates specified by the update object. Descendants introduce properties to describe the details of the updates that should be performed. The UpdateKind parameter indicates whether the update object should modify existing records, insert new records, or delete existing records.

See Also

DataSet (see page 9999)

53.1.8.2.2 TDataSetUpdateObject.GetDataSet Method

GetDataSet returns the value of the DataSet (see page 9999) property.

Pascal

```
function GetDataSet: TDataSet; virtual; abstract;
```

C++

```
virtual __fastcall TDataSet GetDataSet() = 0;
```

Description

Override GetDataSet, along with the SetDataSet (see page 9999) method, to provide an implementation of the DataSet (see page 9999) property. The DataSet (see page 9999) property should represent the dataset that caches the updates to be

applied by the update object.

See Also

DataSet (see page 9999)

SetDataSet (see page 9999)

53.1.8.2.3 TDataSetUpdateObject.SetDataSet Method

SetDataSet sets the value of the DataSet (see page 9999) property.

Pascal

```
procedure SetDataSet(ADataSet: TDataSet); virtual; abstract;
```

C++

```
virtual __fastcall SetDataSet(TDataSet ADataSet) = 0;
```

Description

Override SetDataSet, along with the GetDataSet (see page 9998) method, to provide an implementation of the DataSet (see page 9999) property. The DataSet (see page 9999) property should represent the dataset that caches the updates to be applied by the update object.

See Also

DataSet (see page 9999)

GetDataSet (see page 9998)

53.1.8.3 TDataSetUpdateObject Properties

The properties of the TDataSetUpdateObject class are listed here.

Protected Properties

	Name	Description
	DataSet (see page 9999)	Specifies the dataset that stores the cached updates to be applied by the update object.

53.1.8.3.1 TDataSetUpdateObject.DataSet Property

Specifies the dataset that stores the cached updates to be applied by the update object.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

DataSet is the dataset that stores the updates that this update object applies to a database server. The update object uses the dataset to obtain information about the original and updated field values.

53.1.9 TDBDataSet Class

TDBDataSet encapsulates database connectivity for descendant dataset objects.

Class Hierarchy

Pascal

```
TDBDataSet = class(TBDEDataSet);
```

C++

```
class TDBDataSet : public TBDEDataSet;
```

File

DBTables

Description

TDBDataSet defines database-related connectivity properties and methods for a dataset. Applications never use TDBDataSet objects directly. Instead they use the descendants of TDBDataSet, such as TQuery (see page 10059), TStoredProc (see page 10139), and TTable (see page 10168), which inherit its database-related properties and methods.

Developers who create custom dataset components may want to derive them from TDBDataSet to inherit to the database-specific properties of TDBDataSet in addition to all the functionality of TDataSet and the BDE-related properties and methods of TBDEDataSet (see page 9878). In this case, developers should examine the source code to study the protected methods of TDBDataSet that are not documented for this object.

53.1.9.1 TDBDataSet Members

The following tables list the members exposed by TDBDataSet.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
V	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
V	CloseCursor (see page 10014)	This is CloseCursor, a member of class TDBDataSet.
	ConstraintsStored (see page 10015)	This is ConstraintsStored, a member of class TDBDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
V	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
V	CreateHandle (see page 9900)	This is CreateHandle, a member of class TBDEDataSet.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
V	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
V	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
V	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
V	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
V	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
V	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.
V	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.

	Disconnect (see page 10015)	This is Disconnect, a member of class TDBDataSet.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.

V	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
V	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
V	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
V	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
V	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
V	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
V	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
A	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
V	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
V	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
V	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
V	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
V	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
V	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
V	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
V	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
V	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
V	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
V	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
V	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
V	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
V	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
A	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
V	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
V	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
V	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
V	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
V	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
V	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
V	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
V	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
V	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
A	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
V	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
A	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
V	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
V	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
V	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
V	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
V	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
V	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.

	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 10015)	This is OpenCursor, a member of class TDBDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 10016)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 10017)	Executes a specified SQL command.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 10017)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 6982)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 6982)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 10018)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 6985)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 10018)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 10018)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 6989)	Assigns the specified parameter values to the dataset.

	PSStartTransaction (see page 10019)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 10019)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDBFlag (see page 10020)	This is SetDBFlag, a member of class TDBDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetHandle (see page 10020)	This is SetHandle, a member of class TDBDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.

	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
V	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
V	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
V	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
R	DBFlags (see page 10023)	Keeps track of the commands this dataset has active with the database.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.
	StmtHandle (see page 9935)	Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.
	UpdateMode (see page 10028)	Determines how the Borland (see page 1761) Database (see page 10021) Engine (BDE) finds records when updating to an SQL database.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
V	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	CheckOpen (see page 10014)	Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CloseDatabase (see page 10014)	Closes a database connection associated with the database session.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	Create (see page 10013)	Creates a new TDBDataSet (see page 10000) object.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 6904)	Destroys the TDataSet (see page 6894) instance.
V	Destroy (see page 9890)	Destroys the instance of a dataset component.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
V	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
V	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
V	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
V	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
V	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
V	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
V	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
V	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
V	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
V	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
V	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
V	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	OpenDatabase (see page 10016)	Opens the database that contains the dataset.
V	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
V	Post (see page 9918)	Writes a modified record to the database.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSExecute (see page 7578)	Executes the SQL command associated with the dataset.
	PSGetCommandText (see page 7579)	Gets the SQL command to be executed by PSExecute (see page 7578).
	PSGetCommandType (see page 7580)	Gets the command type to be executed by PSExecute (see page 7578).
	PSGetDefaultOrder (see page 7580)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 7581)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 7581)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetParams (see page 7582)	Returns the current parameter values of the dataset.
	PSGetTableName (see page 7583)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetUpdateException (see page 7583)	Generates an EUpdateError (see page 6732) object based on another exception object.
	PSIsSQLSupported (see page 7584)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 7585)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 7585)	Assigns a specified SQL command to be executed by PSExecute (see page 7578).
	PSSetParams (see page 7586)	Assigns the specified parameter values to the dataset.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.

	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Database (see page 10021)	Identifies the database component for which this dataset represents one or more tables.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DBHandle (see page 10023)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.
R	DBLocale (see page 10024)	Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.
R	DBSession (see page 10024)	Identifies the database session component associated with this dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
	Handle (see page 10027)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the dataset.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	UpdateObject (see page 9936)	Specifies the update object component used to update a read-only result set when cached updates are enabled.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.

R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 10028)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	AutoRefresh (see page 10021)	Specifies whether server-generated field values are refetched automatically.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	DatabaseName (see page 10022)	Specifies the name of the database associated with this dataset.
	Filter (see page 10025)	Specifies the text of the current filter for a dataset.
	Filtered (see page 10026)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 10026)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	SessionName (see page 10027)	Identifies the name of the session with which this dataset is associated.

	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.9.2 TDBDataSet.Create Constructor

Creates a new TDBDataSet (see page 10000) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDBDataSet(TComponent * AOwner);
```

Description

Call Create to instantiate a DB (see page 6725) dataset at runtime.

Create:

- Set the Locale (see page 9934) property of the dataset to the locale of the default session.
- Sets the CacheBlobs (see page 9932) property to true.
- Checks if the specified Owner is a database component, and if so, uses it to set the SessionName (see page 10027) and DatabaseName (see page 10022) properties.

See Also

TTable (see page 10168)

TQuery (see page 10059)

TStoredProc (see page 10139)

53.1.9.3 TDBDataSet Methods

The methods of the TDBDataSet class are listed here.

Protected Methods

	Name	Description
	CloseCursor (see page 10014)	This is CloseCursor, a member of class TDBDataSet.
	ConstraintsStored (see page 10015)	This is ConstraintsStored, a member of class TDBDataSet.
	Disconnect (see page 10015)	This is Disconnect, a member of class TDBDataSet.
	OpenCursor (see page 10015)	This is OpenCursor, a member of class TDBDataSet.
	PSEndTransaction (see page 10016)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecuteStatement (see page 10017)	Executes a specified SQL command.
	PSGetAttributes (see page 10017)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetQuoteChar (see page 10018)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSInTransaction (see page 10018)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 10018)	Indicates whether the dataset includes native SQL support.
	PSStartTransaction (see page 10019)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 10019)	Applies a single update to the underlying database table or tables.
	SetDBFlag (see page 10020)	This is SetDBFlag, a member of class TDBDataSet.
	SetHandle (see page 10020)	This is SetHandle, a member of class TDBDataSet.

Public Methods

	Name	Description
	CheckOpen (see page 10014)	Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	CloseDatabase (see page 10014)	Closes a database connection associated with the database session.
	OpenDatabase (see page 10016)	Opens the database that contains the dataset.

53.1.9.3.1 TDBDataSet.CheckOpen Method

Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).

Pascal

```
function CheckOpen(Status: DBIResult): Boolean;
```

C++

```
__fastcall Boolean CheckOpen(DBIResult Status);
```

Description

Call CheckOpen to determine if a call to the BDE returns an error when an attempt is made to access a dataset. Status is the return result of a previous call to the BDE.

CheckOpen returns true if access is successful. If Status indicates insufficient table rights when accessing a Paradox or dBASE table, CheckOpen calls the database session's GetPassword method to prompt the user for a password. If the dialog is successful, CheckOpen returns true.

Otherwise CheckOpen returns false, indicating that dataset access failed.

See Also

TDatabase (see page 9964)

TSession (see page 10093)

GetPassword (see page 10111)

53.1.9.3.2 TDBDataSet.CloseCursor Method

Pascal

```
procedure CloseCursor; override;
```

C++

```
virtual __fastcall CloseCursor();
```

Description

This is CloseCursor, a member of class TDBDataSet.

53.1.9.3.3 TDBDataSet.CloseDatabase Method

Closes a database connection associated with the database session.

Pascal

```
procedure CloseDatabase(Database: TDatabase);
```

C++

```
__fastcall CloseDatabase(TDatabase Database);
```

Description

Call CloseDatabase to close a persistent database connection, or to close and free a temporary database connection. Database (see page 10021) specifies the name of the database component for which to close the connection.

CloseDatabase decrements the specified database component's reference count, and then, if the reference count is zero and the database component's KeepConnection property is false, CloseDatabase either frees a temporary database component or closes the connection for a persistent database component.

Note: Calling CloseDatabase for a persistent database component does not close the connection. To close a connection for a persistent database component, call the database component's Close method directly.

Temporary database components are closed automatically when the last dataset associated with the database component is closed, but an application can call CloseDatabase prior to that time to force closure. Closing a connection established by a temporary database component does not free the component if the session's KeepConnections property is true (the default). To free temporary database components after closing their connections call DropConnections method of the session.

See Also

TSession (see page 10093)

DBSession (see page 10024)

Database (see page 10021)

DropConnections (see page 10105)

Close (see page 6863)

53.1.9.3.4 TDBDataSet.ConstraintsStored Method

Pascal

```
function ConstraintsStored: Boolean;
```

C++

```
__fastcall Boolean ConstraintsStored();
```

Description

This is ConstraintsStored, a member of class TDBDataSet.

53.1.9.3.5 TDBDataSet.Disconnect Method

Pascal

```
procedure Disconnect; virtual;
```

C++

```
virtual __fastcall Disconnect();
```

Description

This is Disconnect, a member of class TDBDataSet.

53.1.9.3.6 TDBDataSet.OpenCursor Method

Pascal

```
procedure OpenCursor(InfoQuery: Boolean); override;
```

C++

```
virtual __fastcall OpenCursor(Boolean InfoQuery);
```

Description

This is OpenCursor, a member of class TDBDataSet.

53.1.9.3.7 TDBDataSet.OpenDatabase Method

Opens the database that contains the dataset.

Pascal

```
function OpenDatabase: TDatabase;
```

C++

```
__fastcall TDatabase OpenDatabase();
```

Description

Call OpenDatabase to connect to the database that contains the dataset, or to create a temporary database component and connect to a database. The DatabaseName (see page 10022) property specifies the database to open.

OpenDatabase makes the current session active, then determines whether the DatabaseName (see page 10022) property corresponds to the DatabaseName (see page 10022) property of an existing database component. If it does not, OpenDatabase creates a temporary database component, assigning the DatabaseName (see page 10022) parameter to the DatabaseName (see page 10022) property. Finally, OpenDatabase calls the Open method of the database to connect to a database server, then increments the session's database reference count by one.

See Also

TDatabase (see page 9964)

DatabaseName (see page 10022)

Close (see page 6863)

53.1.9.3.8 TDBDataSet.PSEndTransaction Method

Ends a transaction that was started by a call to PSStartTransaction.

Pascal

```
procedure PSEndTransaction(Commit: Boolean); override;
```

C++

```
virtual __fastcall PSEndTransaction(Boolean Commit);
```

Description

The provider component applies updates within a transaction, if possible. To do so, it uses PSEndTransaction in conjunction with the PSStartTransaction method.

The Commit parameter indicates whether the dataset should commit the current transaction (Commit is true), or roll it back (Commit is false).

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there is no transaction already established. That is, it does not assume nested transaction support is available. Thus, there is no need to ensure that PSEndTransaction does not terminate a transaction that was not started by the provider.

See Also

PSStartTransaction (see page 7586)

PSInTransaction (see page 7583)

applyupdates (see page 18459)

53.1.9.3.9 TDBDataSet.PSExecuteStatement Method

Executes a specified SQL command.

Pascal

```
function PSExecuteStatement(const ASQL: string; AParams: TParams; ResultSet: Pointer = nil):
Integer; override;
```

C++

```
virtual __fastcall int PSExecuteStatement(const AnsiString ASQL, TParams AParams, void *
ResultSet = nil);
```

Description

If the value its ResolveToDataSet property is false, a provider component calls PSExecuteStatement (indirectly) to execute SQL statements that it generates for applying updates. Usually, the dataset passes these statements on to its database server for execution.

The ASQL parameter specifies the SQL command to execute.

AParams contains any parameter values that should be applied to ASQL before execution.

ResultSet allows PSExecuteStatement to return a dataset component that contains the results of a SELECT statement. If ResultSet is not nil (Delphi) or NULL (C++), PSExecuteStatement creates a new dataset component as the target of this pointer and fills it with the result set. The caller is responsible for freeing the dataset.

PSExecuteStatement returns the number of rows affected by executing ASQL.

See Also

PSUpdateRecord (see page 7586)

applyupdates (see page 18459)

ResolveToDataSet (see page 18531)

53.1.9.3.10 TDBDataSet.PSGetAttributes Method

Returns information that is stored in data packets as Name/Value pairs.

Pascal

```
procedure PSGetAttributes(List: TList); override;
```

C++

```
virtual __fastcall PSGetAttributes(TList List);
```

Description

The provider component calls PSGetAttributes to add information about the dataset to the metadata stored with generated data packets. This information is stored as Name/Value pairs that are added to the list specified by the List parameter.

See Also

DoGetProviderAttributes (see page 18521)

53.1.9.3.11 TDBDataSet.PSGetQuoteChar Method

Returns the character or characters to use in generated SQL statements to enclose quoted strings.

Pascal

```
function PSGetQuoteChar: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetQuoteChar();
```

Description

The provider component calls PSGetQuoteChar (indirectly) when generating the dynamic SQL statements that apply updates. These statements are subsequently executed by a call to PSExecuteStatement.

PSGetQuoteChar returns the character or characters that delimit quoted strings in the generated SQL. This string appears both before and after quoted strings.

See Also

applyupdates (see page 18459)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

53.1.9.3.12 TDBDataSet.PSInTransaction Method

Indicates whether actions against the dataset occur in the context of a transaction.

Pascal

```
function PSInTransaction: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSInTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it first checks whether a transaction is already underway, and if not, generates one using PSStartTransaction. To determine whether a transaction is already underway, the provider calls PSInTransaction.

PSInTransaction returns true if there is a transaction underway, and false otherwise.

See Also

PSStartTransaction (see page 7586)

PSEndTransaction (see page 7578)

53.1.9.3.13 TDBDataSet.PSIsSQLBased Method

Indicates whether the dataset includes native SQL support.

Pascal

```
function PSIsSQLBased: Boolean; override;
```

C++

```
virtual __fastcall Boolean PSIsSQLBased();
```

Description

The provider calls PSIsSQLBased to determine whether the dataset supports some form of native SQL. This information is used when generating SQL commands that are executed by PSExecuteStatement.

Even if the dataset is not SQL-based, it may still allow the provider to execute SQL statements for applying updates. For example, BDE-enabled local databases such as Paradox and DBASE provide SQL support via the BDE's local SQL engine, but are not SQL-based. However, table and field names are not specified in the same way for the local SQL engine as they are for native SQL. The provider uses PSIsSQLBased to determine how these names should appear in generated SQL.

Note: The PSIsSQLSupported method indicates whether the dataset can execute SQL commands at all, regardless of whether the dataset is SQL-based.

See Also

PSIsSQLSupported (see page 7584)

PSExecuteStatement (see page 7579)

53.1.9.3.14 TDBDataSet.PSStartTransaction Method

Starts a transaction that encapsulates all activity until a call to PSEndTransaction.

Pascal

```
procedure PSStartTransaction; override;
```

C++

```
virtual __fastcall PSStartTransaction();
```

Description

The provider component applies updates within a transaction, if possible. To do so, it calls PSStartTransaction to start a transaction before applying updates, and calls PSEndTransaction when all updates are applied or too many errors are encountered.

Note: TDataSetProvider only starts a transaction (Using PSStartTransaction) if the PSInTransaction method indicates that there is no transaction already established. That is, it does not assume nested transaction support is available.

See Also

PSEndTransaction (see page 7578)

PSInTransaction (see page 7583)

applyupdates (see page 18459)

53.1.9.3.15 TDBDataSet.PSUpdateRecord Method

Applies a single update to the underlying database table or tables.

Pascal

```
function PSUpdateRecord(UpdateKind: TUpdateKind; Delta: TDataSet): Boolean; override;
```

C++

```
virtual __fastcall Boolean PSUpdateRecord(TUpdateKind UpdateKind, TDataSet Delta);
```

Description

Before the provider generates SQL statements to apply an update, it calls PSUpdateRecord to let the dataset apply the update in some other fashion. For example, BDE-enabled datasets generate an OnUpdateRecord to allow the application to apply the

update and, if the OnUpdateRecord event handler does not apply the update, uses any associated TUpdateSQL object to apply the update.

UpdateKind indicates whether the update is an insertion (ukInsert), deletion (ukDelete), or modification (ukModify).

Delta is the delta datapacket. The current record represents the record to be updated.

PSUpdateRecord returns true if it updates the record, false otherwise. If PSUpdateRecord returns false, the provider generates dynamic SQL to perform the update and calls PSExecuteStatement.

Note: PSUpdateRecord is only called if the provider's ResolveToDataSet property is false.

See Also

OnUpdateRecord (see page 9957)

TUpdateSQL (see page 10229)

applyupdates (see page 18459)

ResolveToDataSet (see page 18531)

PSExecuteStatement (see page 7579)

53.1.9.3.16 TDBDataSet.SetDBFlag Method

Pascal

```
function SetDBFlag(Flag: Integer; Value: Boolean): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean SetDBFlag(int Flag, Boolean Value);
```

Description

This is SetDBFlag, a member of class TDBDataSet.

53.1.9.3.17 TDBDataSet.SetHandle Method

Pascal

```
procedure SetHandle(Value: HDBICur);
```

C++

```
__fastcall SetHandle(HDBICur Value);
```

Description

This is SetHandle, a member of class TDBDataSet.

53.1.9.4 TDBDataSet Properties

The properties of the TDBDataSet class are listed here.

Protected Properties

	Name	Description
	DBFlags (see page 10023)	Keeps track of the commands this dataset has active with the database.
	UpdateMode (see page 10028)	Determines how the Borland (see page 1761) Database (see page 10021) Engine (BDE) finds records when updating to an SQL database.

Public Properties

	Name	Description
R	Database (see page 10021)	Identifies the database component for which this dataset represents one or more tables.
R	DBHandle (see page 10023)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.
R	DBLocale (see page 10024)	Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.
R	DBSession (see page 10024)	Identifies the database session component associated with this dataset.
	Handle (see page 10027)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the dataset.

Published Properties

	Name	Description
	AutoRefresh (see page 10021)	Specifies whether server-generated field values are refetched automatically.
	DatabaseName (see page 10022)	Specifies the name of the database associated with this dataset.
	Filter (see page 10025)	Specifies the text of the current filter for a dataset.
	Filtered (see page 10026)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 10026)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
	SessionName (see page 10027)	Identifies the name of the session with which this dataset is associated.

53.1.9.4.1 TDBDataSet.AutoRefresh Property

Specifies whether server-generated field values are refetched automatically.

Pascal

```
property AutoRefresh: Boolean;
```

C++

```
__property Boolean AutoRefresh;
```

Description

When AutoRefresh is false (the default), values that the server creates for autoincrement fields and fields with default values when a record is posted are not automatically refetched by the dataset. Instead, the application must call the dataset's Refresh method to update these field values. When AutoRefresh is true, these field values are automatically refreshed without an explicit call to the Refresh method.

Note: Some database drivers can't determine which fields are autoincrement fields or have default values. For these cases, you must provide this information by setting the AutoGenerateValue property of all fields that should be refreshed. Similarly, you must set the field components' AutoGenerateValue properties when the dataset represents a query or stored procedure.

See Also

AutoGenerateValue (see page 7153)

Refresh (see page 6991)

53.1.9.4.2 TDBDataSet.Database Property

Identifies the database component for which this dataset represents one or more tables.

Pascal

```
property Database: TDatabase;
```

C++

```
__property TDatabase Database;
```

Description

Use Database to access the properties, events, and methods of the database component associated with this dataset. Database is a read-only property that is automatically set when the database specified by the DatabaseName (see page 10022) property is opened.

See Also

DatabaseName (see page 10022)

Connecting Directly to a Database Server

53.1.9.4.3 TDBDataSet.DatabaseName Property

Specifies the name of the database associated with this dataset.

Pascal

```
property DatabaseName: string;
```

C++

```
__property AnsiString DatabaseName;
```

Description

Use DatabaseName to specify the name of the database to associate with this dataset component. DatabaseName should match the name of a database component used in the application.

Note: Attempting to set DatabaseName when a database already associated with this component is open raises an exception.

Tip: At design time double-click a TDatabase (see page 9964) component to invoke the Database (see page 10021) editor and set the DatabaseName.

Delphi Examples:

```
{
This example requires a database with the following name or
in the form of a *.DB file in the following path.  The table
should be closed when changing the database.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Customers.Active := False;
  try
  { First try to use an alias }
    Customers.DatabaseName := 'DBDEMOS';
    Customers.Active := True;
  except
    on EDatabaseError do
    begin
      { If that fails, try to use the drive and directory }
      Customers.TableName := 'Flights';
      Customers.DatabaseName :=
        'c:\Documents and Settings\All Users\Documents\RAD
Studio\5.0\Demos\IntraWeb\Win32\FlightInformation\Data';
      Customers.Active := True;
    end;
```

```
  end;
end;
```

Associating a Dataset with Database and Session Connections

Using Multiple Update Objects

Connecting Directly to a Database Server

53.1.9.4.4 TDBDataSet.DBFlags Property

Keeps track of the commands this dataset has active with the database.

Pascal

```
property DBFlags: TDBFlags;
```

C++

```
__property TDBFlags DBFlags;
```

Description

Applications can't use this protected property. TDBDataSet (see page 10000) uses this property internally to keep track of the statements it has active with the current database connection. When DBFlags is empty, the dataset is not using the database connection.

53.1.9.4.5 TDBDataSet.DBHandle Property

Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.

Pascal

```
property DBHandle: HDBIDB;
```

C++

```
__property HDBIDB DBHandle;
```

Description

Check (see page 10245) DBHandle to determine the database handle for the dataset. DBHandle is only useful in applications that bypass database and dataset methods to write directly to the BDE API. Many BDE function calls require a handle parameter. DBHandle is assigned an initial value when a session is activated.

Note: Do not use this property unless an application requires BDE functionality not available through standard data access components.

See Also

DBLocale (see page 10024)

TDatabase (see page 9964)

Working with BDE Handle Properties

53.1.9.4.6 TDBDataSet.DBLocale Property

Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.

Pascal

```
property DBLocale: TLocale;
```

C++

```
__property TLocale DBLocale;
```

Description

Examine DBLocale to determine the BDE language driver used by the database component associated with which this dataset is associated. Applications that make direct calls to the BDE may need to pass DBLocale information as an API function parameter.

Note: Do not use this property unless an application requires BDE functionality not available through standard data access components.

See Also

DBHandle (see page 10023)

TDatabase (see page 9964)

Working with BDE Handle Properties

53.1.9.4.7 TDBDataSet.DBSession Property

Identifies the database session component associated with this dataset.

Pascal

```
property DBSession: TSession;
```

C++

```
__property TSession DBSession;
```

Description

Use DBSession to determine the session component that controls the database component with which this dataset component is associated. By default, a database component is associated with the default session component, Session (see page 10265), that is automatically created for all database applications.

See Also

SessionName (see page 10027)

Session (see page 9988)

Session (see page 10265)

Associating a Dataset with Database and Session Connections

Using TQuery

53.1.9.4.8 TDBDataSet.Filter Property

Specifies the text of the current filter for a dataset.

Pascal

```
property Filter: string;
```

C++

```
__property AnsiString Filter;
```

Description

Use Filter to specify a dataset filter. When filtering is applied to a dataset, only those records that meet a filter's conditions are available. Filter describes the filter condition. For example, the following filter condition displays only those records where the State field is 'CA' or 'MA':

```
State = 'CA' or State = 'MA'
```

When a filter is set, Blank records do not appear unless explicitly included in the filter. For example:

```
State <> 'CA' or State = NULL
```

When a field name contains spaces, you must enclose the field name in brackets. For example:

```
[Home State] = 'CA' or [Home State] = 'MA'
```

Filter expressions on remote SQL tables and on client datasets support field comparisons. For example:

```
Field1 > Field2
```

Field comparisons are not supported against local tables (Paradox, dBASE, Access, FoxPro).

For a complete list of operators you can use in filter strings, see SettingTheFilterProperty.

Note: Filters are not supported on unidirectional datasets. If you set the Filter property of a unidirectional dataset, it raises an exception.

The FilterOptions property controls case sensitivity and filtering on partial comparisons.

Tip: Applications can set Filter at runtime to change the dataset's filtering condition (for example, in response to user input).

See Also

Filtered (see page 7027)

FilterOptions (see page 7027)

Lookup (see page 6970)

Creating Filters

Navigating Records in a Filtered Dataset

Setting the Filter Property

Displaying and Editing a Subset of Data Using Filters

53.1.9.4.9 TDBDataSet.Filtered Property

Specifies whether or not filtering is active for a dataset.

Pascal

```
property Filtered: Boolean;
```

C++

```
__property Boolean Filtered;
```

Description

Check Filtered to determine whether or not dataset filtering is in effect. If Filtered is true, then filtering is active. To apply filter conditions specified in the Filter property or the OnFilterRecord event handler, set Filtered to true. Because unidirectional datasets do not support filters, when you set Filtered to true on a unidirectional dataset, it raises an exception.

Note: When filtering is enabled, user edits to a record may mean that the record no longer meets a filter's test condition. The next time an attempt is made to the read the record from the dataset while the filter is in effect, the record is not visible. If that happens, the next record that passes the filter condition becomes the active record.

See Also

Filter (see page 7026)

FilterOptions (see page 7027)

OnFilterRecord (see page 7055)

Locate (see page 6970)

Lookup (see page 6970)

Enabling and Disabling Filtering

Setting the Filter Property

53.1.9.4.10 TDBDataSet.FilterOptions Property

Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.

Pascal

```
property FilterOptions: TFilterOptions;
```

C++

```
__property TFilterOptions FilterOptions;
```

Description

Set FilterOptions to specify whether or not filtering is case insensitive when filtering on string or character fields, and whether or not partial comparisons for matching filter conditions is allowed.

Note: Because unidirectional datasets do not support filters, when you set the FilterOptions property of a unidirectional dataset, it raises an exception.

By default, FilterOptions is set to an empty set. For filters based on string fields, set FilterOptions to foCaseInsensitive to catch all variations on a string regardless of capitalization.

When a string in a filter ends with an asterisk (*), it can be used to match partial strings. To disable matching of partial strings and to treat the asterisk as a literal character in string comparisons, set FilterOptions to include foNoPartialCompare.

See Also

Filter (see page 7026)

Filtered (see page 7027)

OnFilterRecord (see page 7055)

Locate (see page 6970)

Lookup (see page 6970)

Setting Filter Options

53.1.9.4.11 TDBDataSet.Handle Property

Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the dataset.

Pascal

```
property Handle: HDBICur;
```

C++

```
__property HDBICur Handle;
```

Description

Use Handle only to bypass TDataSet methods and call directly into the BDE. Many BDE function calls require a cursor handle parameter. Handle is assigned an initial value when a dataset is opened. If used with a BDE call that changes the current record position, call Resync immediately after returning from the BDE call.

TBDEDataSet (see page 9878) allows the Handle property to be set to an existing BDE cursor handle. Setting the Handle property is intended primarily for internal use. Descendant classes redeclare the Handle property to re-establish it as a read-only property

Note: Do not use this property unless an application requires BDE functionality not available through built-in components.

See Also

Locale (see page 9934)

Resync (see page 6994)

Working with BDE Handle Properties

53.1.9.4.12 TDBDataSet.SessionName Property

Identifies the name of the session with which this dataset is associated.

Pascal

```
property SessionName: string;
```

C++

```
__property AnsiString SessionName;
```

Description

Use SessionName to determine the session with which a dataset component is associated. SessionName is automatically set to the name of the SessionName property of the database component with which a dataset component is associated. If SessionName is blank, a dataset component is automatically associated with the default session, Session (see page 10265).

To associate a dataset component with a different session, SessionName must match the SessionName property of an existing

session component that is also used by the database component with which this dataset is associated.

See Also

DBSession (see page 10024)

Database (see page 10021)

Session (see page 10265)

Associating a Database Component with a Session

Associating a Dataset with Database and Session Connections

Using Multiple Update Objects

Adding a Session to the Web Module

53.1.9.4.13 TDBDataSet.UpdateMode Property

Determines how the Borland (see page 1761) Database (see page 10021) Engine (BDE) finds records when updating to an SQL database.

Pascal

```
property UpdateMode: TUpdateMode;
```

C++

```
__property TUpdateMode UpdateMode;
```

Description

Use UpdateMode to specify the criteria to use when locating a record in the dataset. UpdateMode specifies whether modified records are located based on all columns (fields), on only the key fields, or on the key fields plus the original values of fields that have been modified.

See Also

UpdateRecordTypes (see page 9936)

53.1.9.5 TDBDataSet Events

The events of the TDBDataSet class are listed here.

Published Events

	Name	Description
	OnFilterRecord (see page 10028)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.

53.1.9.5.1 TDBDataSet.OnFilterRecord Event

Occurs each time a different record in the dataset becomes the active record and filtering is enabled.

Pascal

```
property OnFilterRecord: TFilterRecordEvent;
```

C++

```
__property TFilterRecordEvent OnFilterRecord;
```

Description

Write an OnFilterRecord event handler to specify for each record in a dataset whether it should be visible to the application. To indicate that a record passes the filter condition, the OnFilterRecord event handler must set the Accept parameter to true. To exclude a record, set the Accept parameter to false. Most TDataSet descendants (such as ADO datasets or BDE-based datasets) initialize Accept to true before calling the OnFilterRecord event handler.

Warning: Do not supply an OnFilterRecord event handler to a unidirectional dataset. Unidirectional datasets do not support filters, and assigning an OnFilterRecord event handler causes the dataset to raise an exception.

Filtering is enabled if the Filtered property is true. When an application is processing a filter, the State property for the dataset is dsFilter.

Use an OnFilterRecord event handler to filter records using a criterion that can't be implemented using the Filter property. For example, using the Filter property, field comparisons are not supported against local tables (Paradox, dBASE, Access, FoxPro), but an OnFilterRecord event handler can implement any criterion at all.

Tip: Be sure that any interactions between the Filter property and the OnFilterRecord event handler do not result in an empty filter set when they are used simultaneously in an application.

53.1.10 TDBError Class

TDBError represents Borland (see page 1761) Database Engine errors for the EDBEngineError (see page 9854) exception class.

Class Hierarchy

DBTables.TDBError

Pascal

```
TDBError = class;
```

C++

```
class TDBError;
```

File

DBTables

Description

The TDBError object is a container for the information pertaining to one database error. One or more TDBError objects are

contained in the Errors property (EDBEngineError (see page 9854)).

An EDBEngineError (see page 9854) exception is raised when Borland (see page 1761) Database Engine (BDE) or a database back-end accessed via the BDE produces an error condition on execution of a database operation. Information about each error involved in an error condition (such as an error code and error message) is passed by the BDE to the EDBEngineError (see page 9854) object. If the error occurs at the level of a database system accessed by the BDE (such as InterBase, Oracle, or Sybase), the error information is passed through the BDE to the application's exception object. EDBEngineError (see page 9854) reads the stack of database engine errors and creates a separate TDBError object to represent each one. These TDBError objects are contained in the Errors property of EDBEngineError (see page 9854).

When an error condition originates with a database system accessed through the BDE, there will typically be two TDBError objects in Errors. The first will be the BDE version of the error and the second the database system's version of the same error. In both cases, the Category (see page 10031), ErrorCode (see page 10032), and SubCode (see page 10033) properties will contain the same values: the BDE error code for the particular type of error condition. In the TDBError object for the BDE's version of the error the NativeCode property is empty and the text for the Message (see page 10032) property contains the BDE error message the type type of error that occurred. In the TDBError object for the database system's version of the error, the NativeCode property contains the database systems specific error code and the Message (see page 10032) property text provided by the database system (and not the BDE).

For example, when a violation of an InterBase CHECK constraint occurs (an error condition that originates with InterBase and not the BDE), the error message provided by the BDE is the generic "General SQL error," while the error message provided by InterBase is a more explanatory error like "Operation violates CHECK constraint INTEG_30 on view or table EMPLOYEE."

It is also possible to have only BDE type errors in the TDBError objects. This is usually only applicable to use of local table types (dBASE, Paradox, and FoxPro), where the BDE is the database back-end and there is no external database system used.

The categories and subcodes for BDE errors are defined in bde.int (Delphi) or bde.hpp (C++). For error information provided by a database system other than the BDE, consult the vendor-supplied documentation for the specific database system for definition or clarification.

See Also

EDBEngineError (see page 9854)

53.1.10.1 TDBError Members

The following tables list the members exposed by TDBError.

Public Methods

	Name	Description
	Create (see page 10030)	Initializes an instance of TDBError (see page 10029) using error information returned by the BDE.

Public Properties

	Name	Description
R	Category (see page 10031)	Indicates the category of error referenced by ErrorCode (see page 10032).
R	ErrorCode (see page 10032)	Indicates the error code returned by the BDE.
R	Message (see page 10032)	Specifies the text of the error message.
R	NativeError (see page 10032)	Indicates the remote error code returned from the server.
R	SubCode (see page 10033)	Indicates the subcode of the error referenced by ErrorCode (see page 10032).

53.1.10.2 TDBError.Create Constructor

Initializes an instance of TDBError (see page 10029) using error information returned by the BDE.

Pascal

```
constructor Create(Owner: EDBEngineError; ErrorCode: DBIResult; NativeError: Longint; Message:
PChar);
```

C++

```
__fastcall TDBError(EDBEngineError Owner, DBIResult ErrorCode, Longint NativeError, const char
* Message);
```

Description

TDBError (see page 10029)'s Create method is called by the EDBEngineError (see page 9854) constructor, just as TDBError (see page 10029) objects are freed by the EDBEngineError (see page 9854) destructor. Application's should never have cause for calling Create directly, except in the case of custom exception-handling objects descending from or similar to the EDBEngineError (see page 9854) exception object.

See Also

EDBEngineError (see page 9854)

Create (see page 9856)

53.1.10.3 TDBError Properties

The properties of the TDBError class are listed here.

Public Properties

	Name	Description
R	Category (see page 10031)	Indicates the category of error referenced by ErrorCode (see page 10032).
R	ErrorCode (see page 10032)	Indicates the error code returned by the BDE.
R	Message (see page 10032)	Specifies the text of the error message.
R	NativeError (see page 10032)	Indicates the remote error code returned from the server.
R	SubCode (see page 10033)	Indicates the subcode of the error referenced by ErrorCode (see page 10032).

53.1.10.3.1 TDBError.Category Property

Indicates the category of error referenced by ErrorCode (see page 10032).

Pascal

```
property Category: Byte;
```

C++

```
__property Byte Category;
```

Description

Category contains the high byte of the BDE error code. Combined with the low byte of the BDE error code (in the SubCode (see page 10033) property) this produces the whole BDE error code (also contained in the ErrorCode (see page 10032) property).

See Also

ErrorCode (see page 10032)

SubCode (see page 10033)

53.1.10.3.2 TDBError.ErrorCode Property

Indicates the error code returned by the BDE.

Pascal

```
property ErrorCode: DBIResult;
```

C++

```
__property DBIResult ErrorCode;
```

Description

Use ErrorCode to determine the error code returned by the BDE. The value of ErrorCode is the combination of the high byte of the BDE error code (also in the Category (see page 10031) property) and the low byte (in the SubCode (see page 10033) property).

See Also

SubCode (see page 10033)

53.1.10.3.3 TDBError.Message Property

Specifies the text of the error message.

Pascal

```
property Message: string;
```

C++

```
__property AnsiString Message;
```

Description

Message contains the remote server message for native (server) errors or the BDE message associated with ErrorCode (see page 10032) for non-server errors. To determine which type of message is contained in the Message property, inspect the NativeError (see page 10032) property. A zero value there indicates a message provided by the BDE. A nonzero value indicates a message provided by the database system (server).

See Also

NativeError (see page 10032)

53.1.10.3.4 TDBError.NativeError Property

Indicates the remote error code returned from the server.

Pascal

```
property NativeError: Longint;
```

C++

```
__property Longint NativeError;
```

Description

Use NativeError to determine whether the error represents a remote error received from the database server. If NativeError is 0, the error is not a server error.

Values in the NativeError property originate with the database system and not the BDE. Refer to vendor documentation for the specific database system used.

See Also

ErrorCode (see page 10032)

53.1.10.3.5 TDBError.SubCode Property

Indicates the subcode of the error referenced by ErrorCode (see page 10032).

Pascal

```
property SubCode: Byte;
```

C++

```
__property Byte SubCode;
```

Description

SubCode contains the low byte of the BDE error code. Combined with the high byte of the BDE error code (in the Category (see page 10031) property) this produces the whole BDE error code (also contained in the ErrorCode (see page 10032) property).

See Also

ErrorCode (see page 10032)

Category (see page 10031)

53.1.11 TIndexFiles Class

Class Hierarchy

Pascal

```
TIndexFiles = class(TStringList);
```

C++

```
class TIndexFiles : public TStringList;
```

File

DBTables

Description

This is class DBTables.TIndexFiles.

53.1.11.1 TIndexFiles Members

The following tables list the members exposed by TIndexFiles.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 3013)	This is Changed, a member of class TStringList.
	Changing (see page 3013)	This is Changing, a member of class TStringList.

V	CompareStrings (see page 3014)	Compares two strings.
V	CompareStrings (see page 3048)	Compares two strings.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
V	Get (see page 3017)	Returns a string given its index.
A	Get (see page 3053)	Returns a string given its index.
V	GetCapacity (see page 3017)	Returns the currently allocated size of the list of strings.
V	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
V	GetCount (see page 3018)	Returns the number of strings in the list
A	GetCount (see page 3054)	Returns the number of strings in the list
V	GetObject (see page 3018)	Returns the object associated with the string at a specified index.
V	GetObject (see page 3055)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
V	InsertItem (see page 3020)	This is InsertItem, a member of class TStringList.
V	Put (see page 3022)	Changes the value of the string with a specified index.
V	Put (see page 3064)	Changes the value of the string with a specified index.
V	PutObject (see page 3022)	Changes the object associated with the string at a specified index.
V	PutObject (see page 3065)	Changes the object associated with the string at a specified index.
V	SetCapacity (see page 3022)	Changes the amount of memory allocated to hold strings in the list.
V	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
V	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
V	SetUpdateState (see page 3023)	Performs internal adjustments before or after a series of updates.
V	SetUpdateState (see page 3069)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
R	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Events

	Name	Description
	OnChange (see page 3028)	Occurs immediately after the list of strings changes.
	OnChanging (see page 3028)	Occurs immediately before the list of strings changes.

Public Methods

	Name	Description
V	Add (see page 10037)	Adds a new string to the list.
V	AddObject (see page 3012)	Adds a string to the list, and associates an object with the string.
V	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
V	AddStrings (see page 3039)	Adds a group of strings to the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 3041)	Adds a string to the list.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	Assign (see page 3043)	Sets the strings in the list, and possibly associated objects, from a source object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 10039)	Deletes all the strings from the list.
	Create (see page 10036)	This is Create, a member of class TIndexFiles.
V	CustomSort (see page 3014)	Sorts the strings in the list in a customized order.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Delete (see page 10039)	Removes the string specified by the Index parameter.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 3009)	Destroys an instance of TStringList (see page 3006).
V	Destroy (see page 3032)	Destroys the TPersistent instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
V	Exchange (see page 3015)	Swaps the position of two strings in the list.
V	Exchange (see page 3053)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
V	Find (see page 3016)	Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3019)	Returns the position of a string in the list.
V	IndexOf (see page 3056)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Insert (see page 10040)	Inserts a string to the list at the position specified by Index.
V	InsertObject (see page 3020)	Inserts a string into the list at the specified position, and associates it with an object.
V	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	Move (see page 3063)	Changes the position of a string in the list.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.

V	Sort (see page 3023)	Sorts the strings in the list in ascending order.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.
	CaseSensitive (see page 3025)	Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	Duplicates (see page 3025)	Specifies whether duplicate strings can be added to sorted lists.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	Sorted (see page 3026)	Specifies whether the strings in the list should be automatically sorted.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

53.1.11.2 TIndexFiles.Create Constructor

Pascal

```
constructor Create(AOwner: TTable);
```

C++

```
__fastcall TIndexFiles(TTable AOwner);
```

Description

This is Create, a member of class TIndexFiles.

53.1.11.3 TIndexFiles Methods

The methods of the TIndexFiles class are listed here.

Public Methods

	Name	Description
V	Add (see page 10037)	Adds a new string to the list.
V	Clear (see page 10039)	Deletes all the strings from the list.
V	Delete (see page 10039)	Removes the string specified by the Index parameter.
V	Insert (see page 10040)	Inserts a string to the list at the position specified by Index.

53.1.11.3.1 TIndexFiles.Add Method

Adds a new string to the list.

Pascal

```
function Add(const S: string): Integer; override;
```

C++

```
virtual __fastcall int Add(const AnsiString S);
```

Description

Call Add to add the string S to the list. If the list is sorted, S is added to the appropriate position in the sort order. If the list is not sorted, S is added to the end of the list. Add returns the position of the item in the list, where the first item in the list has a value of 0.

Note: For sorted lists, Add will raise an EListError exception if the string S already appears in the list and Duplicates is set to dupError. If Duplicates is set to dupIgnore, trying to add a duplicate string causes Add to return the index of the existing entry.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TStrings *StringList = new TStringList();
  try
  {
    StringList->Add("This example uses A string List. ");
```

```
    StringList->Add("It is the easiest way to add strings");
    StringList->Add("to a combobox's list of strings. ");
    StringList->Add("Always remember TStrings is abstract,");
    StringList->Add("So create a TStringList instead.");
    ComboBox1->Width = 210;
    ComboBox1->Items->Assign(StringList);
    ComboBox1->ItemIndex = 0;
  }
  __finally
  {
    delete StringList;
  }
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
  finally
    MyList.Free;
  end;
end;
{
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  StringList: TStringList;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
      Add('This example uses A string List.');
      Add('It is the easiest way to add strings');
      Add('to a combobox''s list of strings.');
      Add('Always remember TStrings.Create method');
      Add('is abstract; So use TStringList.Create');
      Add('method instead.');
    end;
    with ComboBox1 do begin
      Width := 210;
      Items.Assign(StringList);
      ItemIndex := 0;
```

```
    end;
  finally
    StringList.free;
  end;
end;
```

See Also

AddStrings (see page 3039)

Append (see page 3041)

Delete (see page 3015)

Duplicates (see page 3025)

Insert (see page 3019)

Sorted (see page 3026)

53.1.11.3.2 TIndexFiles.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 3015)

Objects

Strings

53.1.11.3.3 TIndexFiles.Delete Method

Removes the string specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add (see page 3010)

AddObject (see page 3012)

Clear (see page 3013)

IndexOf (see page 3019)

InsertObject (see page 3060)

Objects

Strings

53.1.11.3.4 TIndexFiles.Insert Method

Inserts a string to the list at the position specified by Index.

Pascal

```
procedure Insert(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Insert(int Index, const AnsiString S);
```

Description

Call Insert to add the string S to the list at the position specified by Index. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

If the string has an associated object, use the InsertObject method instead.

Note: If the list is sorted, calling Insert or InsertObject will raise an EListError exception. Use Add or AddObject with sorted lists.

See Also

Add (see page 3010)

AddObject (see page 3012)

EListError (see page 2701)

InsertObject (see page 3020)

Sorted (see page 3026)

Strings

53.1.12 TNestedTable Class

TNestedTable encapsulates a dataset that is nested as a field within another table.

Class Hierarchy

Pascal

```
TNestedTable = class(TBDEDataSet);
```

C++

```
class TNestedTable : public TBDEDataSet;
```

File

DBTables

Description

Use TNestedTable to access data contained in a nested dataset. A nested table inherits BDE functionality from TBDEDataSet (see page 9878) and so uses the Borland (see page 1761) Database Engine (BDE) to access the nested table data. A nested table provides much of the functionality of a table component, except that the data it accesses is stored in a nested table.

Note: TNestedTable is used only for dataset fields in tables that have a BDE driver (such as Oracle8 tables). For example, detail sets nested in a client dataset use another client dataset instead.

53.1.12.1 TNestedTable Members

The following tables list the members exposed by TNestedTable.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
V	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.

	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
	CreateHandle (see page 10053)	This is CreateHandle, a member of class TNestedTable.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.
	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 10054)	This is DoAfterPost, a member of class TNestedTable.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 10054)	This is DoBeforeInsert, a member of class TNestedTable.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.

	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.

	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 10054)	This is InternalPost, a member of class TNestedTable.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 6982)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 6982)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.

	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 6985)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 6989)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.

V	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
V	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
V	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
V	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
V	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
V	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
V	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
V	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.

R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.
	StmtHandle (see page 9935)	Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.

	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
V	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	Create (see page 10053)	Creates an instance of a TNestedTable (see page 10040) component.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 6904)	Destroys the TDataSet (see page 6894) instance.
V	Destroy (see page 9890)	Destroys the instance of a dataset component.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
V	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
V	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
V	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
V	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
V	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
V	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
V	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.

	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
	Post (see page 9918)	Writes a modified record to the database.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSEndTransaction (see page 7578)	Ends a transaction that was started by a call to PSStartTransaction (see page 7586).
	PSExecute (see page 7578)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 7579)	Executes a specified SQL command.
	PSGetAttributes (see page 7579)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 7579)	Gets the SQL command to be executed by PSExecute (see page 7578).
	PSGetCommandType (see page 7580)	Gets the command type to be executed by PSExecute (see page 7578).
	PSGetDefaultOrder (see page 7580)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 7581)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 7581)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetParams (see page 7582)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 7582)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetTableName (see page 7583)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetUpdateException (see page 7583)	Generates an EUpdateError (see page 6732) object based on another exception object.
	PSInTransaction (see page 7583)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 7584)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 7584)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 7585)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 7585)	Assigns a specified SQL command to be executed by PSExecute (see page 7578).
	PSSetParams (see page 7586)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 7586)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction (see page 7578).
	PSUpdateRecord (see page 7586)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)

V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	Handle (see page 9933)	Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.

R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	UpdateObject (see page 9936)	Specifies the update object component used to update a read-only result set when cached updates are enabled.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	DataSetField (see page 10054)	Indicates the persistent TDataSetField object that owns a nested dataset.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 10055)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.12.2 TNestedTable.Create Constructor

Creates an instance of a TNestedTable (see page 10040) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TNestedTable(TComponent * AOwner);
```

Description

Call Create to instantiate a nested table declared in an application if it was not placed on a form at design time. Create calls its inherited Create constructor and sets ObjectView (see page 10055) to True.

See Also

ObjectView (see page 7031)

53.1.12.3 TNestedTable Methods

The methods of the TNestedTable class are listed here.

Protected Methods

	Name	Description
	CreateHandle (see page 10053)	This is CreateHandle, a member of class TNestedTable.
	DoAfterPost (see page 10054)	This is DoAfterPost, a member of class TNestedTable.
	DoBeforeInsert (see page 10054)	This is DoBeforeInsert, a member of class TNestedTable.
	InternalPost (see page 10054)	This is InternalPost, a member of class TNestedTable.

53.1.12.3.1 TNestedTable.CreateHandle Method

Pascal

```
function CreateHandle: HDBICur; override;
```

C++

```
virtual __fastcall HDBICur CreateHandle();
```

Description

This is CreateHandle, a member of class TNestedTable.

53.1.12.3.2 TNestedTable.DoAfterPost Method

Pascal

```
procedure DoAfterPost; override;
```

C++

```
virtual __fastcall DoAfterPost();
```

Description

This is DoAfterPost, a member of class TNestedTable.

53.1.12.3.3 TNestedTable.DoBeforeInsert Method

Pascal

```
procedure DoBeforeInsert; override;
```

C++

```
virtual __fastcall DoBeforeInsert();
```

Description

This is DoBeforeInsert, a member of class TNestedTable.

53.1.12.3.4 TNestedTable.InternalPost Method

Pascal

```
procedure InternalPost; override;
```

C++

```
virtual __fastcall InternalPost();
```

Description

This is InternalPost, a member of class TNestedTable.

53.1.12.4 TNestedTable Properties

The properties of the TNestedTable class are listed here.

Published Properties

	Name	Description
	DataSetField (see page 10054)	Indicates the persistent TDataSetField object that owns a nested dataset.
	ObjectView (see page 10055)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.

53.1.12.4.1 TNestedTable.DataSetField Property

Indicates the persistent TDataSetField object that owns a nested dataset.

Pascal

```
property DataSetField: TDataSetField;
```

C++

```
__property TDataSetField DataSetField;
```

Description

Use DataSetField when the dataset is the nested detail set of another dataset, such as an Oracle8 nested dataset. Read DataSetField to access the data set field component in the master dataset that includes this dataset as a detail. Set DataSetField to a field component in the master dataset to assign this dataset as the value of that field.

Note: When setting the DataSetField property, the dataset must be of (or a descendant of) the class specified by the master dataset's NestedDataSetClass property. Otherwise, setting DataSetField raises an exception. Further, setting DataSetField to a TDataSetField that is contained in the same dataset raises an exception (A dataset can't be nested in itself).

NestedDataSet (see page 7070)

NestedDataSetClass (see page 7030)

Using Nested Detail Tables

Working with DataSet Fields

Working with Reference Fields

53.1.12.4.2 TNestedTable.ObjectView Property

Specifies whether fields are stored hierarchically or flattened out in the Fields property.

Pascal

```
property ObjectView: Boolean;
```

C++

```
__property Boolean ObjectView;
```

Description

ObjectView affects the way the Fields property stores object fields and the way data-aware grids display ADT and array fields.

When ObjectView is true, the fields are stored hierarchically in the Fields property, meaning any child fields of an object field are referenced by the object field and don't appear sequentially after the object field in the TFields:: .Fields array. When ObjectView is false, the fields are stored sequentially in the Fields property, meaning any child fields of an object field are stored after the object field as siblings in the Fields array.

When ObjectView is false, object field types, such as TADTField, are not created. This switch is provided for increased compatibility with older data-aware controls, which may not handle object field types properly. The default is false for TBDEDataSet, and true for TClientDataSet.

Note: If the ObjectView property of the dataset provided to a TClientDataSet is false, then the TClientDataSet's ObjectView property always acts as false, since the data received is already flattened.

53.1.13 TParamList Class

TParamList manages a list of session parameters.

Class Hierarchy

System::TObject → DBTables.TParamList

Pascal

```
TParamList = class(TObject);
```

C++

```
class TParamList : public TObject;
```

File

DBTables

Description

Do not use TParamList directly. TParamList is an internal object used to manage a list of session parameters for a TSession (see page 10093) component.

See Also

TSession (see page 10093)

53.1.13.1 TParamList Members

The following tables list the members exposed by TParamList.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 10057)	Creates an instance of TParamList (see page 10056).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 10057)	Destroys an instance of TParamList (see page 10056).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Buffer (see page 10058)	Contains all parameter strings for the parameter list.
	FieldCount (see page 10058)	Indicates the number of session parameters in the parameter list.
	FieldDescs (see page 10059)	Contains the field descriptors for each parameter maintained by the parameter list object.

53.1.13.2 TParamList.Create Constructor

Creates an instance of TParamList (see page 10056).

Pascal

```
constructor Create(Params: TStrings);
```

C++

```
__fastcall TParamList(TStrings Params);
```

Description

Call Create to instantiate a TParamList (see page 10056) object. Most applications do not need to create a TParamList (see page 10056) object because it is automatically created by TSession (see page 10093).

Params is a string list containing the names of the parameters to create for the session. These parameters correspond to Borland (see page 1761) Database Engine (BDE) configuration parameters.

See Also

TSession (see page 10093)

Destroy (see page 10057)

53.1.13.3 TParamList.Destroy Destructor

Destroys an instance of TParamList (see page 10056).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TParamList();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks for a nil reference before calling Destroy.

Destroy frees the memory previously allocated for field descriptors and the buffer used by TParamList (see page 10056).

Note: An application should never need to destroy a TParamList (see page 10056) object. It is automatically destroyed when its parent session object is destroyed.

See Also

Free (see page 22300)

TSession (see page 10093)

Create (see page 10057)

53.1.13.4 TParamList Properties

The properties of the TParamList class are listed here.

Public Properties

	Name	Description
R	Buffer (see page 10058)	Contains all parameter strings for the parameter list.
R	FieldCount (see page 10058)	Indicates the number of session parameters in the parameter list.
R	FieldDescs (see page 10059)	Contains the field descriptors for each parameter maintained by the parameter list object.

53.1.13.4.1 TParamList.Buffer Property

Contains all parameter strings for the parameter list.

Pascal

```
property Buffer: PChar;
```

C++

```
__property const char * Buffer;
```

Description

Buffer is used internally to store parameters in the the parameter list object. While applications can parse this list, there is usually no need to do so.

See Also

FieldDescs (see page 10059)

53.1.13.4.2 TParamList.FieldCount Property

Indicates the number of session parameters in the parameter list.

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

Check (see page 10245) FieldCount to determine how many parameters there are for a session.

See Also

FieldDescs (see page 10059)

53.1.13.4.3 TParamList.FieldDescs Property

Contains the field descriptors for each parameter maintained by the parameter list object.

Pascal

```
property FieldDescs: TFieldDescList;
```

C++

```
__property TFieldDescList FieldDescs;
```

Description

Examine FieldDescs to determine the characteristics of each parameter maintained by the parameter list object. Applications usually have no need to access this property directly.

See Also

FieldCount (see page 10058)

53.1.14 TQuery Class

TQuery represents a dataset with a result set that is based on an SQL (see page 10089) statement.

Class Hierarchy

Pascal

```
TQuery = class(TDBDataSet);
```

C++

```
class TQuery : public TDBDataSet;
```

File

DBTables

Description

Use TQuery to access one or more tables in a database using SQL (see page 10089) statements. Query components can be used with remote database servers (such as Sybase, SQL (see page 10089) Server, Oracle, Informix, DB2, and InterBase), with local tables (Paradox, InterBase, dBASE, Access, and FoxPro), and with ODBC-compliant databases.

Query components are useful because they can

Access more than one table at a time (called a "join" in SQL (see page 10089)).

Automatically access a subset of rows and columns in its underlying table(s), rather than always returning all rows and columns.

Note: TQuery is of particular importance to the development of scalable database applications. If there is any chance that an application built to run against local databases will be scaled to a remote SQL (see page 10089) database server in the future, use TQuery components from the start to ensure easier scaling later.

Using TQueryTableProducer

53.1.14.1 TQuery Members

The following tables list the members exposed by TQuery.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.

	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
	CloseCursor (see page 10014)	This is CloseCursor, a member of class TDBDataSet.
	ConstraintsStored (see page 10015)	This is ConstraintsStored, a member of class TDBDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
	CreateHandle (see page 10074)	This is CreateHandle, a member of class TQuery.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
	DefineProperties (see page 10074)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.
	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.
	Disconnect (see page 10075)	This is Disconnect, a member of class TQuery.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	FreeStatement (see page 10076)	This is FreeStatement, a member of class TQuery.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.

	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 10076)	This is GetDataSource, a member of class TQuery.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetParamsCount (see page 10076)	This is GetParamsCount, a member of class TQuery.
	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetStatementHandle (see page 10077)	This is GetStatementHandle, a member of class TQuery.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.

	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	OpenCursor (see page 10015)	This is OpenCursor, a member of class TDBDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSEndTransaction (see page 10016)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 10078)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 10017)	Executes a specified SQL command.

	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetAttributes (see page 10017)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 10078)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 10079)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 10079)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 10079)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteChar (see page 10018)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 10080)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSInTransaction (see page 10018)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLBased (see page 10018)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 10080)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 10081)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSStartTransaction (see page 10019)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 10019)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.

	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
V	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
V	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
V	SetDBFlag (see page 10081)	This is SetDBFlag, a member of class TQuery.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
V	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
V	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
V	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
V	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
V	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
V	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
V	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetHandle (see page 10020)	This is SetHandle, a member of class TDBDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
V	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
V	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
V	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
V	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
V	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.

V	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
R	DataLink (see page 10084)	This is DataLink, a member of class TQuery.
R	DBFlags (see page 10023)	Keeps track of the commands this dataset has active with the database.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.

	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
V	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	CheckOpen (see page 10014)	Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CloseDatabase (see page 10014)	Closes a database connection associated with the database session.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	Create (see page 10073)	Creates an instance of a query component.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.

	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
	Destroy (see page 10073)	Destroys the instance of a query.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecSQL (see page 10075)	Executes the SQL (see page 10089) statement for the query.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
	GetDetailLinkFields (see page 10076)	Fills lists with the master and detail fields of the link.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.

	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	OpenDatabase (see page 10016)	Opens the database that contains the dataset.
	ParamByName (see page 10077)	Accesses parameter information based on a specified parameter name.
	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
	Post (see page 9918)	Writes a modified record to the database.
	Prepare (see page 10077)	Sends a query to the Borland (see page 1761) Database (see page 10021) Engine (BDE) and the server for optimization prior to execution.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSEndTransaction (see page 7578)	Ends a transaction that was started by a call to PSStartTransaction (see page 7586).
	PSExecuteStatement (see page 7579)	Executes a specified SQL command.
	PSGetAttributes (see page 7579)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetIndexDefs (see page 7581)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 7581)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetQuoteChar (see page 7582)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetUpdateException (see page 7583)	Generates an EUpdateError (see page 6732) object based on another exception object.
	PSInTransaction (see page 7583)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 7584)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 7584)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 7585)	Resets the dataset so that it is positioned on the first record.

	PSStartTransaction (see page 7586)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction (see page 7578).
	PSUpdateRecord (see page 7586)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UnPrepare (see page 10081)	Frees the resources allocated for a previously prepared query.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Database (see page 10021)	Identifies the database component for which this dataset represents one or more tables.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DBHandle (see page 10023)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.
R	DBLocale (see page 10024)	Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.
R	DBSession (see page 10024)	Identifies the database session component associated with this dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.

R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	Handle (see page 9933)	Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.
	Handle (see page 10027)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the dataset.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Local (see page 10085)	Indicates whether a query references one or more Paradox or dBASE tables rather than SQL (see page 10089) tables on a remote server.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ParamCount (see page 10086)	Indicates the current number of parameters for the query.
	Prepared (see page 10087)	Determines whether or not a query is prepared for execution.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
R	RowsAffected (see page 10089)	Returns the number of rows operated upon by the latest query execution.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
	SQLBinary (see page 10090)	Points to the binary data stream that represents an SQL (see page 10089) query statement or result set.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	StmtHandle (see page 10091)	Specifies the Borland Database Engine (BDE) statement handle for the dataset.
R	Text (see page 10091)	Points to the actual text of the SQL (see page 10089) query passed to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.

	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 10028)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	AutoRefresh (see page 10021)	Specifies whether server-generated field values are refetched automatically.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	Constrained (see page 10083)	Indicates whether updates and inserts that don't conform to the result set generated by a SELECT statement are permitted for Paradox and dBASE tables
	Constraints (see page 10083)	Specifies record-level constraints that must be met when editing the data.
	DatabaseName (see page 10022)	Specifies the name of the database associated with this dataset.
	DataSource (see page 10084)	Specifies the data source component from which to extract current field values to use with same-name parameters in the query's SQL (see page 10089) statement.
	Filter (see page 10025)	Specifies the text of the current filter for a dataset.
	Filtered (see page 10026)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 10026)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	ParamCheck (see page 10086)	Specifies whether the parameter list for a query is regenerated if the SQL (see page 10089) property changes at runtime.
	Params (see page 10087)	Contains the parameters for a query's SQL (see page 10089) statement.
	RequestLive (see page 10088)	Requests an updatable query result set from the database.
	SessionName (see page 10027)	Identifies the name of the session with which this dataset is associated.
	SQL (see page 10089)	Contains the text of the SQL statement to execute for the query.
	Tag (see page 2808)	Stores an integer value as part of a component.

	UniDirectional (see page 10092)	Determines whether or not Borland (see page 1761) Database (see page 10021) Engine (BDE) bidirectional cursors are enabled for a query's result set.
	UpdateMode (see page 10092)	Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.
	UpdateObject (see page 10092)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.14.2 TQuery.Create Constructor

Creates an instance of a query component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TQuery(TComponent * AOwner);
```

Description

Call Create to instantiate a query at runtime. Query components placed in forms or data modules at design time are created automatically.

AOwner is the component that is responsible for freeing the query. It becomes the value of the Owner property.

See Also

Destroy (see page 10073)

Owner (see page 2807)

53.1.14.3 TQuery.Destroy Destructor

Destroys the instance of a query.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TQuery();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the TQuery (see page 10059) is not nil before calling Destroy.

Destroy disconnects from the server, frees the SQL (see page 10089) statement list, the parameter list, and the data link and SQL (see page 10089) binary storage area, and then calls its inherited destructor.

See Also

Create (see page 10073)

Free (see page 22300)

53.1.14.4 TQuery Methods

The methods of the TQuery class are listed here.

Protected Methods

	Name	Description
	CreateHandle (see page 10074)	This is CreateHandle, a member of class TQuery.
	DefineProperties (see page 10074)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	Disconnect (see page 10075)	This is Disconnect, a member of class TQuery.
	FreeStatement (see page 10076)	This is FreeStatement, a member of class TQuery.
	GetDataSource (see page 10076)	This is GetDataSource, a member of class TQuery.
	GetParamsCount (see page 10076)	This is GetParamsCount, a member of class TQuery.
	GetStatementHandle (see page 10077)	This is GetStatementHandle, a member of class TQuery.
	PSExecute (see page 10078)	Executes the SQL command associated with the dataset.
	PSGetCommandText (see page 10078)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandType (see page 10079)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 10079)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetParams (see page 10079)	Returns the current parameter values of the dataset.
	PSGetTableName (see page 10080)	Returns the name of the dataset table that appears in generated SQL statements.
	PSSetCommandText (see page 10080)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetParams (see page 10081)	Assigns the specified parameter values to the dataset.
	SetDBFlag (see page 10081)	This is SetDBFlag, a member of class TQuery.

Public Methods

	Name	Description
	ExecSQL (see page 10075)	Executes the SQL (see page 10089) statement for the query.
	GetDetailLinkFields (see page 10076)	Fills lists with the master and detail fields of the link.
	ParamByName (see page 10077)	Accesses parameter information based on a specified parameter name.
	Prepare (see page 10077)	Sends a query to the Borland (see page 1761) Database (see page 10021) Engine (BDE) and the server for optimization prior to execution.
	UnPrepare (see page 10081)	Frees the resources allocated for a previously prepared query.

53.1.14.4.1 TQuery.CreateHandle Method

Pascal

```
function CreateHandle: HDBICur; override;
```

C++

```
virtual __fastcall HDBICur CreateHandle();
```

Description

This is CreateHandle, a member of class TQuery.

53.1.14.4.2 TQuery.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent overrides the DefineProperties method defined in TPersistent to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are

hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

See Also

Ancestor (see page 2839)

DefineBinaryProperty (see page 2837)

DefineProperties (see page 2931)

DefineProperty (see page 2838)

53.1.14.4.3 TQuery.Disconnect Method

Pascal

```
procedure Disconnect; override;
```

C++

```
virtual __fastcall Disconnect();
```

Description

This is Disconnect, a member of class TQuery.

53.1.14.4.4 TQuery.ExecSQL Method

Executes the SQL (see page 10089) statement for the query.

Pascal

```
procedure ExecSQL;
```

C++

```
__fastcall ExecSQL();
```

Description

Call ExecSQL to execute the SQL (see page 10089) statement currently assigned to the SQL (see page 10089) property. Use ExecSQL to execute queries that do not return a cursor to data (such as INSERT, UPDATE, DELETE, and CREATE TABLE).

Note: For SELECT statements, call Open instead of ExecSQL.

ExecSQL prepares the statement in SQL (see page 10089) property for execution if it has not already been prepared. To speed performance, an application should ordinarily call Prepare (see page 10077) before calling ExecSQL for the first time.

See Also

Open (see page 6976)

Prepare (see page 10077)

SQL (see page 10089)

Executing the Commands using TSQLDataSet

Using TQuery

53.1.14.4.5 TQuery.FreeStatement Method

Pascal

```
procedure FreeStatement; virtual;
```

C++

```
virtual __fastcall FreeStatement();
```

Description

This is FreeStatement, a member of class TQuery.

53.1.14.4.6 TQuery.GetDataSource Method

Pascal

```
function GetDataSource: TDataSource; override;
```

C++

```
virtual __fastcall TDataSource GetDataSource();
```

Description

This is GetDataSource, a member of class TQuery.

53.1.14.4.7 TQuery.GetDetailLinkFields Method

Fills lists with the master and detail fields of the link.

Pascal

```
procedure GetDetailLinkFields(MasterFields: TList; DetailFields: TList); override;
```

C++

```
virtual __fastcall GetDetailLinkFields(TList MasterFields, TList DetailFields);
```

Description

Creates two lists of TFields from the master-detail relationship between two tables; one containing the master fields, and the other containing the detail fields.

See Also

Params (see page 10087)

53.1.14.4.8 TQuery.GetParamsCount Method

Pascal

```
function GetParamsCount: Word;
```

C++

```
__fastcall Word GetParamsCount();
```

Description

This is GetParamsCount, a member of class TQuery.

53.1.14.4.9 TQuery.GetStatementHandle Method

Pascal

```
procedure GetStatementHandle(SQLText: PChar); virtual;
```

C++

```
virtual __fastcall GetStatementHandle(const char * SQLText);
```

Description

This is GetStatementHandle, a member of class TQuery.

53.1.14.4.10 TQuery.ParamByName Method

Accesses parameter information based on a specified parameter name.

Pascal

```
function ParamByName(const Value: string): TParam;
```

C++

```
__fastcall TParam ParamByName(const AnsiString Value);
```

Description

Call ParamByName to set or use parameter information for a specific parameter based on its name.

Value is the name of the parameter for which to retrieve information.

ParamByName is primarily used to set an parameter's value at runtime. For example, the following statement retrieves the current value of a parameter called "Contact" into an edit box:

```
Edit1.Text := Query1.ParamByName('Contact').AsString;
Edit1->Text = Query1->ParamByName("Contact")->AsString;
```

Parameters used in SELECT statements cannot be NULL, but they can be NULL for UPDATE and INSERT statements.

See Also

Params (see page 10087)

53.1.14.4.11 TQuery.Prepare Method

Sends a query to the Borland (see page 1761) Database (see page 10021) Engine (BDE) and the server for optimization prior to execution.

Pascal

```
procedure Prepare;
```

C++

```
__fastcall Prepare();
```

Description

Call Prepare to have the BDE and a remote database server allocate resources for the query and to perform additional optimizations. Preparing a query consumes some database resources, so it is good practice to call UnPrepare (see page 10081) once the query is no longer needed.

If the query will only be executed once, the application does not need to explicitly call Prepare or UnPrepare (see page 10081). Executing an unprepared query generates these calls automatically. However, if the same query is to be executed

repeatedly, it is more efficient to prevent these automatic calls by calling Prepare and UnPrepare (see page 10081) explicitly.

Note: When you change the text of a query at runtime, the query is automatically closed and unprepared.

See Also

ExecSQL (see page 10075)

Open (see page 6976)

UnPrepare (see page 10081)

Using TQuery

53.1.14.4.12 TQuery.PSExecute Method

Executes the SQL command associated with the dataset.

Pascal

```
procedure PSExecute; override;
```

C++

```
virtual __fastcall PSExecute();
```

Description

The provider component calls PSExecute to implement its Execute method. If the dataset represents a query or stored procedure that does not return a cursor, this method executes the query or stored procedure. If the provider Options includes poAllowCommandText and the dataset supports the PSSetCommandText method, the statement specified by PSSetCommandText may be executed instead.

If there is not statement to execute, PSExecute raises an EDatabaseError exception.

See Also

PSSetCommandText (see page 7585)

Execute (see page 18466)

Options (see page 18440)

53.1.14.4.13 TQuery.PSGetCommandText Method

Gets the SQL command to be executed by PSExecute.

Pascal

```
function PSGetCommandText: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetCommandText();
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSSetCommandText (see page 7585)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.14.4.14 TQuery.PSGetCommandType Method

Gets the command type to be executed by PSExecute.

Pascal

```
function PSGetCommandType: TPSCommandType; override;
```

C++

```
virtual __fastcall TPSCommandType PSGetCommandType();
```

Description

PSGetCommandType gets the command type executed by PSExecute. The type may be a type of SQL command or other command types, such as stored procedures.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSGetCommandText (see page 7579)

Execute (see page 18466)

Options (see page 18440)

53.1.14.4.15 TQuery.PSGetDefaultOrder Method

Returns the definition of an index that imposes the default order on the data included in data packets.

Pascal

```
function PSGetDefaultOrder: TIndexDef; override;
```

C++

```
virtual __fastcall TIndexDef PSGetDefaultOrder();
```

Description

The provider component calls PSGetDefaultOrder to generate a default index, called DEFAULT_ORDER, for the records that appear in data packets. This index defines the default sort order for records when they appear in the client dataset on the client.

PSGetDefaultOrder creates a TIndexDef object to describe the default index. The provider that calls PSGetDefaultOrder subsequently frees this TIndexDef object.

See Also

CreateDataPacket (see page 18518)

53.1.14.4.16 TQuery.PSGetParams Method

Returns the current parameter values of the dataset.

Pascal

```
function PSGetParams: TParams; override;
```

C++

```
virtual __fastcall TParams PSGetParams();
```

Description

The provider component calls PSGetParams to implement its GetParams method.

PSGetParams returns a TParams object that describes the current values of all parameters of the dataset. If the dataset does not have any parameters, PSGetParams returns nil (Delphi) or NULL (C++).

Note: The PSGetParams method should not create a new instance of TParams for the return value. The provider that calls PSGetParams does not free the returned value.

See Also

GetParams (see page 18467)

53.1.14.4.17 TQuery.PSGetTableName Method

Returns the name of the dataset table that appears in generated SQL statements.

Pascal

```
function PSGetTableName: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetTableName();
```

Description

PSGetTableName returns the name of the underlying database table against which updates are applied when the provider's ResolveToDataSet property is false. This value is used for generating the SQL statements that apply updates. The generated SQL statements are subsequently executed by a call to PSExecuteStatement.

If PSGetTableName does not return a table name, the provider must have an OnGetTableName event handler to supply this value.

See Also

applyupdates (see page 18459)

ongettablename (see page 18542)

53.1.14.4.18 TQuery.PSSetCommandText Method

Assigns a specified SQL command to be executed by PSExecute.

Pascal

```
procedure PSSetCommandText(const CommandText: string); override;
```

C++

```
virtual __fastcall PSSetCommandText(const AnsiString CommandText);
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

The value of the CommandText parameter replaces the dataset's SQL statement (if it has one), or replaces the name of an underlying database table or stored procedure.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.14.4.19 TQuery.PSSetParams Method

Assigns the specified parameter values to the dataset.

Pascal

```
procedure PSSetParams(AParams: TParams); override;
```

C++

```
virtual __fastcall PSSetParams(TParams AParams);
```

Description

PSSetParams assigns the parameter values specified by AParams to the parameters of the dataset.

See Also

Params (see page 8489)

PSGetParams (see page 7582)

53.1.14.4.20 TQuery.SetDBFlag Method

Pascal

```
function SetDBFlag(Flag: Integer; Value: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean SetDBFlag(int Flag, Boolean Value);
```

Description

This is SetDBFlag, a member of class TQuery.

53.1.14.4.21 TQuery.UnPrepare Method

Frees the resources allocated for a previously prepared query.

Pascal

```
procedure UnPrepare;
```

C++

```
__fastcall UnPrepare();
```

Description

Call UnPrepare to free the resources allocated for a previously prepared query on the server and client sides.

Preparing a query consumes some database resources, so it is good practice for an application to unprepare a query once it is done using it. The UnPrepare method unprepares a query.

Note: When you change the text of a query at runtime, the query is automatically closed and unprepared.

ExecSQL (see page 10075)

Open (see page 6976)

Prepare (see page 10077)

53.1.14.5 TQuery Properties

The properties of the TQuery class are listed here.

Protected Properties

	Name	Description
R	DataLink (see page 10084)	This is DataLink, a member of class TQuery.

Public Properties

	Name	Description
R	Local (see page 10085)	Indicates whether a query references one or more Paradox or dBASE tables rather than SQL (see page 10089) tables on a remote server.
R	ParamCount (see page 10086)	Indicates the current number of parameters for the query.
	Prepared (see page 10087)	Determines whether or not a query is prepared for execution.
R	RowsAffected (see page 10089)	Returns the number of rows operated upon by the latest query execution.
	SQLBinary (see page 10090)	Points to the binary data stream that represents an SQL (see page 10089) query statement or result set.
	StmtHandle (see page 10091)	Specifies the Borland Database Engine (BDE) statement handle for the dataset.
R	Text (see page 10091)	Points to the actual text of the SQL (see page 10089) query passed to the Borland (see page 1761) Database (see page 10021) Engine (BDE).

Published Properties

	Name	Description
	Constrained (see page 10083)	Indicates whether updates and inserts that don't conform to the result set generated by a SELECT statement are permitted for Paradox and dBASE tables
	Constraints (see page 10083)	Specifies record-level constraints that must be met when editing the data.
	DataSource (see page 10084)	Specifies the data source component from which to extract current field values to use with same-name parameters in the query's SQL (see page 10089) statement.
	ParamCheck (see page 10086)	Specifies whether the parameter list for a query is regenerated if the SQL (see page 10089) property changes at runtime.
	Params (see page 10087)	Contains the parameters for a query's SQL (see page 10089) statement.
	RequestLive (see page 10088)	Requests an updatable query result set from the database.
	SQL (see page 10089)	Contains the text of the SQL statement to execute for the query.
	UniDirectional (see page 10092)	Determines whether or not Borland (see page 1761) Database (see page 10021) Engine (BDE) bidirectional cursors are enabled for a query's result set.
	UpdateMode (see page 10092)	Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.

	UpdateObject (see page 10092)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.14.5.1 TQuery.Constrained Property

Indicates whether updates and inserts that don't conform to the result set generated by a SELECT statement are permitted for Paradox and dBASE tables

Pascal

```
property Constrained: Boolean;
```

C++

```
__property Boolean Constrained;
```

Description

Use Constrained to determine whether or not edits and insertions are permitted to a Paradox or dBASE table underlying a result set when the UPDATE or INSERT statements contain one or more values that do not comply with the WHERE clause conditions of the SELECT statement that generated the result set. Constrained only applies to live result sets. Constraints (see page 10083) are enforced during the editing process.

If Constrained is false (the default), updates and inserts are permitted regardless of the SELECT statement criteria. If true, updates and inserts are not permitted if they violate the criteria of the SELECT statement that generated the result set.

For example, if Constrained is true and a query component's SQL (see page 10089) property is

```
SELECT *
FROM CUSTOMERS
WHERE (CUSTNO > 1400) AND (CUSTNO < 1500)
```

then the user would not be allowed to enter a value for CustNo that fell outside this range of values.

See Also

SQL (see page 10089)

53.1.14.5.2 TQuery.Constraints Property

Specifies record-level constraints that must be met when editing the data.

Pascal

```
property Constraints: TCheckConstraints;
```

C++

```
__property TCheckConstraints Constraints;
```

Description

Use Constraints to read or add record-level constraints to the dataset. Record-level constraints usually impose relationships between the fields in a single record. Constraints that limit the value of a single field should be added to the individual field components.

See Also

TCheckConstraint (see page 6841)

CustomConstraint (see page 7156)

ImportedConstraint (see page 7167)

Constraining Data Values

53.1.14.5.3 TQuery.DataLink Property

Pascal

```
property DataLink: TDataLink;
```

C++

```
__property TDataLink DataLink;
```

Description

This is DataLink, a member of class TQuery.

53.1.14.5.4 TQuery.DataSource Property

Specifies the data source component from which to extract current field values to use with same-name parameters in the query's SQL (see page 10089) statement.

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Set DataSource to automatically fill parameters in a query with fields values from another dataset. Parameters that have the same name as fields in the other dataset are filled with the field values. Parameters with names that are not the same as fields in the other dataset do not automatically get values, and must be programmatically set. For example, if the SQL (see page 10089) property of the TQuery (see page 10059) contains the SQL (see page 10089) statement below and the dataset referenced through DataSource has a CustNo field, the value from the current record in that other dataset is used in the CustNo parameter.

```
SELECT *
FROM Orders O
WHERE (O.CustNo = :CustNo)
```

DataSource must point to a TDataSource component linked to another dataset component; it cannot point to this query's data source component.

The dataset specified in DataSource must be created, populated, and opened before attempting to bind parameters. Parameters are bound by calling the query's Prepare (see page 10077) method prior to executing the query.

Tip: DataSource is especially of use when creating a master-detail relationship between tables using a linked query. It is also of use to guarantee binding for parameters that are not already set in the Params (see page 10087) property or through a call to the ParamByName (see page 10077) method.

If the SQL (see page 10089) statement used by a query does not contain parameters, or all parameters are bound by the application using the Params (see page 10087) property or the ParamByName (see page 10077) method, DataSource need not be assigned. The example below shows setting the DataSource property of Query2 to the data source for Query1, preparing Query2, and activating Query2.

```
with Query2 do begin
  DataSource := DataSource1;
  Prepare;
  Open;
end;
Query2->DataSource = DataSource1;
Query2->Prepare();
Query2->Open();
```

If the SQL (see page 10089) statement in the TQuery (see page 10059) is a SELECT query, the query is executed using the new field values each time the record pointer in the other dataset is changed. It is not necessary to call the Open method of the TQuery (see page 10059) each time. This makes using the DataSource property to dynamically filter a query result set useful for establishing Master-Detail relationships. Set the DataSource property in the Detail query to the TDataSource component for the Master dataset.

If the SQL (see page 10089) statement uses other than a SELECT query (such as INSERT or UPDATE), the parameters with the same name as fields in the other dataset still get values, but the query must be explicitly executed each time the other dataset's record pointer moves. For example, the SQL (see page 10089) statement below uses the INSERT statement and has the parameters CustNo and CompanyName.

```
INSERT INTO Customer
(CustNo, Company)
VALUES (:CustNo, :CompanyName)
```

Another dataset, Query1 and DataSource1, has a CustNo field but no CompanyName field. If this dataset is used through the DataSource property, the CompanyName parameter must be programmatically assigned a value. Because Query1 has a CustNo field and Query1 is referenced through the DataSource property, the CustNo parameter automatically receives a value.

```
with Query2 do begin
  DataSource := DataSource1;
  ParamByName('CompanyName').AsString := Edit1.Text;
  Prepare;
  ExecSQL;
end;
Query2->DataSource = DataSource1;
Query2->ParamByName("CompanyName")->AsString = Edit1->Text;
Query2->Prepare();
Query2->ExecSQL();
```

If the SQL (see page 10089) statement contains parameters with the same name as fields in the other dataset, do not manually set values for these parameters. Any values programmatically set, such as by using the Params (see page 10087) property or the ParamByName (see page 10077) method, will be overridden with automatic values. Parameters of other names must be programmatically given values. These parameters are unaffected by setting DataSource.

DataSource can be set at runtime or at design-time using the Object Inspector. At design-time, select the desired TDataSource from the drop-down list or type in the name.

See Also

ParamByName (see page 10077)

Params (see page 10087)

SQL (see page 10089)

53.1.14.5.5 TQuery.Local Property

Indicates whether a query references one or more Paradox or dBASE tables rather than SQL (see page 10089) tables on a remote server.

Pascal

```
property Local: Boolean;
```

C++

```
__property Boolean Local;
```

Description

Check (see page 10245) Local to determine if a query accesses one or more Paradox or dBASE tables rather than SQL (see page 10089) tables. If Local is true, then the query only accesses dBASE or Paradox tables. Otherwise Local is false. Local

is set automatically when an application calls the query's Prepare (see page 10077) method prior to executing the query.

Some query component settings, such as Constrained (see page 10083), are only meaningful for queries against Paradox and dBASE tables. Others are only meaningful for queries against remote SQL (see page 10089) servers. Local can provide useful information for branching logic in code based on the type of database accessed. It can also be used to determine whether or not the BDE parsed a query using its local query engine rather than passing SQL (see page 10089) statements directly to a remote server.

See Also

Constrained (see page 10083)

ExecSQL (see page 10075)

Open (see page 6976)

Prepare (see page 10077)

53.1.14.5.6 TQuery.ParamCheck Property

Specifies whether the parameter list for a query is regenerated if the SQL (see page 10089) property changes at runtime.

Pascal

```
property ParamCheck: Boolean;
```

C++

```
__property Boolean ParamCheck;
```

Description

Set ParamCheck to specify whether or not the Params (see page 10087) property is cleared and regenerated if an application modifies the query's SQL (see page 10089) property at runtime. By default ParamCheck is true, meaning that the Params (see page 10087) property is automatically regenerated at runtime. When ParamCheck is true, the proper number of parameters is guaranteed to be generated for the current SQL (see page 10089) statement.

This property is useful for data definition language (DDL) statements that contain parameters as part of the DDL statement and that are not parameters for the TQuery (see page 10059). For example, the DDL statement to create a stored procedure may contain parameter statements that are part of the stored procedure. Set ParamCheck to false to prevent these parameters from being mistaken for parameters of the TQuery (see page 10059) executing the DDL statement.

An application that does not use parameterized queries may choose to set ParamCheck to false, but otherwise ParamCheck should be true.

See Also

Params (see page 10087)

SQL (see page 10089)

TStoredProc (see page 10139)

53.1.14.5.7 TQuery.ParamCount Property

Indicates the current number of parameters for the query.

Pascal

```
property ParamCount: Word;
```

C++

```
__property Word ParamCount;
```

Description

Inspect ParamCount to determine how many parameters are in the Params (see page 10087) property. If the ParamCheck (see page 10086) property is true, ParamCount always corresponds to the number of actual parameters in the SQL (see page 10089) statement for the query.

See Also

Params (see page 10087)

SQL (see page 10089)

53.1.14.5.8 TQuery.Params Property

Contains the parameters for a query's SQL (see page 10089) statement.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Access Params at runtime to view and set parameter names, values, and data types dynamically (at design time use the collection editor for the Params property to set parameter information). Params is a zero-based array of TParams parameter records. Index specifies the array element to access.

Note: An easier way to set and retrieve parameter values when the name of each parameter is known is to call ParamByName (see page 10077). ParamByName (see page 10077) cannot, however, be used to change a parameter's data type or name.

Parameters used in SELECT statements cannot be NULL, but they can be NULL for UPDATE and INSERT statements.

See Also

ParamByName (see page 10077)

SQL (see page 10089)

53.1.14.5.9 TQuery.Prepared Property

Determines whether or not a query is prepared for execution.

Pascal

```
property Prepared: Boolean;
```

C++

```
__property Boolean Prepared;
```

Description

Examine Prepared to determine if a query is already prepared for execution. If Prepared is true, the query is prepared, and if Prepared is false, the query is not prepared. While a query need not be prepared before execution, execution performance is enhanced if the query is prepared beforehand, particularly if it is a parameterized query that is executed more than once using the same parameter values.

Note: An application can change the current setting of Prepared to prepare or unprepare a query. If Prepared is true, setting it to

false calls the UnPrepare (see page 10081) method to unprepare the query. If Prepared is false, setting it to true calls the Prepare (see page 10077) method to prepare the query. Generally, however, it is better programming practice to call Prepare (see page 10077) and UnPrepare (see page 10081) directly. These methods automatically update the Prepared property.

See Also

ExecSQL (see page 10075)

Open (see page 6976)

Prepare (see page 10077)

UnPrepare (see page 10081)

53.1.14.5.10 TQuery.RequestLive Property

Requests an updatable query result set from the database.

Pascal

```
property RequestLive: Boolean;
```

C++

```
__property Boolean RequestLive;
```

Description

RequestLive is a request that a SELECT query returns an updatable (or live) or read-only result set from the database back-end. A false value for RequestLive (the default) causes the result set to always be read-only. No request is made to the database back-end to return an updatable result set. A true value for RequestLive is a request to database back-end to return an updatable result set. An updatable result set can be made available to the application's user for direct data editing through visual data controls.

A true value for RequestLive is a request for an updatable result set. It does not guarantee that the database back-end will return an updatable result set. See the documentation for the specific database system used for the criteria needed for a live query result set. If the database cannot return an updatable result set, a read-only result set is returned instead. This is done automatically and usually without error. Some database systems may raise an exception on requests for live result sets that cannot be fulfilled. Check (see page 10245) the success of the request by inspecting the dataset component's CanModify property.

If the SQL (see page 10089) statement used in a TQuery (see page 10059) is a general, multi-row SELECT statement, RequestLive can be used with either a true or a false value. For all other SQL (see page 10089) statements issued from the TQuery (see page 10059), RequestLive should only be set to false. These other statements include noncursor single-row SELECT statements (more commonly found in stored procedure programming), noncursor Data Manipulation Language (DML) statements like UPDATE or DELETE, and Data Definition Language (DDL) statements like CREATE TABLE and DROP INDEX.

Note: All multi-table queries return read-only result sets. Other conditions may cause a query to return a read-only result set. For local tables (such as dBASE and Paradox), see the local SQL (see page 10089) help file for rules governing live result sets (updatable queries). For other table types (such as InterBase, Oracle, and Sybase), consult the documentation for the specific database system.

Note: Some SQL (see page 10089) database systems require strict case-sensitivity for names of metadata objects in SQL (see page 10089) statements. These SQL (see page 10089) databases typically have problems with the way metadata names are passed by the BDE in live queries and an exception is raised. A workaround that helps in most cases is to enclose the metadata object references (like table and column names) in quotation marks.

CanModify

ExecSQL (see page 10075)

Open (see page 6976)

SQL (see page 10089)

Obtaining an Editable Result Set

Using TQuery

53.1.14.5.11 TQuery.RowsAffected Property

Returns the number of rows operated upon by the latest query execution.

Pascal

```
property RowsAffected: Integer;
```

C++

```
__property int RowsAffected;
```

Description

Inspect RowsAffected to determine how many rows were updated or deleted by the last query operation. If no rows were updated or deleted, RowsAffected has a value of zero. RowsAffected will have a value of –1 if the execution of the SQL (see page 10089) statement could not be executed due to an error condition. This latter situation would typically follow the raising of an exception.

See Also

ExecSQL (see page 10075)

53.1.14.5.12 TQuery.SQL Property

Contains the text of the SQL statement to execute for the query.

Pascal

```
property SQL: TStrings;
```

C++

```
__property TStrings SQL;
```

Description

Use SQL to provide the SQL statement that a query component executes when its ExecSQL (see page 10075) or Open method is called. At design time the SQL property can be edited by invoking the String List editor in the Object Inspector.

The SQL property may contain only one complete SQL statement at a time. In general, multiple "batch" statements are not allowed unless a particular server supports them.

The SQL property can be used to access

Paradox or dBASE tables, using local SQL. The allowable syntax is a subset of SQL-92. See the local SQL help file for information on supported syntax.

Databases on the Local (see page 10085) InterBase Server, using standard SQL-92 and specific InterBase extensions to SQL syntax. For information on syntax and limitations, see the InterBase Language Reference and online help.

Databases on remote database servers using the appropriate SQL Links driver or ODBC (not available in all versions). Any standard statement in the server's SQL dialect is allowed. For information on SQL syntax and limitations, see the server documentation.

The SQL statement in the SQL property may contain replaceable parameters, following standard SQL-92 syntax conventions. Parameters are created and stored in the Params (see page 10087) property.

Note: Developers with advanced versions can also invoke the Visual Query Builder to create an SQL statement for execution. Right-click the TQuery (see page 10059) icon on the form in the IDE and select the command from the context menu.

Using TSQLQuery

53.1.14.5.13 TQuery.SQLBinary Property

Points to the binary data stream that represents an SQL (see page 10089) query statement or result set.

Pascal

```
property SQLBinary: PChar;
```

C++

```
__property const char * SQLBinary;
```

Description

Do not access SQLBinary. It is an internal binary data stream used by the query component to communicate directly with the Borland (see page 1761) Database (see page 10021) Engine. To access or set the SQL (see page 10089) statement that this query component executes, use the SQL (see page 10089) property. To access or set the parameters used in a parameterized SQL (see page 10089) statement, use the Params (see page 10087) property.

See Also

Params (see page 10087)

SQL (see page 10089)

53.1.14.5.14 TQuery.StmtHandle Property

Specifies the Borland Database Engine (BDE) statement handle for the dataset.

Pascal

```
property StmtHandle: HDBIStmt;
```

C++

```
__property HDBIStmt StmtHandle;
```

Description

Use StmtHandle for direct calls to the BDE that bypass the methods of this dataset. Some BDE API calls require a statement handle as a parameter. For example, TBDEDataSet descendants use StmtHandle when preparing a query or binding parameters.

Typically, applications do not need to access this property. In TBDEDataSet, StmtHandle is protected, and so unavailable to applications. Some descendants make this property public so that you can bypass the dataset methods and make direct calls to the BDE.

See Also

Handle (see page 9933)

Prepare (see page 10077)

Prepare (see page 10157)

Params (see page 10087)

Params (see page 10165)

53.1.14.5.15 TQuery.Text Property

Points to the actual text of the SQL (see page 10089) query passed to the Borland (see page 1761) Database (see page 10021) Engine (BDE).

Pascal

```
property Text: string;
```

C++

```
__property AnsiString Text;
```

Description

Text is a read-only property that can be examined to determine the actual contents of SQL (see page 10089) statement passed to the BDE. For parameterized queries, Text contains the SQL (see page 10089) statement with parameters replaced by the parameter substitution symbol (?) in place of actual parameter values.

In general there should be no need to examine the Text property. To access or change the SQL (see page 10089) statement for the query, use the SQL (see page 10089) property. To examine or modify parameters, use the Params (see page 10087) property.

See Also

Params (see page 10087)

SQL (see page 10089)

53.1.14.5.16 TQuery.UniDirectional Property

Determines whether or not Borland (see page 1761) Database (see page 10021) Engine (BDE) bidirectional cursors are enabled for a query's result set.

Pascal

```
property UniDirectional: Boolean;
```

C++

```
__property Boolean UniDirectional;
```

Description

Set UniDirectional to control whether or not a BDE cursor can move forward and backward through a result set. By default UniDirectional is false, enabling forward and backward navigation.

Traditionally SQL (see page 10089) cursors are unidirectional. They can travel only forward through a dataset. The BDE, however, permits bidirectional travel by caching records. If an application does not need bidirectional access to records in a result set, set UniDirectional to true. When UniDirectional is true, an application requires less memory and performance is improved.

Note: Do not confuse the UniDirectional property, which indicates whether the BDE cursor is unidirectional, with the IsUniDirectional property inherited from TDataSet. IsUniDirectional, which implies additional restrictions such as a lack of buffering, is always false for TQuery (see page 10059).

See Also

IsUniDirectional (see page 7029)

53.1.14.5.17 TQuery.UpdateMode Property

Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.

Pascal

```
property UpdateMode: TUpdateMode;
```

C++

```
__property TUpdateMode UpdateMode;
```

Description

Use UpdateMode to specify the criteria to use when locating a record in the dataset. UpdateMode specifies whether modified records are located based on all columns (fields), on only the key fields, or on the key fields plus the original values of fields that have been modified.

See Also

UpdateRecordTypes (see page 9936)

53.1.14.5.18 TQuery.UpdateObject Property

Specifies the update object component used to update a read-only result set when cached updates are enabled.

Pascal

```
property UpdateObject: TDataSetUpdateObject;
```

C++

```
__property TDataSetUpdateObject UpdateObject;
```

Description

Use UpdateObject to specify the TUpdateObject component to use in an application that must be able to update a read-only result set returned by the Borland Database Engine (BDE).

The BDE always attempts to provide an updatable, or "live" query result unless an application specifically requests a read-only view of data. In some cases, such as a query made against multiple tables, a live result set cannot be returned. In these cases, UpdateObject can be used to specify a TUpdateSQL component that performs updates as a separate transaction that is transparent to the application.

53.1.15 TSession Class

TSession provides global management of a group of database connections in an application.

Class Hierarchy

Pascal

```
TSession = class(TComponent, IDBSession);
```

C++

```
class TSession : public TComponent, public IDBSession;
```

File

DBTables

Description

Use TSession to manage a group of database connections within an application. There are three uses for TSession: standard, multiple net files for Paradox, and multi-threaded database applications.

The library automatically creates a globally accessible default TSession component named Session (see page 10265) for all database applications. The default session component handles standard database connections. An application can control the

default session by accessing its properties, events, and methods at runtime.

Database applications that must simultaneously access Paradox tables located in different network locations can establish multiple sessions, one for each network location.

Finally, database applications that must establish multiple, concurrent connections to the same database, such as performing two queries against the same data at once, are multi-threaded applications. Multi-threaded applications must create and maintain one additional session component for each simultaneous connection to a single database server.

Note: Applications that maintain multiple sessions can manage them through the TSessionList (see page 10129) component. A default session list component, called Sessions (see page 10266)—note the plural which distinguishes it from the default session component, Session (see page 10265)—is automatically created for all database applications.

Note: TSession implements the IDBSession interface, which allows the global PasswordDialog function to supply passwords to the component.

Associating a Database Component with a Session

Understanding Database and Session Component Interactions

53.1.15.1 TSession Members

The following tables list the members exposed by TSession.

Protected Events

	Name	Description
	OnDBNotify (see page 10128)	This is OnDBNotify, a member of class TSession.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 10114)	Initializes the component after the form file has been read into memory.
	ModifyConfigParams (see page 10115)	This is ModifyConfigParams, a member of class TSession.
V	Notification (see page 10116)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 10119)	Sets the value of the Name property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	BDEOwnsLoginCbDb (see page 10122)	This is BDEOwnsLoginCbDb, a member of class TSession.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddAlias (see page 10100)	Adds a specified Borland (see page 1761) Database Engine (BDE) alias to the session for an SQL database server.
	AddDriver (see page 10101)	Adds a specified Borland (see page 1761) Database Engine (BDE) driver to the session for an SQL database server.
	AddPassword (see page 10102)	Adds a password to the current session for accessing encrypted Paradox or dBase tables.
	AddStandardAlias (see page 10102)	Adds a standard Borland (see page 1761) Database Engine (BDE) alias to the session for Paradox, dBASE, or ASCII tables.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Close (see page 10103)	Disconnects from all databases, and closes the session.
	CloseDatabase (see page 10103)	Closes a database connection associated with the current session.
V	Create (see page 10098)	Creates an instance of a TSession (see page 10093) component.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DeleteAlias (see page 10104)	Removes a specified Borland (see page 1761) Database Engine (BDE) alias from the session.
	DeleteDriver (see page 10105)	Removes a specified Borland (see page 1761) Database Engine (BDE) driver from the session.
V	Destroy (see page 10099)	Destroys the instance of a session component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DropConnections (see page 10105)	Frees all temporary database components associated with a session if they are inactive.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindDatabase (see page 10105)	Searches a session's list of database components for a specified database.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetAliasDriverName (see page 10106)	Provides the name of the database driver used by a specified Borland (see page 1761) Database Engine (BDE) alias associated with the session.
	GetAliasNames (see page 10107)	Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases.
	GetAliasParams (see page 10108)	Retrieves the parameters associated with a specified Borland (see page 1761) Database Engine (BDE) alias.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetConfigParams (see page 10108)	Retrieves Borland (see page 1761) Database Engine (BDE) configuration information.
	GetDatabaseNames (see page 10109)	Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases and the names of all databases components known to the session.
	GetDriverNames (see page 10110)	Populates a string list with the names of all Borland (see page 1761) Database Engine (BDE) drivers available to the session.
	GetDriverParams (see page 10110)	Populates a string list with the parameters for a specified Borland (see page 1761) Database Engine (BDE) driver.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFieldNames (see page 10110)	Populates a string list with the names of all fields in a specified table.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.

	GetPassword (see page 10111)	Invokes the OnPassword (see page 10128) event handler for the session or displays the default password dialog box.
	GetStoredProcNames (see page 10112)	Populates a string list with the names of all stored procedures associated with a specified database component that is connected to an SQL database server.
	GetTableNames (see page 10113)	Populates a string list with the names of tables associated with a specified database component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsAlias (see page 10113)	Determines whether or not a string value corresponds to an existing Borland (see page 1761) Database Engine (BDE) database alias known to the session.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	ModifyAlias (see page 10114)	Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) alias.
	ModifyDriver (see page 10115)	Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) driver.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Open (see page 10116)	Starts a session and makes it the current session.
	OpenDatabase (see page 10117)	Opens an existing database, or creates a temporary database component and opens it.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveAllPasswords (see page 10118)	Deletes all passwords previously added to the current session for accessing encrypted Paradox tables.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	RemovePassword (see page 10118)	Deletes a single password previously added to the current session for accessing an encrypted Paradox table.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveConfigFile (see page 10119)	Writes the current information in the Borland (see page 1761) Database Engine (BDE) persistent store from memory to the BDE configuration file on disk.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	ConfigMode (see page 10122)	Specifies how the Borland (see page 1761) Database Engine (BDE) should handle aliases for the session.
R	DatabaseCount (see page 10123)	Indicates the number of active database components currently associated with the session.
R	Databases (see page 10123)	Provides an indexed array of all active database component names for a session.
	DesignInfo (see page 2805)	Contains information used by the Form designer.

R	Handle (see page 10123)	Specifies the Borland (see page 1761) Database Engine (BDE) handle for the session.
R	Locale (see page 10124)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the session component.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	TraceFlags (see page 10127)	Specifies the database operations to track with the SQL Monitor at runtime.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnPassword (see page 10128)	Occurs when an application attempts to open a Paradox table for the first time and the Borland (see page 1761) Database Engine (BDE) reports insufficient access rights.
	OnStartup (see page 10129)	Occurs when an application activates a session.

Published Properties

	Name	Description
	Active (see page 10120)	Specifies whether or not a session is active.
	AutoSessionName (see page 10121)	Indicates whether or not a unique session name is automatically generated for a session.
	KeepConnections (see page 10124)	Specifies whether or not a temporary database component created in the context of a session maintains a database server connection even if there are no active datasets associated with the database component.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	NetFileDir (see page 10125)	Specifies the directory that contains the Borland (see page 1761) Database Engine (BDE) network control file, PDOXUSRS.NET.
	PrivateDir (see page 10125)	Specifies the directory in which to store temporary table processing files generated by the Borland (see page 1761) Database Engine (BDE) for database components associated with a session.
	SessionName (see page 10126)	Specifies a unique session name that can be used by database and dataset components to link to this session.
	SQLHourGlass (see page 10126)	Indicates whether or not the mouse cursor changes to an hourglass during BDE operations.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.15.2 TSession.Create Constructor

Creates an instance of a TSession (see page 10093) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSession(TComponent * AOwner);
```

Description

Do not call Create directly. The default session component, Session (see page 10265), is created automatically for all database applications. To create additional sessions for a multi-threaded database application at runtime call Sessions.OpenSession instead of Create. OpenSession calls Create only if the session does not already exist. (At design time, create additional sessions by dropping them on a data module.)

Create calls its inherited constructor and ensures that the session component cannot be inherited should the data module or form on which it is placed be stored in the Object Repository.

See Also

KeepConnections (see page 10124)

Handle (see page 10123)

Destroy (see page 10099)

OpenSession (see page 10132)

53.1.15.3 TSession.Destroy Destructor

Destroys the instance of a session component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSession();
```

Description

Do not call Destroy directly. For session components other than the default session, an application should call Free, which verifies that the session component is not nil before calling Destroy.

Warning: Never destroy the default session. Freeing of the default session is handled automatically when an application terminates.

Destroy performs the following actions before calling its inherited destructor:

Makes the session inactive, which closes all database connections.

Removes the session from the session list.

Resets database session references, if necessary.

Frees the list of database components associated with the session.

See Also

Active (see page 10120)

Create (see page 10098)

OpenSession (see page 10132)

Free (see page 22300)

TSessionList (see page 10129)

53.1.15.4 TSession Methods

The methods of the TSession class are listed here.

Protected Methods

	Name	Description
V	Loaded (see page 10114)	Initializes the component after the form file has been read into memory.
	ModifyConfigParams (see page 10115)	This is ModifyConfigParams, a member of class TSession.
V	Notification (see page 10116)	Forwards notification messages to all owned components.
V	SetName (see page 10119)	Sets the value of the Name property.

Public Methods

	Name	Description
	AddAlias (see page 10100)	Adds a specified Borland (see page 1761) Database Engine (BDE) alias to the session for an SQL database server.
	AddDriver (see page 10101)	Adds a specified Borland (see page 1761) Database Engine (BDE) driver to the session for an SQL database server.
	AddPassword (see page 10102)	Adds a password to the current session for accessing encrypted Paradox or dBase tables.
	AddStandardAlias (see page 10102)	Adds a standard Borland (see page 1761) Database Engine (BDE) alias to the session for Paradox, dBASE, or ASCII tables.
	Close (see page 10103)	Disconnects from all databases, and closes the session.
	CloseDatabase (see page 10103)	Closes a database connection associated with the current session.
	DeleteAlias (see page 10104)	Removes a specified Borland (see page 1761) Database Engine (BDE) alias from the session.
	DeleteDriver (see page 10105)	Removes a specified Borland (see page 1761) Database Engine (BDE) driver from the session.
	DropConnections (see page 10105)	Frees all temporary database components associated with a session if they are inactive.
	FindDatabase (see page 10105)	Searches a session's list of database components for a specified database.
	GetAliasDriverName (see page 10106)	Provides the name of the database driver used by a specified Borland (see page 1761) Database Engine (BDE) alias associated with the session.
	GetAliasNames (see page 10107)	Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases.
	GetAliasParams (see page 10108)	Retrieves the parameters associated with a specified Borland (see page 1761) Database Engine (BDE) alias.
	GetConfigParams (see page 10108)	Retrieves Borland (see page 1761) Database Engine (BDE) configuration information.
	GetDatabaseNames (see page 10109)	Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases and the names of all databases components known to the session.
	GetDriverNames (see page 10110)	Populates a string list with the names of all Borland (see page 1761) Database Engine (BDE) drivers available to the session.
	GetDriverParams (see page 10110)	Populates a string list with the parameters for a specified Borland (see page 1761) Database Engine (BDE) driver.
	GetFieldNames (see page 10110)	Populates a string list with the names of all fields in a specified table.
	GetPassword (see page 10111)	Invokes the OnPassword (see page 10128) event handler for the session or displays the default password dialog box.
	GetStoredProcNames (see page 10112)	Populates a string list with the names of all stored procedures associated with a specified database component that is connected to an SQL database server.
	GetTableNames (see page 10113)	Populates a string list with the names of tables associated with a specified database component.
	IsAlias (see page 10113)	Determines whether or not a string value corresponds to an existing Borland (see page 1761) Database Engine (BDE) database alias known to the session.
	ModifyAlias (see page 10114)	Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) alias.
	ModifyDriver (see page 10115)	Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) driver.
	Open (see page 10116)	Starts a session and makes it the current session.
	OpenDatabase (see page 10117)	Opens an existing database, or creates a temporary database component and opens it.
	RemoveAllPasswords (see page 10118)	Deletes all passwords previously added to the current session for accessing encrypted Paradox tables.
	RemovePassword (see page 10118)	Deletes a single password previously added to the current session for accessing an encrypted Paradox table.
	SaveConfigFile (see page 10119)	Writes the current information in the Borland (see page 1761) Database Engine (BDE) persistent store from memory to the BDE configuration file on disk.

53.1.15.4.1 TSession.AddAlias Method

Adds a specified Borland (see page 1761) Database Engine (BDE) alias to the session for an SQL database server.

Pascal

```
procedure AddAlias(const Name: string; const Driver: string; List: TStrings);
```

C++

```
__fastcall AddAlias(const AnsiString Name, const AnsiString Driver, TStrings List);
```

Description

Call AddAlias at runtime to create a session-specific BDE alias for an SQL database server. Name is the unique name to assign to the alias. Driver is the name of the SQL Links database driver to use for the alias. List is a string list containing parameters for the alias.

A session's ConfigMode (see page 10122) property determines whether an alias is local to the session, or is available to all applications in the BDE persistent store as long as any BDE clients are active. To save an alias permanently, call the SaveConfigFile (see page 10119) method before ending the session.

Note: Although AddAlias can be used to create a Paradox or dBASE alias, AddStandardAlias (see page 10102) provides a simpler method for Paradox and dBASE alias creation.

See Also

ConfigMode (see page 10122)

AddStandardAlias (see page 10102)

DeleteAlias (see page 10104)

IsAlias (see page 10113)

ModifyAlias (see page 10114)

SaveConfigFile (see page 10119)

Working with BDE Aliases

53.1.15.4.2 TSession.AddDriver Method

Adds a specified Borland (see page 1761) Database Engine (BDE) driver to the session for an SQL database server.

Pascal

```
procedure AddDriver(const Name: string; List: TStrings);
```

C++

```
__fastcall AddDriver(const AnsiString Name, TStrings List);
```

Description

Call AddDriver at runtime to create a BDE driver for an SQL database server. AddDriver can also be used to create ODBC driver entries. Name is the unique name to assign to the driver. List is a string list containing parameters for the alias.

A session's ConfigMode (see page 10122) property determines whether a driver is local to the session, or is available to all applications in the BDE persistent store as long as any BDE clients are active. To save a driver permanently, call the SaveConfigFile (see page 10119) method before ending the session.

See Also

ConfigMode (see page 10122)

DeleteDriver (see page 10105)

IsAlias (see page 10113)

SaveConfigFile (see page 10119)

53.1.15.4.3 TSession.AddPassword Method

Adds a password to the current session for accessing encrypted Paradox or dBase tables.

Pascal

```
procedure AddPassword(const Password: string);
```

C++

```
__fastcall AddPassword(const AnsiString Password);
```

Description

Call AddPassword to provide a password for a session prior to opening an encrypted Paradox or dBase table that requires a password. If an application opens a table that requires a password for access, the session does not have a password assigned to it, and the application does not provide its own OnPassword (see page 10128) event handler, the library displays a dialog box prompting the user for a valid password before allowing table access.

For example, to provide the String literal "secret" as a password for the session:

```
Session.AddPassword('secret');
Session->AddPassword("secret");
```

Note: If an application defines its own OnPassword (see page 10128) event handler, the handler should call this method to add passwords for the session. All passwords assigned by AddPassword should be deleted with RemoveAllPasswords (see page 10118) or RemovePassword (see page 10118) before an application closes.

See Also

OnPassword (see page 10128)

RemoveAllPasswords (see page 10118)

RemovePassword (see page 10118)

GetPassword (see page 10111)

PasswordDialog (see page 9849)

Working with Password-protected Paradox and dBASE Tables

53.1.15.4.4 TSession.AddStandardAlias Method

Adds a standard Borland (see page 1761) Database Engine (BDE) alias to the session for Paradox, dBASE, or ASCII tables.

Pascal

```
procedure AddStandardAlias(const Name: string; const Path: string; const DefaultDriver:
string);
```

C++

```
__fastcall AddStandardAlias(const AnsiString Name, const AnsiString Path, const AnsiString
DefaultDriver);
```

Description

Call AddStandardAlias at runtime to create a session-specific BDE alias for Paradox, dBASE or ASCII tables. Name is the unique name to assign to the alias. Path specifies the directory where the database is located. DefaultDriver is the name of the standard BDE driver to use for the alias. If set, DefaultDriver must be one of "Paradox," "DBASE," or "ASCIIDRV". If left blank DefaultDriver defaults to "Paradox". DefaultDriver is used when attempting to open a table that both does not have an extension and is defined as a table of type ttDefault.

A session's ConfigMode (see page 10122) property determines whether an alias is local to the session, or is available to all applications in the BDE persistent store as long as any BDE clients are active. the lifetime of the session. To save an alias permanently, call the SaveConfigFile (see page 10119) method before ending the session.

Note: To create an alias for an SQL database, call AddAlias (see page 10100) instead of AddStandardAlias.

See Also

ConfigMode (see page 10122)

AddAlias (see page 10100)

DeleteAlias (see page 10104)

IsAlias (see page 10113)

ModifyAlias (see page 10114)

SaveConfigFile (see page 10119)

Working with BDE Aliases

53.1.15.4.5 TSession.Close Method

Disconnects from all databases, and closes the session.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Call Close to end a session. Close disconnects from all active databases by freeing temporary database components, and calling the Close methods persistent database components, and then sets its own session handle to nil (Delphi) or NULL (C++).

Note: Setting the Active (see page 10120) property to false also closes a session.

See Also

Active (see page 10120)

Open (see page 10116)

Close (see page 6863)

Dropping Inactive Database Connections

53.1.15.4.6 TSession.CloseDatabase Method

Closes a database connection associated with the current session.

Pascal

```
procedure CloseDatabase(Database: TDatabase);
```

C++

```
__fastcall CloseDatabase(TDatabase Database);
```

Description

Call CloseDatabase to close a persistent database connection, or to close and free a temporary database connection. Database

specifies the name of the database component for which to close the connection.

CloseDatabase decrements the specified database component's reference count, and then, if the reference count is zero and the database component's KeepConnection property is false, CloseDatabase either frees a temporary database component or closes the connection for a persistent database component.

Note: Calling CloseDatabase for a persistent database component does not close the connection. To close a connection for a persistent database component, call the database component's Close (see page 10103) method directly.

Temporary database components are closed automatically when the last dataset associated with the database component is closed, but an application can call CloseDatabase prior to that time to force closure. Closing a connection established by a temporary database component does not free the component if the session's KeepConnections (see page 10124) property is true (the default). To free temporary database components after closing their connections call DropConnections (see page 10105).

See Also

KeepConnections (see page 10124)

DropConnections (see page 10105)

OpenDatabase (see page 10117)

KeepConnection (see page 9984)

Close (see page 6863)

Closing Database Connections

53.1.15.4.7 TSession.DeleteAlias Method

Removes a specified Borland (see page 1761) Database Engine (BDE) alias from the session.

Pascal

```
procedure DeleteAlias(const Name: string);
```

C++

```
__fastcall DeleteAlias(const AnsiString Name);
```

Description

Call DeleteAlias to remove a BDE alias from a session. Removing an alias makes the alias unavailable to the session, but does not remove it from the BDE configuration file if the alias was stored there when it was created. To remove an alias from the BDE configuration file follow the call to DeleteAlias with a call to SaveConfigFile (see page 10119).

See Also

ConfigMode (see page 10122)

AddAlias (see page 10100)

AddStandardAlias (see page 10102)

IsAlias (see page 10113)

SaveConfigFile (see page 10119)

Working with BDE Aliases

53.1.15.4.8 TSession.DeleteDriver Method

Removes a specified Borland (see page 1761) Database Engine (BDE) driver from the session.

Pascal

```
procedure DeleteDriver(const Name: string);
```

C++

```
__fastcall DeleteDriver(const AnsiString Name);
```

Description

Call DeleteDriver to remove a BDE driver from a session. Removing a driver makes the driver unavailable to the session, but does not remove it from the BDE configuration file if the driver was stored there when it was created. To remove a driver from the BDE configuration file follow the call to DeleteDriver with a call to SaveConfigFile (see page 10119).

See Also

ConfigMode (see page 10122)

AddDriver (see page 10101)

SaveConfigFile (see page 10119)

53.1.15.4.9 TSession.DropConnections Method

Frees all temporary database components associated with a session if they are inactive.

Pascal

```
procedure DropConnections;
```

C++

```
__fastcall DropConnections();
```

Description

Use DropConnections to free all temporary database components that are currently inactive. If the KeepConnections (see page 10124) property of the session is true (the default), then temporary database components created as needed for the session by the library at runtime are not automatically freed when their database connections are closed. DropConnections enables an application to free these components when they are no longer needed.

KeepConnections (see page 10124)

CloseDatabase (see page 10103)

Understanding Database and Session Component Interactions

Specifying Default Database Connection Behavior

Dropping Inactive Database Connections

53.1.15.4.10 TSession.FindDatabase Method

Searches a session's list of database components for a specified database.

Pascal

```
function FindDatabase(const DatabaseName: string): TDatabase;
```

C++

```
__fastcall TDatabase FindDatabase(const AnsiString DatabaseName);
```

Description

Call FindDatabase to determine whether or not a specified database is associated with a session. DatabaseName specifies the name of the database component for which to search.

FindDatabase compares DatabaseName to the DatabaseName property for each database component in a session's list. If a match is found, FindDatabase returns a pointer to the database component. Otherwise FindDatabase returns nil (Delphi) or NULL (C++).

An application can call FindDatabase to see if a database component already exists before creating a new database component for a session.

```
var
  DB: TDatabase;
begin
  DB := Session.FindDatabase('DBDEMOS');
if (DB = nil) then { database doesn't exist for session so,}
    DB := Session.OpenDatabase('DBDEMOS'); { create and open it}
if Assigned(DB) and DB.Active then begin
    DB.StartTransaction;
...
end;
end;
```

See Also

Databases (see page 10123)

OpenDatabase (see page 10117)

DatabaseName (see page 9980)

Searching for a Database Connection

53.1.15.4.11 TSession.GetAliasDriverName Method

Provides the name of the database driver used by a specified Borland (see page 1761) Database Engine (BDE) alias associated with the session.

Pascal

```
function GetAliasDriverName(const AliasName: string): string;
```

C++

```
__fastcall AnsiString GetAliasDriverName(const AnsiString AliasName);
```

Description

Call GetAliasDriverName to determine the BDE database driver used by a specific alias. AliasName is the name of the alias for which to return driver information.

For aliases corresponding to Paradox and dBASE tables, GetAliasDriverName returns "STANDARD". For ASCII tables the return value is "ASCIIDRV". For SQL databases, the driver name depends on the database server.

See Also

GetAliasNames (see page 10107)

GetAliasParams (see page 10108)

GetDriverNames (see page 10110)

GetDriverParams (see page 10110)

Retrieving Information About a Session

Working with BDE Aliases

53.1.15.4.12 TSession.GetAliasNames Method

Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases.

Pascal

```
procedure GetAliasNames(List: TStrings);
```

C++

```
__fastcall GetAliasNames(TStrings List);
```

Description

Call GetAliasNames to retrieve a list of persistent BDE aliases—those aliases that exist in persistent storage or in the BDE configuration file. List is a string list object, created and maintained by the application, into which to store the alias names.

A session's ConfigMode (see page 10122) property determines whether an alias created in the context of this session is reported by GetAliasNames. If ConfigMode (see page 10122) is cmAll (see page 10268), aliases created within the session are reported.

C++ Examples:

```
/*
This example calls the TSession GetAliasNames method to fill
the list box with Borland Database Engine (BDE) alias names.
*/
void __fastcall TAdhocForm::Button1Click(TObject *Sender)
{
  TStringList *MyStringList = new TStringList();
  try
  {
    Session->GetAliasNames(MyStringList);
    // fill a list box with alias names for the user to select from
    for (int I = 0; I < MyStringList->Count; I++)
      ListBox1->Items->Add(MyStringList->Strings[I]);
  }
  __finally
  {
    delete MyStringList;
  }
}
```

Delphi Examples:

```
{
This example calls the TSession GetAliasNames method to fill
the list box with Borland Database Engine (BDE) alias names.
}
procedure TAdhocForm.Button1Click(Sender: TObject);
var
  MyStringList: TStringList;
  I: Integer;
begin
  MyStringList := TStringList.Create;
  try
    Session.GetAliasNames(MyStringList);
    { fill a list box with alias names for the user to select from }
    for I := 0 to MyStringList.Count - 1 do
      ListBox1.Items.Add(MyStringList[I]);
```

```
    finally
      MyStringList.Free;
    end;
  end;
```

SaveConfigFile (see page 10119)

Retrieving Information About a Session

Working with BDE Aliases

53.1.15.4.13 TSession.GetAliasParams Method

Retrieves the parameters associated with a specified Borland (see page 1761) Database Engine (BDE) alias.

Pascal

```
procedure GetAliasParams(const AliasName: string; List: TStrings);
```

C++

```
__fastcall GetAliasParams(const AnsiString AliasName, TStrings List);
```

Description

Call GetAliasParams to retrieve the BDE configuration parameters for a specified alias. AliasName is the name of the alias for which to retrieve parameters. List is a string list object, created and maintained by the application, into which to store the parameters.

See Also

GetAliasDriverName (see page 10106)

GetConfigParams (see page 10108)

Retrieving Information About a Session

Working with BDE Aliases

53.1.15.4.14 TSession.GetConfigParams Method

Retrieves Borland (see page 1761) Database Engine (BDE) configuration information.

Pascal

```
procedure GetConfigParams(const Path: string; const Section: string; List: TStrings);
```

C++

```
__fastcall GetConfigParams(const AnsiString Path, const AnsiString Section, TStrings List);
```

Description

Call GetConfigParams to retrieve specific types of configuration information from the BDE configuration file used to initialize the application.

Path represents the internal node structure of the BDE configuration file, and must always start at the root, denoted by a backslash. Each node must be separated from others by a backslash, and no node may be empty. For example, a Path of \SYSTEM\FORMATS\TIME, returns the time format used by the BDE configuration file.

Path can contain a replaceable string formatting symbol (%s) in one of its node designations. If it does, Section must contain the missing node information. In this case, GetConfigParams inserts the contents of Section into Path before calling the BDE for the requested information.

List is a string list object, created and maintained by the application, into which to store the configuration information. For example, if Path is \DATABASES\%s\DB (see page 6725) INFO, and Section is an alias name, then GetConfigParams returns the parameters for the alias in List.

For more information about the BDE Configuration File, see the online BDE help.

Retrieving Information About a Session

53.1.15.4.15 TSession.GetDatabaseNames Method

Populates a string list with the names of persistent Borland (see page 1761) Database Engine (BDE) aliases and the names of all databases components known to the session.

Pascal

```
procedure GetDatabaseNames(List: TStrings);
```

C++

```
__fastcall GetDatabaseNames(TStrings List);
```

Description

Call GetDatabaseNames to retrieve a sorted, combined list of persistent BDE aliases—those aliases that exist in persistent storage or in the BDE configuration file—and the names of all database components known to the session. List is a string list object, created and maintained by the application, into which to store the database and alias names.

GetDriverNames (see page 10110)

SaveConfigFile (see page 10119)

Retrieving Information About a Session

53.1.15.4.16 TSession.GetDriverNames Method

Populates a string list with the names of all Borland (see page 1761) Database Engine (BDE) drivers available to the session.

Pascal

```
procedure GetDriverNames(List: TStrings);
```

C++

```
__fastcall GetDriverNames(TStrings List);
```

Description

Call GetDriverNames to retrieve the names of all BDE drivers that can be used by a session. List is a string list object, created and maintained by the application, into which to store the driver names.

See Also

GetDriverParams (see page 10110)

Retrieving Information About a Session

Working with BDE Aliases

53.1.15.4.17 TSession.GetDriverParams Method

Populates a string list with the parameters for a specified Borland (see page 1761) Database Engine (BDE) driver.

Pascal

```
procedure GetDriverParams(const DriverName: string; List: TStrings);
```

C++

```
__fastcall GetDriverParams(const AnsiString DriverName, TStrings List);
```

Description

Call GetDriverParams to retrieve a list of parameters associated with a specified BDE driver. DriverName is the BDE driver for which to return a parameter list. List is a string list object, created and maintained by the application, into which to store the driver parameters.

The actual number of parameters returned by GetDriverParams depends on the specified driver. For example, for the STANDARD driver used by Paradox and dBASE, returns only a few parameters. For SQL Links drivers multiple parameters are returned.

See Also

GetDriverNames (see page 10110)

Retrieving Information About a Session

Working with BDE Aliases

53.1.15.4.18 TSession.GetFieldNames Method

Populates a string list with the names of all fields in a specified table.

Pascal

```
procedure GetFieldNames(const DatabaseName: string; const TableName: string; List: TStrings);
```

C++

```
__fastcall GetFieldNames(const AnsiString DatabaseName, const AnsiString TableName, TStrings
List);
```

Description

Call GetFieldNames to retrieve a list of all the columns (fields) in a specified table.

DatabaseName is the name of the database that contains the table. It can be the name of an existing Borland (see page 1761) Database Engine (BDE) alias, the name of a TDatabase (see page 9964) component's DatabaseName property, or a fully qualified path name for the location of a Paradox or dBASE table.

TableName is the name of the table for which you want to list the fields.

List is a string list object, created and maintained by the application, into which GetFieldNames adds the names of all fields in the table specified by TableName.

See Also

DatabaseName (see page 9980)

GetFieldNames (see page 9975)

GetTableNames (see page 10113)

GetStoredProcNames (see page 10112)

GetDatabaseNames (see page 10109)

Retrieving Information About a Session

53.1.15.4.19 TSession.GetPassword Method

Invokes the OnPassword (see page 10128) event handler for the session or displays the default password dialog box.

Pascal

```
function GetPassword: Boolean;
```

C++

```
__fastcall Boolean GetPassword();
```

Description

Call GetPassword to invoke the OnPassword (see page 10128) event handler for the session and handle response logic when an application is working with password-protected Paradox files. If an OnPassword (see page 10128) event handler is not defined, GetPassword displays the default password dialog box.

An application can use the return value of GetPassword to control program logic. GetPassword returns true if a user chooses OK, or false if the user chooses Cancel.

```
var
  rslt: Boolean;
begin
  rslt := Session.GetPassword;
try
if rslt then
      Table1.Open
else
      ShowMessage('No password given');
except
    ShowMessage('Could not open table!');
end;
ifnot Table1.Active then
```

```
    Application.Terminate;
end;
void __fastcall TForm1::OpenTableButtonClick(TObject *Sender)
{
bool rslt = Session->GetPassword();
try
  {
if (rslt)
      Table1->Open();
else
      ShowMessage("No password given");
  }
catch (...)
  {
    ShowMessage("Could not open table!");
  }
if (!Table1->Active)
    Application.Terminate();
}
```

See Also

Working with Password-protected Paradox and dBASE Tables

53.1.15.4.20 TSession.GetStoredProcNames Method

Populates a string list with the names of all stored procedures associated with a specified database component that is connected to an SQL database server.

Pascal

```
procedure GetStoredProcNames(const DatabaseName: string; List: TStrings);
```

C++

```
__fastcall GetStoredProcNames(const AnsiString DatabaseName, TStrings List);
```

Description

Call GetStoredProcNames to retrieve a list of all stored procedures for a database component that is attached to an SQL database server. DatabaseName specifies the name of the database for which to retrieve stored procedure names. List is a string list object, created and maintained by the application, into which to return the stored procedure names.

Note: GetStoredProcNames raises an exception if called on Paradox or dBASE databases.

See Also

GetAliasNames (see page 10107)

GetAliasDriverName (see page 10106)

GetDriverNames (see page 10110)

GetTableNames (see page 10113)

Retrieving Information About a Session

53.1.15.4.21 TSession.GetTableNames Method

Populates a string list with the names of tables associated with a specified database component.

Pascal

```
procedure GetTableNames(const DatabaseName: string; const Pattern: string; Extensions:
Boolean; SystemTables: Boolean; List: TStrings);
```

C++

```
__fastcall GetTableNames(const AnsiString DatabaseName, const AnsiString Pattern, Boolean
Extensions, Boolean SystemTables, TStrings List);
```

Description

Call GetTableNames to retrieve a list of the tables associated with a given database. DatabaseName specifies the name of the database from which to retrieve table names.

Pattern specifies a delimiter string that restricts the tables returned to those that match the string. Pattern can include wildcard symbols. Pass an empty Pattern string to match all files not restricted by other criteria.

For searches on Paradox and dBASE, set Extensions to true to include filename extensions as part of the table name. For SQL-based databases, set Extension to false.

Set SystemTables to true for SQL-based databases to return both data tables and the system tables that define the database structure. Set SystemTables to false for Paradox and dBASE tables.

List is a string list object, created and maintained by the application, into which to return the table names.

GetFieldNames (see page 10110)

Retrieving Information About a Session

53.1.15.4.22 TSession.IsAlias Method

Determines whether or not a string value corresponds to an existing Borland (see page 1761) Database Engine (BDE) database alias known to the session.

Pascal

```
function IsAlias(const Name: string): Boolean;
```

C++

```
__fastcall Boolean IsAlias(const AnsiString Name);
```

Description

Call IsAlias to determine if a string corresponds to the name of an existing BDE alias that can be used by the session. Name is the string to test.

If IsAlias returns true, Name is a valid alias.

Note: The aliases known to IsAlias depend on the session's ConfigMode (see page 10122) property. If ConfigMode (see page 10122) is cmAll (see page 10268), then all aliases are available to the session.

See Also

ConfigMode (see page 10122)

AddAlias (see page 10100)

AddStandardAlias (see page 10102)

DeleteAlias (see page 10104)

GetAliasNames (see page 10107)

GetAliasParams (see page 10108)

ModifyAlias (see page 10114)

53.1.15.4.23 TSession.Loaded Method

Initializes the component after the form file has been read into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The streaming system calls this method after it loads the component's form from a stream.

When the streaming system loads a form or data module from its form file, it first constructs the form component by calling its constructor, then reads its property values from the form file. After reading all the property values for all the components, the streaming system calls the Loaded methods of each component in the order the components were created. This gives the components a chance to initialize any data that depends on the values of other components or other parts of itself.

Note: All references to sibling components are resolved by the time Loaded is called. Loaded is the first place that sibling pointers can be used after being streamed in.

As implemented in TComponent, Loaded clears the csLoading flag in the ComponentState property, indicating that the component is no longer loading.

Warning: Loaded may be called multiple times on inherited forms. It is called every time a level of inheritance is streamed in. Do not allocate memory in an overridden Loaded method without first checking that the memory has not been allocated in a previous call.

See Also

ComponentState (see page 2804)

Create (see page 2766)

TReader (see page 2933)

53.1.15.4.24 TSession.ModifyAlias Method

Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) alias.

Pascal

```
procedure ModifyAlias(Name: string; List: TStrings);
```

C++

```
__fastcall ModifyAlias(AnsiString Name, TStrings List);
```

Description

Call ModifyAlias to change the parameters for a specified BDE alias. Name is the name of the alias to modify. List is a string list object previously populated with parameter values to add or change. An application must create and maintain List.

Populate List with parameter strings before calling ModifyAlias. List need only contain the parameters to change. If ModifyAlias passes a parameter for which a value already exists, the new parameter replaces the existing one. New parameters that are not yet defined for the alias are added to the existing parameters. If List is empty, ModifyAlias does not change any existing parameters.

ModifyAlias changes the alias parameters for the session, but does not change them in the BDE configuration file. To modify a driver in the BDE configuration file, follow the call to ModifyAlias with a call to SaveConfigFile (see page 10119).

See Also

ConfigMode (see page 10122)

GetAliasParams (see page 10108)

Params (see page 9986)

SaveConfigFile (see page 10119)

Working with BDE Aliases

53.1.15.4.25 TSession.ModifyConfigParams Method

Pascal

```
procedure ModifyConfigParams(const Path: string; const Node: string; List: TStrings);
```

C++

```
__fastcall ModifyConfigParams(const AnsiString Path, const AnsiString Node, TStrings List);
```

Description

This is ModifyConfigParams, a member of class TSession.

53.1.15.4.26 TSession.ModifyDriver Method

Adds or changes parameters for a Borland (see page 1761) Database Engine (BDE) driver.

Pascal

```
procedure ModifyDriver(Name: string; List: TStrings);
```

C++

```
__fastcall ModifyDriver(AnsiString Name, TStrings List);
```

Description

Call ModifyDriver to change the parameters for a specified BDE database driver. Name is the name of the driver to modify. List is a string list object previously populated with parameter values to add or change. An application must create and maintain List.

Populate List with parameter strings before calling ModifyDriver. List need only contain the parameters to change. If ModifyDriver passes a parameter for which a value already exists, the new parameter replaces the existing one. New parameters that are not

yet defined for the driver are added to the existing parameters. If List is empty, ModifyDriver does not change any existing parameters.

A session's ConfigMode (see page 10122) property determines whether a driver is local to the session, or is available to all applications in the BDE persistent store as long as any BDE clients are active. To save a driver permanently, call the SaveConfigFile (see page 10119) method before ending the session.

See Also

ConfigMode (see page 10122)

GetDriverParams (see page 10110)

Params (see page 9986)

53.1.15.4.27 TSession.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

53.1.15.4.28 TSession.Open Method

Starts a session and makes it the current session.

Pascal

```
procedure Open;
```

C++

```
__fastcall Open();
```

Description

Call Open to start a session other than the default session in a database application. Open sets Active (see page 10120) to true, triggers an OnStartup (see page 10129) event handler for the session and initializes the NetFileDir (see page 10125),

PrivateDir (see page 10125), and ConfigMode (see page 10122) properties.

See Also

Active (see page 10120)

NetFileDir (see page 10125)

PrivateDir (see page 10125)

ConfigMode (see page 10122)

OnStartup (see page 10129)

Close (see page 10103)

OpenDatabase (see page 10117)

Fetching the Data using TSQLDataSet

Connecting to Databases with TDatabase

Using TQuery

Using TSimpleDataSet

Using TSQLQuery

Using TSQLStoredProc

53.1.15.4.29 TSession.OpenDatabase Method

Opens an existing database, or creates a temporary database component and opens it.

Pascal

```
function OpenDatabase(const DatabaseName: string): TDatabase;
```

C++

```
__fastcall TDatabase OpenDatabase(const AnsiString DatabaseName);
```

Description

Call OpenDatabase to connect to a database for which a persistent database component already exists, or to create a temporary database component and connect to a database. DatabaseName specifies the database to open.

OpenDatabase makes the current session active, then calls FindDatabase (see page 10105) to determine if the DatabaseName parameter corresponds to the DatabaseName property of an existing database component. If it does not, OpenDatabase creates a temporary database component, assigning the DatabaseName parameter to the DatabaseName property. Finally, OpenDatabase calls the Open (see page 10116) method of the database to connect to a database server, then increments the session's database reference count by one.

Activating a Session

Opening Database Connections

53.1.15.4.30 TSession.RemoveAllPasswords Method

Deletes all passwords previously added to the current session for accessing encrypted Paradox tables.

Pascal

```
procedure RemoveAllPasswords;
```

C++

```
__fastcall RemoveAllPasswords();
```

Description

Call RemoveAllPasswords to delete all current Paradox table passwords associated with the current session. Subsequent attempts to access encrypted Paradox tables fail unless an application first calls AddPassword (see page 10102) to reestablish a password.

Note: Ordinarily an application should call RemoveAllPasswords to remove all session-specific passwords it creates from the Borland (see page 1761) Database Engine (BDE) persistent store before terminating.

See Also

AddPassword (see page 10102)

RemovePassword (see page 10118)

PasswordDialog (see page 9849)

Working with Password-protected Paradox and dBASE Tables

53.1.15.4.31 TSession.RemovePassword Method

Deletes a single password previously added to the current session for accessing an encrypted Paradox table.

Pascal

```
procedure RemovePassword(const Password: string);
```

C++

```
__fastcall RemovePassword(const AnsiString Password);
```

Description

Call RemovePassword to delete a single Paradox table password associated with the current session from the Borland (see page 1761) Database Engine (BDE) persistent store. Subsequent attempts to access the encrypted Paradox table fails unless an application first calls AddPassword (see page 10102) to reestablish a password.

```
Session.AddPassword('secret');
Session.RemovePassword('secret');
Session->AddPassword("secret");
Session->RemovePassword("secret");
```

See Also

AddPassword (see page 10102)

RemoveAllPasswords (see page 10118)

PasswordDialog (see page 9849)

Working with Password-protected Paradox and dBASE Tables

53.1.15.4.32 TSession.SaveConfigFile Method

Writes the current information in the Borland (see page 1761) Database Engine (BDE) persistent store from memory to the BDE configuration file on disk.

Pascal

```
procedure SaveConfigFile;
```

C++

```
__fastcall SaveConfigFile();
```

Description

Call SaveConfigFile to write any BDE configuration changes currently in memory to the BDE configuration file on disk. When the BDE is first initialized, the current BDE configuration file is read into persistent storage in memory. Applications can read or modify the configuration file in memory, but modification exist only in memory, not on disk.

For example, if an application defines a new BDE alias with AddAlias (see page 10100), the alias exists in memory only for as long as the BDE resides in memory. To store the new alias for later use by all applications that use the BDE, call SaveConfigFile. SaveConfigFile overwrites the disk image of the configuration file with the in-memory image of the persistent configuration file.

Note: If a session's ConfigMode (see page 10122) property is cmSession (see page 10268), added aliases cannot be saved to the BDE configuration file.

See Also

ConfigMode (see page 10122)

AddAlias (see page 10100)

Working with BDE Aliases

53.1.15.4.33 TSession.SetName Method

Sets the value of the Name property.

Pascal

```
procedure SetName(const NewName: TComponentName); override;
```

C++

```
virtual __fastcall SetName(const TComponentName NewName);
```

Description

SetName is the virtual property setter for the Name property. It calls the ChangeName method, which performs the actual name change.

ChangeName is not virtual; override SetName instead when modifying the behavior of the Name property.

Warning: Using SetName to change the name of a component at runtime causes any references to the old name to become undefined. Any subsequent code that uses the old name will cause an exception.

See Also

ChangeName (see page 2770)

Name (see page 2805)

ValidateRename (see page 2792)

53.1.15.5 TSession Properties

The properties of the TSession class are listed here.

Protected Properties

	Name	Description
	BDEOwnsLoginCbDb (see page 10122)	This is BDEOwnsLoginCbDb, a member of class TSession.

Public Properties

	Name	Description
	ConfigMode (see page 10122)	Specifies how the Borland (see page 1761) Database Engine (BDE) should handle aliases for the session.
R	DatabaseCount (see page 10123)	Indicates the number of active database components currently associated with the session.
R	Databases (see page 10123)	Provides an indexed array of all active database component names for a session.
R	Handle (see page 10123)	Specifies the Borland (see page 1761) Database Engine (BDE) handle for the session.
R	Locale (see page 10124)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the session component.
	TraceFlags (see page 10127)	Specifies the database operations to track with the SQL Monitor at runtime.

Published Properties

	Name	Description
	Active (see page 10120)	Specifies whether or not a session is active.
	AutoSessionName (see page 10121)	Indicates whether or not a unique session name is automatically generated for a session.
	KeepConnections (see page 10124)	Specifies whether or not a temporary database component created in the context of a session maintains a database server connection even if there are no active datasets associated with the database component.
	NetFileDir (see page 10125)	Specifies the directory that contains the Borland (see page 1761) Database Engine (BDE) network control file, PDOXUSRS.NET.
	PrivateDir (see page 10125)	Specifies the directory in which to store temporary table processing files generated by the Borland (see page 1761) Database Engine (BDE) for database components associated with a session.
	SessionName (see page 10126)	Specifies a unique session name that can be used by database and dataset components to link to this session.
	SQLHourGlass (see page 10126)	Indicates whether or not the mouse cursor changes to an hourglass during BDE operations.

53.1.15.5.1 TSession.Active Property

Specifies whether or not a session is active.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Examine Active at runtime for the default session, Session (see page 10265), to determine if it is active or not. Active is false by default, meaning there are no open database connections or datasets associated with the session. If Active is true, the session is active even if there are currently no active database connections.

Set the Active property at design time or runtime for additional session components in a database application. Setting Active to true starts the session and makes it the current session. Setting Active to true triggers an OnStartup (see page 10129) event handler for the session and initializes the NetFileDir (see page 10125), PrivateDir (see page 10125), and ConfigMode (

see page 10122) properties.

Setting Active to false (the default), closes any open datasets, and disconnects from attached database servers.

Note: An application can close the default session by setting Active to false, but this is not recommended.

See Also

ConfigMode (see page 10122)

NetFileDir (see page 10125)

PrivateDir (see page 10125)

Close (see page 10103)

Open (see page 10116)

Activating a Session

Debugging dbExpress Applications using TSQLMonitor

53.1.15.5.2 TSession.AutoSessionName Property

Indicates whether or not a unique session name is automatically generated for a session.

Pascal

```
property AutoSessionName: Boolean;
```

C++

```
__property Boolean AutoSessionName;
```

Description

Set AutoSessionName to control whether or not a unique session name is automatically generated. AutoSessionName is intended to guarantee developers of multi-threaded applications that sessions spawned for each thread are unique at runtime.

When AutoSessionName is false (the default), the application must set the SessionName (see page 10126) property for a session component. When AutoSessionName is true, TSession (see page 10093) assigns the SessionName (see page 10126) property automatically and replicates the session name across the SessionName (see page 10126) properties of all dataset components in the data module or form where the session component appears. This allows applications to use sessions in data modules that are replicated over multiple threads. TSession (see page 10093) constructs a session name by taking the current value of the Name property and appending an underscore (_) followed by a numeric value. For example, if Name is CustomerSession, then the AutoSessionName might be CustomerSession_2.

Note: The following restrictions apply to AutoSessionName:

- You cannot set AutoSessionName for a session in a data module or form that contains more than one session component.
- You cannot add a session component to a data module or form that already contains a session component with AutoSessionName set to true.
- You cannot directly set the SessionName (see page 10126) property of a session when AutoSessionName is true.

See Also

Name (see page 2805)

SessionName (see page 10126)

Managing Multiple Sessions

Adding a Session to the Web Module

53.1.15.5.3 TSession.BDEOwnsLoginCbDb Property

Pascal

```
property BDEOwnsLoginCbDb: Boolean;
```

C++

```
__property Boolean BDEOwnsLoginCbDb;
```

Description

This is BDEOwnsLoginCbDb, a member of class TSession.

53.1.15.5.4 TSession.ConfigMode Property

Specifies how the Borland (see page 1761) Database Engine (BDE) should handle aliases for the session.

Pascal

```
property ConfigMode: TConfigMode;
```

C++

```
__property TConfigMode ConfigMode;
```

Description

Set ConfigMode to specify how the BDE should handle aliases created using the AddAlias (see page 10100) or AddStandardAlias (see page 10102) methods within the context of a session. ConfigMode also determines which BDE aliases are reported to a session when an application calls the GetAliasNames (see page 10107) method.

The default setting for ConfigMode is cmAll (see page 10268), which is a constant that includes all possible set items defined in TConfigModes (see page 10253). The following table summarizes the possible BDE configuration modes that can be set for aliases:

Mode	Meaning
cfmVirtual	All aliases in the BDE configuration file, the BDE persistent store, and aliases local to the session are available to the session.
cfmPersistent	Only aliases in the BDE configuration file, or that are added to the persistent store are available to the session.
cfmSession	Only aliases created within this session are available to the session.

The main purpose of ConfigMode is to enable an application to specify and restrict aliases at the session level.

For backward compatibility with the older TConfigMode (see page 10260), use the constants cmVirtual (see page 10269), cmPersistent (see page 10268), cmSession (see page 10268), and cmAll (see page 10268). The first three correspond to the three TConfigModes (see page 10253) values of the same names. The constant cmAll (see page 10268) represents a ConfigMode setting of all three. The two command lines below, the first using TConfigModes (see page 10253) values and the second using the corresponding constant, are functionally the same.

```
Session.ConfigMode := [cfmSession];
Session.ConfigMode := cmSession;
```

Note: Aliases created within a session are not automatically saved to the BDE configuration file. To save an alias to the configuration file, call the SaveConfigFile (see page 10119) method.

See Also

AddAlias (see page 10100)

AddStandardAlias (see page 10102)

GetAliasNames (see page 10107)

SaveConfigFile (see page 10119)

53.1.15.5.5 TSession.DatabaseCount Property

Indicates the number of active database components currently associated with the session.

Pascal

```
property DatabaseCount: Integer;
```

C++

```
__property int DatabaseCount;
```

Description

Examine DatabaseCount to determine the number of active database components associated with a session. As database connections are opened or closed during a session's life-span, this number can change. If DatabaseCount is zero, there are currently no active database components for the session.

DatabaseCount is typically used with the Databases (see page 10123) property to iterate through the current set of active databases in a session.

See Also

Databases (see page 10123)

TDatabase (see page 9964)

53.1.15.5.6 TSession.Databases Property

Provides an indexed array of all active database component names for a session.

Pascal

```
property Databases [Index: Integer]: TDatabase;
```

C++

```
__property TDatabase Databases[int Index];
```

Description

Use Databases to access active database components associated with a session. An active database is one that is currently connected to a database server.

Databases is typically used with the DatabaseCount (see page 10123) property to iterate through the current set of active databases in a session.

See Also

DatabaseCount (see page 10123)

53.1.15.5.7 TSession.Handle Property

Specifies the Borland (see page 1761) Database Engine (BDE) handle for the session.

Pascal

```
property Handle: HDBISES;
```

C++

```
__property HDBISES Handle;
```

Description

Use Handle only to bypass TSession (see page 10093) methods and write directly to the BDE API. Many BDE function calls require a handle parameter. Handle is assigned an initial value when a session is activated.

Note: Do not use this property unless an application requires BDE functionality not available through library components.

See Also

Locale (see page 10124)

53.1.15.5.8 TSession.KeepConnections Property

Specifies whether or not a temporary database component created in the context of a session maintains a database server connection even if there are no active datasets associated with the database component.

Pascal

```
property KeepConnections: Boolean;
```

C++

```
__property Boolean KeepConnections;
```

Description

Use KeepConnections to specify whether or not temporary database components created at runtime maintain server connections even when they have no active datasets. If KeepConnections is true (the default), the application maintains database connections until the application exits or calls the DropConnections (see page 10105) method. For connections to remote database servers, or for applications that frequently open and close datasets, KeepConnections should remain true to reduce network traffic and speed up processing.

When KeepConnections is false, an application disconnects from a database when all datasets associated with a database component are closed. Dropping a connection releases system resources allocated to the connection, but if a dataset is later reopened that uses the same database, the connection must be reestablished and initialized.

Note: Duration of server connection for a persistent database component is determined by the database component's KeepConnection property instead of the session's KeepConnections property.

See Also

DropConnections (see page 10105)

TDatabase (see page 9964)

KeepConnection (see page 9984)

Understanding Database and Session Component Interactions

Specifying Default Database Connection Behavior

53.1.15.5.9 TSession.Locale Property

Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the session component.

Pascal

```
property Locale: TLocale;
```

C++

```
__property TLocale Locale;
```

Description

Examine Locale to determine the BDE language driver used by the session component. Applications that make direct calls to the BDE may need to pass Locale information as an API function parameter.

Do not use this property unless an application requires BDE functionality not available through standard data access components.

See Also

Handle (see page 10123)

53.1.15.5.10 TSession.NetFileDir Property

Specifies the directory that contains the Borland (see page 1761) Database Engine (BDE) network control file, PDOXUSRS.NET.

Pascal

```
property NetFileDir: string;
```

C++

```
__property AnsiString NetFileDir;
```

Description

Use NetFileDir to specify the directory that contains the BDE network control file, PDOXUSRS.NET. This file governs the sharing of Paradox tables on network drives. All applications that share Paradox tables on a network directory must specify the same value for this property, and must have read, write, and create rights for the directory.

The library derives an initial value for NetFileDir from the BDE configuration file for the Paradox driver. Any value assigned to NetFileDir at design time or runtime overrides the BDE configuration setting.

Note: Any value you assign to NetFileDir is not saved to the BDE configuration file. (Even if you call the SaveConfigFile (see page 10119) method.)

See Also

PrivateDir (see page 10125)

53.1.15.5.11 TSession.PrivateDir Property

Specifies the directory in which to store temporary table processing files generated by the Borland (see page 1761) Database Engine (BDE) for database components associated with a session.

Pascal

```
property PrivateDir: string;
```

C++

```
__property AnsiString PrivateDir;
```

Description

Use PrivateDir to set the directory in which to store temporary table processing files for all database connections, such as those generated by the BDE to handle local SQL statements. Ordinarily this value is only set at runtime, so that a user's local hard disk is used to store temporary files. Local storage of these files improves performance. If no value is specified for PrivateDir, the BDE automatically stores temporary files in the directory current at the time the BDE was initialized.

Note: For applications that run directly from a networked file server, the application should set PrivateDir to a user's local drive to improve performance and to prevent temporary files from being created on the server where they might conflict with temporary files created by other instances of the application.

See Also

NetFileDir (see page 10125)

53.1.15.5.12 TSession.SessionName Property

Specifies a unique session name that can be used by database and dataset components to link to this session.

Pascal

```
property SessionName: string;
```

C++

```
__property AnsiString SessionName;
```

Description

Set SessionName to a unique and meaningful name that can be used to link database and dataset components to the session. Database and dataset components each have corresponding SessionName properties that must either match the SessionName property of an active session or that be blank, indicating that they should be associated with the default session, Session (see page 10265).

Note: If the AutoSessionName (see page 10121) property is true, an application cannot set SessionName directly.

See Also

TDatabase (see page 9964)

TDataSet (see page 6894)

SessionName (see page 9989)

SessionName (see page 10027)

AutoSessionName (see page 10121)

Associating a Database Component with a Session

Connecting to Databases with TDatabase

Using TQuery

Using TStoredProc

Using TTable

53.1.15.5.13 TSession.SQLHourGlass Property

Indicates whether or not the mouse cursor changes to an hourglass during BDE operations.

Pascal

```
property SQLHourGlass: Boolean;
```

C++

```
__property Boolean SQLHourGlass;
```

Description

Set SQLHourGlass to false if you do not want the mouse cursor to change to an hourglass while the BDE is waiting for an SQL

server to perform an operation. This property must be set before the session is opened.

53.1.15.5.14 TSession.TraceFlags Property

Specifies the database operations to track with the SQL Monitor at runtime.

Pascal

```
property TraceFlags: TTraceFlags;
```

C++

```
__property TTraceFlags TraceFlags;
```

Description

Use TraceFlags to specify which database operations the SQL Monitor should track in an application at runtime. TraceFlags is only meaningful for the SQL Monitor, which is provided to enable performance tuning and SQL debugging when working with remote SQL database servers.

Note: Normally trace options are set from the SQL Monitor rather than setting TraceFlags in application code.

The value of a session component's TraceFlags property determines the initial settings of the TraceFlags property for database components associated with the session.

The TTraceFlags (see page 10263) type defines the individual values that can be included in the TraceFlags property. The following table summarizes those values:

Values	Meaning
tfQPrepare	Monitor Prepare statements.
tfQExecute	Monitor ExecSQL statements.
tfError	Monitor server error messages. Such messages may include an error code.
tfStmt	Monitor all SQL statements.
tfConnect	Monitor database connect and disconnect operations, including allocation of connection handles, and freeing connection handles.
tfTransact	Monitor transaction statements, such as StartTransaction, Commit, and Rollback.
tfBlob	Monitor operations on blob data types.
tfMisc	Monitor any statements not covered by other flag options.
tfVendor	Monitor direct API function calls to the database server.
tfDataIn	Monitor data received from a server.
tfDataOut	Monitor data sent to a server.

Because TraceFlags is a set property, an application can specify different combinations of flags to monitor different combinations of statements. For example, the following statement limits monitoring to database connections and SQL statement preparation:

```
TraceFlags := [tfConnect, tfQPrepare];
TraceFlags << tfConnect << tfQPrepare;
```

SessionName (see page 10126)

TraceFlags (see page 9990)

53.1.15.6 TSession Events

The events of the TSession class are listed here.

Protected Events

	Name	Description
	OnDBNotify (see page 10128)	This is OnDBNotify, a member of class TSession.

Published Events

	Name	Description
	OnPassword (see page 10128)	Occurs when an application attempts to open a Paradox table for the first time and the Borland (see page 1761) Database Engine (BDE) reports insufficient access rights.
	OnStartup (see page 10129)	Occurs when an application activates a session.

53.1.15.6.1 TSession.OnDBNotify Event

Pascal

```
property OnDBNotify: TDatabaseNotifyEvent;
```

C++

```
__property TDatabaseNotifyEvent OnDBNotify;
```

Description

This is OnDBNotify, a member of class TSession.

53.1.15.6.2 TSession.OnPassword Event

Occurs when an application attempts to open a Paradox table for the first time and the Borland (see page 1761) Database Engine (BDE) reports insufficient access rights.

Pascal

```
property OnPassword: TPasswordEvent;
```

C++

```
__property TPasswordEvent OnPassword;
```

Description

Write an OnPassword event handler to take specific action when an application attempts to open a password-protected Paradox table for the first time. To gain access to the Paradox table, the event handler must pass a valid password to the BDE. The event handler should call the AddPassword (see page 10102) method to make the password available to the session.

Use Continue to conditionally finalize adding the password. If Continue is set to True, the password addition is attempted. If set to False, the attempt to add the password is abandoned.

Note: If an OnPassword event does not exist, but the BDE reports insufficient access rights, the library displays a default dialog box that prompts for a password.

See Also

AddPassword (see page 10102)

GetPassword (see page 10111)

RemovePassword (see page 10118)

PasswordDialog (see page 9849)

Understanding Database and Session Component Interactions

Working with Password-protected Paradox and dBASE Tables

53.1.15.6.3 TSession.OnStartup Event

Occurs when an application activates a session.

Pascal

```
property OnStartup: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStartup;
```

Description

Write an OnStartup event handler to take specific actions when an application activates a session. A session is activated by setting its Active (see page 10120) property to true, or by opening a database or dataset associated with the session (both of which set Active (see page 10120) to true).

Activating a Session

53.1.16 TSessionList Class

TSessionList manages one or more Borland (see page 1761) Database Engine (BDE) sessions in a database application.

Class Hierarchy

Pascal

```
TSessionList = class(TObject);
```

C++

```
class TSessionList : public TObject;
```

File

DBTables

Description

Use TSessionList to manage session components in applications that provide multiple sessions. The library automatically creates a globally accessible default session list component named Sessions (see page 10134) for all database applications. In a multi-session application there can be more than one active session, but only one session can be current at a time. TSessionList enables an application to switch current sessions.

Note: Applications should not instantiate additional session list components.

See Also

TSession (see page 10093)

Sessions (see page 10266)

53.1.16.1 TSessionList Members

The following tables list the members exposed by TSessionList.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 10131)	Creates an instance of a TSessionList (see page 10129) component.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 10131)	Destroys the instance of a session list component.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindSession (see page 10132)	Searches the list of sessions for a specified session.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetSessionNames (see page 10132)	Populates a string list with the names of all available sessions.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	OpenSession (see page 10132)	Makes an existing session active, or creates a new session component and makes it active.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Count (see page 10133)	Indicates the number of available sessions for the application.
	CurrentSession (see page 10134)	Returns a pointer to the current session component
R	List (see page 10134)	Returns a specified session component.
R	Sessions (see page 10134)	Lists all active session components in the session list.

53.1.16.2 TSessionList.Create Constructor

Creates an instance of a TSessionList (see page 10129) component.

Pascal

```
constructor Create;
```

C++

```
__fastcall TSessionList();
```

Description

Do not create instances of TSessionList (see page 10129). A default session list component, Sessions (see page 10134), is automatically created for all database applications. Secondary session lists are not necessary.

Create calls its inherited constructor, creates an empty list object to keep track of session components, and both creates and initializes a critical section for opening databases.

See Also

Destroy (see page 10131)

53.1.16.3 TSessionList.Destroy Destructor

Destroys the instance of a session list component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSessionList();
```

Description

Do not call Destroy. Delphi automatically handles the destruction of the default session list component, Sessions (see page 10134), when an application closes.

Destroy closes all session components, deletes the BDE critical section, and calls its inherited destructor.

Create (see page 10131)

Free (see page 22300)

53.1.16.4 TSessionList Methods

The methods of the TSessionList class are listed here.

Public Methods

	Name	Description
	FindSession (see page 10132)	Searches the list of sessions for a specified session.
	GetSessionNames (see page 10132)	Populates a string list with the names of all available sessions.
	OpenSession (see page 10132)	Makes an existing session active, or creates a new session component and makes it active.

53.1.16.4.1 TSessionList.FindSession Method

Searches the list of sessions for a specified session.

Pascal

```
function FindSession(const SessionName: string): TSession;
```

C++

```
__fastcall TSession FindSession(const AnsiString SessionName);
```

Description

Call FindSession to determine whether or not a specified session exists. SessionName specifies the session to search for.

FindSession compares the SessionName parameter to the SessionName property for each session component in the session list. If a match is found, FindSession returns a pointer to the session component. If an application passes an empty string in SessionName, FindSession returns the default session, Session (see page 10265). If a match is not found, FindSession returns nil (Delphi) or NULL (C++).

See Also

List (see page 10134)

GetSessionNames (see page 10132)

SessionName (see page 10126)

TSession (see page 10093)

53.1.16.4.2 TSessionList.GetSessionNames Method

Populates a string list with the names of all available sessions.

Pascal

```
procedure GetSessionNames(List: TStrings);
```

C++

```
__fastcall GetSessionNames(TStrings List);
```

Description

Call GetSessionNames to retrieve a list of all available sessions. List (see page 10134) is a string list object, created and maintained by the application, into which to store session names. Names returned by GetSessionNames correspond to the SessionName properties of all available sessions.

See Also

FindSession (see page 10132)

SessionName (see page 10126)

53.1.16.4.3 TSessionList.OpenSession Method

Makes an existing session active, or creates a new session component and makes it active.

Pascal

```
function OpenSession(const SessionName: string): TSession;
```

C++

```
__fastcall TSession OpenSession(const AnsiString SessionName);
```

Description

Call OpenSession to make an existing session active, or to create a new session and make it active. SessionName specifies the name of the session to open.

OpenSession calls FindSession (see page 10132) to see if the session specified in the SessionName parameter already exists. If it finds a match, it starts that session if necessary, and makes the session active. If OpenSession does not find an existing session, it creates a new session using the name specified in the SessionName parameter, starts the session, and makes it active.

In either case, OpenSession returns a session object.

See Also

List (see page 10134)

Sessions (see page 10134)

FindSession (see page 10132)

53.1.16.5 TSessionList Properties

The properties of the TSessionList class are listed here.

Public Properties

	Name	Description
R	Count (see page 10133)	Indicates the number of available sessions for the application.
	CurrentSession (see page 10134)	Returns a pointer to the current session component
R	List (see page 10134)	Returns a specified session component.
R	Sessions (see page 10134)	Lists all active session components in the session list.

53.1.16.5.1 TSessionList.Count Property

Indicates the number of available sessions for the application.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read Count to determine the current number of available sessions. Count is typically used to iterate through the list of available sessions to perform some universal action on all sessions. Used with the Sessions (see page 10134) property, which enables an application to access a session by index number, Count specifies the maximum number of index entries for Sessions (see page 10134) (Count - 1).

See Also

CurrentSession (see page 10134)

List (see page 10134)

Sessions (see page 10134)

53.1.16.5.2 TSessionList.CurrentSession Property

Returns a pointer to the current session component

Pascal

```
property CurrentSession: TSession;
```

C++

```
__property TSession CurrentSession;
```

Description

Use CurrentSession to determine or specify which session in a database application is the current session. By default the current session is a pointer to the default session component, Session (see page 10265), that is created automatically by the library for all database applications. Setting CurrentSession makes the specified session component the current one. While any number of sessions may be active, only one session can be current at a time.

See Also

List (see page 10134)

FindSession (see page 10132)

OpenSession (see page 10132)

53.1.16.5.3 TSessionList.List Property

Returns a specified session component.

Pascal

```
property List [const SessionName: string]: TSession;
```

C++

```
__property TSession List[AnsiString const SessionName];
```

Description

Use List to return a pointer to a specific session component managed by the session list. List does not change which session is current. SessionName specifies the session component to return, and must match the SessionName property of an existing session component. If no such session exists, List raises an EDatabaseError exception with a message specifying the invalid session name.

Note: To prevent raising an exception, call the FindSession (see page 10132) method instead of using the List property.

See Also

CurrentSession (see page 10134)

Sessions (see page 10134)

FindSession (see page 10132)

SessionName (see page 10126)

EDatabaseError (see page 6731)

53.1.16.5.4 TSessionList.Sessions Property

Lists all active session components in the session list.

Pascal

```
property Sessions [Index: Integer]: TSession;
```

C++

```
__property TSession Sessions[int Index];
```

Description

Use Sessions to access available session components. Index specifies the session to access. Index must be in the range of zero to the current value of the Count (see page 10133) property minus one, or an EListError exception is raised describing the out of bounds condition.

For example, an application might iterate through all available sessions in the list to perform a global action on them.

53.1.17 TSQLUpdateObject Class

TSQLUpdateObject is the base class for classes that use an SQL command to apply cached updates on behalf of queries or stored procedures that can't post updates directly.

Class Hierarchy

Pascal

```
TSQLUpdateObject = class(TDataSetUpdateObject);
```

C++

```
class TSQLUpdateObject : public TDataSetUpdateObject;
```

File

DBTables

Description

Use TSQLUpdateObject as a base class when creating customized update objects that can update BDE datasets. TSQLUpdateObject adds support for accessing a SQL statement that applies an update to the properties and methods introduced by TDataSetUpdateObject (see page 9994).

TSQLUpdateObject is an abstract base class and cannot be instantiated.

See Also

TUpdateSQL (see page 10229)

EAbstractError (see page 22722)

53.1.17.1 TSQLUpdateObject Members

The following tables list the members exposed by TSQLUpdateObject.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
A	GetDataSet (see page 9998)	GetDataSet returns the value of the DataSet (see page 9999) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
A	GetSQL (see page 10138)	Returns the SQL statement that performs a specified update operation.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
A	SetDataSet (see page 9999)	SetDataSet sets the value of the DataSet (see page 9999) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.

	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	DataSet (see page 9999)	Specifies the dataset that stores the cached updates to be applied by the update object.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
A	Apply (see page 9998)	Apply applies changes to the dataset specified by the DataSet (see page 9999) property.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.

	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.17.2 TSQLUpdateObject Methods

The methods of the TSQLUpdateObject class are listed here.

Protected Methods

	Name	Description
A	GetSQL (see page 10138)	Returns the SQL statement that performs a specified update operation.

53.1.17.2.1 TSQLUpdateObject.GetSQL Method

Returns the SQL statement that performs a specified update operation.

Pascal

```
function GetSQL(UpdateKind: TUpdateKind): TStrings; virtual; abstract;
```

C++

```
virtual __fastcall TStrings GetSQL(TUpdateKind UpdateKind) = 0;
```

Description

Override GetSQL to allow the update object to access an SQL statement that applies an update of the type specified by UpdateKind.

GetSQL provides the underlying implementation for the SQL property in the descendant class TUpdateSQL (see page 10229).

See Also

SQL (see page 10242)

53.1.18 TStoredProc Class

TStoredProc encapsulates a stored procedure in a BDE-based application.

Class Hierarchy

Pascal

```
TStoredProc = class(TDBDataSet);
```

C++

```
class TStoredProc : public TDBDataSet;
```

File

DBTables

Description

Use a TStoredProc object in BDE-based applications to use a stored procedure on a database server. A stored procedure is a grouped set of statements, stored as part of a database server's metadata (just like tables, indexes, and domains), that performs a frequently repeated, database-related task on the server and passes results to the client.

Note: Not all database servers support stored procedures. See a specific server's documentation to determine if it supports stored procedures.

Many stored procedures require a series of input arguments, or parameters, that are used during processing. TStoredProc provides a Params (see page 10165) property that enables an application to set these parameters before executing the stored procedure.

TStoredProc reuses the Params (see page 10165) property to hold the results returned by a stored procedure. Params (see page 10165) is an array of values. Depending on server implementation, a stored procedure can return either a single set of values, or a result set similar to the result set returned by a query.

TQuery (see page 10059)

TTable (see page 10168)

Types of Datasets

53.1.18.1 TStoredProc Members

The following tables list the members exposed by TStoredProc.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
V	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
V	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
V	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
V	CloseCursor (see page 10014)	This is CloseCursor, a member of class TDBDataSet.
	ConstraintsStored (see page 10015)	This is ConstraintsStored, a member of class TDBDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
V	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
V	CreateHandle (see page 10154)	This is CreateHandle, a member of class TStoredProc.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
V	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
V	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.

	DataEvent (see page 6924)	This is DataEvent, a member of class TDataSet.
	DataEvent (see page 9901)	This is DataEvent, a member of class TBDEDataSet.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
	DefChanged (see page 6924)	This is DefChanged, a member of class TDataSet.
	DefineProperties (see page 10155)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DestroyHandle (see page 9901)	This is DestroyHandle, a member of class TBDEDataSet.
	DestroyLookupCursor (see page 9902)	This is DestroyLookupCursor, a member of class TBDEDataSet.
	Disconnect (see page 10156)	This is Disconnect, a member of class TStoredProc.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 6931)	This is DoOnNewRecord, a member of class TDataSet.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 6950)	This is GetCanModify, a member of class TDataSet.
	GetCanModify (see page 9905)	This is GetCanModify, a member of class TBDEDataSet.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 6951)	This is GetDataSource, a member of class TDataSet.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.

	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.
	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetHandle (see page 9907)	This is GetHandle, a member of class TBDEDataSet.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLookupCursor (see page 9909)	This is GetLookupCursor, a member of class TBDEDataSet.
	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetParamsCount (see page 10156)	This is GetParamsCount, a member of class TStoredProc.
	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
	InitFieldDefs (see page 6958)	This is InitFieldDefs, a member of class TDataSet.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.
	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.

	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	OpenCursor (see page 10015)	This is OpenCursor, a member of class TDBDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 9919)	This is PrepareCursor, a member of class TBDEDataSet.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSEndTransaction (see page 10016)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 10158)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 10017)	Executes a specified SQL command.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetAttributes (see page 10017)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 10158)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 10159)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 6983)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 6983)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 6984)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 10159)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.

	PSGetQuoteChar (see page 10018)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 10160)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSInTransaction (see page 10018)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLBased (see page 10018)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 10160)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 10161)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSStartTransaction (see page 10019)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 10019)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDBFlag (see page 10161)	This is SetDBFlag, a member of class TStoredProc.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.
	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.

	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetHandle (see page 10020)	This is SetHandle, a member of class TDBDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetOverLoad (see page 10161)	This is SetOverLoad, a member of class TStoredProc.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetPrepare (see page 10162)	This is SetPrepare, a member of class TStoredProc.
	SetPrepared (see page 10162)	This is SetPrepared, a member of class TStoredProc.
	SetProcName (see page 10162)	This is SetProcName, a member of class TStoredProc.
	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateIndexDefs (see page 7002)	This is UpdateIndexDefs, a member of class TDataSet.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
	Constraints (see page 7013)	Specifies record-level constraints that must be met when editing the data.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
R	DBFlags (see page 10023)	Keeps track of the commands this dataset has active with the database.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.
	UpdateMode (see page 10028)	Determines how the Borland (see page 1761) Database (see page 10021) Engine (BDE) finds records when updating to an SQL database.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.

	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
V	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	CheckOpen (see page 10014)	Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CloseDatabase (see page 10014)	Closes a database connection associated with the database session.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
	CopyParams (see page 10154)	Copies a stored procedure's parameters into another parameter list.
V	Create (see page 10152)	Creates an instance of a stored procedure component.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.
	DescriptionsAvailable (see page 10155)	Determines if parameter information is available from the stored procedure on the server.
V	Destroy (see page 10153)	Destroys the instance of a stored procedure.
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecProc (see page 10156)	Executes the stored procedure on the server.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
V	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
V	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
V	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
V	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
V	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
V	GetDetailLinkFields (see page 6951)	Introduces a method to list the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
V	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.
	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.

	GetResults (see page 10157)	Returns the output parameter values from a Sybase or MSSQL stored procedure.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
V	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
V	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
V	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
V	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
V	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	OpenDatabase (see page 10016)	Opens the database that contains the dataset.
	ParamByName (see page 10157)	Accesses parameter information based on a specified parameter name.
V	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
V	Post (see page 9918)	Writes a modified record to the database.
	Prepare (see page 10157)	Prepares a stored procedure for execution.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSEndTransaction (see page 7578)	Ends a transaction that was started by a call to PSStartTransaction (see page 7586).
	PSExecuteStatement (see page 7579)	Executes a specified SQL command.
	PSGetAttributes (see page 7579)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetDefaultOrder (see page 7580)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 7581)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 7581)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetQuoteChar (see page 7582)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetUpdateException (see page 7583)	Generates an EUpdateError (see page 6732) object based on another exception object.
	PSInTransaction (see page 7583)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 7584)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 7584)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 7585)	Resets the dataset so that it is positioned on the first record.

	PSStartTransaction (see page 7586)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction (see page 7578).
	PSUpdateRecord (see page 7586)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UnPrepare (see page 10162)	Frees the resources allocated for a previously prepared stored procedure.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Database (see page 10021)	Identifies the database component for which this dataset represents one or more tables.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DBHandle (see page 10023)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.
R	DBLocale (see page 10024)	Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.
R	DBSession (see page 10024)	Identifies the database session component associated with this dataset.

R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
	FieldDefs (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	Handle (see page 10163)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the stored procedure.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ParamCount (see page 10165)	Indicates the number of parameters for the stored procedure component.
	Prepared (see page 10165)	Determines whether or not a stored procedure is prepared for execution.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.
	StmtHandle (see page 10166)	Specifies the Borland Database Engine (BDE) statement handle for the dataset.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.

	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 10028)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	AutoRefresh (see page 10021)	Specifies whether server-generated field values are refetched automatically.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	DatabaseName (see page 10022)	Specifies the name of the database associated with this dataset.
	Filter (see page 10025)	Specifies the text of the current filter for a dataset.
	Filtered (see page 10026)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 10026)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
	Overload (see page 10163)	Specifies which Oracle overloaded stored procedure to execute.
	ParamBindMode (see page 10164)	Determines the order in which a component's parameters are assigned to the parameter list for the stored procedure on the server.
	Params (see page 10165)	Stores the input and output parameters for a stored procedure.
	SessionName (see page 10027)	Identifies the name of the session with which this dataset is associated.
	StoredProcName (see page 10167)	Identifies the name of the stored procedure on the server for which this object is an encapsulation.
	Tag (see page 2808)	Stores an integer value as part of a component.
	UpdateObject (see page 10167)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.18.2 TStoredProc.Create Constructor

Creates an instance of a stored procedure component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TStoredProc(TComponent * AOwner);
```

Description

Call Create to instantiate a stored procedure declared in an application. Create calls its inherited Create constructor, creates an empty parameter list for the newly instantiated stored procedure, and initializes its parameter, server, and record buffers to nil (Delphi) or NULL (C++).

See Also

Destroy (see page 10153)

53.1.18.3 TStoredProc.Destroy Destructor

Destroys the instance of a stored procedure.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TStoredProc();
```

Description

Do not call Destroy directly. Instead, call Free, which verifies that the stored procedure is not nil before calling Destroy.

Destroy disconnects from the server, frees the parameter list, and calls its inherited Destroy destructor.

See Also

Create (see page 10152)

Params (see page 10165)

53.1.18.4 TStoredProc Methods

The methods of the TStoredProc class are listed here.

Protected Methods

	Name	Description
	CreateHandle (see page 10154)	This is CreateHandle, a member of class TStoredProc.
	DefineProperties (see page 10155)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	Disconnect (see page 10156)	This is Disconnect, a member of class TStoredProc.
	GetParamsCount (see page 10156)	This is GetParamsCount, a member of class TStoredProc.
	PSExecute (see page 10158)	Executes the SQL command associated with the dataset.
	PSGetCommandText (see page 10158)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandType (see page 10159)	Gets the command type to be executed by PSExecute.
	PSGetParams (see page 10159)	Returns the current parameter values of the dataset.
	PSGetTableName (see page 10160)	Returns the name of the dataset table that appears in generated SQL statements.
	PSSetCommandText (see page 10160)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetParams (see page 10161)	Assigns the specified parameter values to the dataset.
	SetDBFlag (see page 10161)	This is SetDBFlag, a member of class TStoredProc.
	SetOverLoad (see page 10161)	This is SetOverLoad, a member of class TStoredProc.
	SetPrepare (see page 10162)	This is SetPrepare, a member of class TStoredProc.
	SetPrepared (see page 10162)	This is SetPrepared, a member of class TStoredProc.

	SetProcName (see page 10162)	This is SetProcName, a member of class TStoredProc.

Public Methods

	Name	Description
	CopyParams (see page 10154)	Copies a stored procedure's parameters into another parameter list.
	DescriptionsAvailable (see page 10155)	Determines if parameter information is available from the stored procedure on the server.
	ExecProc (see page 10156)	Executes the stored procedure on the server.
	GetResults (see page 10157)	Returns the output parameter values from a Sybase or MSSQL stored procedure.
	ParamByName (see page 10157)	Accesses parameter information based on a specified parameter name.
	Prepare (see page 10157)	Prepares a stored procedure for execution.
	UnPrepare (see page 10162)	Frees the resources allocated for a previously prepared stored procedure.

53.1.18.4.1 TStoredProc.CopyParams Method

Copies a stored procedure's parameters into another parameter list.

Pascal

```
procedure CopyParams(Value: TParams);
```

C++

```
__fastcall CopyParams(TParams Value);
```

Description

Call CopyParams to copy this stored procedure's parameters into a separate parameter list object. Value is the parameter list into which to assign this stored procedure's parameters. Value can be the parameter list of another stored procedure. For example:

```
TStoredProc1.CopyParams(TStoredProc2.Params);
StoredProc1->CopyParams(StoredProc2->Params);
```

If the stored procedure is not prepared when an application calls CopyParams, CopyParams calls Prepare (see page 10157) before assigning the parameters to the target parameters list, and then calls UnPrepare (see page 10162) to return the stored procedure to its previous state.

See Also

Params (see page 10165)

Prepare (see page 10157)

UnPrepare (see page 10162)

53.1.18.4.2 TStoredProc.CreateHandle Method

Pascal

```
function CreateHandle: HDBICur; override;
```

C++

```
virtual __fastcall HDBICur CreateHandle();
```

Description

This is CreateHandle, a member of class TStoredProc.

53.1.18.4.3 TStoredProc.DefineProperties Method

Designates methods for storing an object's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

TComponent overrides the DefineProperties method defined in TPersistent to define "fake" Top and Left properties. These are defined so that components that are not controls can be manipulated at design-time. However, the Top and Left properties are hidden, that is, they are not published, because only controls appear at run-time.

DefineProperties is virtual; descendant classes can override it. When overriding DefineProperties, be aware that the Ancestor property of Filer might be set, and that this property can determine whether or not it is appropriate to write properties.

DefineProperties is called automatically as part of the component streaming system; do not call it directly.

See Also

Ancestor (see page 2839)

DefineBinaryProperty (see page 2837)

DefineProperties (see page 2931)

DefineProperty (see page 2838)

53.1.18.4.4 TStoredProc.DescriptionsAvailable Method

Determines if parameter information is available from the stored procedure on the server.

Pascal

```
function DescriptionsAvailable: Boolean;
```

C++

```
__fastcall Boolean DescriptionsAvailable();
```

Description

Call DescriptionsAvailable to determine if a stored procedure on a server can return parameter information to the application. If DescriptionsAvailable returns true, parameter information is available from the server. If DescriptionsAvailable returns false, parameter information is not available.

Note: If DescriptionsAvailable returns false, the application must still provide correct parameter information to the stored procedure on the server. It is up to the application developer to know the necessary parameters at design time.

See Also

ExecProc (see page 10156)

GetResults (see page 10157)

Params (see page 10165)

53.1.18.4.5 TStoredProc.Disconnect Method

Pascal

```
procedure Disconnect; override;
```

C++

```
virtual __fastcall Disconnect();
```

Description

This is Disconnect, a member of class TStoredProc.

53.1.18.4.6 TStoredProc.ExecProc Method

Executes the stored procedure on the server.

Pascal

```
procedure ExecProc;
```

C++

```
__fastcall ExecProc();
```

Description

Call ExecProc to execute a stored procedure on the server. Before calling ExecProc:

1. Provide any input parameters in the Params (see page 10165) property. At design time, a developer can provide parameters using the Parameters editor. At runtime an application must access Params (see page 10165) directly.
2. Call Prepare (see page 10157) to bind the parameters.
3. If a stored procedure returns output parameters, they are stored in the Params (see page 10165) property when ExecProc returns control to the application. An application can access the output parameters by indexing into the Params (see page 10165) list, or by using the ParamByName (see page 10157) method.

Tip: If an application is only interested in the result set returned by a stored procedure, call its Open method or set its Active (see page 9929) property to true.

See Also

Params (see page 10165)

ParamByName (see page 10157)

Prepare (see page 10157)

Executing the Commands using TSQLDataSet

53.1.18.4.7 TStoredProc.GetParamsCount Method

Pascal

```
function GetParamsCount: Word;
```

C++

```
__fastcall Word GetParamsCount();
```

Description

This is GetParamsCount, a member of class TStoredProc.

53.1.18.4.8 TStoredProc.GetResults Method

Returns the output parameter values from a Sybase or MSSQL stored procedure.

Pascal

```
procedure GetResults;
```

C++

```
__fastcall GetResults();
```

Description

Call GetResults to force a Sybase or MSSQL stored procedure to return its result set, if any, to the client. For stored procedures on all other servers, result sets are automatically flushed to the client, but Sybase and MSSQL stored procedures do not return a result set until the cursor is positioned at the end of the set. GetResults forces the cursor to the end of the set.

If a stored procedure returns a result set and output parameters in response to GetResults, the output parameters are stored in the Params (see page 10165) property. An application can access the output parameters by indexing into the Params (see page 10165) list, or by using the ParamByName (see page 10157) method.

Tip: If an application is only interested in the result set returned by a stored procedure, call Open or set the Active (see page 9929) property to true.

See Also

ExecProc (see page 10156)

Params (see page 10165)

ParamByName (see page 10157)

53.1.18.4.9 TStoredProc.ParamByName Method

Accesses parameter information based on a specified parameter name.

Pascal

```
function ParamByName(const Value: string): TParam;
```

C++

```
__fastcall TParam ParamByName(const AnsiString Value);
```

Description

Call ParamByName to return parameter information for a specific parameter based on its name. Value is the name of the parameter for which to retrieve information. Typically ParamByName is used to set an input parameter's value at runtime, or to retrieve the value of an output parameter. The following command line assigns the value "Jane Smith" as the value for the parameter named Contact:

```
StoredProc1.ParamByName('Contact').AsString := 'Jane Smith';
StoredProc1->ParamByName("Contact")->AsString = "Jane Smith";
```

See Also

Params (see page 10165)

53.1.18.4.10 TStoredProc.Prepare Method

Prepares a stored procedure for execution.

Pascal

```
procedure Prepare;
```

C++

```
__fastcall Prepare();
```

Description

Call Prepare to bind a stored procedure's parameters before calling ExecProc (see page 10156) to execute the procedure. Prepare readies a stored procedure's parameters, initializes the Borland (see page 1761) Database (see page 10021) Engine (BDE), and informs the server of the stored procedure's readiness. These steps allocate system resources and optimize the query for server performance.

Note: If an application attempts to execute a stored procedure that has not been prepared, the library automatically prepares the procedure before executing it, and then unprepares it when execution is complete. If a stored procedure will be executed more than once, it is more efficient for an application to call Prepare explicitly once to avoid repeated and unnecessary preparing and unpreparing of the stored procedure, and then call UnPrepare (see page 10162) when the stored procedure is no longer needed.

See Also

ExecProc (see page 10156)

Prepared (see page 10165)

UnPrepare (see page 10162)

53.1.18.4.11 TStoredProc.PSExecute Method

Executes the SQL command associated with the dataset.

Pascal

```
procedure PSExecute; override;
```

C++

```
virtual __fastcall PSExecute();
```

Description

The provider component calls PSExecute to implement its Execute method. If the dataset represents a query or stored procedure that does not return a cursor, this method executes the query or stored procedure. If the provider Options includes poAllowCommandText and the dataset supports the PSSetCommandText method, the statement specified by PSSetCommandText may be executed instead.

If there is not statement to execute, PSExecute raises an EDatabaseError exception.

See Also

PSSetCommandText (see page 7585)

Execute (see page 18466)

Options (see page 18440)

53.1.18.4.12 TStoredProc.PSGetCommandText Method

Gets the SQL command to be executed by PSExecute.

Pascal

```
function PSGetCommandText: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetCommandText();
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSSetCommandText (see page 7585)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.18.4.13 TStoredProc.PSGetCommandType Method

Gets the command type to be executed by PSExecute.

Pascal

```
function PSGetCommandType: TPSCommandType; override;
```

C++

```
virtual __fastcall TPSCommandType PSGetCommandType();
```

Description

PSGetCommandType gets the command type executed by PSExecute. The type may be a type of SQL command or other command types, such as stored procedures.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSGetCommandText (see page 7579)

Execute (see page 18466)

Options (see page 18440)

53.1.18.4.14 TStoredProc.PSGetParams Method

Returns the current parameter values of the dataset.

Pascal

```
function PSGetParams: TParams; override;
```

C++

```
virtual __fastcall TParams PSGetParams();
```

Description

The provider component calls PSGetParams to implement its GetParams method.

PSGetParams returns a TParams object that describes the current values of all parameters of the dataset. If the dataset does not have any parameters, PSGetParams returns nil (Delphi) or NULL (C++).

Note: The PSGetParams method should not create a new instance of TParams for the return value. The provider that calls PSGetParams does not free the returned value.

See Also

GetParams (see page 18467)

53.1.18.4.15 TStoredProc.PSGetTableName Method

Returns the name of the dataset table that appears in generated SQL statements.

Pascal

```
function PSGetTableName: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetTableName();
```

Description

PSGetTableName returns the name of the underlying database table against which updates are applied when the provider's ResolveToDataSet property is false. This value is used for generating the SQL statements that apply updates. The generated SQL statements are subsequently executed by a call to PSExecuteStatement.

If PSGetTableName does not return a table name, the provider must have an OnGetTableName event handler to supply this value.

See Also

applyupdates (see page 18459)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

ongettablename (see page 18542)

53.1.18.4.16 TStoredProc.PSSetCommandText Method

Assigns a specified SQL command to be executed by PSExecute.

Pascal

```
procedure PSSetCommandText(const CommandText: string); override;
```

C++

```
virtual __fastcall PSSetCommandText(const AnsiString CommandText);
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed

by a call to PSExecute.

The value of the CommandText parameter replaces the dataset's SQL statement (if it has one), or replaces the name of an underlying database table or stored procedure.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.18.4.17 TStoredProc.PSSetParams Method

Assigns the specified parameter values to the dataset.

Pascal

```
procedure PSSetParams(AParams: TParams); override;
```

C++

```
virtual __fastcall PSSetParams(TParams AParams);
```

Description

PSSetParams assigns the parameter values specified by AParams to the parameters of the dataset.

See Also

Params (see page 8489)

PSGetParams (see page 7582)

53.1.18.4.18 TStoredProc.SetDBFlag Method

Pascal

```
function SetDBFlag(Flag: Integer; Value: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean SetDBFlag(int Flag, Boolean Value);
```

Description

This is SetDBFlag, a member of class TStoredProc.

53.1.18.4.19 TStoredProc.SetOverLoad Method

Pascal

```
procedure SetOverLoad(Value: Word);
```

C++

```
__fastcall SetOverLoad(Word Value);
```

Description

This is SetOverLoad, a member of class TStoredProc.

53.1.18.4.20 TStoredProc.SetPrepare Method

Pascal

```
procedure SetPrepare(Value: Boolean);
```

C++

```
__fastcall SetPrepare(Boolean Value);
```

Description

This is SetPrepare, a member of class TStoredProc.

53.1.18.4.21 TStoredProc.SetPrepared Method

Pascal

```
procedure SetPrepared(Value: Boolean);
```

C++

```
__fastcall SetPrepared(Boolean Value);
```

Description

This is SetPrepared, a member of class TStoredProc.

53.1.18.4.22 TStoredProc.SetProcName Method

Pascal

```
procedure SetProcName(const Value: string);
```

C++

```
__fastcall SetProcName(const AnsiString Value);
```

Description

This is SetProcName, a member of class TStoredProc.

53.1.18.4.23 TStoredProc.UnPrepare Method

Frees the resources allocated for a previously prepared stored procedure.

Pascal

```
procedure UnPrepare;
```

C++

```
__fastcall UnPrepare();
```

Description

Call UnPrepare to free the resources allocated for a previously prepared stored procedure on the server and client sides.

See Also

ExecProc (see page 10156)

Prepare (see page 10157)

53.1.18.5 TStoredProc Properties

The properties of the TStoredProc class are listed here.

Public Properties

	Name	Description
R	Handle (see page 10163)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the stored procedure.
R	ParamCount (see page 10165)	Indicates the number of parameters for the stored procedure component.
	Prepared (see page 10165)	Determines whether or not a stored procedure is prepared for execution.
	StmtHandle (see page 10166)	Specifies the Borland Database Engine (BDE) statement handle for the dataset.

Published Properties

	Name	Description
	Overload (see page 10163)	Specifies which Oracle overloaded stored procedure to execute.
	ParamBindMode (see page 10164)	Determines the order in which a component's parameters are assigned to the parameter list for the stored procedure on the server.
	Params (see page 10165)	Stores the input and output parameters for a stored procedure.
	StoredProcName (see page 10167)	Identifies the name of the stored procedure on the server for which this object is an encapsulation.
	UpdateObject (see page 10167)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.18.5.1 TStoredProc.Handle Property

Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the stored procedure.

Pascal

```
property Handle: HDBICur;
```

C++

```
__property HDBICur Handle;
```

Description

Use Handle only to bypass TStoredProc (see page 10139) methods and call directly into the BDE. Many BDE function calls require a cursor handle parameter. Handle is assigned an initial value when a stored procedure is executed. If used with a BDE call that changes the current record position, call Resync immediately after returning from the BDE call.

Note: Do not use this property unless an application requires BDE functionality not available through built-in components.

See Also

Locale (see page 9934)

Resync (see page 6994)

53.1.18.5.2 TStoredProc.Overload Property

Specifies which Oracle overloaded stored procedure to execute.

Pascal

```
property Overload: Word;
```

C++

```
__property Word Overload;
```

Description

Use Overload to specify which overloaded stored procedure to execute on an Oracle server. An Oracle overloaded stored procedure is one that shares a name with one or more other stored procedures. Oracle distinguishes among overloaded stored procedures by assigning each procedure a unique numeric identifier. An application can specify this identifier using the Overload property.

By default, Overload is zero, which assumes there is no procedure overloading. For all servers except Oracle, do not change this value. If an application attempts to access an Oracle overloaded procedure without setting Overload, the Borland (see page 1761) Database (see page 10021) Engine (BDE) accesses the lowest numbered, or first, overloaded procedure on the server.

If Overload is 1, the BDE executes the first overloaded procedure on the server. If Overload is 2, it executes the second, and so on.

Note: While Oracle overloaded procedures share names, their parameter lists are unique. An application must ensure that it passes the correct parameter list to an overloaded procedure.

See Also

Params (see page 10165)

Working with Oracle Overloaded Stored Procedures

53.1.18.5.3 TStoredProc.ParamBindMode Property

Determines the order in which a component's parameters are assigned to the parameter list for the stored procedure on the server.

Pascal

```
property ParamBindMode: TParamBindMode;
```

C++

```
__property TParamBindMode ParamBindMode;
```

Description

Examine or set ParamBindMode to determine the order in which parameters in the Params (see page 10165) property are matched to the parameters used by the stored procedure on the server. ParamBindMode can be one of the following:

Value	Ordering
pbByName	Parameters specified in the Params (see page 10165) property are matched to identically named parameters on the server. This is the default.
pbByNumber	Parameters in Params (see page 10165) are assigned one-by-one to the next available parameter on the server (for example, the first parameter in Params (see page 10165) is assigned to the first parameter used by the stored procedure, and so on).

Whenever possible, ParamBindMode should be pbByName. This guarantees that parameters are matched to the correct parameters used by the stored procedure regardless of physical ordering in Params (see page 10165). At design time, the names of known parameters appear in the Parameters editor.

In some cases stored procedures on the server (for example, Informix) do not provide the Borland (see page 1761) Database (see page 10021) Engine (BDE) with parameter names. If parameter names as they exist on the server side are not known at design or runtime, it may be necessary to set ParamBindMode to pbByNumber. In this case, however, it is necessary to know the correct data type for each parameter in sequence. Otherwise an exception may be raised on execution.

ExecProc (see page 10156)

ParamCount (see page 10165)

Params (see page 10165)

Binding Parameters

Using TStoredProc

53.1.18.5.4 TStoredProc.ParamCount Property

Indicates the number of parameters for the stored procedure component.

Pascal

```
property ParamCount: Word;
```

C++

```
__property Word ParamCount;
```

Description

Examine ParamCount to determine the number of parameters currently stored in the Params (see page 10165) property.

See Also

ExecProc (see page 10156)

Params (see page 10165)

Prepare (see page 10157)

53.1.18.5.5 TStoredProc.Params Property

Stores the input and output parameters for a stored procedure.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

Access Params at runtime to set input parameter names, values, and data types dynamically (at design time use the Parameters editor to set parameter information). Params is an array of parameter values.

An application can also access Params after executing a stored procedure to retrieve the output parameters returned to the procedure by the server.

See Also

ExecProc (see page 10156)

ParamByName (see page 10157)

Prepare (see page 10157)

53.1.18.5.6 TStoredProc.Prepared Property

Determines whether or not a stored procedure is prepared for execution.

Pascal

```
property Prepared: Boolean;
```

C++

```
__property Boolean Prepared;
```

Description

Examine Prepared to determine if a stored procedure is already prepared for execution. If Prepared is true, the stored procedure is prepared, and if Prepared is false, the procedure is not prepared. A stored procedure must be prepared before it can be executed.

Note: The library automatically prepares a stored procedure if it is unprepared when the application calls ExecProc (see page 10156) and unprepares it afterwards. If a procedure will be executed a number of times, it is more efficient for the application to prepare the stored procedure once, and unprepare it when it is no longer needed.

An application can change the current setting of Prepared to prepare or unprepare a stored procedure. If Prepared is true, setting it to false calls the Unprepare method to unprepare the stored procedure. If Prepared is false, setting it to true calls the Prepare (see page 10157) method to prepare the procedure. Generally, however, it is better programming practice to call Prepare (see page 10157) and Unprepare directly. These methods automatically update the Prepared property.

See Also

ExecProc (see page 10156)

Prepare (see page 10157)

UnPrepare (see page 10162)

Executing the Commands using TSQLDataSet

Fetching the Data using TSQLDataSet

53.1.18.5.7 TStoredProc.StmtHandle Property

Specifies the Borland Database Engine (BDE) statement handle for the dataset.

Pascal

```
property StmtHandle: HDBIStmt;
```

C++

```
__property HDBIStmt StmtHandle;
```

Description

Use StmtHandle for direct calls to the BDE that bypass the methods of this dataset. Some BDE API calls require a statement handle as a parameter. For example, TBDEDataSet descendants use StmtHandle when preparing a query or binding parameters.

Typically, applications do not need to access this property. In TBDEDataSet, StmtHandle is protected, and so unavailable to applications. Some descendants make this property public so that you can bypass the dataset methods and make direct calls to the BDE.

See Also

Handle (see page 9933)

Prepare (see page 10077)

Prepare (see page 10157)

Params (see page 10087)

Params (see page 10165)

53.1.18.5.8 TStoredProc.StoredProcName Property

Identifies the name of the stored procedure on the server for which this object is an encapsulation.

Pascal

```
property StoredProcName: string;
```

C++

```
__property AnsiString StoredProcName;
```

Description

Set StoredProcName to specify the name of the stored procedure to call on the server. If StoredProcName does not match the name of an existing stored procedure on the server, then when the application attempts to prepare the procedure prior to execution, an exception is raised.

See Also

Prepare (see page 10157)

ExecProc (see page 10156)

Using TStoredProc

53.1.18.5.9 TStoredProc.UpdateObject Property

Specifies the update object component used to update a read-only result set when cached updates are enabled.

Pascal

```
property UpdateObject: TDataSetUpdateObject;
```

C++

```
__property TDataSetUpdateObject UpdateObject;
```

Description

Use UpdateObject to specify the TUpdateObject component to use in an application that must be able to update a read-only result set returned by the Borland Database Engine (BDE).

The BDE always attempts to provide an updatable, or "live" query result unless an application specifically requests a read-only view of data. In some cases, such as a query made against multiple tables, a live result set cannot be returned. In these cases, UpdateObject can be used to specify a TUpdateSQL component that performs updates as a separate transaction that is transparent to the application.

53.1.19 TTable Class

TTable encapsulates a database table.

Class Hierarchy

Pascal

```
TTable = class(TDBDataSet);
```

C++

```
class TTable : public TDBDataSet;
```

File

DBTables

Description

Use TTable to access data in a single database table using the Borland (see page 1761) Database (see page 10021) Engine (BDE). TTable provides direct access to every record and field in an underlying database table, whether it is from Paradox, dBASE, Access, FoxPro, an ODBC-compliant database, or an SQL database on a remote server, such as InterBase, Oracle, Sybase, MS-SQL Server, Informix, or DB2. A table component can also work with a subset of records within a database table using ranges and filters.

At design time, create, delete, update, or rename the database table connected to a TTable by right-clicking on the TTable and using the pop-up menu.

Types of Datasets

53.1.19.1 TTable Members

The following tables list the members exposed by TTable.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	ActivateBuffers (see page 6909)	This is ActivateBuffers, a member of class TDataSet.
	ActivateFilters (see page 9893)	This is ActivateFilters, a member of class TBDEDataSet.
	AddFieldDesc (see page 9893)	This is AddFieldDesc, a member of class TBDEDataSet.
	AllocCachedUpdateBuffers (see page 9893)	This is AllocCachedUpdateBuffers, a member of class TBDEDataSet.
	AllocKeyBuffers (see page 9893)	This is AllocKeyBuffers, a member of class TBDEDataSet.
V	AllocRecordBuffer (see page 6909)	This is AllocRecordBuffer, a member of class TDataSet.
V	AllocRecordBuffer (see page 9894)	This is AllocRecordBuffer, a member of class TBDEDataSet.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BindFields (see page 6915)	This is BindFields, a member of class TDataSet.
V	BlockReadNext (see page 6915)	This is BlockReadNext, a member of class TDataSet.
V	BlockReadNext (see page 9894)	This is BlockReadNext, a member of class TBDEDataSet.
	BookmarkAvailable (see page 6916)	This is BookmarkAvailable, a member of class TDataSet.
	CachedUpdateCallBack (see page 9895)	This is CachedUpdateCallBack, a member of class TBDEDataSet.
V	CalculateFields (see page 6916)	This is CalculateFields, a member of class TDataSet.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	CheckActive (see page 6917)	This is CheckActive, a member of class TDataSet.
	CheckBiDirectional (see page 6918)	This is CheckBiDirectional, a member of class TDataSet.
	CheckCachedUpdateMode (see page 9896)	This is CheckCachedUpdateMode, a member of class TBDEDataSet.
V	CheckFieldCompatibility (see page 6919)	This is CheckFieldCompatibility, a member of class TDataSet.
V	CheckInactive (see page 6919)	This is CheckInactive, a member of class TDataSet.
	CheckSetKeyMode (see page 9896)	This is CheckSetKeyMode, a member of class TBDEDataSet.
V	ClearBuffers (see page 6919)	This is ClearBuffers, a member of class TDataSet.
V	ClearCalcFields (see page 6919)	This is ClearCalcFields, a member of class TDataSet.
V	ClearCalcFields (see page 9897)	This is ClearCalcFields, a member of class TBDEDataSet.
V	CloseBlob (see page 6921)	This is CloseBlob, a member of class TDataSet.
V	CloseBlob (see page 9897)	This is CloseBlob, a member of class TBDEDataSet.
V	CloseCursor (see page 6921)	This is CloseCursor, a member of class TDataSet.
V	CloseCursor (see page 9897)	This is CloseCursor, a member of class TBDEDataSet.
V	CloseCursor (see page 10014)	This is CloseCursor, a member of class TDBDataSet.
	ConstraintsStored (see page 10015)	This is ConstraintsStored, a member of class TDBDataSet.
	CreateExprFilter (see page 9900)	This is CreateExprFilter, a member of class TBDEDataSet.
V	CreateFields (see page 6923)	This is CreateFields, a member of class TDataSet.
	CreateFuncFilter (see page 9900)	This is CreateFuncFilter, a member of class TBDEDataSet.
V	CreateHandle (see page 10189)	This is CreateHandle, a member of class TTable.
	CreateLookupFilter (see page 9901)	This is CreateLookupFilter, a member of class TBDEDataSet.
V	CreateNestedDataSet (see page 6923)	This is CreateNestedDataSet, a member of class TDataSet.
V	DataConvert (see page 6924)	This is DataConvert, a member of class TDataSet.
V	DataEvent (see page 10191)	This is DataEvent, a member of class TTable.
	DeactivateFilters (see page 9901)	This is DeactivateFilters, a member of class TBDEDataSet.
V	DefChanged (see page 10191)	This is DefChanged, a member of class TTable.

	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DestroyFields (see page 6925)	This is DestroyFields, a member of class TDataSet.
	DestroyHandle (see page 10193)	This is DestroyHandle, a member of class TTable.
	DestroyLookupCursor (see page 10193)	This is DestroyLookupCursor, a member of class TTable.
	Disconnect (see page 10015)	This is Disconnect, a member of class TDBDataSet.
	DoAfterCancel (see page 6927)	This is DoAfterCancel, a member of class TDataSet.
	DoAfterClose (see page 6927)	This is DoAfterClose, a member of class TDataSet.
	DoAfterDelete (see page 6928)	This is DoAfterDelete, a member of class TDataSet.
	DoAfterEdit (see page 6928)	This is DoAfterEdit, a member of class TDataSet.
	DoAfterInsert (see page 6928)	This is DoAfterInsert, a member of class TDataSet.
	DoAfterOpen (see page 6928)	This is DoAfterOpen, a member of class TDataSet.
	DoAfterPost (see page 6929)	This is DoAfterPost, a member of class TDataSet.
	DoAfterRefresh (see page 6929)	This is DoAfterRefresh, a member of class TDataSet.
	DoAfterScroll (see page 6929)	This is DoAfterScroll, a member of class TDataSet.
	DoBeforeCancel (see page 6929)	This is DoBeforeCancel, a member of class TDataSet.
	DoBeforeClose (see page 6929)	This is DoBeforeClose, a member of class TDataSet.
	DoBeforeDelete (see page 6930)	This is DoBeforeDelete, a member of class TDataSet.
	DoBeforeEdit (see page 6930)	This is DoBeforeEdit, a member of class TDataSet.
	DoBeforeInsert (see page 6930)	This is DoBeforeInsert, a member of class TDataSet.
	DoBeforeOpen (see page 6930)	This is DoBeforeOpen, a member of class TDataSet.
	DoBeforePost (see page 6931)	This is DoBeforePost, a member of class TDataSet.
	DoBeforeRefresh (see page 6931)	This is DoBeforeRefresh, a member of class TDataSet.
	DoBeforeScroll (see page 6931)	This is DoBeforeScroll, a member of class TDataSet.
	DoOnCalcFields (see page 6931)	This is DoOnCalcFields, a member of class TDataSet.
	DoOnNewRecord (see page 10194)	This is DoOnNewRecord, a member of class TTable.
	EncodeFieldDesc (see page 10196)	This is EncodeFieldDesc, a member of class TTable.
	EncodeIndexDesc (see page 10196)	This is EncodeIndexDesc, a member of class TTable.
	FieldByNumber (see page 6938)	This is FieldByNumber, a member of class TDataSet.
	FindRecord (see page 6942)	This is FindRecord, a member of class TDataSet.
	FindRecord (see page 9903)	This is FindRecord, a member of class TBDEDataSet.
	ForceUpdateCallback (see page 9904)	This is ForceUpdateCallback, a member of class TBDEDataSet.
	FreeFieldBuffers (see page 6946)	This is FreeFieldBuffers, a member of class TDataSet.
	FreeKeyBuffers (see page 9904)	This is FreeKeyBuffers, a member of class TBDEDataSet.
	FreeRecordBuffer (see page 6947)	This is FreeRecordBuffer, a member of class TDataSet.
	FreeRecordBuffer (see page 9904)	This is FreeRecordBuffer, a member of class TBDEDataSet.
	GetAggRecordCount (see page 6947)	This is GetAggRecordCount, a member of class TDataSet.
	GetAggregateValue (see page 6947)	This is GetAggregateValue, a member of class TDataSet.
	GetBookmarkData (see page 6949)	This is GetBookmarkData, a member of class TDataSet.
	GetBookmarkData (see page 9905)	This is GetBookmarkData, a member of class TBDEDataSet.
	GetBookmarkFlag (see page 6949)	This is GetBookmarkFlag, a member of class TDataSet.
	GetBookmarkFlag (see page 9905)	This is GetBookmarkFlag, a member of class TBDEDataSet.
	GetBookmarkStr (see page 6949)	This is GetBookmarkStr, a member of class TDataSet.
	GetCalcFields (see page 6950)	This is GetCalcFields, a member of class TDataSet.
	GetCanModify (see page 10198)	This is GetCanModify, a member of class TTable.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6950)	This is GetChildren, a member of class TDataSet.
	GetDataSource (see page 10199)	This is GetDataSource, a member of class TTable.
	GetFieldClass (see page 6952)	This is GetFieldClass, a member of class TDataSet.
	GetFieldFullName (see page 6953)	This is GetFieldFullName, a member of class TDataSet.

V	GetFieldFullName (see page 9907)	This is GetFieldFullName, a member of class TBDEDataSet.
	GetFileName (see page 10199)	This is GetFileName, a member of class TTable.
	GetHandle (see page 10199)	This is GetHandle, a member of class TTable.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetIndexDefs (see page 6954)	This is GetIndexDefs, a member of class TDataSet.
	GetIndexField (see page 9907)	This is GetIndexField, a member of class TBDEDataSet.
	GetIndexFieldCount (see page 9907)	This is GetIndexFieldCount, a member of class TBDEDataSet.
V	GetIsIndexField (see page 6954)	This is GetIsIndexField, a member of class TDataSet.
V	GetIsIndexField (see page 9908)	This is GetIsIndexField, a member of class TBDEDataSet.
	GetKeyBuffer (see page 9908)	This is GetKeyBuffer, a member of class TBDEDataSet.
	GetKeyExclusive (see page 9908)	This is GetKeyExclusive, a member of class TBDEDataSet.
	GetKeyFieldCount (see page 9909)	This is GetKeyFieldCount, a member of class TBDEDataSet.
	GetLanguageDriverName (see page 10200)	This is GetLanguageDriverName, a member of class TTable.
V	GetLookupCursor (see page 10200)	This is GetLookupCursor, a member of class TTable.
V	GetNextRecord (see page 6955)	This is GetNextRecord, a member of class TDataSet.
V	GetNextRecords (see page 6955)	This is GetNextRecords, a member of class TDataSet.
	GetObjectTypeNames (see page 9909)	This is GetObjectTypeNames, a member of class TBDEDataSet.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetPriorRecord (see page 6955)	This is GetPriorRecord, a member of class TDataSet.
V	GetPriorRecords (see page 6955)	This is GetPriorRecords, a member of class TDataSet.
V	GetRecNo (see page 6956)	This is GetRecNo, a member of class TDataSet.
V	GetRecNo (see page 9909)	This is GetRecNo, a member of class TBDEDataSet.
A	GetRecord (see page 6956)	This is GetRecord, a member of class TDataSet.
V	GetRecord (see page 9910)	This is GetRecord, a member of class TBDEDataSet.
V	GetRecordCount (see page 6956)	This is GetRecordCount, a member of class TDataSet.
V	GetRecordCount (see page 9910)	This is GetRecordCount, a member of class TBDEDataSet.
V	GetRecordSize (see page 6956)	This is GetRecordSize, a member of class TDataSet.
V	GetRecordSize (see page 9910)	This is GetRecordSize, a member of class TBDEDataSet.
V	GetStateFieldValue (see page 6956)	This is GetStateFieldValue, a member of class TDataSet.
V	GetStateFieldValue (see page 9910)	This is GetStateFieldValue, a member of class TBDEDataSet.
	GetTableType (see page 10200)	This is GetTableType, a member of class TTable.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	GetUpdateRecordSet (see page 9910)	This is GetUpdateRecordSet, a member of class TBDEDataSet.
	GetUpdatesPending (see page 9911)	This is GetUpdatesPending, a member of class TBDEDataSet.
V	InitFieldDefs (see page 10203)	This is InitFieldDefs, a member of class TTable.
	InitFieldDefsFromFields (see page 6959)	This is InitFieldDefsFromFields, a member of class TDataSet.
	InitKeyBuffer (see page 9911)	This is InitKeyBuffer, a member of class TBDEDataSet.
V	InitRecord (see page 6959)	This is InitRecord, a member of class TDataSet.
V	InitRecord (see page 9911)	This is InitRecord, a member of class TBDEDataSet.
V	InternalAddRecord (see page 6963)	This is InternalAddRecord, a member of class TDataSet.
V	InternalAddRecord (see page 9911)	This is InternalAddRecord, a member of class TBDEDataSet.
V	InternalCancel (see page 6963)	This is InternalCancel, a member of class TDataSet.
V	InternalCancel (see page 9912)	This is InternalCancel, a member of class TBDEDataSet.
A	InternalClose (see page 6963)	This is InternalClose, a member of class TDataSet.
V	InternalClose (see page 9912)	This is InternalClose, a member of class TBDEDataSet.
V	InternalDelete (see page 6964)	This is InternalDelete, a member of class TDataSet.
V	InternalDelete (see page 9912)	This is InternalDelete, a member of class TBDEDataSet.
V	InternalEdit (see page 6964)	This is InternalEdit, a member of class TDataSet.
V	InternalEdit (see page 9912)	This is InternalEdit, a member of class TBDEDataSet.
V	InternalFirst (see page 6964)	This is InternalFirst, a member of class TDataSet.
V	InternalFirst (see page 9912)	This is InternalFirst, a member of class TBDEDataSet.

	InternalGotoBookmark (see page 6964)	This is InternalGotoBookmark, a member of class TDataSet.
	InternalGotoBookmark (see page 9913)	This is InternalGotoBookmark, a member of class TBDEDataSet.
	InternalHandleException (see page 6964)	This is InternalHandleException, a member of class TDataSet.
	InternalHandleException (see page 9913)	This is InternalHandleException, a member of class TBDEDataSet.
	InternalInitFieldDefs (see page 6965)	This is InternalInitFieldDefs, a member of class TDataSet.
	InternalInitFieldDefs (see page 9913)	This is InternalInitFieldDefs, a member of class TBDEDataSet.
	InternalInitRecord (see page 6965)	This is InternalInitRecord, a member of class TDataSet.
	InternalInitRecord (see page 9913)	This is InternalInitRecord, a member of class TBDEDataSet.
	InternalInsert (see page 6965)	This is InternalInsert, a member of class TDataSet.
	InternalInsert (see page 9914)	This is InternalInsert, a member of class TBDEDataSet.
	InternalLast (see page 6965)	This is InternalLast, a member of class TDataSet.
	InternalLast (see page 9914)	This is InternalLast, a member of class TBDEDataSet.
	InternalOpen (see page 6966)	This is InternalOpen, a member of class TDataSet.
	InternalOpen (see page 9914)	This is InternalOpen, a member of class TBDEDataSet.
	InternalPost (see page 6966)	This is InternalPost, a member of class TDataSet.
	InternalPost (see page 9914)	This is InternalPost, a member of class TBDEDataSet.
	InternalRefresh (see page 6966)	This is InternalRefresh, a member of class TDataSet.
	InternalRefresh (see page 9914)	This is InternalRefresh, a member of class TBDEDataSet.
	InternalSetToRecord (see page 6966)	This is InternalSetToRecord, a member of class TDataSet.
	InternalSetToRecord (see page 9915)	This is InternalSetToRecord, a member of class TBDEDataSet.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsCursorOpen (see page 6966)	This is IsCursorOpen, a member of class TDataSet.
	IsCursorOpen (see page 9915)	This is IsCursorOpen, a member of class TBDEDataSet.
	IsProductionIndex (see page 10203)	This is IsProductionIndex, a member of class TTable.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6969)	Initializes the component after the form file has been read into memory.
	LocateRecord (see page 9916)	This is LocateRecord, a member of class TBDEDataSet.
	MapsToIndex (see page 9918)	This is MapsToIndex, a member of class TBDEDataSet.
	NativeTableName (see page 10203)	This is NativeTableName, a member of class TTable.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	OpenCursor (see page 6976)	This is OpenCursor, a member of class TDataSet.
	OpenCursor (see page 9918)	This is OpenCursor, a member of class TBDEDataSet.
	OpenCursor (see page 10015)	This is OpenCursor, a member of class TDBDataSet.
	OpenCursorComplete (see page 6977)	This is OpenCursorComplete, a member of class TDataSet.
	OpenParentDataSet (see page 6977)	This is OpenParentDataSet, a member of class TDataSet.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PostKeyBuffer (see page 9919)	This is PostKeyBuffer, a member of class TBDEDataSet.
	PrepareCursor (see page 10204)	This is PrepareCursor, a member of class TTable.
	ProcessUpdates (see page 9919)	This is ProcessUpdates, a member of class TBDEDataSet.
	PSEndTransaction (see page 6979)	Ends a transaction that was started by a call to PSStartTransaction.
	PSEndTransaction (see page 10016)	Ends a transaction that was started by a call to PSStartTransaction.
	PSExecute (see page 6980)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 10017)	Executes a specified SQL command.
	PSExecuteStatement (see page 6980)	This is the overview for the PSExecuteStatement method overload.
	PSGetAttributes (see page 6981)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetAttributes (see page 10017)	Returns information that is stored in data packets as Name/Value pairs.
	PSGetCommandText (see page 10204)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandTextW (see page 6982)	This is PSGetCommandTextW, a member of class TDataSet.
	PSGetCommandType (see page 10205)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 10205)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 10205)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 10206)	Returns the names of all fields required to uniquely identify records in the data packet.

	PSGetKeyFieldsW (see page 6984)	This is PSGetKeyFieldsW, a member of class TDataSet.
	PSGetParams (see page 6984)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 6985)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteChar (see page 10018)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetQuoteCharW (see page 6985)	This is PSGetQuoteCharW, a member of class TDataSet.
	PSGetTableName (see page 10206)	Returns the name of the dataset table that appears in generated SQL statements.
	PSGetTableNameW (see page 6986)	This is PSGetTableNameW, a member of class TDataSet.
	PSGetUpdateException (see page 6986)	Generates an EUpdateError object based on another exception object.
	PSGetUpdateException (see page 9920)	Generates an EUpdateError object based on another exception object.
	PSInTransaction (see page 6987)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSInTransaction (see page 10018)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 6987)	Indicates whether the dataset includes native SQL support.
	PSIsSQLBased (see page 10018)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 6987)	Indicates whether the dataset can execute SQL statements.
	PSIsSQLSupported (see page 9920)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 6988)	Resets the dataset so that it is positioned on the first record.
	PSReset (see page 9921)	Resets the dataset so that it is positioned on the first record.
	PSSetCommandText (see page 10207)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetCommandText (see page 6988)	This is the overview for the PSSetCommandText method overload.
	PSSetParams (see page 10207)	Assigns the specified parameter values to the dataset.
	PSStartTransaction (see page 6989)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSStartTransaction (see page 10019)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction.
	PSUpdateRecord (see page 6990)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 9921)	Applies a single update to the underlying database table or tables.
	PSUpdateRecord (see page 10019)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RefreshInternalCalcFields (see page 6993)	This is RefreshInternalCalcFields, a member of class TDataSet.
	ResetAggField (see page 6993)	This is ResetAggField, a member of class TDataSet.
	ResetCursorRange (see page 9922)	This is ResetCursorRange, a member of class TBDEDataSet.
	RestoreState (see page 6993)	This is RestoreState, a member of class TDataSet.
	SetActive (see page 6994)	This is SetActive, a member of class TDataSet.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetBlockReadSize (see page 6994)	This is SetBlockReadSize, a member of class TDataSet.
	SetBlockReadSize (see page 9922)	This is SetBlockReadSize, a member of class TBDEDataSet.
	SetBookmarkData (see page 6994)	This is SetBookmarkData, a member of class TDataSet.
	SetBookmarkData (see page 9922)	This is SetBookmarkData, a member of class TBDEDataSet.
	SetBookmarkFlag (see page 6995)	This is SetBookmarkFlag, a member of class TDataSet.
	SetBookmarkFlag (see page 9923)	This is SetBookmarkFlag, a member of class TBDEDataSet.
	SetBookmarkStr (see page 6995)	This is SetBookmarkStr, a member of class TDataSet.
	SetBufListSize (see page 6995)	This is SetBufListSize, a member of class TDataSet.
	SetCachedUpdates (see page 9923)	This is SetCachedUpdates, a member of class TBDEDataSet.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6995)	This is SetChildOrder, a member of class TDataSet.
	SetCurrentRecord (see page 6996)	This is SetCurrentRecord, a member of class TDataSet.
	SetCursorRange (see page 9923)	This is SetCursorRange, a member of class TBDEDataSet.
	SetDataSetField (see page 6996)	This is SetDataSetField, a member of class TDataSet.
	SetDBFlag (see page 10020)	This is SetDBFlag, a member of class TDBDataSet.
	SetDefaultFields (see page 6996)	This is SetDefaultFields, a member of class TDataSet.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetFieldData (see page 9923)	This is SetFieldData, a member of class TBDEDataSet.

	SetFieldData (see page 6996)	This is the overview for the SetFieldData method overload.
	SetFilterData (see page 9923)	This is SetFilterData, a member of class TBDEDataSet.
	SetFiltered (see page 6997)	This is SetFiltered, a member of class TDataSet.
	SetFiltered (see page 9924)	This is SetFiltered, a member of class TBDEDataSet.
	SetFilterHandle (see page 9924)	This is SetFilterHandle, a member of class TBDEDataSet.
	SetFilterOptions (see page 6998)	This is SetFilterOptions, a member of class TDataSet.
	SetFilterOptions (see page 9924)	This is SetFilterOptions, a member of class TBDEDataSet.
	SetFilterText (see page 6998)	This is SetFilterText, a member of class TDataSet.
	SetFilterText (see page 9924)	This is SetFilterText, a member of class TBDEDataSet.
	SetFound (see page 6998)	This is SetFound, a member of class TDataSet.
	SetHandle (see page 10020)	This is SetHandle, a member of class TDBDataSet.
	SetIndexField (see page 9925)	This is SetIndexField, a member of class TBDEDataSet.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetKeyBuffer (see page 9925)	This is SetKeyBuffer, a member of class TBDEDataSet.
	SetKeyExclusive (see page 9925)	This is SetKeyExclusive, a member of class TBDEDataSet.
	SetKeyFieldCount (see page 9925)	This is SetKeyFieldCount, a member of class TBDEDataSet.
	SetKeyFields (see page 9925)	This is SetKeyFields, a member of class TBDEDataSet.
	SetLinkRanges (see page 9926)	This is SetLinkRanges, a member of class TBDEDataSet.
	SetLocale (see page 9926)	This is SetLocale, a member of class TBDEDataSet.
	SetModified (see page 6998)	This is SetModified, a member of class TDataSet.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 6999)	Sets the value of the Name property.
	SetObjectView (see page 6999)	This is SetObjectView, a member of class TDataSet.
	SetOnFilterRecord (see page 6999)	This is SetOnFilterRecord, a member of class TDataSet.
	SetOnFilterRecord (see page 9926)	This is SetOnFilterRecord, a member of class TBDEDataSet.
	SetOnUpdateError (see page 9926)	This is SetOnUpdateError, a member of class TBDEDataSet.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetRecNo (see page 6999)	This is SetRecNo, a member of class TDataSet.
	SetRecNo (see page 9927)	This is SetRecNo, a member of class TBDEDataSet.
	SetState (see page 7000)	This is SetState, a member of class TDataSet.
	SetStateFieldValue (see page 7000)	This is SetStateFieldValue, a member of class TDataSet.
	SetStateFieldValue (see page 9927)	This is SetStateFieldValue, a member of class TBDEDataSet.
	SetTempState (see page 7000)	This is SetTempState, a member of class TDataSet.
	SetUniDirectional (see page 7000)	This is SetUniDirectional, a member of class TDataSet.
	SetupCallBack (see page 9927)	This is SetupCallBack, a member of class TBDEDataSet.
	SetUpdateObject (see page 9927)	This is SetUpdateObject, a member of class TBDEDataSet.
	SetUpdateRecordSet (see page 9927)	This is SetUpdateRecordSet, a member of class TBDEDataSet.
	SwitchToIndex (see page 9928)	This is SwitchToIndex, a member of class TBDEDataSet.
	TempBuffer (see page 7001)	This is TempBuffer, a member of class TDataSet.
	UpdateBufferCount (see page 7001)	This is UpdateBufferCount, a member of class TDataSet.
	UpdateCallbackRequired (see page 9928)	This is UpdateCallbackRequired, a member of class TBDEDataSet.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateIndexDefs (see page 10213)	This is UpdateIndexDefs, a member of class TTable.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ActiveRecord (see page 7005)	Indicates the index of the active record in the internal cache of records.
R	BlobFieldCount (see page 7007)	Indicates the number of columns in the dataset that represent Binary large object (BLOB) fields.
	BookmarkSize (see page 7010)	Indicates the number of bytes used to represent a bookmark.
R	BufferCount (see page 7010)	Indicates the number of records in the internal cache.
R	Buffers (see page 7011)	Provides indexed access to the record buffers in the internal cache.
R	CalcBuffer (see page 7011)	Points to the record buffer used during an OnCalcFields (see page 7053) event.
R	CalcFieldsSize (see page 7012)	Indicates the number of bytes in a record buffer dedicated to storing calculated fields and lookup fields.
R	CurrentRecord (see page 7013)	Indicates the index of the current record in the internal cache of record buffers.
R	DBFlags (see page 10023)	Keeps track of the commands this dataset has active with the database.
	FieldNoOfs (see page 7022)	Specifies the offset needed to convert indexes in the Fields (see page 7023) property to field numbers.
R	InternalCalcFields (see page 7028)	Indicates whether the dataset includes internally calculated fields.
R	MasterLink (see page 10224)	This is MasterLink, a member of class TTable.
	NestedDataSetClass (see page 7030)	Indicates the class type to use when creating nested datasets.
R	NestedDataSets (see page 7030)	Lists all nested datasets.
	Reserved (see page 7035)	For internal use only.
	StmtHandle (see page 9935)	Specifies the Borland (see page 1761) Database Engine (BDE) statement handle for the dataset.

Public Events

	Name	Description
	AfterCancel (see page 7038)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 7040)	Occurs after an application closes a dataset.
	AfterDelete (see page 7041)	Occurs after an application deletes a record.
	AfterEdit (see page 7044)	Occurs after an application starts editing a record.
	AfterInsert (see page 7044)	Occurs after an application inserts a new record.
	AfterOpen (see page 7045)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 7046)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 7047)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 7047)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 7048)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 7048)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 7049)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 7049)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 7050)	Occurs before an application enters insert mode.
	BeforeOpen (see page 7051)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 7052)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 7052)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 7053)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 7053)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 7054)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 7054)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 7055)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 7056)	Occurs when an application inserts or appends a new dataset record.

	OnPostError (see page 7056)	Occurs when an application attempts to modify or insert a record and an exception is raised.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActiveBuffer (see page 6909)	Returns a pointer to the buffer for the active record.
	AddIndex (see page 10184)	Creates a new index for the table.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 6910)	Adds a new, empty record to the end of the dataset.
	AppendRecord (see page 6911)	Adds a new, populated record to the end of the dataset and posts it.
	ApplyRange (see page 10185)	Applies a range to the dataset.
	ApplyUpdates (see page 9894)	Writes a dataset's pending cached updates to the database.
V	Assign (see page 2930)	Copies the contents of another, similar object.
	BatchMove (see page 10186)	Moves records from a dataset into this table.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BookmarkValid (see page 6916)	Indicates the validity of a specified bookmark.
V	BookmarkValid (see page 9895)	Tests the validity of a specified bookmark.
V	Cancel (see page 6916)	Cancels modifications to the active record if those changes are not yet posted.
V	Cancel (see page 9895)	Cancels modifications to the current record if those changes are not yet posted.
	CancelRange (see page 10186)	Removes any ranges currently in effect for the table.
	CancelUpdates (see page 9896)	Clears all pending cached updates from the cache and restores the dataset its prior state.
	CheckBrowseMode (see page 6918)	Automatically posts or cancels data changes when the active record changes.
	CheckOpen (see page 10014)	Checks the result of a call to the Borland (see page 1761) Database (see page 10021) Engine (BDE).
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearFields (see page 6919)	Clears the contents of all fields for the active record.
	Close (see page 6920)	Closes a dataset.
	CloseDatabase (see page 10014)	Closes a database connection associated with the database session.
	CloseIndexFile (see page 10188)	Closes a specified dBASE non-production index file.
	CommitUpdates (see page 9897)	Clears the cached updates buffer.
V	CompareBookmarks (see page 6921)	Implements a virtual function to compare two bookmarks.
V	CompareBookmarks (see page 9898)	Indicates the relationship between two bookmarks.
	ConstraintCallBack (see page 9898)	Specifies the callback function that allows the dataset to communicate with the BDE constraint layer.
	ConstraintsDisabled (see page 9899)	Indicates whether constraints are enabled for a dataset.
	ControlsDisabled (see page 6921)	Indicates whether data-aware controls update their display to reflect changes to the dataset.
	CopyFields (see page 6922)	This is CopyFields, a member of class TDataSet.
V	Create (see page 10182)	Creates an instance of a table component.
V	CreateBlobStream (see page 6922)	Provides the interface for a method that creates a blob stream for a Binary large object (BLOB) field in the dataset.
V	CreateBlobStream (see page 9899)	Returns a TStream object for reading or writing the data in a specified blob field.
	CreateTable (see page 10189)	Builds a new table using new structure information.
	CursorPosChanged (see page 6923)	Marks the internal cursor position as invalid.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 6924)	Deletes the active record and positions the dataset on the next record.

	DeleteIndex (see page 10191)	Deletes a secondary index for the table.
	DeleteTable (see page 10192)	Deletes an existing database table.
V	Destroy (see page 10182)	Destroys the instance of a table.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableConstraints (see page 9902)	Disables application of server constraints on the dataset.
	DisableControls (see page 6925)	Disables data display in data-aware controls associated with the dataset.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6932)	Enables editing of data in the dataset.
	EditKey (see page 10194)	Enables modification of the search key buffer.
	EditRangeEnd (see page 10194)	Enables changing the ending value for an existing range.
	EditRangeStart (see page 10195)	Enables changing the starting value for an existing range.
	EmptyTable (see page 10196)	Deletes all records from the table.
	EnableConstraints (see page 9902)	Enables application of server constraints against dataset entries.
	EnableControls (see page 6934)	Re-enables data display in data-aware controls associated with the dataset.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FetchAll (see page 9903)	Retrieves all records from the current cursor position to the end of the file and stores them locally.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FieldByName (see page 6936)	Finds a field based on its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindField (see page 6938)	Searches for a specified field in the dataset.
	FindFirst (see page 6939)	Implements a virtual method for positioning the dataset on the first record, respecting any filters.
	FindKey (see page 10196)	Searches for a record containing specified field values.
	FindLast (see page 6940)	Implements a virtual method for positioning the dataset on the last record, respecting any filters.
	FindNearest (see page 10197)	Moves the cursor to the record that most closely matches a specified set of key values.
	FindNext (see page 6940)	Implements a virtual method for positioning the dataset on the next record, respecting any filters.
	FindPrior (see page 6941)	Implements a virtual method for positioning the dataset on the previous record, respecting any filters.
	First (see page 6942)	Moves to the first record in the dataset.
	FlushBuffers (see page 9903)	Posts all changes that have been written to the record buffer.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeBookmark (see page 6945)	Frees the resources allocated for a specified bookmark.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
V	GetBlobFieldData (see page 6947)	Reads BLOB data into a buffer.
V	GetBlobFieldData (see page 9904)	Reads BLOB data into a buffer.
V	GetBookmark (see page 6948)	Allocates a bookmark for the active record in the dataset.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
V	GetCurrentRecord (see page 6950)	Implements a virtual function to retrieve the current record in a buffer.
V	GetCurrentRecord (see page 9905)	Retrieves the current record into a buffer.
V	GetDetailDataSets (see page 6951)	Fills a list with a dataset for every detail dataset that is not the value of a nested dataset field.
V	GetDetailLinkFields (see page 10199)	Lists the field components that link this dataset as a detail of a master dataset.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
V	GetFieldData (see page 6952)	This is the overview for the GetFieldData method overload.
V	GetFieldData (see page 9906)	This is the overview for the GetFieldData method overload.
	GetFieldList (see page 6953)	Retrieves a specified set of field objects into a list.
V	GetFieldNames (see page 6953)	This is the overview for the GetFieldNames method overload.

	GetIndexInfo (see page 9907)	Retrieves information about the current index into the index data fields of the dataset.
	GetIndexNames (see page 10200)	Retrieves a list of available indexes for a table.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GotoBookmark (see page 6957)	Implements a virtual method to position the dataset on the record to which a specified bookmark points.
	GotoCurrent (see page 10201)	Synchronizes the current record for this table with the current record of a specified table component.
	GotoKey (see page 10201)	Moves the cursor to a record specified by the current key.
	GotoNearest (see page 10202)	Moves the cursor to the record that most closely matches the current key.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 6959)	Inserts a new, empty record in the dataset.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertRecord (see page 6961)	Inserts a new, populated record to the dataset and posts it.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsEmpty (see page 6967)	Indicates whether the dataset contains no records.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsLinkedTo (see page 6967)	Indicates whether a dataset is linked to a specified data source.
V	IsSequenced (see page 6967)	Indicates whether the underlying database table uses record numbers to indicate the order of records.
V	IsSequenced (see page 9915)	IsSequenced indicates whether sequence numbers are available for database records.
	Last (see page 6968)	Moves to the last record in the dataset.
V	Locate (see page 6970)	Implements a virtual method for searching a dataset for a specified record and making it the active record.
V	Locate (see page 9915)	Searches the dataset for a specified record and makes that record the current record.
	LockTable (see page 10203)	Locks a Paradox or dBASE table.
V	Lookup (see page 6970)	Implements a virtual method to retrieve field values from a record that matches specified search values.
V	Lookup (see page 9916)	Retrieves field values from a record that matches specified search values.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveBy (see page 6971)	Moves to another record relative to the active record in the dataset.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 6973)	Moves to the next record in the dataset.
	Open (see page 6976)	Opens the dataset.
	OpenDatabase (see page 10016)	Opens the database that contains the dataset.
	OpenIndexFile (see page 10204)	Opens a specified dBASE non-production index file.
V	Post (see page 6977)	Implements a virtual method to write a modified record to the database or change log.
V	Post (see page 9918)	Writes a modified record to the database.
	Prior (see page 6979)	Moves to the previous record in the dataset.
	PSEndTransaction (see page 7578)	Ends a transaction that was started by a call to PSStartTransaction (see page 7586).
	PSExecute (see page 7578)	Executes the SQL command associated with the dataset.
	PSExecuteStatement (see page 7579)	Executes a specified SQL command.
	PSGetAttributes (see page 7579)	Returns information that is stored in data packets as Name/Value pairs.

	PSGetParams (see page 7582)	Returns the current parameter values of the dataset.
	PSGetQuoteChar (see page 7582)	Returns the character or characters to use in generated SQL statements to enclose quoted strings.
	PSGetUpdateException (see page 7583)	Generates an EUpdateError (see page 6732) object based on another exception object.
	PSInTransaction (see page 7583)	Indicates whether actions against the dataset occur in the context of a transaction.
	PSIsSQLBased (see page 7584)	Indicates whether the dataset includes native SQL support.
	PSIsSQLSupported (see page 7584)	Indicates whether the dataset can execute SQL statements.
	PSReset (see page 7585)	Resets the dataset so that it is positioned on the first record.
	PSStartTransaction (see page 7586)	Starts a transaction that encapsulates all activity until a call to PSEndTransaction (see page 7578).
	PSUpdateRecord (see page 7586)	Applies a single update to the underlying database table or tables.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 6991)	Re-fetches data from the database to update a dataset's view of data.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	RenameTable (see page 10208)	Renames the Paradox or dBASE table associated with this table component.
V	Resync (see page 6994)	Re-fetches the active record and the records that precede and follow it.
	RevertRecord (see page 9922)	Restores the current record in the dataset to an unmodified state when cached updates are enabled.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetFields (see page 6997)	Sets the values for all fields in a record
	SetKey (see page 10208)	Enables setting of keys and ranges for a dataset prior to a search.
	SetRange (see page 10209)	Sets the starting and ending values of a range, and applies it.
	SetRangeEnd (see page 10211)	Indicates that subsequent assignments to field values specify the end of the range of rows to include in the dataset.
	SetRangeStart (see page 10212)	Indicates that subsequent assignments to field values specify the start of the range of rows to include in the dataset.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	Translate (see page 7001)	Implements a virtual procedure to copy a data string from a source to a destination, optionally performing character translation during the copy.
V	Translate (see page 9928)	Converts a data string between the Microsoft ANSI character set, and the local code page (OEM character set).
	UnlockTable (see page 10212)	Removes a previously applied lock on a Paradox or dBASE table.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateCursorPos (see page 7001)	Positions the cursor on the active record.
	UpdateRecord (see page 7002)	Ensures that data-aware controls and detail datasets reflect record updates.
V	UpdateStatus (see page 7002)	Reports the update status for the active record.
V	UpdateStatus (see page 9928)	Reports the update status for the current record.

Public Properties

	Name	Description
	Active (see page 7004)	Specifies whether or not a dataset is open.
R	AggFields (see page 7006)	Contains any aggregate fields.
	AutoCalcFields (see page 7006)	Determines when the OnCalcFields (see page 7053) event is triggered and when lookup field values are calculated.
	BlockReadSize (see page 7007)	Determines how many record buffers are read in each block.
R	Bof (see page 7008)	Indicates whether the first record in the dataset is active.
	Bookmark (see page 7009)	Specifies the current bookmark in the dataset.
	CacheBlobs (see page 9932)	Determines whether BLOB fields are cached in memory.
R	CanModify (see page 7012)	Indicates whether the dataset permits write access to data.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.

R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	Database (see page 10021)	Identifies the database component for which this dataset represents one or more tables.
	DataSetField (see page 7013)	Indicates the persistent TDataSetField (see page 7060) object that owns a nested dataset.
R	DataSource (see page 7014)	Represents the data source of another dataset that supplies values to the dataset.
R	DBHandle (see page 10023)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) database handle for the dataset.
R	DBLocale (see page 10024)	Identifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) language driver for the dataset component.
R	DBSession (see page 10024)	Identifies the database session component associated with this dataset.
R	DefaultFields (see page 7014)	Indicates whether a dataset's underlying field components are generated dynamically when the dataset is opened.
R	Designer (see page 7015)	Returns a pointer to the Dataset designer for the dataset.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Eof (see page 7015)	Indicates whether a dataset is positioned at the last record.
R	Exists (see page 10215)	Indicates whether the underlying database table exists.
R	ExpIndex (see page 9933)	Indicates whether a dataset is using a dBASE expression index.
R	FieldCount (see page 7017)	Indicates the number of field components associated with the dataset.
R	FieldDefList (see page 7019)	Points to the list of field definitions for the dataset.
R	FieldList (see page 7022)	Lists the field components of a dataset.
R	Fields (see page 7023)	Lists all non-aggregate field components of the dataset.
	FieldValues (see page 7025)	Provides access to the values for all fields in the active record for the dataset
	Filter (see page 7026)	Specifies the text of the current filter for a dataset.
	Filtered (see page 7027)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 7027)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
R	Found (see page 7028)	Indicates whether or not moving to a different record is successful.
R	Handle (see page 9933)	Specifies the Borland (see page 1761) Database Engine (BDE) cursor handle for the dataset.
	Handle (see page 10027)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) cursor handle for the dataset.
R	IndexFieldCount (see page 10220)	Indicates the number of fields that comprise the current key.
	IndexFields (see page 10221)	Lists the fields of the current index.
R	IsUniDirectional (see page 7029)	Indicates whether the dataset is unidirectional.
	KeyExclusive (see page 10223)	Specifies how the upper and lower boundaries for a range should be interpreted.
	KeyFieldCount (see page 10223)	Specifies the number of fields to use when conducting a partial key search on a multi-field key.
R	KeySize (see page 9934)	Specifies the size of the key for the current index of the dataset.
R	Locale (see page 9934)	Identifies the Borland (see page 1761) Database Engine (BDE) language driver for the dataset.
R	Modified (see page 7029)	Indicates whether the active record is modified.
	ObjectView (see page 7031)	Specifies whether fields are stored hierarchically or flattened out in the Fields (see page 7023) property.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RecNo (see page 7031)	Indicates the active record in the dataset.
R	RecordCount (see page 7032)	Indicates the total number of records associated with the dataset.
R	RecordSize (see page 7035)	Indicates the size of a record in the dataset.
	SparseArrays (see page 7036)	Determines whether a unique TField (see page 7115) object is created for each element of an array field.
R	State (see page 7036)	Indicates the current operating mode of the dataset.

	TableLevel (see page 10226)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) driver-dependent table level.
	UpdateRecordTypes (see page 9936)	Specifies the type of records visible in a dataset when cached updates are enabled.
R	UpdatesPending (see page 9937)	Indicates whether the cached updates buffer contains records that are not yet applied.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	AfterCancel (see page 9938)	Occurs after an application completes a request to cancel modifications to the active record.
	AfterClose (see page 9940)	Occurs after an application closes a dataset.
	AfterDelete (see page 9942)	Occurs after an application deletes a record.
	AfterEdit (see page 9944)	Occurs after an application starts editing a record.
	AfterInsert (see page 9945)	Occurs after an application inserts a new record.
	AfterOpen (see page 9946)	Occurs after an application completes opening a dataset and before any data access occurs.
	AfterPost (see page 9947)	Occurs after an application writes the active record to the database or change log and returns to browse state.
	AfterRefresh (see page 9947)	Occurs after an application refreshes the data in the dataset.
	AfterScroll (see page 9948)	Occurs after an application scrolls from one record to another.
	BeforeCancel (see page 9948)	Occurs before an application executes a request to cancel changes to the active record.
	BeforeClose (see page 9949)	Occurs immediately before the dataset closes.
	BeforeDelete (see page 9949)	Occurs before an application attempts to delete the active record.
	BeforeEdit (see page 9950)	Occurs before an application enters edit mode for the active record.
	BeforeInsert (see page 9950)	Occurs before an application enters insert mode.
	BeforeOpen (see page 9952)	Occurs before an application executes a request to open a dataset.
	BeforePost (see page 9952)	Occurs before an application posts changes for the active record to the database or change log.
	BeforeRefresh (see page 9953)	Occurs immediately before an application refreshes the data in the dataset.
	BeforeScroll (see page 9953)	Occurs before an application scrolls from one record to another.
	OnCalcFields (see page 9954)	Occurs when an application recalculates calculated fields.
	OnDeleteError (see page 9955)	Occurs when an application attempts to delete a record and an exception is raised.
	OnEditError (see page 9955)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnFilterRecord (see page 10028)	Occurs each time a different record in the dataset becomes the active record and filtering is enabled.
	OnNewRecord (see page 9955)	Occurs when an application inserts or appends a new dataset record.
	OnPostError (see page 9956)	Occurs when an application attempts to modify or insert a record and an exception is raised.
	OnUpdateError (see page 9956)	Occurs if an exception is generated when cached updates are applied to a database.
	OnUpdateRecord (see page 9957)	Occurs when cached updates are applied to a record.

Published Properties

	Name	Description
	Active (see page 9929)	Specifies whether or not a dataset is open.
	AutoCalcFields (see page 9931)	Determines when the OnCalcFields event is triggered and when lookup field values are calculated.
	AutoRefresh (see page 10021)	Specifies whether server-generated field values are refetched automatically.
	CachedUpdates (see page 9932)	Specifies whether cached updates are enabled for a dataset.
	Constraints (see page 10214)	Specifies record-level constraints that must be met when editing the data.
	DatabaseName (see page 10022)	Specifies the name of the database associated with this dataset.
	DefaultIndex (see page 10214)	Specifies if the data in the table should be ordered on a default index when opened.
	Exclusive (see page 10215)	Enables an application to gain sole access to a Paradox or dBASE table.

	FieldDefs (see page 10217)	Points to the list of field definitions for the dataset.
	Filter (see page 10025)	Specifies the text of the current filter for a dataset.
	Filtered (see page 10026)	Specifies whether or not filtering is active for a dataset.
	FilterOptions (see page 10026)	Specifies whether or not filtering is case insensitive, and whether or not partial comparisons are permitted when filtering records.
	IndexDefs (see page 10219)	Contains information about the indexes for a table.
	IndexFieldNames (see page 10220)	Lists the columns to use as an index for a table.
	IndexFiles (see page 10221)	Specifies one or more dBASE index file to use for a dBASE table that uses non-production indexes.
	IndexName (see page 10222)	Identifies a secondary index for the table.
	MasterFields (see page 10224)	Specifies one or more fields in a master table to link with corresponding fields in this table in order to establish a master-detail relationship between the tables.
	MasterSource (see page 10224)	Specifies the name of the data source for a dataset to use as a master table in establishing a detail-master relationship between this table and another one.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectView (see page 9935)	Specifies whether fields are stored hierarchically or flattened out in the Fields property.
R	Ranged (see page 10225)	This is Ranged, a member of class TTable.
	ReadOnly (see page 10225)	Specifies whether a table is read-only for this application.
	SessionName (see page 10027)	Identifies the name of the session with which this dataset is associated.
	StoreDefs (see page 10226)	Indicates whether the table's field and index definitions persist with the data module or form.
	TableName (see page 10226)	Indicates the name of the database table that this component encapsulates.
	TableType (see page 10227)	Indicates the database table structure for the table that this component represents.
	Tag (see page 2808)	Stores an integer value as part of a component.
	UpdateMode (see page 10228)	Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.
	UpdateObject (see page 10228)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.19.2 TTable.Create Constructor

Creates an instance of a table component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTable(TComponent * AOwner);
```

Description

Call Create to instantiate a table declared in an application if it was not placed on a form or data module at design time. Create calls its inherited constructor, creates an empty index definitions list, creates an empty data link, and creates an empty list of index files.

See Also

TDataLink (see page 6876)

TIndexDefs (see page 7292)

53.1.19.3 TTable.Destroy Destructor

Destroys the instance of a table.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTable();
```

Description

Do not call Destroy directly. Instead, call Free, which verifies that the table is not nil before calling Destroy. Destroy frees the index files list for the table, frees its data link, frees its index definitions, and then calls its inherited destructor.

See Also

Create (see page 10182)

Free (see page 22300)

53.1.19.4 TTable Methods

The methods of the TTable class are listed here.

Protected Methods

	Name	Description
	CreateHandle (see page 10189)	This is CreateHandle, a member of class TTable.
	DataEvent (see page 10191)	This is DataEvent, a member of class TTable.
	DefChanged (see page 10191)	This is DefChanged, a member of class TTable.
	DestroyHandle (see page 10193)	This is DestroyHandle, a member of class TTable.
	DestroyLookupCursor (see page 10193)	This is DestroyLookupCursor, a member of class TTable.
	DoOnNewRecord (see page 10194)	This is DoOnNewRecord, a member of class TTable.
	EncodeFieldDesc (see page 10196)	This is EncodeFieldDesc, a member of class TTable.
	EncodeIndexDesc (see page 10196)	This is EncodeIndexDesc, a member of class TTable.
	GetCanModify (see page 10198)	This is GetCanModify, a member of class TTable.
	GetDataSource (see page 10199)	This is GetDataSource, a member of class TTable.
	GetFileName (see page 10199)	This is GetFileName, a member of class TTable.
	GetHandle (see page 10199)	This is GetHandle, a member of class TTable.
	GetLanguageDriverName (see page 10200)	This is GetLanguageDriverName, a member of class TTable.
	GetLookupCursor (see page 10200)	This is GetLookupCursor, a member of class TTable.
	GetTableType (see page 10200)	This is GetTableType, a member of class TTable.
	InitFieldDefs (see page 10203)	This is InitFieldDefs, a member of class TTable.
	IsProductionIndex (see page 10203)	This is IsProductionIndex, a member of class TTable.
	NativeTableName (see page 10203)	This is NativeTableName, a member of class TTable.
	PrepareCursor (see page 10204)	This is PrepareCursor, a member of class TTable.
	PSGetCommandText (see page 10204)	Gets the SQL command to be executed by PSExecute.
	PSGetCommandType (see page 10205)	Gets the command type to be executed by PSExecute.
	PSGetDefaultOrder (see page 10205)	Returns the definition of an index that imposes the default order on the data included in data packets.
	PSGetIndexDefs (see page 10205)	Returns the definitions of all specified indexes defined for the dataset.
	PSGetKeyFields (see page 10206)	Returns the names of all fields required to uniquely identify records in the data packet.
	PSGetTableName (see page 10206)	Returns the name of the dataset table that appears in generated SQL statements.
	PSSetCommandText (see page 10207)	Assigns a specified SQL command to be executed by PSExecute.
	PSSetParams (see page 10207)	Assigns the specified parameter values to the dataset.
	UpdateIndexDefs (see page 10213)	This is UpdateIndexDefs, a member of class TTable.

Public Methods

	Name	Description
	AddIndex (see page 10184)	Creates a new index for the table.
	ApplyRange (see page 10185)	Applies a range to the dataset.
	BatchMove (see page 10186)	Moves records from a dataset into this table.
	CancelRange (see page 10186)	Removes any ranges currently in effect for the table.
	CloseIndexFile (see page 10188)	Closes a specified dBASE non-production index file.
	CreateTable (see page 10189)	Builds a new table using new structure information.
	DeleteIndex (see page 10191)	Deletes a secondary index for the table.
	DeleteTable (see page 10192)	Deletes an existing database table.
	EditKey (see page 10194)	Enables modification of the search key buffer.
	EditRangeEnd (see page 10194)	Enables changing the ending value for an existing range.
	EditRangeStart (see page 10195)	Enables changing the starting value for an existing range.
	EmptyTable (see page 10196)	Deletes all records from the table.
	FindKey (see page 10196)	Searches for a record containing specified field values.
	FindNearest (see page 10197)	Moves the cursor to the record that most closely matches a specified set of key values.
V	GetDetailLinkFields (see page 10199)	Lists the field components that link this dataset as a detail of a master dataset.
	GetIndexNames (see page 10200)	Retrieves a list of available indexes for a table.
	GotoCurrent (see page 10201)	Synchronizes the current record for this table with the current record of a specified table component.
	GotoKey (see page 10201)	Moves the cursor to a record specified by the current key.
	GotoNearest (see page 10202)	Moves the cursor to the record that most closely matches the current key.
	LockTable (see page 10203)	Locks a Paradox or dBASE table.
	OpenIndexFile (see page 10204)	Opens a specified dBASE non-production index file.
	RenameTable (see page 10208)	Renames the Paradox or dBASE table associated with this table component.
	SetKey (see page 10208)	Enables setting of keys and ranges for a dataset prior to a search.
	SetRange (see page 10209)	Sets the starting and ending values of a range, and applies it.
	SetRangeEnd (see page 10211)	Indicates that subsequent assignments to field values specify the end of the range of rows to include in the dataset.
	SetRangeStart (see page 10212)	Indicates that subsequent assignments to field values specify the start of the range of rows to include in the dataset.
	UnlockTable (see page 10212)	Removes a previously applied lock on a Paradox or dBASE table.

53.1.19.4.1 TTable.AddIndex Method

Creates a new index for the table.

Pascal

```
procedure AddIndex(const Name: string; const Fields: string; Options: TIndexOptions; const
DescFields: string = '');
```

C++

```
__fastcall AddIndex(const AnsiString Name, const AnsiString Fields, TIndexOptions Options,
const AnsiString DescFields = '');
```

Description

Call AddIndex to create a new index for the already-existing table associated with a dataset component. The index created with this procedure is added to the database table underlying the dataset component.

Name is the name of the new index. Name must contain an index name that is valid for the particular database type used (naming rules vary from one database type to another).

Fields contains the names of the fields on which the new index will be based. If more than one field is used, separate the field names in the list with semicolons.

Options is a set of attributes for the index. The Options parameter may contain any one, multiple, or none of the TIndexOptions constants: ixPrimary, ixUnique, ixDescending, ixCaseInsensitive, and ixExpression. Not all database systems will necessarily support all of these options. Even within a particular table type, any given option may only be supported in certain versions of a table type. Consult the documentation for the particular database system used to determine which options are and are not supported. See the topic for the TIndexOptions type for definitions of individual constants and the implications of their use.

DescFields is a string containing a list of field names, separated by semicolons. The fields specified in DescFields are the fields in the new index for which the ordering will be descending. Fields in the index definition but not in the DescFields list use the default ascending ordering. It is possible that a single index can have fields using both ascending and descending ordering.

```
Table1.AddIndex('MostPaid', 'CustNo;SaleDate;AmountPaid', [ixCaseInsensitive],
'SaleDate;AmountPaid');
TIndexOptions Options;
Options << ixCaseInsensitive;
Table1->AddIndex("MostPaid", "CustNo;SaleDate;AmountPaid", Options, "SaleDate;AmountPaid");
```

Warning: Attempting to create an index using options that are not applicable to the table type causes AddIndex to raise an exception.

dBASE tables only support primary indexes and true unique indexes when the table level is 7 or higher (concurrent with Visual dBASE 7). dBASE tables do not support case-insensitive indexes at all. You must use the ixExpression constant when the index is based on multiple fields or uses dBASE Data Manipulation Language (DML) functions (that is, for expression indexes). Multi-field dBASE indexes cannot be created simply with a list of field names (separated by semicolons) in the Fields parameter of AddIndex. The ixExpression constant is only applicable to dBASE tables.

Paradox tables support the ixDescending option for secondary indexes if the table level is 7 or higher and ixUnique if the table level is 5 or higher. The ixDescending and ixCaseInsensitive constants are not applicable to primary indexes.

For other table types, see the vendor-supplied documentation for the particular database system for details on what index options are applicable.

See Also

DeleteIndex (see page 10191)

IndexDefs (see page 10219)

AddIndexDef (see page 7296)

IndexFiles (see page 10221)

IndexName (see page 10222)

53.1.19.4.2 TTable.ApplyRange Method

Applies a range to the dataset.

Pascal

```
procedure ApplyRange;
```

C++

```
__fastcall ApplyRange();
```

Description

Call ApplyRange to cause a range established with SetRangeStart (see page 10212) and SetRangeEnd (see page 10211), or EditRangeStart (see page 10195) and EditRangeEnd (see page 10194), to take effect. When a range is in effect, only those records that fall within the range are available to the application for viewing and editing.

After a call to ApplyRange, the cursor is left on the first record in the range.

See Also

CancelRange (see page 10186)

EditRangeEnd (see page 10194)

EditRangeStart (see page 10195)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

Applying or Canceling a Range

Modifying a Range

53.1.19.4.3 TTable.BatchMove Method

Moves records from a dataset into this table.

Pascal

```
function BatchMove(ASource: TBDEDataSet; AMode: TBatchMode): Longint;
```

C++

```
__fastcall Longint BatchMove(TBDEDataSet ASource, TBatchMode AMode);
```

Description

Call BatchMove to

Copy records from another table into this table.

Update records in this table that occur in another table.

Append records from another table to the end of this table.

Delete records in this table that occur in another table.

ASource is a dataset component containing the records to import or (if deleting) match. The AMode parameter indicates what operation to perform (copy, update, append, or delete). This table is the destination of the batch operation.

BatchMove returns the number of records operated on.

See Also

TBatchMove (see page 9858)

Importing Data from Another Table

Using TTable

53.1.19.4.4 TTable.CancelRange Method

Removes any ranges currently in effect for the table.

Pascal

```
procedure CancelRange;
```

C++

```
__fastcall CancelRange();
```

Description

Call CancelRange to remove a range currently applied to a table. Canceling a range reenables access to all records in the dataset.

Delphi Examples:

```
{
The following example sets a range for a dataset. The form
requires two edit boxes, a data source, a client dataset or
table, a db grid, and a button.  Make sure that the Table1
info in FormActivate agrees with the table used.  Also, the
caption for the button must be initialized to '&ApplyRange'.
}

procedure TForm1.FormActivate(Sender: TObject);
begin
  Table1.DatabaseName := 'DBDEMOS';
  Table1.TableName := 'CustInfo';
  Table1.Active := True;
  Table1.IndexName := '';
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  if Button2.Caption = '&Apply Range' then
    begin
      Table1.SetRange([Edit1.Text],[Edit2.Text]);
      Button2.Caption := '&Drop Range';
    end
  else
    begin
      Table1.CancelRange;
      Table1.Refresh;
      Button2.Caption := '&Apply Range';
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
```

```
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= False;
  end;
```

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

Applying or Canceling a Range

53.1.19.4.5 TTable.CloseIndexFile Method

Closes a specified dBASE non-production index file.

Pascal

```
procedure CloseIndexFile(const IndexFileName: string);
```

C++

```
__fastcall CloseIndexFile(const AnsiString IndexFileName);
```

Description

Call CloseIndexFile to shut down a specified dBASE non-production index file. IndexFileName is the name of the file to close, and is either the name of an index file previously opened with a call to OpenIndexFile (see page 10204) or previously opened because the file's name is listed in the IndexFiles (see page 10221) property.

Once closed, non-production index files are no longer maintained. Subsequent changes made to the dataset are not reflected in the index.

See Also

IndexFiles (see page 10221)

OpenIndexFile (see page 10204)

53.1.19.4.6 TTable.CreateHandle Method

Pascal

```
function CreateHandle: HDBICur; override;
```

C++

```
virtual __fastcall HDBICur CreateHandle();
```

Description

This is CreateHandle, a member of class TTable.

53.1.19.4.7 TTable.CreateTable Method

Builds a new table using new structure information.

Pascal

```
procedure CreateTable;
```

C++

```
__fastcall CreateTable();
```

Description

Call CreateTable at runtime to create a table using this dataset's current definitions. If the table already exists, CreateTable overwrites the table's structure and data. To avoid overwriting an existing table, check the Exists (see page 10215) property before calling CreateTable.

If the FieldDefs (see page 10217) property contains values, these values are used to create field definitions. Otherwise the Fields property is used. One or both of these properties must contain values in order to create a database table.

If the IndexDefs (see page 10219) property contain values, these values are used to create indexes on the table.

Delphi Examples:

```
{ The following example shows how to create a table. }
procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Close;
  Table1.DeleteTable;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
```

```
    Table1:= TTable.Create(Form1);
    with Table1 do
    begin
      DatabaseName := 'DBDEMOS';
      TableType := ttParadox;
      TableName := 'CustInfo';
      Table1.Active := False;
      { Don't overwrite an existing table }
      if Table1.Exists then
        MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
      else
      begin
        { The Table component must not be active }
        { First, describe the type of table and give }
        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
            DataType := ftInteger;
            Required := True;
          end;
          with AddFieldDef do
          begin
            Name := 'Field2';
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= True;
  end;
```

53.1.19.4.8 TTable.DataEvent Method

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); override;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

This is DataEvent, a member of class TTable.

53.1.19.4.9 TTable.DefChanged Method

Pascal

```
procedure DefChanged(Sender: TObject); override;
```

C++

```
virtual __fastcall DefChanged(TObject * Sender);
```

Description

This is DefChanged, a member of class TTable.

53.1.19.4.10 TTable.DeleteIndex Method

Deletes a secondary index for the table.

Pascal

```
procedure DeleteIndex(const Name: string);
```

C++

```
__fastcall DeleteIndex(const AnsiString Name);
```

Description

Call DeleteIndex to remove a secondary index for a table. Name is the name of the index to delete. DeleteIndex cannot remove a primary index.

Note: To delete an index, an application must first open the table for exclusive access.

See Also

AddIndex (see page 10184)

Exclusive (see page 10215)

IndexDefs (see page 10219)

53.1.19.4.11 TTable.DeleteTable Method

Deletes an existing database table.

Pascal

```
procedure DeleteTable;
```

C++

```
__fastcall DeleteTable();
```

Description

Call DeleteTable to delete an existing database table associated with the table component through its DatabaseName (see page 10022) and TableName (see page 10226) properties. A table must be closed before it can be deleted.

Warning: Deleting a table erases any data the table contains and destroys the table's structure information.

Delphi Examples:

```
{ The following example shows how to create a table. }
procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Close;
  Table1.DeleteTable;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
```

```
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= True;
  end;
```

See Also

Active (see page 7004)

Close (see page 6920)

53.1.19.4.12 TTable.DestroyHandle Method

Pascal

```
procedure DestroyHandle; override;
```

C++

```
virtual __fastcall DestroyHandle();
```

Description

This is DestroyHandle, a member of class TTable.

53.1.19.4.13 TTable.DestroyLookupCursor Method

Pascal

```
procedure DestroyLookupCursor; override;
```

C++

```
virtual __fastcall DestroyLookupCursor();
```

Description

This is DestroyLookupCursor, a member of class TTable.

53.1.19.4.14 TTable.DoOnNewRecord Method

Pascal

```
procedure DoOnNewRecord; override;
```

C++

```
virtual __fastcall DoOnNewRecord();
```

Description

This is DoOnNewRecord, a member of class TTable.

53.1.19.4.15 TTable.EditKey Method

Enables modification of the search key buffer.

Pascal

```
procedure EditKey;
```

C++

```
__fastcall EditKey();
```

Description

Call EditKey to put the dataset in dsSetKey state while preserving the current contents of the current search key buffer. To determine current search keys, you can use the IndexFields (see page 10221) property to iterate over the fields used by the current index.

EditKey is especially useful when performing multiple searches where only one or two field values among many change between each search.

State (see page 7036)

53.1.19.4.16 TTable.EditRangeEnd Method

Enables changing the ending value for an existing range.

Pascal

```
procedure EditRangeEnd;
```

C++

```
__fastcall EditRangeEnd();
```

Description

Call EditRangeEnd to change the ending value for an existing range. To specify an end range value, call FieldByName after calling EditRangeEnd. After assigning a new ending value, call ApplyRange (see page 10185) to activate the modified range.

Note: With Paradox or dBASE tables, EditRangeEnd works only on indexed fields. With SQL databases, EditRangeEnd also works with any columns specified in the IndexFieldNames (see page 10220) property.

See Also

ApplyRange (see page 10185)

CancelRange (see page 10186)

EditRangeStart (see page 10195)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

Modifying a Range

53.1.19.4.17 TTable.EditRangeStart Method

Enables changing the starting value for an existing range.

Pascal

```
procedure EditRangeStart;
```

C++

```
__fastcall EditRangeStart();
```

Description

Call EditRangeStart to change the starting value for an existing range. To specify a start range value, call FieldByName after calling EditRangeStart. After assigning a new ending value, call ApplyRange (see page 10185) to activate the modified range.

Note: With Paradox or dBASE tables, EditRangeStart works only on indexed fields. With SQL databases, EditRangeStart also works with any columns specified in the IndexFieldNames (see page 10220) property.

See Also

ApplyRange (see page 10185)

CancelRange (see page 10186)

EditRangeEnd (see page 10194)

FieldByName (see page 6936)

IndexFieldNames (see page 10220)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

Modifying a Range

53.1.19.4.18 TTable.EmptyTable Method

Deletes all records from the table.

Pascal

```
procedure EmptyTable;
```

C++

```
__fastcall EmptyTable();
```

Description

The EmptyTable method deletes all records from the database table specified by the DatabaseName (see page 10022) and TableName (see page 10226) properties.

Note: Deletion of records can fail if the user lacks sufficient privileges to perform the delete operation.

See Also

DeleteTable (see page 10192)

53.1.19.4.19 TTable.EncodeFieldDesc Method

Pascal

```
procedure EncodeFieldDesc(var FieldDesc: BDEFLDDesc; const Name: string; DataType: TFieldType;
Size: Integer; Precision: Integer);
```

C++

```
__fastcall EncodeFieldDesc(BDEFLDDesc FieldDesc, const AnsiString Name, TFieldType DataType,
int Size, int Precision);
```

Description

This is EncodeFieldDesc, a member of class TTable.

53.1.19.4.20 TTable.EncodeIndexDesc Method

Pascal

```
procedure EncodeIndexDesc(var IndexDesc: IDXDesc; const Name: string; const FieldExpression:
string; Options: TIndexOptions; const DescFields: string = '');
```

C++

```
__fastcall EncodeIndexDesc(IDXDesc IndexDesc, const AnsiString Name, const AnsiString
FieldExpression, TIndexOptions Options, const AnsiString DescFields = '');
```

Description

This is EncodeIndexDesc, a member of class TTable.

53.1.19.4.21 TTable.FindKey Method

Searches for a record containing specified field values.

Pascal

```
function FindKey(const KeyValues: array of const): Boolean;
```

C++

```
__fastcall Boolean FindKey(const array of const KeyValues);
```

Description

Call FindKey to search for a specific record in a dataset. KeyValues contains a comma-delimited array of field values, called a key. Each value in the key can be a literal, a variable, nil (Delphi) or NULL (C++). If the number of values passed in KeyValues is less than the number of columns in the index used for the search, the missing values are assumed to be null. KeyValues_Size specifies the index of the last value in KeyValues (one less than the total number of values supplied). In the statement below, the FindKey method is used to find the table row with the value "'Princess Island SCUBA" in the index field.

```
Table1.FindKey(['Princess Island SCUBA']);
TVarRec vr = ("Princess Island SCUBA");
Table1->FindKey(&vr, 0);
```

Note: In C++ code, the search values can be passed to FindKey using either a TVarRec (as above) or an ARRAYOFCONST construct. The example below performs the same search as the preceding example, but using ARRAYOFCONST.

```
Table1->FindKey(ARRAYOFCONST(("Princess Island SCUBA")));
```

For Paradox and dBASE tables, the key must always be an index, which can be specified in the IndexName (see page 10222) property. If IndexName (see page 10222) is empty, FindKey uses the table's primary index. Note that FindKey does not work with dBASE expression indexes. Use the GotoKey (see page 10201) or GotoNearest (see page 10202) method instead.

For SQL tables, the key may correspond to a specified index in IndexName (see page 10222), or to a list of field names in the IndexFieldNames (see page 10220) property.

If the search is successful, FindKey positions the cursor on the matching record and returns true. Otherwise the cursor is not moved, and FindKey returns false.

See Also

FindNearest (see page 10197)

GotoKey (see page 10201)

GotoNearest (see page 10202)

IndexName (see page 10222)

IndexFieldNames (see page 10220)

KeyExclusive (see page 10223)

Locate (see page 9915)

Executing a Search with Find Methods

53.1.19.4.22 TTable.FindNearest Method

Moves the cursor to the record that most closely matches a specified set of key values.

Pascal

```
procedure FindNearest(const KeyValues: array of const);
```

C++

```
__fastcall FindNearest(const array of const KeyValues);
```

Description

Call FindNearest to move the cursor to a specific record in a dataset or to the first record in the dataset that is greater than the values specified in the KeyValues parameter. KeyValues contains a comma-delimited array of field values, called a key. Each value in the key can be a literal, a variable, or nil (Delphi) or NULL (C++). If the number of values passed in KeyValues is less than the number of columns in the index used for the search, the missing values are assumed to be null. KeyValues_Size specifies the index of the last value in KeyValues (one less than the total number of values supplied). In the statement below, the FindKey (see page 10196) method is used to find the table row with the value "'Princess Island SCUBA" in the index field.

```
Table1.FindNearest(['Princess Island SCUBA']);
TVarRec vr = ("Princess Island SCUBA");
Table1->FindNearest(&vr, 0);
```

Note: In C++ code, the search values can be passed to FindNearest using either a TVarRec (as above) or an ARRAYOFCONST construct. The example below performs the same search as the preceding example, but using ARRAYOFCONST.

```
Table1->FindNearest(ARRAYOFCONST(("Princess Island SCUBA")));
```

For Paradox and dBASE tables, the key must always be an index, which can be specified in the IndexName (see page 10222) property. If IndexName (see page 10222) is empty, FindNearest uses the table's primary index. Note that FindKey (see page 10196) does not work with dBASE expression indexes. Use the GotoKey (see page 10201) or GotoNearest (see page 10202) method instead.

For SQL tables, the key may correspond to a specified index in IndexName (see page 10222), or to a list of field names in the IndexFieldNames (see page 10220) property.

FindNearest positions the cursor either on a record that exactly matches the search criteria, or on the first record whose values are greater than those specified in the search criteria. If there are no records that match or exceed the specified criteria, FindNearest positions the cursor on the last record in the table. KeyExclusive (see page 10223) affects the boundary conditions of ranges and will affect the record selected by FindNearest.

Executing a Search with Find Methods

53.1.19.4.23 TTable.GetCanModify Method

Pascal

```
function GetCanModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetCanModify();
```

Description

This is GetCanModify, a member of class TTable.

53.1.19.4.24 TTable.GetDataSource Method

Pascal

```
function GetDataSource: TDataSource; override;
```

C++

```
virtual __fastcall TDataSource GetDataSource();
```

Description

This is GetDataSource, a member of class TTable.

53.1.19.4.25 TTable.GetDetailLinkFields Method

Lists the field components that link this dataset as a detail of a master dataset.

Pascal

```
procedure GetDetailLinkFields(MasterFields: TList; DetailFields: TList); override;
```

C++

```
virtual __fastcall GetDetailLinkFields(TList MasterFields, TList DetailFields);
```

Description

GetDetailLinkFields fills two lists of TFields that define a master-detail relationship between this table and another (master) dataset. The MasterFields (see page 10224) list is filled with fields from the master table whose values must equal the values of the fields in the DetailFields list. The DetailFields list is filled with fields from the calling dataset.

See Also

MasterFields (see page 10224)

MasterSource (see page 10224)

53.1.19.4.26 TTable.GetFileName Method

Pascal

```
function GetFileName: string;
```

C++

```
__fastcall AnsiString GetFileName();
```

Description

This is GetFileName, a member of class TTable.

53.1.19.4.27 TTable.GetHandle Method

Pascal

```
function GetHandle(const IndexName: string; const IndexTag: string): HDBICur;
```

C++

```
__fastcall HDBICur GetHandle(const AnsiString IndexName, const AnsiString IndexTag);
```

Description

This is GetHandle, a member of class TTable.

53.1.19.4.28 TTable.GetIndexNames Method

Retrieves a list of available indexes for a table.

Pascal

```
procedure GetIndexNames(List: TStrings);
```

C++

```
__fastcall GetIndexNames(TStrings List);
```

Description

Call GetIndexNames to retrieve a list of all available indexes for a table. List is a string list object, created and maintained by the application, into which to retrieve the index names.

```
Table1.GetIndexNames(ListBox1.Items);
Table1->GetIndexNames(ListBox1->Items);
```

See Also

IndexName (see page 10222)

Obtaining Information About Indexes

53.1.19.4.29 TTable.GetLanguageDriverName Method

Pascal

```
function GetLanguageDriverName: string;
```

C++

```
__fastcall AnsiString GetLanguageDriverName();
```

Description

This is GetLanguageDriverName, a member of class TTable.

53.1.19.4.30 TTable.GetLookupCursor Method

Pascal

```
function GetLookupCursor(const KeyFields: string; CaseInsensitive: Boolean): HDBICur; override;
```

C++

```
virtual __fastcall HDBICur GetLookupCursor(const AnsiString KeyFields, Boolean
CaseInsensitive);
```

Description

This is GetLookupCursor, a member of class TTable.

53.1.19.4.31 TTable.GetTableType Method

Pascal

```
function GetTableType: TTableType;
```

C++

```
__fastcall TTableType GetTableType();
```

Description

This is GetTableType, a member of class TTable.

53.1.19.4.32 TTable.GotoCurrent Method

Synchronizes the current record for this table with the current record of a specified table component.

Pascal

```
procedure GotoCurrent(Table: TTable);
```

C++

```
__fastcall GotoCurrent(TTable Table);
```

Description

Call GotoCurrent to synchronize the cursor position for this table with the cursor position in another dataset that uses a different data source component, but which is connected to the same underlying database table. Table is the name of the table component whose cursor position to use for synchronizing.

Note: This procedure works only for table components that have the same DatabaseName (see page 10022) and TableName (see page 10226) properties. Otherwise, GotoCurrent raises an exception.

GotoCurrent is mainly for use in applications that have two table components that are linked to the same underlying database table through different data source components. It enables an application to ensure that separate views of the data appear to be linked.

See Also

DatabaseName (see page 10022)

TableName (see page 10226)

TDataSource (see page 7070)

53.1.19.4.33 TTable.GotoKey Method

Moves the cursor to a record specified by the current key.

Pascal

```
function GotoKey: Boolean;
```

C++

```
__fastcall Boolean GotoKey();
```

Description

Use GotoKey to move to a record specified by key values assigned with previous calls to SetKey (see page 10208) or EditKey (see page 10194) and actual search values indicated in the Fields property.

If GotoKey finds a matching record, it positions the cursor on the record and returns true. Otherwise the current cursor position remains unchanged, and GotoKey returns false.

For Paradox and dBASE tables, the key must always be an index, which can be specified in the IndexName (see page 10222) property. If IndexName (see page 10222) is empty, GotoKey uses the table's primary index. GotoKey works with dBASE expression indexes.

For SQL tables, the key may correspond to a specified index in IndexName (see page 10222), or to a list of field names in the IndexFieldNames (see page 10220) property.

See Also

Fields (see page 7023)

FindNearest (see page 10197)

GotoNearest (see page 10202)

SetKey (see page 10208)

State (see page 7036)

Executing a Search with Goto Methods

53.1.19.4.34 TTable.GotoNearest Method

Moves the cursor to the record that most closely matches the current key.

Pascal

```
procedure GotoNearest;
```

C++

```
__fastcall GotoNearest();
```

Description

Call GotoNearest to position the cursor on the record that is either the exact record specified by the current key values in the key buffer, or on the first record whose values exceed those specified. If there are no records that match or exceed the specified criteria, GotoNearest positions the cursor on the last record in the table.

Before calling GotoNearest, an application must specify key values by calling SetKey (see page 10208) or EditKey (see page 10194) to put the dataset is dsSetKey state, and then use FieldByName to populate the key buffer property with search values.

For Paradox and dBASE tables, the key must always be an index, which can be specified in the IndexName (see page 10222) property. If IndexName (see page 10222) is empty, GotoNearest uses the table's primary index. GotoNearest works with dBASE expression indexes.

For SQL tables, the key may correspond to a specified index in IndexName (see page 10222), or to a list of field names in the IndexFieldNames (see page 10220) property.

Note: KeyExclusive (see page 10223) determines which records are considered part of a search range.

See Also

FieldByName (see page 6936)

FindKey (see page 10196)

FindNearest (see page 10197)

Executing a Search with Goto Methods

53.1.19.4.35 TTable.InitFieldDefs Method

Pascal

```
procedure InitFieldDefs; override;
```

C++

```
virtual __fastcall InitFieldDefs();
```

Description

This is InitFieldDefs, a member of class TTable.

53.1.19.4.36 TTable.IsProductionIndex Method

Pascal

```
function IsProductionIndex(const IndexName: string): Boolean;
```

C++

```
__fastcall Boolean IsProductionIndex(const AnsiString IndexName);
```

Description

This is IsProductionIndex, a member of class TTable.

53.1.19.4.37 TTable.LockTable Method

Locks a Paradox or dBASE table.

Pascal

```
procedure LockTable(LockType: TLockType);
```

C++

```
__fastcall LockTable(TLockType LockType);
```

Description

Call LockTable to lock a Paradox or dBASE table to prevent other applications from placing a particular type of lock on the table. LockType specifies the lock requested by this application.

Requesting a read lock prevents other applications from reading a table. Requesting a write lock prevents other application from writing to a table.

An application can request both types of lock by calling LockTable twice, once for each lock type.

UnlockTable (see page 10212)

Exclusive (see page 10215)

53.1.19.4.38 TTable.NativeTableName Method

Pascal

```
function NativeTableName: PChar;
```

C++

```
__fastcall const char * NativeTableName();
```

Description

This is NativeTableName, a member of class TTable.

53.1.19.4.39 TTable.OpenIndexFile Method

Opens a specified dBASE non-production index file.

Pascal

```
procedure OpenIndexFile(const IndexName: string);
```

C++

```
__fastcall OpenIndexFile(const AnsiString IndexName);
```

Description

Call OpenIndexFile to open a specified dBASE non-production index file. IndexFileName is the name of the file to open. OpenIndexFile opens the file and adds its name to the list of index files in the IndexFiles (see page 10221) property.

While a non-production index file is open, it is maintained.

See Also

IndexFiles (see page 10221)

CloseIndexFile (see page 10188)

53.1.19.4.40 TTable.PrepareCursor Method

Pascal

```
procedure PrepareCursor; override;
```

C++

```
virtual __fastcall PrepareCursor();
```

Description

This is PrepareCursor, a member of class TTable.

53.1.19.4.41 TTable.PSGetCommandText Method

Gets the SQL command to be executed by PSExecute.

Pascal

```
function PSGetCommandText: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetCommandText();
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSSetCommandText (see page 7585)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.19.4.42 TTable.PSGetCommandType Method

Gets the command type to be executed by PSExecute.

Pascal

```
function PSGetCommandType: TPSCommandType; override;
```

C++

```
virtual __fastcall TPSCommandType PSGetCommandType();
```

Description

PSGetCommandType gets the command type executed by PSExecute. The type may be a type of SQL command or other command types, such as stored procedures.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

PSGetCommandText (see page 7579)

Execute (see page 18466)

Options (see page 18440)

53.1.19.4.43 TTable.PSGetDefaultOrder Method

Returns the definition of an index that imposes the default order on the data included in data packets.

Pascal

```
function PSGetDefaultOrder: TIndexDef; override;
```

C++

```
virtual __fastcall TIndexDef PSGetDefaultOrder();
```

Description

The provider component calls PSGetDefaultOrder to generate a default index, called DEFAULT_ORDER, for the records that appear in data packets. This index defines the default sort order for records when they appear in the client dataset on the client.

PSGetDefaultOrder creates a TIndexDef object to describe the default index. The provider that calls PSGetDefaultOrder subsequently frees this TIndexDef object.

See Also

CreateDataPacket (see page 18518)

53.1.19.4.44 TTable.PSGetIndexDefs Method

Returns the definitions of all specified indexes defined for the dataset.

Pascal

```
function PSGetIndexDefs(IndexTypes: TIndexOptions): TIndexDefs; override;
```

C++

```
virtual __fastcall TIndexDefs PSGetIndexDefs(TIndexOptions IndexTypes);
```

Description

The provider component calls PSGetIndexDefs to locate an index that contains information it needs. For example, it uses PSGetIndexDefs to locate an index that contains the key fields returned by PSGetKeyFields. This information allows the provider to locate the records that need to change when it applies updates. The provider also calls this method to locate indexes that it adds to the metadata of data packets.

IndexTypes indicates the options required of the returned indexes. PSGetIndexDefs returns all indexes whose Options property includes the specified flags.

PSGetIndexDefs returns a TIndexDefs object that contains all the indexes of the dataset that match the IndexTypes parameter.

See Also

Options (see page 7291)

PSGetKeyFields (see page 7581)

PSGetDefaultOrder (see page 7580)

53.1.19.4.45 TTable.PSGetKeyFields Method

Returns the names of all fields required to uniquely identify records in the data packet.

Pascal

```
function PSGetKeyFields: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetKeyFields();
```

Description

The provider component calls PSGetKeyFields to determine what information is required to uniquely identify records in the data packet. This information allows it to locate the records that need to change when it applies updates.

PSGetKeyFields returns a semicolon-delimited string that lists the names of the key fields of the dataset. By default (as implemented by TDataSet), these are the fields with pfInKey included in their ProviderFlags property.

See Also

PSGetDefaultOrder (see page 7580)

ProviderFlags (see page 7176)

PSGetIndexDefs (see page 7581)

53.1.19.4.46 TTable.PSGetTableName Method

Returns the name of the dataset table that appears in generated SQL statements.

Pascal

```
function PSGetTableName: string; override;
```

C++

```
virtual __fastcall AnsiString PSGetTableName();
```

Description

PSGetTableName returns the name of the underlying database table against which updates are applied when the provider's ResolveToDataSet property is false. This value is used for generating the SQL statements that apply updates. The generated SQL statements are subsequently executed by a call to PSExecuteStatement.

If PSGetTableName does not return a table name, the provider must have an OnGetTableName event handler to supply this value.

See Also

applyupdates (see page 18459)

PSExecuteStatement (see page 7579)

ResolveToDataSet (see page 18531)

ongettablename (see page 18542)

53.1.19.4.47 TTable.PSSetCommandText Method

Assigns a specified SQL command to be executed by PSExecute.

Pascal

```
procedure PSSetCommandText(const CommandText: string); override;
```

C++

```
virtual __fastcall PSSetCommandText(const AnsiString CommandText);
```

Description

If the provider's Options property includes poAllowCommandText, clients can supply an SQL command along with a call to GetRecords or Execute. This command is passed to the dataset by a call to PSSetCommandText, and subsequently executed by a call to PSExecute.

The value of the CommandText parameter replaces the dataset's SQL statement (if it has one), or replaces the name of an underlying database table or stored procedure.

See Also

CommandText (see page 8465)

PSExecute (see page 7578)

GetRecords (see page 18468)

Execute (see page 18466)

Options (see page 18440)

53.1.19.4.48 TTable.PSSetParams Method

Assigns the specified parameter values to the dataset.

Pascal

```
procedure PSSetParams(AParams: TParams); override;
```

C++

```
virtual __fastcall PSSetParams(TParams AParams);
```

Description

PSSetParams assigns the parameter values specified by AParams to the parameters of the dataset.

See Also

Params (see page 8489)

PSGetParams (see page 7582)

53.1.19.4.49 TTable.RenameTable Method

Renames the Paradox or dBASE table associated with this table component.

Pascal

```
procedure RenameTable(const NewTableName: string);
```

C++

```
__fastcall RenameTable(const AnsiString NewTableName);
```

Description

Call RenameTable to give a new name to the Paradox or dBASE table underlying this table component. RenameTable renames the table and any support files (for example, Paradox .DB (see page 6725) and .MB files).

See Also

CreateTable (see page 10189)

DeleteTable (see page 10192)

EmptyTable (see page 10196)

LockTable (see page 10203)

UnlockTable (see page 10212)

BatchMove (see page 10186)

Renaming a Table

Using TTable

53.1.19.4.50 TTable.SetKey Method

Enables setting of keys and ranges for a dataset prior to a search.

Pascal

```
procedure SetKey;
```

C++

```
__fastcall SetKey();
```

Description

Call SetKey to put the dataset into dsSetKey state and clear the current contents of the key buffer. The FieldByName method can then be used to supply a new set of search values prior to conducting a search.

Note: To modify an existing key or range, call EditKey (see page 10194).

See Also

EditKey (see page 10194)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

State (see page 7036)

Executing a Search with Goto Methods

53.1.19.4.51 TTable.SetRange Method

Sets the starting and ending values of a range, and applies it.

Pascal

```
procedure SetRange(const StartValues: array of const; const EndValues: array of const);
```

C++

```
__fastcall SetRange(const array of const StartValues, const array of const EndValues);
```

Description

Call SetRange to specify a range and apply it to the dataset. The new range replaces the currently applied range, if any.

StartValues indicates the field values that designate the first record in the range. StartValues_Size specifies the index of the last value in StartValues (one less than the total number of values).

EndValues indicates the field values that designate the last record in the range. EndValues_Size specifies the index of the last value in EndValues (one less than the total number of values).

SetRange combines the functionality of SetRangeStart (see page 10212), SetRangeEnd (see page 10211), and ApplyRange (see page 10185) in a single procedure call. SetRange performs the following functions:

1Puts the dataset into dsSetKey state.

2Erases any previously specified starting range values and ending range values.

3Sets the start and end range values.

4Applies the range to the dataset.

If either StartValues or EndValues has fewer elements than the number of fields in the current index, then the remaining entries are set to NULL.

After a call to SetRange, the cursor is left on the first record in the range.

Note: With Paradox or dBASE tables, SetRange works only on indexed fields. With SQL databases, SetRange also works with any columns specified in the IndexFieldNames (see page 10220) property.

Delphi Examples:

```
{
The following example sets a range for a dataset. The form
requires two edit boxes, a data source, a client dataset or
table, a db grid, and a button.  Make sure that the Table1
info in FormActivate agrees with the table used.  Also, the
caption for the button must be initialized to '&ApplyRange'.
}
```

```
procedure TForm1.FormActivate(Sender: TObject);
begin
  Table1.DatabaseName := 'DBDEMOS';
  Table1.TableName := 'CustInfo';
  Table1.Active := True;
  Table1.IndexName := '';
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  if Button2.Caption = '&Apply Range' then
    begin
      Table1.SetRange([Edit1.Text],[Edit2.Text]);
      Button2.Caption := '&Drop Range';
    end
  else
    begin
      Table1.CancelRange;
      Table1.Refresh;
      Button2.Caption := '&Apply Range';
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftString;
          Size := 30;
        end;
      end;
      { Next, describe any indexes }
      with IndexDefs do
      begin
        Clear;
        { The 1st index has no name because it is
        { a Paradox primary key }
```

```
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= False;
  end;
```

See Also

ApplyRange (see page 10185)

CancelRange (see page 10186)

EditRangeEnd (see page 10194)

EditRangeStart (see page 10195)

FieldValues (see page 7025)

IndexFieldNames (see page 10220)

KeyExclusive (see page 10223)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

53.1.19.4.52 TTable.SetRangeEnd Method

Indicates that subsequent assignments to field values specify the end of the range of rows to include in the dataset.

Pascal

```
procedure SetRangeEnd;
```

C++

```
__fastcall SetRangeEnd();
```

Description

Call SetRangeEnd to put the dataset into dsSetKey state, erase any previous end range values, and set them to NULL. Subsequent key buffer field assignments can be made using the FieldByName method to set the ending values for a range.

After assigning end-range values to FieldValues, call ApplyRange (see page 10185) to activate the modified range.

Note: With Paradox or dBASE tables, SetRangeEnd works only on indexed fields. With SQL databases, SetRangeEnd also works with any columns specified in the IndexFieldNames (see page 10220) property.

See Also

ApplyRange (see page 10185)

CancelRange (see page 10186)

EditRangeEnd (see page 10194)

EditRangeStart (see page 10195)

IndexFieldNames (see page 10220)

KeyExclusive (see page 10223)

SetRange (see page 10209)

SetRangeStart (see page 10212)

53.1.19.4.53 TTable.SetRangeStart Method

Indicates that subsequent assignments to field values specify the start of the range of rows to include in the dataset.

Pascal

```
procedure SetRangeStart;
```

C++

```
__fastcall SetRangeStart();
```

Description

Call SetRangeStart to put the dataset into dsSetKey state, erase any previous start range values, and set them to NULL. Subsequent field assignments to the FieldValues property indicate the actual set of starting values for a range.

After assigning start-range values to FieldValues, call ApplyRange (see page 10185) to activate the modified range.

Note: With Paradox or dBASE tables, SetRangeStart works only on indexed fields. With SQL databases, SetRangeStart also works with any columns specified in the IndexFieldNames (see page 10220) property.

See Also

ApplyRange (see page 10185)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

53.1.19.4.54 TTable.UnlockTable Method

Removes a previously applied lock on a Paradox or dBASE table.

Pascal

```
procedure UnlockTable(LockType: TLockType);
```

C++

```
__fastcall UnlockTable(TLockType LockType);
```

Description

Call UnlockTable to remove a lock previously applied to a Paradox or dBASE table. LockType specifies the lock to remove.

Removing a read lock enables other applications to read a table. Removing a write lock enables other application to write to a table.

An application can remove both types of lock by calling UnlockTable twice, once for each lock type.

See Also

LockTable (see page 10203)

53.1.19.4.55 TTable.UpdateIndexDefs Method

Pascal

```
procedure UpdateIndexDefs; override;
```

C++

```
virtual __fastcall UpdateIndexDefs();
```

Description

This is UpdateIndexDefs, a member of class TTable.

53.1.19.5 TTable Properties

The properties of the TTable class are listed here.

Protected Properties

	Name	Description
R	MasterLink (see page 10224)	This is MasterLink, a member of class TTable.

Public Properties

	Name	Description
R	Exists (see page 10215)	Indicates whether the underlying database table exists.
R	IndexFieldCount (see page 10220)	Indicates the number of fields that comprise the current key.
	IndexFields (see page 10221)	Lists the fields of the current index.
	KeyExclusive (see page 10223)	Specifies how the upper and lower boundaries for a range should be interpreted.
	KeyFieldCount (see page 10223)	Specifies the number of fields to use when conducting a partial key search on a multi-field key.
	TableLevel (see page 10226)	Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) driver-dependent table level.

Published Properties

	Name	Description
	Constraints (see page 10214)	Specifies record-level constraints that must be met when editing the data.
	DefaultIndex (see page 10214)	Specifies if the data in the table should be ordered on a default index when opened.
	Exclusive (see page 10215)	Enables an application to gain sole access to a Paradox or dBASE table.
	FieldDefs (see page 10217)	Points to the list of field definitions for the dataset.

	IndexDefs (see page 10219)	Contains information about the indexes for a table.
	IndexFieldNames (see page 10220)	Lists the columns to use as an index for a table.
	IndexFiles (see page 10221)	Specifies one or more dBASE index file to use for a dBASE table that uses non-production indexes.
	IndexName (see page 10222)	Identifies a secondary index for the table.
	MasterFields (see page 10224)	Specifies one or more fields in a master table to link with corresponding fields in this table in order to establish a master-detail relationship between the tables.
	MasterSource (see page 10224)	Specifies the name of the data source for a dataset to use as a master table in establishing a detail-master relationship between this table and another one.
R	Ranged (see page 10225)	This is Ranged, a member of class TTable.
	ReadOnly (see page 10225)	Specifies whether a table is read-only for this application.
	StoreDefs (see page 10226)	Indicates whether the table's field and index definitions persist with the data module or form.
	TableName (see page 10226)	Indicates the name of the database table that this component encapsulates.
	TableType (see page 10227)	Indicates the database table structure for the table that this component represents.
	UpdateMode (see page 10228)	Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.
	UpdateObject (see page 10228)	Specifies the update object component used to update a read-only result set when cached updates are enabled.

53.1.19.5.1 TTable.Constraints Property

Specifies record-level constraints that must be met when editing the data.

Pascal

```
property Constraints: TCheckConstraints;
```

C++

```
__property TCheckConstraints Constraints;
```

Description

Use Constraints to read or add record-level constraints to the dataset. Record-level constraints usually impose relationships between the fields in a single record. Constraints that limit the value of a single field should be added to the individual field components.

See Also

TCheckConstraint (see page 6841)

CustomConstraint (see page 7156)

ImportedConstraint (see page 7167)

Constraining Data Values

53.1.19.5.2 TTable.DefaultIndex Property

Specifies if the data in the table should be ordered on a default index when opened.

Pascal

```
property DefaultIndex: Boolean;
```

C++

```
__property Boolean DefaultIndex;
```

Description

When this property is set to false, the BDE does not use an ORDER BY clause when opening a table on a SQL server. When

DefaultIndex is true, the BDE attempts to order the data based on the primary key or a unique index when opening the table. DefaultIndex defaults to true.

See Also

Active (see page 7004)

53.1.19.5.3 TTable.Exclusive Property

Enables an application to gain sole access to a Paradox or dBASE table.

Pascal

```
property Exclusive: Boolean;
```

C++

```
__property Boolean Exclusive;
```

Description

Use Exclusive to prevent other applications from accessing a Paradox or dBASE table while it is open in this application. Before opening the table, set Exclusive to true. A table must be closed before changing the Exclusive property.

When Exclusive is true, then when the application successfully opens the table, no other application can access it. If the table for which the application has requested exclusive access is already in use by another application, an exception is raised. To handle such exceptions, wrap the code that opens the table in a try..catchexcept block.

Do not set Exclusive to true at design time if you also set the Active (see page 9929) property to true at design time. In this case an exception is raised because the table is already in use by the IDE.

Note: An application can attempt to set Exclusive to true for SQL tables, but some SQL servers do not support exclusive table locking. Others may grant an exclusive read/write lock, but still permit read-only access to other applications. For more information about exclusive locking of database tables for a specific server, see the server's documentation.

See Also

Active (see page 7004)

Close (see page 6920)

Open (see page 6976)

Controlling Read/Write Access to Local Tables

Using TTable

53.1.19.5.4 TTable.Exists Property

Indicates whether the underlying database table exists.

Pascal

```
property Exists: Boolean;
```

C++

```
__property Boolean Exists;
```

Description

Read Exists at runtime to determine whether a database table exists. If the table does not exist, create a table from the field definitions and index definitions using the CreateTable (see page 10189) method.

This property is read-only.

Delphi Examples:

```
{ The following example shows how to create a table. }
procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Close;
  Table1.DeleteTable;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftString;
          Size := 30;
        end;
      end;
      { Next, describe any indexes }
      with IndexDefs do
      begin
        Clear;
        { The 1st index has no name because it is
        { a Paradox primary key }
        with AddIndexDef do
        begin
          Name := '';
          Fields := 'Field1';
          Options := [ixPrimary];
        end;
        with AddIndexDef do
        begin
          Name := 'Fld2Indx';
          Fields := 'Field2';
          Options := [ixCaseInsensitive];
        end;
      end;
      { Call the CreateTable method to create the table }
      CreateTable;
```

```
      Table1.Active:= True;
      for i := 1 to 20 do
        Table1.AppendRecord([i*111, i*222]);
    end;
  end;
  DS2.DataSet:= Table1;
  DBGrid2.DataSource.DataSet:= Table1;
  Table1.Active:= True;
end;
```

See Also

CreateTable (see page 10189)

RenameTable (see page 10208)

53.1.19.5.5 TTable.FieldDefs Property

Points to the list of field definitions for the dataset.

Pascal

```
property FieldDefs: TFieldDefs;
```

C++

```
__property TFieldDefs FieldDefs;
```

Description

FieldDefs lists the field definitions for a dataset. While an application can examine FieldDefs to explore the field definitions for a dataset, it should not change these definitions unless creating a new table with CreateTable or CreateDataSet.

To access fields and field values in a dataset, use the Fields, AggFields, and FieldValues properties, and the FieldsByName method.

Note: If the dataset includes object field descendants, FieldDefs represents a hierarchical view of the data, meaning that the definitions include object field definitions. To determine the definitions in a flattened view, use FieldDefList instead.

C++ Examples:

```
/*
The following code creates and activates a client dataset in
the form's OnCreate event handler.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TFieldDefs *pDefs = CDS2->FieldDefs;
  TFieldDef *pDef = pDefs->AddFieldDef();
  pDef->DataType = ftInteger;
  pDef->Name = "Field1";

  pDef = pDefs->AddFieldDef();
  pDef->DataType = ftString;
  pDef->Size = 10;
  pDef->Name = "Field2";

  TIndexDef *pIDef = CDS2->IndexDefs->AddIndexDef();
  pIDef->Fields = "Field1";
  pIDef->Name = "IntIndex";

  CDS2->CreateDataSet();
}
```

Delphi Examples:

```
{
The following code creates and activates a client dataset in
the form’s OnCreate event handler.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with CDS2 do
  begin
    with FieldDefs.AddFieldDef do
    begin
      DataType := ftInteger;
      Name := 'Field1';
    end;
    with FieldDefs.AddFieldDef do
    begin
      DataType := ftString;
      Size := 10;
      Name := 'Field2';
    end;
    with IndexDefs.AddIndexDef do
    begin
      Fields := 'Field1';
      Name := 'IntIndex';
    end;
    CreateDataSet;
  end;
end;
{ The following example shows how to create a table. }
procedure TForm1.Button1Click(Sender: TObject);
begin
  Table1.Close;
  Table1.DeleteTable;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  Table1:= TTable.Create(Form1);
  with Table1 do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'CustInfo';
    Table1.Active := False;
    { Don't overwrite an existing table }
    if Table1.Exists then
      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
    else
    begin
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
```

```
            DataType := ftString;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Table1.Active:= True;
        for i := 1 to 20 do
          Table1.AppendRecord([i*111, i*222]);
      end;
    end;
    DS2.DataSet:= Table1;
    DBGrid2.DataSource.DataSet:= Table1;
    Table1.Active:= True;
  end;
```

Creating and Deleting Tables

53.1.19.5.6 TTable.IndexDefs Property

Contains information about the indexes for a table.

Pascal

```
property IndexDefs: TIndexDefs;
```

C++

```
__property TIndexDefs IndexDefs;
```

Description

IndexDefs is a collection of index definitions, each of which describes an available index for the table. Define the index definitions of a table before calling CreateTable (see page 10189) or creating a table at design time.

Ordinarily, an application accesses or specifies indexes at runtime through the IndexFieldNames (see page 10220) or IndexFields (see page 10221) properties.

If IndexDefs is updated or manually edited, the StoreDefs (see page 10226) property becomes true.

Note: The index definitions in IndexDefs may not always reflect the current indexes available for a table. Before examining IndexDefs, call its Update method to refresh the list.

See Also

IndexFieldNames (see page 10220)

StoreDefs (see page 10226)

TIndexDef (see page 7283)

CreateTable (see page 10189)

53.1.19.5.7 TTable.IndexFieldCount Property

Indicates the number of fields that comprise the current key.

Pascal

```
property IndexFieldCount: Integer;
```

C++

```
__property int IndexFieldCount;
```

Description

Examine IndexFieldCount to determine the number of fields that comprise the current index. For indexes based on a single column, IndexFieldCount returns 1. For multi-column indexes, IndexFieldCount indicates the number of fields upon which the index is based.

See Also

IndexDefs (see page 10219)

IndexFields (see page 10221)

53.1.19.5.8 TTable.IndexFieldNames Property

Lists the columns to use as an index for a table.

Pascal

```
property IndexFieldNames: string;
```

C++

```
__property AnsiString IndexFieldNames;
```

Description

Use IndexFieldNames as an alternative method of specifying the index to use for a table. In IndexFieldNames, specify the name of each column to use as an index for a table. Ordering of column names is significant. Separate names with semicolon.

For Paradox and dBASE any column names specified in IndexFieldNames must already be indexed. This must be a single index using the same fields in the same order as specified in IndexFieldNames.

For SQL-based tables, the specified columns need not be indexed.

Note: The IndexFieldNames and IndexName (see page 10222) properties are mutually exclusive. Setting one clears the other.

IndexName (see page 10222)

Creating an Index with IndexFieldNames

Specifying the Data to Display using TSQLDataSet

53.1.19.5.9 TTable.IndexFields Property

Lists the fields of the current index.

Pascal

```
property IndexFields [Index: Integer]: TField;
```

C++

```
__property TField IndexFields[int Index];
```

Description

IndexFields is a zero-based array of field objects, each of which corresponds to a field in the current index. Index is an ordinal value indicating the position of a field in the index. The first field in the index is IndexFields[0], the second is IndexFields[1], and so on.

Note: Do not set IndexFields directly. Instead use the IndexFieldNames (see page 10220) property to order datasets on the fly at runtime.

See Also

AddIndex (see page 10184)

IndexDefs (see page 10219)

IndexFieldNames (see page 10220)

IndexName (see page 10222)

53.1.19.5.10 TTable.IndexFiles Property

Specifies one or more dBASE index file to use for a dBASE table that uses non-production indexes.

Pascal

```
property IndexFiles: TStrings;
```

C++

```
__property TStrings IndexFiles;
```

Description

Use IndexFiles to specify dBASE non-production index files and dBASE III PLUS-style .NDX indexes to use with the table. Set IndexFiles to the name of the non-production .MDX file. All index tags in the file become available for activation. This is as opposed to the index tags for a production index that become available automatically on opening the table. When using dBASE III PLUS-style .NDX indexes, add individual files to the list in the IndexFiles property. Both types of indexes become accessible through such means as the IndexName (see page 10222) property and the GetIndexNames (see page 10200) method.

When index files are added to the list of available indexes, the table component opens them. The indexes are updated as data is added to, changed in, or deleted from the table. When files are removed from the list, the table component closes them, and they are no longer maintained.

Note: At design time, use the Object Inspector to add or remove index file names for the IndexFiles property. At runtime, set IndexFiles as a string list.

IndexName (see page 10222)

GetIndexNames (see page 10200)

Specifying a dBASE Index File

Using TTable

53.1.19.5.11 TTable.IndexName Property

Identifies a secondary index for the table.

Pascal

```
property IndexName: string;
```

C++

```
__property AnsiString IndexName;
```

Description

Use IndexName to specify an alternative index for a table. If IndexName is empty, a table's sort order is based on its default index, or, for dBASE tables, on its physical record order.

If IndexName contains a valid index name, then that index determines the sort order of records. For dBASE tables, an index name supplied to the IndexName property must either reside in the table's master index file, or in another index file already specified in the IndexFiles (see page 10221) property.

Note: IndexFieldNames (see page 10220) and IndexName are mutually exclusive. Setting one clears the other.

Using TTable

53.1.19.5.12 TTable.KeyExclusive Property

Specifies how the upper and lower boundaries for a range should be interpreted.

Pascal

```
property KeyExclusive: Boolean;
```

C++

```
__property Boolean KeyExclusive;
```

Description

Use KeyExclusive to specify whether a range includes or excludes the records that match the starting and ending values of the range. By default, KeyExclusive is false, meaning that matching values are included.

To restrict a range to those records that are greater than the specified starting value and less than the specified ending value, set KeyExclusive to true.

See Also

FindNearest (see page 10197)

GotoNearest (see page 10202)

SetRange (see page 10209)

SetRangeEnd (see page 10211)

SetRangeStart (see page 10212)

53.1.19.5.13 TTable.KeyFieldCount Property

Specifies the number of fields to use when conducting a partial key search on a multi-field key.

Pascal

```
property KeyFieldCount: Integer;
```

C++

```
__property int KeyFieldCount;
```

Description

Use KeyFieldCount to limit a search based on a multi-field key to a consecutive subset of those fields. For example, if the primary key for a dataset consists of three fields, a partial-key search can be conducted using only the first field in the key by setting KeyFieldCount to 1. If KeyFieldCount is 0, the dataset searches on all fields in the key.

Note: Searches are only conducted based on consecutive key fields beginning with the first field in the key. For example if a key consists of three fields, an application can set KeyFieldCount to 1 to search on the first field, 2 to search on the first and second fields, or 3 to search on all fields. By default KeyFieldCount is initially set to include all fields in a search.

FindKey (see page 10196)

FindNearest (see page 10197)

GotoKey (see page 10201)

GotoNearest (see page 10202)

Locate (see page 9915)

53.1.19.5.14 TTable.MasterFields Property

Specifies one or more fields in a master table to link with corresponding fields in this table in order to establish a master-detail relationship between the tables.

Pascal

```
property MasterFields: string;
```

C++

```
__property AnsiString MasterFields;
```

Description

Use MasterFields after setting the MasterSource (see page 10224) property to specify the names of one or more fields to use in establishing a detail-master relationship between this table and the one specified in MasterSource (see page 10224).

MasterFields is a string containing one or more field names in the master table. Separate field names with semicolons.

Each time the current record in the master table changes, the new values in those fields are used to select corresponding records in this table for display.

Note: At design time, use the Field Link designer to establish the master-detail relationship between two tables.

See Also

MasterSource (see page 10224)

Making the Table a Detail of Another Dataset

53.1.19.5.15 TTable.MasterLink Property

Pascal

```
property MasterLink: TMasterDataLink;
```

C++

```
__property TMasterDataLink MasterLink;
```

Description

This is MasterLink, a member of class TTable.

53.1.19.5.16 TTable.MasterSource Property

Specifies the name of the data source for a dataset to use as a master table in establishing a detail-master relationship between this table and another one.

Pascal

```
property MasterSource: TDataSource;
```

C++

```
__property TDataSource MasterSource;
```

Description

Use MasterSource to specify the name of the data source component whose DataSet property identifies a dataset to use as a master table in establishing a detail-master relationship between this table and another one.

Note: At design time choose an available data source from the MasterSource property's drop-down list in the Object Inspector.

After setting the MasterSource property, specify which fields to use in the master table by setting the MasterFields (see page 10224) property. At runtime each time the current record in the master table changes, the new values in those fields are used to select corresponding records in this table for display.

Note: At design time, use the Field Link designer to establish the master-detail relationship between two tables.

See Also

MasterFields (see page 10224)

Making the Table a Detail of Another Dataset

53.1.19.5.17 TTable.Ranged Property

Pascal

```
property Ranged: Boolean;
```

C++

```
__property Boolean Ranged;
```

Description

This is Ranged, a member of class TTable.

53.1.19.5.18 TTable.ReadOnly Property

Specifies whether a table is read-only for this application.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use the ReadOnly property to prevent users from updating, inserting, or deleting data in the table. By default, ReadOnly is false, meaning users can potentially alter a table's data.

Note: Even if ReadOnly is false, users may not be able to modify or add data to a table. Other factors, such as insufficient SQL privileges for the application or its current user may prevent successful alterations.

To guarantee that users cannot modify or add data to a table,

1Set the Active (see page 9929) property to false.

2Set ReadOnly to true.

When ReadOnly is true, the table's CanModify property is false.

See Also

Active (see page 7004)

CanModify

Controlling Read/Write Access to Local Tables

53.1.19.5.19 TTable.StoreDefs Property

Indicates whether the table's field and index definitions persist with the data module or form.

Pascal

```
property StoreDefs: Boolean;
```

C++

```
__property Boolean StoreDefs;
```

Description

If StoreDefs is true, the table's index and field definitions are stored with the data module or form. Setting StoreDefs to true makes the CreateTable (see page 10189) method into a one-step procedure that creates fields, indexes, and validity checks at runtime.

StoreDefs is false by default. It becomes true whenever FieldDefs (see page 10217) or IndexDefs (see page 10219) is updated or edited manually; to prevent edited (or imported) definitions from being stored, reset StoreDefs to false.

See Also

FieldDefs (see page 7019)

IndexDefs (see page 10219)

CreateTable (see page 10189)

53.1.19.5.20 TTable.TableLevel Property

Specifies the Borland (see page 1761) Database (see page 10021) Engine (BDE) driver-dependent table level.

Pascal

```
property TableLevel: Integer;
```

C++

```
__property int TableLevel;
```

Description

Use TableLevel when creating a table to specify that the table associated with this dataset requires a specific level of BDE driver. If TableLevel is 0, the default, this property is ignored.

For more information about BDE driver table level specification, see the online BDE help file, BDE32.HLP.

See Also

CreateTable (see page 10189)

Database (see page 10021)

TableType (see page 10227)

53.1.19.5.21 TTable.TableName Property

Indicates the name of the database table that this component encapsulates.

Pascal

```
property TableName: TFileName;
```

C++

```
__property TFileName TableName;
```

Description

Use TableName to specify the name of the database table this component encapsulates. To set TableName to a meaningful value, the DatabaseName (see page 10022) property should already be set. If DatabaseName (see page 10022) is set at design time, then select a valid table name from the TableName drop-down list in the Object Inspector.

Note: To set TableName, the Active (see page 9929) property must be false.

Using TSQLTable

53.1.19.5.22 TTable.TableType Property

Indicates the database table structure for the table that this component represents.

Pascal

```
property TableType: TTableType;
```

C++

```
__property TTableType TableType;
```

Description

Use TableType to specify the database table structure for a dBASE, Paradox, FoxPro or ASCII table. TableType does not apply to tables for remote SQL servers. TableType can be set to any of the following values:

Value	Meaning
ttDefault	(Default) Determine table type based on file extension for the table.
ttParadox	Table is a Paradox table.
ttDBase	Table is a dBASE table.
ttFoxPro	Table is a FoxPro table.
ttASCII	Table is a text file with comma-delimited, quoted strings for each field
DB (see page 6725) or none	Paradox table
DBF	dBASE table
TXT	ASCII table

If TableType is set to ttDefault, the table's file-name extension determines the table type:

Extension	Meaning
DB (see page 6725) or none	Paradox table
DBF	dBASE table
TXT	ASCII table

If TableType is ttParadox, ttDBase, ttFoxPro or ttASCII, the table type is assumed to be of the type specified, regardless of the table's file name extension.

Using TTable

53.1.19.5.23 TTable.UpdateMode Property

Determines how the Borland Database Engine (BDE) finds records when updating to an SQL database.

Pascal

```
property UpdateMode: TUpdateMode;
```

C++

```
__property TUpdateMode UpdateMode;
```

Description

Use UpdateMode to specify the criteria to use when locating a record in the dataset. UpdateMode specifies whether modified records are located based on all columns (fields), on only the key fields, or on the key fields plus the original values of fields that have been modified.

See Also

UpdateRecordTypes (see page 9936)

53.1.19.5.24 TTable.UpdateObject Property

Specifies the update object component used to update a read-only result set when cached updates are enabled.

Pascal

```
property UpdateObject: TDataSetUpdateObject;
```

C++

```
__property TDataSetUpdateObject UpdateObject;
```

Description

Use UpdateObject to specify the TUpdateObject component to use in an application that must be able to update a read-only result set returned by the Borland Database Engine (BDE).

The BDE always attempts to provide an updatable, or "live" query result unless an application specifically requests a read-only

view of data. In some cases, such as a query made against multiple tables, a live result set cannot be returned. In these cases, UpdateObject can be used to specify a TUpdateSQL component that performs updates as a separate transaction that is transparent to the application.

53.1.20 TUpdateSQL Class

TUpdateSQL applies cached updates on behalf of queries or stored procedures that can't post updates directly.

Class Hierarchy

Pascal

```
TUpdateSQL = class(TSQLUpdateObject);
```

C++

```
class TUpdateSQL : public TSQLUpdateObject;
```

File

DBTables

Description

Use a TUpdateSQL object to provide SQL (see page 10242) statements used to update read-only datasets represented by TQuery (see page 10059) or TStoredProc (see page 10139) components when cached updates are enabled. A dataset is read-only either by design or circumstance. If a dataset is read-only by design, the application itself does not provide a user interface for updating data, but may institute a programmatic scheme behind the scenes. If a dataset is read-only by circumstance, it indicates that the Borland (see page 1761) Database Engine (BDE) returned a read-only result set. This usually happens for queries made against multiple tables. Such queries are, by SQL (see page 10242)-92 definitions, read-only.

TUpdateSQL provides a mechanism for circumventing what some developers consider an SQL (see page 10242)-92 limitation. It enables a developer to provide INSERT, UPDATE, and DELETE statements for performing separate update queries on otherwise read-only result sets in such a manner that the separate update queries are transparent to the end user.

In practical application, a TUpdateSQL object is placed on a data module or form, and linked to a TQuery (see page 10059) or TStoredProc (see page 10139) component through that component's UpdateObject property. If the UpdateObject property

points to a valid TUpdateSQL object, the SQL (see page 10242) statements belonging to the update object are automatically applied when cached updates are applied.

53.1.20.1 TUpdateSQL Members

The following tables list the members exposed by TUpdateSQL.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetDataSet (see page 10235)	GetDataSet returns the value of the DataSet property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetSQL (see page 10236)	Returns the SQL statement that performs a specified update operation.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetDataSet (see page 10236)	SetDataSet sets the value of the DataSet property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.

	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SQLChanged (see page 10237)	This is SQLChanged, a member of class TUpdateSQL.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Apply (see page 10234)	This is the overview for the Apply method overload.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 10233)	Creates an instance of an update object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 10233)	Frees an instance of an update object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	ExecSQL (see page 10235)	Executes a specified type of SQL (see page 10242) statement to perform an update for an otherwise read-only results set when cached updates is enabled.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.

	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SetParams (see page 10236)	This is the overview for the SetParams method overload.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DatabaseName (see page 10238)	Identifies the database to which updates are applied.
	DataSet (see page 10239)	Identifies the dataset that holds the updated data that the update object applies.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	Query (see page 10241)	Returns the query object used to perform a specified kind of update.
	SessionName (see page 10242)	Identifies the session under which updates are applied.
	SQL (see page 10242)	Returns a specified SQL statement used when applying cached updates.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	DeleteSQL (see page 10239)	Specifies the SQL (see page 10242) DELETE statement to use when applying a cached deletion of a record.
	InsertSQL (see page 10240)	Specifies the SQL (see page 10242) INSERT statement to use when applying a cached insertion of a record.
	ModifySQL (see page 10240)	Specifies the SQL (see page 10242) UPDATE statement to use when applying an update to a record and cached updates is enabled.

	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

53.1.20.2 TUpdateSQL.Create Constructor

Creates an instance of an update object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TUpdateSQL(TComponent * AOwner);
```

Description

Call Create to instantiate an update object at run time. You do not need to call Create for update objects placed in a data module or form at design time. Delphi automatically handles these objects.

See Also

Destroy (see page 10233)

53.1.20.3 TUpdateSQL.Destroy Destructor

Frees an instance of an update object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TUpdateSQL();
```

Description

Do not call Destroy directly in an application. Usually destruction of update objects is handled automatically by Delphi. If an application creates its own instance of an update object, however, the application should call Free, which verifies that the update object is not nil before calling Destroy

See Also

Create (see page 10233)

Free (see page 22300)

53.1.20.4 TUpdateSQL Methods

The methods of the TUpdateSQL class are listed here.

Protected Methods

	Name	Description
	GetDataSet (see page 10235)	GetDataSet returns the value of the DataSet property.
	GetSQL (see page 10236)	Returns the SQL statement that performs a specified update operation.
	SetDataSet (see page 10236)	SetDataSet sets the value of the DataSet property.
	SQLChanged (see page 10237)	This is SQLChanged, a member of class TUpdateSQL.

Public Methods

	Name	Description
	Apply (see page 10234)	This is the overview for the Apply method overload.
V	ExecSQL (see page 10235)	Executes a specified type of SQL (see page 10242) statement to perform an update for an otherwise read-only results set when cached updates is enabled.
V	SetParams (see page 10236)	This is the overview for the SetParams method overload.

53.1.20.4.1 Apply Method

This is the overview for the Apply method overload.

Overload List

	Name	Description
	TUpdateSQL.Apply (TDataset, TUpdateKind) (see page 10234)	Sets the parameters for a specified SQL (see page 10242) statement type, and executes the resulting statement.
V	TUpdateSQL.Apply (TUpdateKind) (see page 10234)	Sets the parameters for a specified SQL (see page 10242) statement type, and executes the resulting statement.

53.1.20.4.1.1 TUpdateSQL.Apply Method (TDataset, TUpdateKind)

Sets the parameters for a specified SQL (see page 10242) statement type, and executes the resulting statement.

Pascal

```
procedure Apply(UpdateKind: TUpdateKind); override; overload;
procedure Apply(ADataset: TDataset; UpdateKind: TUpdateKind); overload; reintroduce;
```

C++

```
virtual __fastcall Apply(TUpdateKind UpdateKind);
__fastcall Apply(TDataset ADataset, TUpdateKind UpdateKind);
```

Description

Call Apply to set parameters for an SQL (see page 10242) statement and execute it to update a record. UpdateKind indicates which SQL (see page 10242) statement to bind and execute, and can be one of the following values:

Value	Meaning
ukDelete	Bind and execute the SQL (see page 10242) statement in the DeleteSQL (see page 10239) property
ukInsert	Bind and execute the SQL (see page 10242) statement in the InsertSQL (see page 10240) property
ukModify	Bind and execute the SQL (see page 10242) statement in the ModifySQL (see page 10240) property

Apply is primarily intended for manually executing update statements from an OnUpdateRecord event handler.

Note: If an SQL (see page 10242) statement does not contain parameters, it is more efficient to call ExecSQL (see page 10235) instead of Apply.

See Also

DeleteSQL (see page 10239)

ExecSQL (see page 10235)

InsertSQL (see page 10240)

ModifySQL (see page 10240)

SetParams (see page 10237)

Using Multiple Update Objects

53.1.20.4.2 TUpdateSQL.ExecSQL Method

Executes a specified type of SQL (see page 10242) statement to perform an update for an otherwise read-only results set when cached updates is enabled.

Pascal

```
procedure ExecSQL(UpdateKind: TUpdateKind); virtual;
```

C++

```
virtual __fastcall ExecSQL(TUpdateKind UpdateKind);
```

Description

Call ExecSQL to execute the SQL (see page 10242) statement necessary for updating the records belonging to a read-only result set when cached updates is enabled. UpdateKind specifies the statement to execute, and can be one of the following values:

Value	Meaning
ukDelete	Execute the SQL (see page 10242) statement used to delete records in the dataset (DeleteSQL (see page 10239)).
ukInsert	Execute the SQL (see page 10242) statement used to insert new records into the dataset (InsertSQL (see page 10240)).
ukModify	Execute the SQL (see page 10242) statement used to update records in the dataset (ModifySQL (see page 10240)).

If the statement to execute contains any parameters, an application must call SetParams (see page 10237) to bind the parameters before calling ExecSQL. To determine if a statement contains parameters, examine the appropriate ModifySQL (see page 10240), InsertSQL (see page 10240), or DeleteSQL (see page 10239) property, depending on the statement type intended for execution.

Note: To both bind parameters and execute a statement, call Apply (see page 10234).

See Also

Apply (see page 10234)

DeleteSQL (see page 10239)

InsertSQL (see page 10240)

ModifySQL (see page 10240)

SetParams (see page 10237)

Using Multiple Update Objects

53.1.20.4.3 TUpdateSQL.GetDataSet Method

GetDataSet returns the value of the DataSet property.

Pascal

```
function GetDataSet: TDataSet; override;
```

C++

```
virtual __fastcall TDataSet GetDataSet();
```

Description

Override GetDataSet, along with the SetDataSet method, to provide an implementation of the DataSet property. The DataSet property should represent the dataset that caches the updates to be applied by the update object.

See Also

DataSet (see page 9999)

SetDataSet (see page 9999)

53.1.20.4.4 TUpdateSQL.GetSQL Method

Returns the SQL statement that performs a specified update operation.

Pascal

```
function GetSQL(UpdateKind: TUpdateKind): TStrings; override;
```

C++

```
virtual __fastcall TStrings GetSQL(TUpdateKind UpdateKind);
```

Description

Override GetSQL to allow the update object to access an SQL statement that applies an update of the type specified by UpdateKind.

GetSQL provides the underlying implementation for the SQL property in the descendant class TUpdateSQL.

See Also

SQL (see page 10242)

53.1.20.4.5 TUpdateSQL.SetDataSet Method

SetDataSet sets the value of the DataSet property.

Pascal

```
procedure SetDataSet(ADataSet: TDataSet); override;
```

C++

```
virtual __fastcall SetDataSet(TDataSet ADataSet);
```

Description

Override SetDataSet, along with the GetDataSet method, to provide an implementation of the DataSet property. The DataSet property should represent the dataset that caches the updates to be applied by the update object.

See Also

DataSet (see page 9999)

GetDataSet (see page 9998)

53.1.20.4.6 SetParams Method

This is the overview for the SetParams method overload.

Overload List

	Name	Description
	TUpdateSQL.SetParams (TDataset, TUpdateKind) (see page 10237)	Binds parameters in an SQL (see page 10242) statement prior to statement execution.
	TUpdateSQL.SetParams (TUpdateKind) (see page 10237)	Binds parameters in an SQL (see page 10242) statement prior to statement execution.

53.1.20.4.6.1 TUpdateSQL.SetParams Method (TDataset, TUpdateKind)

Binds parameters in an SQL (see page 10242) statement prior to statement execution.

Pascal

```
procedure SetParams(ADataset: TDataset; UpdateKind: TUpdateKind); virtual; overload;
procedure SetParams(UpdateKind: TUpdateKind); virtual; overload;
```

C++

```
virtual __fastcall SetParams(TDataset ADataset, TUpdateKind UpdateKind);
virtual __fastcall SetParams(TUpdateKind UpdateKind);
```

Description

Call SetParams to bind parameters in an SQL (see page 10242) statement associated with the update object prior to executing the statement. UpdateKind indicates the type of statement for which to bind parameters, and can be one of the following values:

Value	Meaning
ukDelete	Bind parameters for the SQL (see page 10242) statement used to delete records (DeleteSQL (see page 10239)).
ukInsert	Bind parameters for the SQL (see page 10242) statement used to insert new records (InsertSQL (see page 10240)).
ukModify	Bind parameters for SQL (see page 10242) statement used to update records (ModifySQL (see page 10240)).

Parameters are indicated in an SQL (see page 10242) statement by a colon. Except for the leading colon in the parameter name, the parameter name must exactly match the name of an existing field name for the dataset.

Note: Parameter names can be prefaced by the 'OLD_' indicator. If so, the old value of the field is used to perform the update instead of any updates in the cache.

See Also

DeleteSQL (see page 10239)

ExecSQL (see page 10235)

InsertSQL (see page 10240)

ModifySQL (see page 10240)

53.1.20.4.7 TUpdateSQL.SQLChanged Method

Pascal

```
procedure SQLChanged(Sender: TObject);
```

C++

```
__fastcall SQLChanged(TObject * Sender);
```

Description

This is SQLChanged, a member of class TUpdateSQL.

53.1.20.5 TUpdateSQL Properties

The properties of the TUpdateSQL class are listed here.

Public Properties

	Name	Description
	DatabaseName (see page 10238)	Identifies the database to which updates are applied.
	DataSet (see page 10239)	Identifies the dataset that holds the updated data that the update object applies.
R	Query (see page 10241)	Returns the query object used to perform a specified kind of update.
	SessionName (see page 10242)	Identifies the session under which updates are applied.
	SQL (see page 10242)	Returns a specified SQL statement used when applying cached updates.

Published Properties

	Name	Description
	DeleteSQL (see page 10239)	Specifies the SQL (see page 10242) DELETE statement to use when applying a cached deletion of a record.
	InsertSQL (see page 10240)	Specifies the SQL (see page 10242) INSERT statement to use when applying a cached insertion of a record.
	ModifySQL (see page 10240)	Specifies the SQL (see page 10242) UPDATE statement to use when applying an update to a record and cached updates is enabled.

53.1.20.5.1 TUpdateSQL.DatabaseName Property

Identifies the database to which updates are applied.

Pascal

```
property DatabaseName: string;
```

C++

```
__property AnsiString DatabaseName;
```

Description

When the DataSet (see page 10239) property is not a BDE-enabled dataset, you must set DatabaseName to identify the database to which updates are applied. DatabaseName should be the same as the DatabaseName property of the source dataset (the dataset that fetches data from the database server). This property is used to set the DatabaseName property of the internal queries that apply the updates.

See Also

DatabaseName (see page 10022)

DataSet (see page 10239)

Query (see page 10241)

Using Multiple Update Objects

53.1.20.5.2 TUpdateSQL.DataSet Property

Identifies the dataset that holds the updated data that the update object applies.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

TUpdateSQL (see page 10229) uses the DataSet property for two purposes:

It fetches the original and updated field values from this dataset when performing parameter substitution.

If this dataset is a TDBDataSet (see page 10000) descendant, it uses its DatabaseName (see page 10238) and SessionName (see page 10242) properties to identify the database and session that it uses when performing its update queries.

If you are using a single update object, then the DataSet property is set automatically when you set the source dataset's UpdateObject property.

If you are using multiple update objects, you must set the DataSet property at runtime in a BeforeUpdateRecord or OnUpdateRecord event handler. If you are using the source dataset to cache its own updates, set DataSet to the source dataset in an OnUpdateRecord event handler. If you are using a client dataset to cache updates, set DataSet to the DeltaDS parameter of the BeforeUpdateRecord event handler.

See Also

UpdateObject (see page 9936)

TDBDataSet (see page 10000)

OnUpdateRecord (see page 9957)

beforeupdaterecord (see page 18442)

Using Multiple Update Objects

53.1.20.5.3 TUpdateSQL.DeleteSQL Property

Specifies the SQL (see page 10242) DELETE statement to use when applying a cached deletion of a record.

Pascal

```
property DeleteSQL: TStrings;
```

C++

```
__property TStrings DeleteSQL;
```

Description

Set DeleteSQL to the SQL (see page 10242) DELETE statement to use when applying a deletion to a record. Statements can be parameterized queries. To create a DELETE statement at design time, use the UpdateSQL editor to create statements, such as:

```
DELETE FROM "Country.db"
WHERE Name = :OLD_Name
```

At run time, an application can write a statement directly to this property to set or change the DELETE statement.

Note: As the example illustrates, DeleteSQL supports an extension to normal parameter binding. To retrieve the value of a field as it exists prior to application of cached updates, the field name with 'OLD_'. This is especially useful when doing field comparisons in the WHERE clause of the statement.

See Also

InsertSQL (see page 10240)

ModifySQL (see page 10240)

Using Update Objects to Update a Dataset

Updating a Read-only Result Set

Using TQuery

Using TUpdateSQL to Update a Dataset

53.1.20.5.4 TUpdateSQL.InsertSQL Property

Specifies the SQL (see page 10242) INSERT statement to use when applying a cached insertion of a record.

Pascal

```
property InsertSQL: TStrings;
```

C++

```
__property TStrings InsertSQL;
```

Description

Set InsertSQL to the SQL (see page 10242) INSERT statement to use when applying an insertion to a dataset. Statements can be parameterized queries. To create a INSERT statement at design time, use the UpdateSQL editor to create statements, such as:

```
INSERT INTO "Country.db"
(Name, Capital, Continent)
VALUES (:Name, :Capital, :Continent)
WHERE :OLD_Name = "Rangoon"
```

At run time, an application can write a statement directly to this property to set or change the INSERT statement.

Note: As the example illustrates, InsertSQL supports an extension to normal parameter binding. To retrieve the value of a field as it exists prior to application of cached updates, the field name with 'OLD_'. This is especially useful when doing field comparisons in the WHERE clause of the statement.

DeleteSQL (see page 10239)

ModifySQL (see page 10240)

Using Update Objects to Update a Dataset

Updating a Read-only Result Set

Using TQuery

Using TUpdateSQL to Update a Dataset

53.1.20.5.5 TUpdateSQL.ModifySQL Property

Specifies the SQL (see page 10242) UPDATE statement to use when applying an update to a record and cached updates is

enabled.

Pascal

```
property ModifySQL: TStrings;
```

C++

```
__property TStrings ModifySQL;
```

Description

Set ModifySQL to the SQL (see page 10242) UPDATE statement to use when applying an updated record to a dataset. Statements can be parameterized queries. To create a UPDATE statement at design time, use the UpdateSQL editor to create statements, such as:

```
UPDATE "Country.db"
SET Name = :Name, Capital = :Capital, Continent = :Continent
WHERE Name = :OLD_Name
```

At run time, an application can write a statement directly to this property to set or change the UPDATE statement.

Note: As the example illustrates, ModifySQL supports an extension to normal parameter binding. To retrieve the value of a field as it exists prior to application of cached updates, the field name with 'OLD_'. This is especially useful when doing field comparisons in the WHERE clause of the statement.

DeleteSQL (see page 10239)

InsertSQL (see page 10240)

Using Update Objects to Update a Dataset

Updating a Read-only Result Set

Using TUpdateSQL to Update a Dataset

53.1.20.5.6 TUpdateSQL.Query Property

Returns the query object used to perform a specified kind of update.

Pascal

```
property Query [UpdateKind: TUpdateKind]: TQuery;
```

C++

```
__property TQuery Query[TUpdateKind UpdateKind];
```

Description

Query is a read-only property that provides a reference to the internal TQuery (see page 10059) that executes the SQL (see page 10242) that applies the cached data updates. Use properties and methods of TQuery (see page 10059) to work with this reference.

Using one of the TUpdateKind constants as an index for the Query property, the internal TQuery (see page 10059) object will have the SQL (see page 10242) specified in the corresponding update SQL (see page 10242) property: DeleteSQL (see page 10239), InsertSQL (see page 10240), or ModifySQL (see page 10240). UpdateKind can be one of the following:

Value	Meaning
ukDelete	Return the query object used to execute DELETE statements (DeleteSQL (see page 10239)).
ukInsert	Return the query object used to execute INSERT statements (InsertSQL (see page 10240)).
ukModify	Return the query object used to execute UPDATE statements (ModifySQL (see page 10240)).

Each query object executes a particular kind of SQL (see page 10242) statement. The contents of the SQL (see page 10242) statements executed by these objects can be accessed directly using the ModifySQL (see page 10240), InsertSQL (see page 10240), and DeleteSQL (see page 10239) properties.

The main purpose of Query is to provide a a way for an application to set the properties for an update query object or to call the query object's methods.

Note: If a particular kind of update statement is not provided, then its corresponding query object is nil (Delphi) or NULL (C++). For example, if an application does not provide an SQL (see page 10242) statement for the DeleteSQL (see page 10239) property, then setting Query[ukDelete] returns nil (Delphi) or NULL (C++).

See Also

DeleteSQL (see page 10239)

InsertSQL (see page 10240)

ModifySQL (see page 10240)

53.1.20.5.7 TUpdateSQL.SessionName Property

Identifies the session under which updates are applied.

Pascal

```
property SessionName: string;
```

C++

```
__property AnsiString SessionName;
```

Description

When the DataSet (see page 10239) property is not a BDE-enabled dataset, you must set SessionName to identify the session under which updates are applied. SessionName should be the same as the SessionName property of the source dataset (the dataset that fetches data from the database server). This property is used to set the SessionName property of the internal queries that apply the updates.

See Also

SessionName (see page 10027)

DataSet (see page 10239)

Query (see page 10241)

Using Multiple Update Objects

53.1.20.5.8 TUpdateSQL.SQL Property

Returns a specified SQL statement used when applying cached updates.

Pascal

```
property SQL [UpdateKind: TUpdateKind]: TStrings;
```

C++

```
__property TStrings SQL[TUpdateKind UpdateKind];
```

Description

Returns the SQL statement in the ModifySQL (see page 10240), InsertSQL (see page 10240), or DeleteSQL (see page 10239) property, depending on the setting of the UpdateKind index. UpdateKind can be any of the following:

Value	Meaning
ukDelete	Return the query object used to execute DELETE statements (DeleteSQL (see page 10239)).
ukInsert	Return the query object used to execute INSERT statements (InsertSQL (see page 10240)).
ukModify	Return the query object used to execute UPDATE statements (ModifySQL (see page 10240)).

See Also

DeleteSQL (see page 10239)

InsertSQL (see page 10240)

ModifySQL (see page 10240)

53.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiToNative (see page 10244)	Converts a string from the ANSI character set to the character set associated with a given locale.
	AnsiToNativeBuf (see page 10245)	Converts a string from the ANSI character set to the character set associated with a given locale.
	Check (see page 10245)	Determines whether a value returned from the Borland (see page 1761) Database Engine (BDE) represents an error condition.
	DbiError (see page 10246)	Creates and raises an EDBEngineError (see page 9854) exception for an error code returned by the Borland (see page 1761) Database Engine (BDE).
	GetFieldSource (see page 10246)	This is function DBTables.GetFieldSource.
	NativeCompareStr (see page 10246)	Compares strings based on a database locale case sensitively.
	NativeCompareStrBuf (see page 10247)	Compares null-terminated strings based on a database locale case sensitively.
	NativeCompareText (see page 10248)	Compares strings based on a database locale without case sensitivity.
	NativeCompareTextBuf (see page 10248)	Compares null-terminated strings based on a database locale and is not case sensitive.
	NativeToAnsi (see page 10249)	Converts a string from the character set of the given locale to the ANSI character set.
	NativeToAnsiBuf (see page 10249)	Converts a string from the character set of a specified locale into the ANSI character set.
	RegisterBDEInitProc (see page 10250)	This is function DBTables.RegisterBDEInitProc.

53.2.1 DBTables.AnsiToNative Function

Converts a string from the ANSI character set to the character set associated with a given locale.

Pascal

```
function AnsiToNative(Locale: TLocale; const AnsiStr: string; NativeStr: PChar; MaxLen:
Integer): PChar;
```

C++

```
const char * AnsiToNative(TLocale Locale, const AnsiString AnsiStr, const char * NativeStr,
int MaxLen);
```

DBTables

Description

Call AnsiToNative to convert a string represented in the ANSI character set (used internally) to the character set associated with the database locale specified by the Locale parameter. The resulting string is copied into the buffer pointed to by the NativeStr parameter. Use the MaxLen parameter to specify the size of this buffer. If the buffer is too small to contain all characters in the converted version of AnsiStr, the returned value is truncated. AnsiToNative returns a pointer to NativeStr.

Use AnsiToNative to convert strings typed by the user into the character set used by a database table.

See Also

AnsiToNativeBuf

NativeToAnsi

53.2.2 DBTables.AnsiToNativeBuf Function

Converts a string from the ANSI character set to the character set associated with a given locale.

Pascal

```
procedure AnsiToNativeBuf(Locale: TLocale; Source: PChar; Dest: PChar; Len: Integer);
```

C++

```
AnsiToNativeBuf(TLocale Locale, const char * Source, const char * Dest, int Len);
```

File

DBTables

Description

Call AnsiToNativeBuf to convert a null-terminated string in the ANSI character set (used internally by Windows) to the character set associated with the database locale specified by the Locale parameter. The resulting string is copied into the buffer pointed to by the Dest parameter. Use the Len parameter to specify the size of this buffer.

Use AnsiToNativeBuf to convert strings typed by the user into the character set used by a database table.

See Also

AnsiToNative

NativeToAnsiBuf

TLocale

53.2.3 DBTables.Check Function

Determines whether a value returned from the Borland (see page 1761) Database Engine (BDE) represents an error condition.

Pascal

```
procedure Check(Status: DBIResult);
```

C++

```
Check(DBIResult Status);
```

File

DBTables

Description

Pass the return code from a direct BDE API call as the Status parameter when calling Check. Check determines whether Status indicates an error condition, and if so, calls DbiError (see page 10246) to raise an exception.

See Also

DbiError

53.2.4 DBTables.DbiError Function

Creates and raises an EDBEngineError (see page 9854) exception for an error code returned by the Borland (see page 1761) Database Engine (BDE).

Pascal

```
procedure DbiError(ErrorCode: DBIResult);
```

C++

```
DbiError(DBIResult ErrorCode);
```

File

DBTables

Description

Call DbiError to raise an EDBEngineError (see page 9854) for the error code passed as the ErrorCode parameter. DbiError obtains the error string from the BDE for the error and raises an EDBEngineError (see page 9854) exception.

Check

DatabaseError

EDBEngineError

53.2.5 DBTables.GetFieldSource Function

Pascal

```
function GetFieldSource(ADataSet: TDataSet; var ADataSources: DataSources): Boolean;
```

C++

```
Boolean GetFieldSource(TDataSet ADataSet, DataSources ADataSources);
```

File

DBTables

Description

This is function DBTables.GetFieldSource.

53.2.6 DBTables.NativeCompareStr Function

Compares strings based on a database locale case sensitively.

Pascal

```
function NativeCompareStr(Locale: TLocale; const S1: string; const S2: string; Len: Integer):
Integer;
```

C++

```
int NativeCompareStr(TLocale Locale, const AnsiString S1, const AnsiString S2, int Len);
```

File

DBTables

Description

NativeCompareStr compares S1 to S2, up to a length of Len characters. If the Len parameter is 0, NativeCompareStr compares the strings up to their entire length. The comparison is performed with case sensitivity. The compare operation is controlled by the database locale specified as the Locale parameter. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

See Also

NativeCompareText

NativeCompareStrBuf

53.2.7 DBTables.NativeCompareStrBuf Function

Compares null-terminated strings based on a database locale case sensitively.

Pascal

```
function NativeCompareStrBuf(Locale: TLocale; const S1: PChar; const S2: PChar; Len: Integer):
Integer;
```

C++

```
int NativeCompareStrBuf(TLocale Locale, const const char * S1, const const char * S2, int Len);
```

File

DBTables

Description

NativeCompareStrBuf compares up to the first Len characters of S1 to those of S2, with case sensitivity. If the Len parameter is 0, NativeCompareStrBuf compares the strings up to their entire length. The compare operation is controlled by the database locale specified as the Locale parameter. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

See Also

NativeCompareText

NativeCompareStr

53.2.8 DBTables.NativeCompareText Function

Compares strings based on a database locale without case sensitivity.

Pascal

```
function NativeCompareText(Locale: TLocale; const S1: string; const S2: string; Len: Integer):
Integer;
```

C++

```
int NativeCompareText(TLocale Locale, const AnsiString S1, const AnsiString S2, int Len);
```

File

DBTables

Description

NativeCompareText compares up to the first Len characters of S1 to those of S2, without case sensitivity. If the Len parameter is 0, NativeCompareText compares the strings up to their entire length. The compare operation is controlled by the database locale specified as the Locale parameter. NativeCompareText returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

NativeCompareStr

NativeCompareTextBuf

53.2.9 DBTables.NativeCompareTextBuf Function

Compares null-terminated strings based on a database locale and is not case sensitive.

Pascal

```
function NativeCompareTextBuf(Locale: TLocale; const S1: PChar; const S2: PChar; Len:
Integer): Integer;
```

C++

```
int NativeCompareTextBuf(TLocale Locale, const const char * S1, const const char * S2, int
Len);
```

File

DBTables

Description

NativeCompareTextBuf compares up to the first Len characters of S1 to those of S2, without case sensitivity. If the Len parameter is 0, NativeCompareTextBuf compares the strings up to their entire length. The compare operation is controlled by the database locale specified as the Locale parameter. NativeCompareTextBuf returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

NativeCompareStr

NativeCompareText

53.2.10 DBTables.NativeToAnsi Function

Converts a string from the character set of the given locale to the ANSI character set.

Pascal

```
procedure NativeToAnsi(Locale: TLocale; NativeStr: PChar; var AnsiStr: string);
```

C++

```
NativeToAnsi(TLocale Locale, const char * NativeStr, AnsiString AnsiStr);
```

File

DBTables

Description

Call NativeToAnsi to convert a string represented in the character set of the Locale parameter to the ANSI character set (used internally). The resulting string is returned as the AnsiStr parameter.

Use NativeToAnsi to convert strings retrieved from a database table into strings that can be displayed in the user interface.

See Also

AnsiToNative

NativeToAnsiBuf

53.2.11 DBTables.NativeToAnsiBuf Function

Converts a string from the character set of a specified locale into the ANSI character set.

Pascal

```
procedure NativeToAnsiBuf(Locale: TLocale; Source: PChar; Dest: PChar; Len: Integer);
```

C++

```
NativeToAnsiBuf(TLocale Locale, const char * Source, const char * Dest, int Len);
```

File

DBTables

Description

Call NativeToAnsiBuf to convert a null-terminated string in the character set of the Locale parameter to the ANSI character set (used internally). The resulting string is copied into the buffer pointed to by the Dest parameter. Use the Len parameter to specify the size of this buffer.

Use NativeToAnsiBuf to convert strings from a database table into the ANSI character set so that they can be displayed in the user interface.

See Also

AnsiToNativeBuf

NativeToAnsi

53.2.12 DBTables.RegisterBDEInitProc Function

Pascal

```
procedure RegisterBDEInitProc(const InitProc: TBDEInitProc);
```

C++

```
RegisterBDEInitProc(const TBDEInitProc InitProc);
```

File

DBTables

Description

This is function DBTables.RegisterBDEInitProc.

53.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBatchMode (see page 10251)	TBatchMode indicates the type of batch operation to be performed on a database table.
	TConfigModes (see page 10253)	This is record DBTables.TConfigModes.
	TDatabaseEvent (see page 10253)	This is record DBTables.TDatabaseEvent.
	TLockType (see page 10254)	Indicates how a Paradox or dBASE table can be locked.
	TParamBindMode (see page 10254)	This is record DBTables.TParamBindMode.
	TRecNoStatus (see page 10255)	This is record DBTables.TRecNoStatus.
	TTableType (see page 10256)	This is record DBTables.TTableType.
	TTraceFlag (see page 10256)	This is record DBTables.TTraceFlag.
	TTransIsolation (see page 10257)	This is record DBTables.TTransIsolation.

Records

	Name	Description
	TBDEKeyBuffer (see page 10252)	This is record DBTables.TBDEKeyBuffer.
	TBDERecInfo (see page 10252)	This is record DBTables.TBDERecInfo.
	TServerDesc (see page 10255)	This is record DBTables.TServerDesc.

53.3.1 DBTables.TBatchMode Enumeration

TBatchMode indicates the type of batch operation to be performed on a database table.

Pascal

```
TBatchMode = (
  batAppend,
  batUpdate,
  batAppendUpdate,
  batDelete,
  batCopy
);
```

C++

```
enum TBatchMode {
  batAppend,
  batUpdate,
  batAppendUpdate,
  batDelete,
  batCopy
};
```

File

DBTables

Description

TBatchMode can take the following values:

Value	Meaning
batAppend	Append all records from the source table to the end of destination table. The destination and source tables must not have records with duplicate keys.
batAppendUpdate	If a matching record exists in the destination table, replace it with the corresponding record from the source table. Otherwise, append records to the destination table. The destination table must have an index defined for matching records.
batCopy	Copy the structure and records from the source table into the destination table. If the destination table already exists, delete it and replace it with the new copy of the source.
batDelete	Delete all records in the destination table that also appear in the source table.
batUpdate	If a matching record exists in the destination table, replace it with the corresponding record from the source table. The destination table must have an index defined for matching records.

53.3.2 DBTables.TBDEKeyBuffer Record

Pascal

```
TBDEKeyBuffer = packed record
  Modified: Boolean;
  Exclusive: Boolean;
  FieldCount: Integer;
end;
```

C++

```
struct TBDEKeyBuffer {
  Boolean Modified;
  Boolean Exclusive;
  int FieldCount;
};
```

File

DBTables

Description

This is record DBTables.TBDEKeyBuffer.

53.3.3 DBTables.TBDERecInfo Record

Pascal

```
TBDERecInfo = packed record
  RecordNumber: Longint;
  UpdateStatus: TUpdateStatus;
  BookmarkFlag: TBookmarkFlag;
end;
```

C++

```
struct TBDERecInfo {
  Longint RecordNumber;
  TUpdateStatus UpdateStatus;
  TBookmarkFlag BookmarkFlag;
};
```

File

DBTables

Description

This is record DBTables.TBDERecInfo.

53.3.4 DBTables.TConfigModes Enumeration

Pascal

```
TConfigModes = (
  cfmVirtual,
  cfmPersistent,
  cfmSession
);
```

C++

```
enum TConfigModes {
  cfmVirtual,
  cfmPersistent,
  cfmSession
};
```

File

DBTables

Description

This is record DBTables.TConfigModes.

53.3.5 DBTables.TDatabaseEvent Enumeration

Pascal

```
TDatabaseEvent = (
  dbOpen,
  dbClose,
  dbAdd,
  dbRemove,
  dbAddAlias,
  dbDeleteAlias,
  dbAddDriver,
  dbDeleteDriver
);
```

C++

```
enum TDatabaseEvent {
  dbOpen,
  dbClose,
  dbAdd,
  dbRemove,
  dbAddAlias,
  dbDeleteAlias,
  dbAddDriver,
  dbDeleteDriver
};
```

File

DBTables

Description

This is record DBTables.TDatabaseEvent.

53.3.6 DBTables.TLockType Enumeration

Indicates how a Paradox or dBASE table can be locked.

Pascal

```
TLockType = (
  ltReadLock,
  ltWriteLock
);
```

C++

```
enum TLockType {
  ltReadLock,
  ltWriteLock
};
```

File

DBTables

Description

TLockType identifies the type of a BDE lock on a Paradox or dBASE table. The following table lists the possible values:

Value	Description
ltReadLock	Other applications (or sessions) can not read from the table.
ltWriteLock	Other applications (or sessions) can not write to the table.'

53.3.7 DBTables.TParamBindMode Enumeration

Pascal

```
TParamBindMode = (
  pbByName,
  pbByNumber
);
```

C++

```
enum TParamBindMode {
  pbByName,
  pbByNumber
};
```

File

DBTables

Description

This is record DBTables.TParamBindMode.

53.3.8 DBTables.TRecNoStatus Enumeration

Pascal

```
TRecNoStatus = (
  rnDbase,
  rnParadox,
  rnNotSupported
);
```

C++

```
enum TRecNoStatus {
  rnDbase,
  rnParadox,
  rnNotSupported
};
```

File

DBTables

Description

This is record DBTables.TRecNoStatus.

53.3.9 DBTables.TServerDesc Record

Pascal

```
TServerDesc = record
  ParamName: string[DBIMAXSPNAMELEN];
  BindType: TFieldType;
end;
```

C++

```
struct TServerDesc {
  string[DBIMAXSPNAMELEN] ParamName;
  TFieldType BindType;
};
```

File

DBTables

Description

This is record DBTables.TServerDesc.

53.3.10 DBTables.TTableType Enumeration

Pascal

```
TTableType = (
  ttDefault,
  ttParadox,
  ttDBase,
  ttFoxPro,
  ttASCII
);
```

C++

```
enum TTableType {
  ttDefault,
  ttParadox,
  ttDBase,
  ttFoxPro,
  ttASCII
};
```

File

DBTables

Description

This is record DBTables.TTableType.

53.3.11 DBTables.TTraceFlag Enumeration

Pascal

```
TTraceFlag = (
  tfQPrepare,
  tfQExecute,
  tfError,
  tfStmt,
  tfConnect,
  tfTransact,
  tfBlob,
  tfMisc,
  tfVendor,
  tfDataIn,
  tfDataOut
);
```

C++

```
enum TTraceFlag {
  tfQPrepare,
  tfQExecute,
  tfError,
  tfStmt,
  tfConnect,
  tfTransact,
  tfBlob,
  tfMisc,
  tfVendor,
```

```
    tfDataIn,
    tfDataOut
  };
```

File

DBTables

Description

This is record DBTables.TTraceFlag.

53.3.12 DBTables.TTransIsolation Enumeration

Pascal

```
  TTransIsolation = (
    tiDirtyRead,
    tiReadCommitted,
    tiRepeatableRead
  );
```

C++

```
  enum TTransIsolation {
    tiDirtyRead,
    tiReadCommitted,
    tiRepeatableRead
  };
```

File

DBTables

Description

This is record DBTables.TTransIsolation.

53.4 Types

The following table lists types in this documentation.

Types

Name	Description
PKeyBuffer (see page 10258)	This is type DBTables.PKeyBuffer.
PRecInfo (see page 10258)	This is type DBTables.PRecInfo.
TBDECallbackEvent (see page 10259)	This is type DBTables.TBDECallbackEvent.
TBDEInitProc (see page 10259)	This is type DBTables.TBDEInitProc.
TBlobDataArray (see page 10259)	This is type DBTables.TBlobDataArray.
TConfigMode (see page 10260)	This is type DBTables.TConfigMode.
TDatabaseLoginEvent (see page 10260)	This is type DBTables.TDatabaseLoginEvent.
TDatabaseNotifyEvent (see page 10260)	This is type DBTables.TDatabaseNotifyEvent.
TDBFlags (see page 10261)	This is type DBTables.TDBFlags.
TFieldDescList (see page 10261)	This is type DBTables.TFieldDescList.
TIndexDescList (see page 10261)	This is type DBTables.TIndexDescList.
TIndexName (see page 10262)	This is type DBTables.TIndexName.
TLocale (see page 10262)	TLocale is the type for the Locale or DBLocale property.
TPasswordEvent (see page 10262)	This is type DBTables.TPasswordEvent.
TServerDescList (see page 10263)	This is type DBTables.TServerDescList.
TSPParamDescList (see page 10263)	This is type DBTables.TSPParamDescList.
TTraceFlags (see page 10263)	TTraceFlags and TTraceFlags indicate the types of messages that pass between an application and the InterBase server.
TValCheckList (see page 10264)	This is type DBTables.TValCheckList.

53.4.1 DBTables.PKeyBuffer Type

Pascal

```
PKeyBuffer = ^TBDEKeyBuffer;
```

C++

```
^TBDEKeyBuffer PKeyBuffer;
```

File

DBTables

Description

This is type DBTables.PKeyBuffer.

53.4.2 DBTables.PRecInfo Type

Pascal

```
PRecInfo = ^TBDERecInfo;
```

C++

```
^TBDERecInfo PRecInfo;
```

File

DBTables

Description

This is type DBTables.PRecInfo.

53.4.3 DBTables.TBDECallbackEvent Type

Pascal

```
TBDECallbackEvent = function (CBInfo: Pointer): CBRType of object;
```

C++

```
(CBInfo: Pointer): CBRType ( TBDECallbackEvent)();
```

File

DBTables

Description

This is type DBTables.TBDECallbackEvent.

53.4.4 DBTables.TBDEInitProc Type

Pascal

```
TBDEInitProc = procedure (Session: TSession);
```

C++

```
(Session: TSession) ( TBDEInitProc)();
```

File

DBTables

Description

This is type DBTables.TBDEInitProc.

53.4.5 DBTables.TBlobDataArray Type

Pascal

```
TBlobDataArray = array of TBlobData;
```

C++

```
array of TBlobData TBlobDataArray;
```

File

DBTables

Description

This is type DBTables.TBlobDataArray.

53.4.6 DBTables.TConfigMode Type

Pascal

```
TConfigMode = set of TConfigModes;
```

C++

```
TConfigModes TConfigMode;
```

File

DBTables

Description

This is type DBTables.TConfigMode.

53.4.7 DBTables.TDatabaseLoginEvent Type

Pascal

```
TDatabaseLoginEvent = procedure (Database: TDatabase; LoginParams: TStrings) of object;
```

C++

```
(Database: TDatabase; LoginParams: TStrings) ( TDatabaseLoginEvent)();
```

File

DBTables

Description

This is type DBTables.TDatabaseLoginEvent.

53.4.8 DBTables.TDatabaseNotifyEvent Type

Pascal

```
TDatabaseNotifyEvent = procedure (DBEvent: TDatabaseEvent; const Param) of object;
```

C++

```
(DBEvent: TDatabaseEvent; const Param) ( TDatabaseNotifyEvent)();
```

File

DBTables

Description

This is type DBTables.TDatabaseNotifyEvent.

53.4.9 DBTables.TDBFlags Type

Pascal

```
TDBFlags = set of 0..15;
```

C++

```
0..15 TDBFlags;
```

File

DBTables

Description

This is type DBTables.TDBFlags.

53.4.10 DBTables.TFieldDescList Type

Pascal

```
TFieldDescList = array of BDEFLDDesc;
```

C++

```
array of BDEFLDDesc TFieldDescList;
```

File

DBTables

Description

This is type DBTables.TFieldDescList.

53.4.11 DBTables.TIndexDescList Type

Pascal

```
TIndexDescList = array of IDXDesc;
```

C++

```
array of IDXDesc TIndexDescList;
```

File

DBTables

Description

This is type DBTables.TIndexDescList.

53.4.12 DBTables.TIndexName Type

Pascal

```
TIndexName = type string;
```

C++

```
type string TIndexName;
```

File

DBTables

Description

This is type DBTables.TIndexName.

53.4.13 DBTables.TLocale Type

TLocale is the type for the Locale or DBLocale property.

Pascal

```
TLocale = Pointer;
```

C++

```
void * TLocale;
```

File

DBTables

Description

The TLocale type is the type of a Locale or DBLocale property. It is used for direct calls to BDE. These properties are only used or needed when making direct calls to the Borland (see page 1761) Database Engine.

Note: Do not confuse TLocale with the TSysLocale type that represents a Windows locale. TLocale is specific to the Borland (see page 1761) Database Engine.

See Also

TSysLocale

53.4.14 DBTables.TPasswordEvent Type

Pascal

```
TPasswordEvent = procedure (Sender: TObject; var Continue: Boolean) of object;
```

C++

```
(Sender: TObject; var Continue: Boolean) ( TPasswordEvent)();
```

File

DBTables

Description

This is type DBTables.TPasswordEvent.

53.4.15 DBTables.TServerDescList Type

Pascal

```
TServerDescList = array of TServerDesc;
```

C++

```
array of TServerDesc TServerDescList;
```

File

DBTables

Description

This is type DBTables.TServerDescList.

53.4.16 DBTables.TSPParamDescList Type

Pascal

```
TSPParamDescList = array of BDESPParamDesc;
```

C++

```
array of BDESPParamDesc TSPParamDescList;
```

File

DBTables

Description

This is type DBTables.TSPParamDescList.

53.4.17 DBTables.TTraceFlags Type

TTraceFlags and TTraceFlags indicate the types of messages that pass between an application and the InterBase server.

Pascal

```
TTraceFlags = set of TTraceFlag;
```

C++

```
TTraceFlag TTraceFlags;
```

File

DBTables

Description

TTraceFlags is a set of TTraceFlag (see page 10256) values. The following table lists the possible values:

Value	Meaning
tfQPrepare	Monitor Prepare statements.
tfQExecute	Monitor ExecSQL statements.
tfError	Monitor server error messages. Such messages may include an error code.
tfStmt	Monitor all SQL statements.
tfConnect	Monitor database connect and disconnect operations, including allocation of connection handles, and freeing connection handles.
tfTransact	Monitor transaction statements, such as StartTransaction, Commit, and Rollback.
tfBlob	Monitor operations on blob data types.
tfService	Monitor messages to one of the IB services.
tfMisc	Monitor any statements not covered by other flag options.

53.4.18 DBTables.TValCheckList Type

Pascal

```
TValCheckList = array of VCHKDesc;
```

C++

```
array of VCHKDesc TValCheckList;
```

File

DBTables

Description

This is type DBTables.TValCheckList.

53.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
GetObjectContextProc (see page 10265)	This is variable DBTables.GetObjectContextProc.
Session (see page 10265)	Maintains database components used by an application.
Sessions (see page 10266)	Provides access to TSessionList (see page 10129) methods and properties.

53.5.1 DBTables.GetObjectContextProc Variable

Pascal

```
GetObjectContextProc: function: IUnknown;
```

C++

```
function: IUnknown GetObjectContextProc;
```

File

DBTables

Description

This is variable DBTables.GetObjectContextProc.

53.5.2 DBTables.Session Variable

Maintains database components used by an application.

Pascal

```
Session: TSession;
```

C++

```
TSession Session;
```

File

DBTables

Description

Session is responsible for maintaining all of the database components used by an application. It is created automatically as part of an application's initialization and destroyed as part of the application's termination. The Session variable must remain active at all times; it can not be destroyed and recreated.

See Also

Sessions

53.5.3 DBTables.Sessions Variable

Provides access to TSessionList (see page 10129) methods and properties.

Pascal

```
Sessions: TSessionList;
```

C++

```
TSessionList Sessions;
```

File

DBTables

Description

Sessions is a way to access TSessionList (see page 10129) methods and properties for manipulating sessions. The DB (see page 6725) unit automatically creates and destroys Sessions for you; you don't need to do anything but use it.

The Session (see page 10265) variable, on the other hand, is responsible for maintaining all of the database components used by your application. It is created automatically as part of your application's initialization and destroyed as part of your application's termination. The Session (see page 10265) variable must remain active at all times; it can not be destroyed and recreated.

See Also

Session

TSession

53.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
BlobTypeMap (see page 10267)	This is constant DBTables.BlobTypeMap.
cmAll (see page 10268)	This is constant DBTables.cmAll.
cmPersistent (see page 10268)	This is constant DBTables.cmPersistent.
cmSession (see page 10268)	This is constant DBTables.cmSession.
cmVirtual (see page 10269)	This is constant DBTables.cmVirtual.
DataTypeMap (see page 10269)	This is constant DBTables.DataTypeMap.
dbfDatabase (see page 10269)	This is constant DBTables.dbfDatabase.
dbfExecProc (see page 10270)	This is constant DBTables.dbfExecProc.
dbfExecSQL (see page 10270)	This is constant DBTables.dbfExecSQL.
dbfFieldList (see page 10270)	This is constant DBTables.dbfFieldList.
dbfIndexList (see page 10271)	This is constant DBTables.dbfIndexList.
dbfOpened (see page 10271)	This is constant DBTables.dbfOpened.
dbfPrepared (see page 10271)	This is constant DBTables.dbfPrepared.
dbfProcDesc (see page 10272)	This is constant DBTables.dbfProcDesc.
dbfProvider (see page 10272)	This is constant DBTables.dbfProvider.
dbfStoredProc (see page 10272)	This is constant DBTables.dbfStoredProc.
dbfTable (see page 10273)	This is constant DBTables.dbfTable.
FldSubTypeMap (see page 10273)	This is constant DBTables.FldSubTypeMap.
FldTypeMap (see page 10273)	This is constant DBTables.FldTypeMap.
smTraceBufSize (see page 10274)	This is constant DBTables.smTraceBufSize.

53.6.1 DBTables.BlobTypeMap Constant

Pascal

```
BlobTypeMap: array[fldstMEMO..fldstBFILE] of TFieldType = ( ftMemo, ftBlob, ftFmtMemo,
ftParadoxOle, ftGraphic, ftDBaseOle, ftTypedBinary, ftBlob, ftBlob, ftBlob, ftBlob, ftOraClob,
ftOraBlob, ftBlob, ftBlob);
```

C++

```
array[fldstMEMO..fldstBFILE] of TFieldType BlobTypeMap = ( ftMemo, ftBlob, ftFmtMemo,
ftParadoxOle, ftGraphic, ftDBaseOle, ftTypedBinary, ftBlob, ftBlob, ftBlob, ftBlob, ftOraClob,
ftOraBlob, ftBlob, ftBlob);
```

File

DBTables

Description

This is constant DBTables.BlobTypeMap.

53.6.2 DBTables.cmAll Constant

Pascal

```
cmAll = [cfmVirtual, cfmPersistent, cfmSession];
```

C++

```
cmAll = [cfmVirtual, cfmPersistent, cfmSession];
```

File

DBTables

Description

This is constant DBTables.cmAll.

53.6.3 DBTables.cmPersistent Constant

Pascal

```
cmPersistent = [cfmPersistent];
```

C++

```
cmPersistent = [cfmPersistent];
```

File

DBTables

Description

This is constant DBTables.cmPersistent.

53.6.4 DBTables.cmSession Constant

Pascal

```
cmSession = [cfmSession];
```

C++

```
cmSession = [cfmSession];
```

File

DBTables

Description

This is constant DBTables.cmSession.

53.6.5 DBTables.cmVirtual Constant

Pascal

```
cmVirtual = [cfmVirtual];
```

C++

```
cmVirtual = [cfmVirtual];
```

File

DBTables

Description

This is constant DBTables.cmVirtual.

53.6.6 DBTables.DataTypeMap Constant

Pascal

```
DataTypeMap: array[0..MAXLOGFLDTYPES - 1] of TFieldType = ( ftUnknown, ftString, ftDate,
ftBlob, ftBoolean, ftSmallint, ftInteger, ftFloat, ftBCD, ftBytes, ftTime, ftDateTime, ftWord,
ftInteger, ftUnknown, ftVarBytes, ftUnknown, ftUnknown, ftLargeInt, ftLargeInt, ftADT,
ftArray, ftReference, ftDataSet, ftTimeStamp);
```

C++

```
array[0..MAXLOGFLDTYPES - 1] of TFieldType DataTypeMap = ( ftUnknown, ftString, ftDate,
ftBlob, ftBoolean, ftSmallint, ftInteger, ftFloat, ftBCD, ftBytes, ftTime, ftDateTime, ftWord,
ftInteger, ftUnknown, ftVarBytes, ftUnknown, ftUnknown, ftLargeInt, ftLargeInt, ftADT,
ftArray, ftReference, ftDataSet, ftTimeStamp);
```

File

DBTables

Description

This is constant DBTables.DataTypeMap.

53.6.7 DBTables.dbfDatabase Constant

Pascal

```
dbfDatabase = 9;
```

C++

```
dbfDatabase = 9;
```

File

DBTables

Description

This is constant DBTables.dbfDatabase.

53.6.8 DBTables.dbfExecProc Constant

Pascal

```
dbfExecProc = 7;
```

C++

```
dbfExecProc = 7;
```

File

DBTables

Description

This is constant DBTables.dbfExecProc.

53.6.9 DBTables.dbfExecSQL Constant

Pascal

```
dbfExecSQL = 2;
```

C++

```
dbfExecSQL = 2;
```

File

DBTables

Description

This is constant DBTables.dbfExecSQL.

53.6.10 DBTables.dbfFieldList Constant

Pascal

```
dbfFieldList = 4;
```

C++

```
dbfFieldList = 4;
```

File

DBTables

Description

This is constant DBTables.dbfFieldList.

53.6.11 DBTables.dbfIndexList Constant

Pascal

```
dbfIndexList = 5;
```

C++

```
dbfIndexList = 5;
```

File

DBTables

Description

This is constant DBTables.dbfIndexList.

53.6.12 DBTables.dbfOpened Constant

Pascal

```
dbfOpened = 0;
```

C++

```
dbfOpened = 0;
```

File

DBTables

Description

This is constant DBTables.dbfOpened.

53.6.13 DBTables.dbfPrepared Constant

Pascal

```
dbfPrepared = 1;
```

C++

```
dbfPrepared = 1;
```

File

DBTables

Description

This is constant DBTables.dbfPrepared.

53.6.14 DBTables.dbfProcDesc Constant

Pascal

```
dbfProcDesc = 8;
```

C++

```
dbfProcDesc = 8;
```

File

DBTables

Description

This is constant DBTables.dbfProcDesc.

53.6.15 DBTables.dbfProvider Constant

Pascal

```
dbfProvider = 10;
```

C++

```
dbfProvider = 10;
```

File

DBTables

Description

This is constant DBTables.dbfProvider.

53.6.16 DBTables.dbfStoredProc Constant

Pascal

```
dbfStoredProc = 6;
```

C++

```
dbfStoredProc = 6;
```

File

DBTables

Description

This is constant DBTables.dbfStoredProc.

53.6.17 DBTables.dbfTable Constant

Pascal

```
dbfTable = 3;
```

C++

```
dbfTable = 3;
```

File

DBTables

Description

This is constant DBTables.dbfTable.

53.6.18 DBTables.FldSubTypeMap Constant

Pascal

```
FldSubTypeMap: array[TFieldType] of Word = ( 0, 0, 0, 0, 0, 0, 0, fldstMONEY, 0, 0, 0, 0, 0,
0, fldstAUTOINC, fldstBINARY, fldstMEMO, fldstGRAPHIC, fldstFMTMEMO, fldstOLEOBJ,
fldstDBSOLEOBJ, fldstTYPEDBINARY, 0, fldstFIXED, fldstUNICODE, 0, 0, 0, 0, 0, fldstHBINARY,
fldstHMEMO, 0, 0, 0, 0, 0, 0, fldstFIXED, fldstMEMO, 0, 0 );
```

C++

```
array[TFieldType] of Word FldSubTypeMap = ( 0, 0, 0, 0, 0, 0, 0, fldstMONEY, 0, 0, 0, 0, 0, 0,
fldstAUTOINC, fldstBINARY, fldstMEMO, fldstGRAPHIC, fldstFMTMEMO, fldstOLEOBJ, fldstDBSOLEOBJ,
fldstTYPEDBINARY, 0, fldstFIXED, fldstUNICODE, 0, 0, 0, 0, 0, fldstHBINARY, fldstHMEMO, 0, 0,
0, 0, 0, 0, fldstFIXED, fldstMEMO, 0, 0 );
```

File

DBTables

Description

This is constant DBTables.FldSubTypeMap.

53.6.19 DBTables.FldTypeMap Constant

Pascal

```
FldTypeMap: TFieldMap = ( fldUNKNOWN, fldZSTRING, fldINT16, fldINT32, fldUINT16, fldBOOL,
fldFLOAT, fldFLOAT, fldBCD, fldDATE, fldTIME, fldTIMESTAMP, fldBYTES, fldVARBYTES, fldINT32,
fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldCURSOR, fldZSTRING,
fldZSTRING, fldINT64, fldADT, fldArray, fldREF, fldTABLE, fldBLOB, fldBLOB, fldUNKNOWN,
fldUNKNOWN, fldUNKNOWN, fldZSTRING, fldDATETIME, fldBCD, fldZSTRING, fldBLOB, fldDATETIME,
fldINT32);
```

C++

```
TFieldMap FldTypeMap = ( fldUNKNOWN, fldZSTRING, fldINT16, fldINT32, fldUINT16, fldBOOL,
fldFLOAT, fldFLOAT, fldBCD, fldDATE, fldTIME, fldTIMESTAMP, fldBYTES, fldVARBYTES, fldINT32,
fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldBLOB, fldCURSOR, fldZSTRING,
```

```
fldZSTRING, fldINT64, fldADT, fldArray, fldREF, fldTABLE, fldBLOB, fldBLOB, fldUNKNOWN,
fldUNKNOWN, fldUNKNOWN, fldZSTRING, fldDATETIME, fldBCD, fldZSTRING, fldBLOB, fldDATETIME,
fldINT32);
```

File

DBTables

Description

This is constant DBTables.FldTypeMap.

53.6.20 DBTables.smTraceBufSize Constant

Pascal

```
smTraceBufSize = 32767 + SizeOf(TraceDesc);
```

C++

```
smTraceBufSize = 32767 + SizeOf(TraceDesc);
```

File

DBTables

Description

This is constant DBTables.smTraceBufSize.

54 DBWeb Namespace

This is namespace DBWeb.

Topics

Name	Description
Classes (see page 10277)	The following table lists classes in this documentation.
Functions (see page 10346)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 10347)	The following table lists structs, records, enums in this documentation.
Types (see page 10349)	The following table lists types in this documentation.

Classes

	Name	Description
	TDataSetTableProducer (see page 10277)	TDataSetTableProducer assembles a sequence of HTML commands to display the records from a dataset in a tabular format.
	TDSTableProducer (see page 10290)	TDSTableProducer is the base class for objects that produce a set of HTML commands to display the records from a dataset in a tabular format.
	TDSTableProducerEditor (see page 10315)	TDSTableProducer (see page 10290) is the base class for the helper object used by TDSTableProducer (see page 10290) objects to communicate with a property editor at design time.
	THTMLTableColumn (see page 10318)	THTMLTableColumn represents the display attributes and field binding of a column in the HTML representation of a dataset.
	THTMLTableColumns (see page 10327)	THTMLTableColumns is a collection of THTMLTableColumn (see page 10318) objects that describe the display attributes and field bindings of the columns in an HTML representation of tabular data.
	THTTPDataLink (see page 10335)	THTTPDataLink helps TDSTableProducer (see page 10290) manage its link to the data source.

Functions

	Name	Description
	HtmlTable (see page 10346)	Generates the HTML image of a dataset, using the properties and events of a table producer object.

Structs, Records, Enums

	Name	Description
	THTMLCaptionAlignment (see page 10347)	This is record DBWeb.THTMLCaptionAlignment.
	THTMLColumnState (see page 10347)	This is record DBWeb.THTMLColumnState.

Types

Name	Description
TCreateContentEvent (see page 10349)	This is type DBWeb.TCreateContentEvent.
THTMLDataSetEmpty (see page 10349)	This is type DBWeb.THTMLDataSetEmpty.
THTMLFormatCellEvent (see page 10350)	This is type DBWeb.THTMLFormatCellEvent.
THTMLGetTableCaptionEvent (see page 10350)	This is type DBWeb.THTMLGetTableCaptionEvent.
THTMLTableColumnClass (see page 10350)	This is type DBWeb.THTMLTableColumnClass.

54.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDataSetTableProducer (see page 10277)	TDataSetTableProducer assembles a sequence of HTML commands to display the records from a dataset in a tabular format.
	TDSTableProducer (see page 10290)	TDSTableProducer is the base class for objects that produce a set of HTML commands to display the records from a dataset in a tabular format.
	TDSTableProducerEditor (see page 10315)	TDSTableProducer (see page 10290) is the base class for the helper object used by TDSTableProducer (see page 10290) objects to communicate with a property editor at design time.
	THTMLTableColumn (see page 10318)	THTMLTableColumn represents the display attributes and field binding of a column in the HTML representation of a dataset.
	THTMLTableColumns (see page 10327)	THTMLTableColumns is a collection of THTMLTableColumn (see page 10318) objects that describe the display attributes and field bindings of the columns in an HTML representation of tabular data.
	THTTPDataLink (see page 10335)	THTTPDataLink helps TDSTableProducer (see page 10290) manage its link to the data source.

54.1.1 TDataSetTableProducer Class

TDataSetTableProducer assembles a sequence of HTML commands to display the records from a dataset in a tabular format.

Class Hierarchy

Pascal

```
TDataSetTableProducer = class(TDSTableProducer);
```

C++

```
class TDataSetTableProducer : public TDSTableProducer;
```

File

DBWeb

Description

Use TDataSetTableProducer to produce an HTML table for the records of a TDataSet object. If the dataset is a query that requires input parameters from an HTTP request message, use TQueryTableProducer instead.

TDataSetTableProducer allows an application to create images of a dataset for an HTTP response message.

See Also

TDataSet (see page 6894)

TQueryTableProducer (see page 8152)

TSQLQueryTableProducer (see page 10842)

TWebResponse (see page 15191)

TDataSetPageProducer (see page 11807)

The Web Module

Using TDataSetTableProducer

54.1.1.1 TDataSetTableProducer Members

The following tables list the members exposed by TDataSetTableProducer.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AcquireLayoutLock (see page 10296)	Calls BeginLayout (see page 10297) when the HTML table is not currently being laid out.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BeginLayout (see page 10297)	Increments a counter that indicates the number of times the computation of the column order was begun but not completed.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ColumnHeader (see page 10298)	Returns the string of HTML <TH> tags that define the column headers for the table.
	DefineFieldMap (see page 10298)	Builds the Fields array in DataLink (see page 10309).
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DoCreateContent (see page 10299)	This is DoCreateContent, a member of class TDSTableProducer.
	DoFormatCell (see page 10299)	Generates an OnFormatCell (see page 10314) event.
	DoGetCaption (see page 10300)	Generates an OnGetCaption event.
	EndLayout (see page 10300)	Decrements a counter that indicates the number of times the computation of the column order has been begun but not completed.
	FormatCell (see page 10301)	Returns an HTML tag of a specified type that reflects a set of specified options.
	GetAppDispatcher (see page 15108)	This is GetAppDispatcher, a member of class TCustomContentProducer.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetDataSet (see page 10283)	Provides the abstract prototype of a method to access the DataSet property.
	GetDataSource (see page 10302)	Returns the value of the DataSource (see page 10309) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	LayoutChanged (see page 10303)	Causes the Columns (see page 10308) property to be recomputed when the dataset changes or changes are made to individual column objects.
	LinkActive (see page 10303)	Recomputes the Columns (see page 10308) property when the dataset becomes active.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 10283)	Adjusts the properties of TDSTableProducer when its helper objects are destroyed.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	ProduceContent (see page 15108)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15109)	This is ProduceContentFromStream, a member of class TCustomContentProducer.
	ProduceContentFromString (see page 15109)	This is ProduceContentFromString, a member of class TCustomContentProducer.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RowHeader (see page 10304)	Returns the HTML <TR> tag that defines each row of the HTML table.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAppDispatcher (see page 15109)	This is SetAppDispatcher, a member of class TCustomContentProducer.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetColumns (see page 10304)	Sets the Columns (see page 10308) property.
V	SetDataSet (see page 10283)	Provides the abstract prototype of a method to set the DataSet property.
	SetDataSource (see page 10305)	Sets the DataSource (see page 10309) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	StoreColumns (see page 10305)	Indicates whether the Columns (see page 10308) property is stored when the TDSTableProducer (see page 10290) is saved.
	TableCaption (see page 10306)	Returns the HTML <Caption (see page 10307)> tag that defines the caption for the HTML table.
	TableHeader (see page 10306)	Returns the HTML <Table> tag for the HTML table.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	DataLink (see page 10309)	Manages the link to the dataset.
	DataSource (see page 10309)	Represents the link to the DataSet (see page 10309) of the TDSTableProducer (see page 10290).
R	InternalDataSource (see page 10311)	Represents the link to the dataset.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 10297)	Increments a counter that indicates the number of changes to the contents of the HTML table that have been initiated but not completed.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Content (see page 10282)	Returns the HTML representation of the records in the dataset.
V	ContentFromStream (see page 15107)	Returns the content produced in response to input read from a stream.
V	ContentFromString (see page 15107)	Returns the content produced in response to an input string.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 10295)	Creates an instance of TDSTableProducer (see page 10290).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 10295)	Destroys an instance of TDSTableProducer (see page 10290).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 10301)	Decrements a counter that indicates the number of changes to the contents of the HTML table.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetAppDispatcher (see page 15220)	This is GetAppDispatcher, a member of class IGetAppDispatcher.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.

	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ProduceContent (see page 15224)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15225)	This is ProduceContentFromStream, a member of class IProduceContentFrom.
	ProduceContentFromString (see page 15226)	This is ProduceContentFromString, a member of class IProduceContentFrom.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetAppDispatcher (see page 15227)	This is SetAppDispatcher, a member of class ISetAppDispatcher.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Dispatcher (see page 15109)	Provides access to the dispatcher for the Web server application that includes the TCustomContentProducer (see page 15102) object.
R	DispatcherComponent (see page 15110)	Provides access to the dispatcher component.
	Editor (see page 10310)	Writes changes made in the property editor at design time to the TDSTableProducer (see page 10290) object.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCreateContent (see page 10289)	Occurs in descendants of TDSTableProducer when the Content method needs to generate the HTML table image.
	OnFormatCell (see page 10289)	Occurs when the HTML for a specified cell specified is about to be generated.
	OnGetTableCaption (see page 10290)	Occurs when the HTML table producer is about to generate the HTML for the table caption.

Published Properties

	Name	Description
	Caption (see page 10284)	Specifies the caption string that appears with the HTML table.
	CaptionAlignment (see page 10284)	Specifies where the Caption string should appear relative to the HTML table.

	Columns (see page 10285)	Describes the field bindings and display attributes of the columns in the HTML table.
	DataSet (see page 10285)	Specifies the dataset from which the data in the HTML table is taken.
	Footer (see page 10286)	Specifies a set of HTML commands that appear in the HTML document following the HTML table.
	Header (see page 10286)	Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.
	MaxRows (see page 10287)	Specifies the maximum number of rows that appear in the HTML table.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	RowAttributes (see page 10287)	Specifies the display attributes of all the rows in the HTML table.
	TableAttributes (see page 10288)	Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer.
	Tag (see page 2808)	Stores an integer value as part of a component.

54.1.1.2 TDataSetTableProducer Methods

The methods of the TDataSetTableProducer class are listed here.

Protected Methods

	Name	Description
	GetDataSet (see page 10283)	Provides the abstract prototype of a method to access the DataSet property.
	Notification (see page 10283)	Adjusts the properties of TDSTableProducer when its helper objects are destroyed.
	SetDataSet (see page 10283)	Provides the abstract prototype of a method to set the DataSet property.

Public Methods

	Name	Description
	Content (see page 10282)	Returns the HTML representation of the records in the dataset.

54.1.1.2.1 TDataSetTableProducer.Content Method

Returns the HTML representation of the records in the dataset.

Pascal

```
function Content: string; override;
```

C++

```
virtual __fastcall AnsiString Content();
```

Description

Call Content to retrieve the HTML representation specified by the properties of the TDataSetTableProducer (see page 10277) object. Content calls the OnCreateContent (see page 10289) event handler. If the OnCreateContent (see page 10289) event handler indicates that the Content method should continue, Content returns the Header (see page 10286) property, followed by an HTML table image of the records in the dataset, followed by the Footer (see page 10286) property. If the OnCreateContent (see page 10289) event handler indicates that the Content method should not continue, Content returns an empty string.

The string returned by Content can be used as the Content property of the response to an HTTP request message.

See Also

Footer (see page 10310)

Header (see page 10311)

OnCreateContent (see page 10313)

TWebRequest (see page 15161)

Content (see page 15207)

54.1.1.2.2 TDataSetTableProducer.GetDataSet Method

Provides the abstract prototype of a method to access the DataSet property.

Pascal

```
function GetDataSet: TDataSet; override;
```

C++

```
virtual __fastcall TDataSet GetDataSet();
```

Description

Descendants of TDSTableProducer implement the GetDataSet method to access their specific implementation of the DataSet property. Descendants of TDSTableProducer restrict the DataSet property to different classes of TDataSet objects.

See Also

DataSet (see page 10309)

SetDataSet (see page 10305)

54.1.1.2.3 TDataSetTableProducer.Notification Method

Adjusts the properties of TDSTableProducer when its helper objects are destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification overrides the inherited method to respond to messages that the DataSource or one of its field objects is about to be destroyed. Notification sets the DataSource property to nil (Delphi) or NULL (C++), or unbinds the column that references the field component.

See Also

DataSource (see page 10309)

Columns (see page 10308)

54.1.1.2.4 TDataSetTableProducer.SetDataSet Method

Provides the abstract prototype of a method to set the DataSet property.

Pascal

```
procedure SetDataSet(ADataSet: TDataSet); override;
```

C++

```
virtual __fastcall SetDataSet(TDataSet ADataSet);
```

Description

Descendants of TDSTableProducer override SetDataSet to ensure that the DataSet property can only be set to an appropriate

descendant of TDataSet.

See Also

DataSet (see page 10309)

GetDataSet (see page 10302)

54.1.1.3 TDataSetTableProducer Properties

The properties of the TDataSetTableProducer class are listed here.

Published Properties

	Name	Description
	Caption (see page 10284)	Specifies the caption string that appears with the HTML table.
	CaptionAlignment (see page 10284)	Specifies where the Caption string should appear relative to the HTML table.
	Columns (see page 10285)	Describes the field bindings and display attributes of the columns in the HTML table.
	DataSet (see page 10285)	Specifies the dataset from which the data in the HTML table is taken.
	Footer (see page 10286)	Specifies a set of HTML commands that appear in the HTML document following the HTML table.
	Header (see page 10286)	Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.
	MaxRows (see page 10287)	Specifies the maximum number of rows that appear in the HTML table.
	RowAttributes (see page 10287)	Specifies the display attributes of all the rows in the HTML table.
	TableAttributes (see page 10288)	Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer.

54.1.1.3.1 TDataSetTableProducer.Caption Property

Specifies the caption string that appears with the HTML table.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

Description

Set Caption to add a caption to the HTML table that represents the dataset. Caption indicates the text that should appear inside the HTML CAPTION tag.

See Also

CaptionAlignment (see page 10308)

OnGetTableCaption (see page 10314)

Embedding Tables in HTML Documents

54.1.1.3.2 TDataSetTableProducer.CaptionAlignment Property

Specifies where the Caption string should appear relative to the HTML table.

Pascal

```
property CaptionAlignment: THTMLCaptionAlignment;
```

C++

```
__property THTMLCaptionAlignment CaptionAlignment;
```

Description

Set CaptionAlignment to specify whether the Caption should appear above or below the HTML table.

CaptionAlignment is the value of the ALIGN option on the HTML CAPTION tag.

See Also

Caption (see page 10307)

Embedding Tables in HTML Documents

54.1.1.3.3 TDataSetTableProducer.Columns Property

Describes the field bindings and display attributes of the columns in the HTML table.

Pascal

```
property Columns: THTMLTableColumns;
```

C++

```
__property THTMLTableColumns Columns;
```

Description

Use Columns to read or set the field bindings and display attributes of the columns in the HTML table. Each THTMLTableColumn object specifies the display attributes of the corresponding column. Each column object also specifies the name of the field the column represents. The field binding of a column designates a field within the dataset specified by the DataSet property.

Columns can be set at design time through a property editor, or programmatically at runtime.

See Also

DataSet (see page 10309)

DefineFieldMap (see page 10298)

Editor (see page 10310)

RowAttributes (see page 10312)

SetColumns (see page 10304)

StoreColumns (see page 10305)

TableAttributes (see page 10313)

THTMLTableColumn (see page 10318)

THTMLTableColumns (see page 10327)

Specifying the Columns

54.1.1.3.4 TDataSetTableProducer.DataSet Property

Specifies the dataset from which the data in the HTML table is taken.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Set DataSet to specify where the TDSTableProducer should look for the data it displays in the HTML table. The individual field bindings specified by the THTMLTableColumn objects in the Columns property refer to fields in DataSet.

Specify the data binding of a TDSTableProducer using the DataSet property rather than through a DataSource property. TDSTableProducer objects do not use an external TDataSource object.

See Also

DataSource (see page 10309)

InternalDataSource (see page 10311)

Columns (see page 10308)

GetDataSet (see page 10302)

SetDataSet (see page 10305)

FieldName (see page 10326)

Using TDataSetTableProducer

54.1.1.3.5 TDataSetTableProducer.Footer Property

Specifies a set of HTML commands that appear in the HTML document following the HTML table.

Pascal

```
property Footer: TStrings;
```

C++

```
__property TStrings Footer;
```

Description

Set Footer to embed the representation of DataSet in a larger document. The Content method of TDSTableProducer descendants returns any Header commands, followed by the HTML table that represents the DataSet, followed by any Footer commands.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Header (see page 10311)

Embedding Tables in HTML Documents

54.1.1.3.6 TDataSetTableProducer.Header Property

Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.

Pascal

```
property Header: TStrings;
```

C++

```
__property TStrings Header;
```

Description

Set Header to embed the representation of DataSet in a larger document. The Content method of TDSTableProducer descendants returns any Header commands, followed by the HTML table that represents the DataSet, followed by any Footer commands.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Footer (see page 10310)

Embedding Tables in HTML Documents

54.1.1.3.7 TDataSetTableProducer.MaxRows Property

Specifies the maximum number of rows that appear in the HTML table.

Pascal

```
property MaxRows: Integer;
```

C++

```
__property int MaxRows;
```

Description

Set MaxRows to change the upper limit on the size of the HTML table produced to represent the DataSet. MaxRows is initialized to 20.

If DataSet contains more than MaxRows records, only the first MaxRows records appear in the HTML commands produced by Content. If DataSet contains fewer than MaxRows records, the HTML table produced by TDSTableProducer will contain only enough rows to display all the records in DataSet.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Specifying the Row Attributes

54.1.1.3.8 TDataSetTableProducer.RowAttributes Property

Specifies the display attributes of all the rows in the HTML table.

Pascal

```
property RowAttributes: THTMLTableRowAttributes;
```

C++

```
__property THTMLTableRowAttributes RowAttributes;
```

Description

Set RowAttributes to a THTMLTableRowAttributes object that describes the display attributes of the rows in the HTML table. Setting RowAttributes calls the Assign method of the THTMLTableRowAttributes object stored internally by TDSTableProducer. Thus, the memory for any row attributes object assigned to the RowAttributes property is never owned or freed by TDSTableProducer.

Note: Not all the properties of the row attributes object are copied when one row attributes object is assigned to another. To ensure that all the attributes represented by RowAttributes are set appropriately, read RowAttributes and set the individual properties of the THTMLTableRowAttributes object.

See Also

TableAttributes (see page 10313)

Title (see page 10327)

AssignTo (see page 15297)

Specifying the Row Attributes

54.1.1.3.9 TDataSetTableProducer.TableAttributes Property

Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer.

Pascal

```
property TableAttributes: THTMLTableAttributes;
```

C++

```
__property THTMLTableAttributes TableAttributes;
```

Description

Set TableAttributes to a THTMLTableAttributes object that describes the display attributes for the HTML TABLE tag. Setting TableAttributes calls the Assign method of the THTMLTableAttributes object stored internally by TDSTableProducer. Thus, the memory for any table attributes object assigned to the TableAttributes property is never owned or freed by TDSTableProducer.

Note: Not all the properties of the table attributes object are copied when one table attributes object is assigned to another. To ensure that all the attributes represented by TableAttributes are set appropriately, read TableAttributes and set the individual properties of the THTMLTableAttributes object.

See Also

RowAttributes (see page 10312)

AssignTo (see page 15291)

Title (see page 10327)

Specifying the Table Attributes

54.1.1.4 TDataSetTableProducer Events

The events of the TDataSetTableProducer class are listed here.

Published Events

	Name	Description
	OnCreateContent (see page 10289)	Occurs in descendants of TDSTableProducer when the Content method needs to generate the HTML table image.
	OnFormatCell (see page 10289)	Occurs when the HTML for a specified cell specified is about to be generated.
	OnGetTableCaption (see page 10290)	Occurs when the HTML table producer is about to generate the HTML for the table caption.

54.1.1.4.1 TDataSetTableProducer.OnCreateContent Event

Occurs in descendants of TDSTableProducer when the Content method needs to generate the HTML table image.

Pascal

```
property OnCreateContent: TCreateContentEvent;
```

C++

```
__property TCreateContentEvent OnCreateContent;
```

Description

Write an OnCreateContent event handler to conditionally prevent the Content method from producing any HTML commands. Set the Continue parameter to false to make Content return an empty string.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

docreatecontent (see page 10299)

54.1.1.4.2 TDataSetTableProducer.OnFormatCell Event

Occurs when the HTML for a specified cell specified is about to be generated.

Pascal

```
property OnFormatCell: THTMLFormatCellEvent;
```

C++

```
__property THTMLFormatCellEvent OnFormatCell;
```

Description

Write an OnFormatCell event handler to change the appearance or contents of individual cells in the HTML table from the default values produced by TDSTableProducer.

See Also

Columns (see page 10308)

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DoFormatCell (see page 10299)

DisplayText (see page 7162)

Align (see page 10324)

BgColor (see page 10325)

Custom (see page 10325)

VAlign (see page 10327)

54.1.1.4.3 TDataSetTableProducer.OnGetTableCaption Event

Occurs when the HTML table producer is about to generate the HTML for the table caption.

Pascal

```
property OnGetTableCaption: THTMLGetTableCaptionEvent;
```

C++

```
__property THTMLGetTableCaptionEvent OnGetTableCaption;
```

Description

Write an OnGetTableCaption event handler to change the value or placement of the HTML table caption. The Caption and Alignment parameters are originally set to the values of the Caption and CaptionAlignment properties, respectively. The OnGetTableCaption event handler can change these values to alter the caption for the HTML table returned by the Content method.

See Also

Caption (see page 10307)

CaptionAlignment (see page 10308)

Content (see page 15106)

DoGetCaption (see page 10300)

54.1.2 TDSTableProducer Class

TDSTableProducer is the base class for objects that produce a set of HTML commands to display the records from a dataset in a tabular format.

Class Hierarchy

Pascal

```
TDSTableProducer = class(TCustomContentProducer);
```

C++

```
class TDSTableProducer : public TCustomContentProducer;
```

File

DBWeb

Description

Use TDSTableProducer as a base class when defining a class that produces an HTML table that represents the records of a dataset. TDSTableProducer introduces many properties to describe the appearance and data binding of the HTML table. The events and methods of TDSTableProducer allow an application to retrieve the database information and produce the HTML commands that describe the table.

See Also

TDataSetTableProducer (see page 10277)

TQueryTableProducer (see page 8152)

TSQLQueryTableProducer (see page 10842)

54.1.2.1 TDSTableProducer Members

The following tables list the members exposed by TDSTableProducer.

Protected Events

	Name	Description
	OnCreateContent (see page 10313)	Occurs in descendants of TDSTableProducer (see page 10290) when the Content method needs to generate the HTML table image.
	OnFormatCell (see page 10314)	Occurs when the HTML for a specified cell specified is about to be generated.
	OnGetTableCaption (see page 10314)	Occurs when the HTML table producer is about to generate the HTML for the table caption.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AcquireLayoutLock (see page 10296)	Calls BeginLayout (see page 10297) when the HTML table is not currently being laid out.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	BeginLayout (see page 10297)	Increments a counter that indicates the number of times the computation of the column order was begun but not completed.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ColumnHeader (see page 10298)	Returns the string of HTML <TH> tags that define the column headers for the table.
	DefineFieldMap (see page 10298)	Builds the Fields array in DataLink (see page 10309).
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	DoCreateContent (see page 10299)	This is DoCreateContent, a member of class TDSTableProducer.
	DoFormatCell (see page 10299)	Generates an OnFormatCell (see page 10314) event.
	DoGetCaption (see page 10300)	Generates an OnGetCaption event.
	EndLayout (see page 10300)	Decrements a counter that indicates the number of times the computation of the column order has been begun but not completed.
	FormatCell (see page 10301)	Returns an HTML tag of a specified type that reflects a set of specified options.
	GetAppDispatcher (see page 15108)	This is GetAppDispatcher, a member of class TCustomContentProducer.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
A	GetDataSet (see page 10302)	Provides the abstract prototype of a method to access the DataSet (see page 10309) property.
	GetDataSource (see page 10302)	Returns the value of the DataSource (see page 10309) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	LayoutChanged (see page 10303)	Causes the Columns (see page 10308) property to be recomputed when the dataset changes or changes are made to individual column objects.
	LinkActive (see page 10303)	Recomputes the Columns (see page 10308) property when the dataset becomes active.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 10304)	Adjusts the properties of TDSTableProducer (see page 10290) when its helper objects are destroyed.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	ProduceContent (see page 15108)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15109)	This is ProduceContentFromStream, a member of class TCustomContentProducer.
	ProduceContentFromString (see page 15109)	This is ProduceContentFromString, a member of class TCustomContentProducer.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RowHeader (see page 10304)	Returns the HTML <TR> tag that defines each row of the HTML table.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAppDispatcher (see page 15109)	This is SetAppDispatcher, a member of class TCustomContentProducer.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetColumns (see page 10304)	Sets the Columns (see page 10308) property.
A	SetDataSet (see page 10305)	Provides the abstract prototype of a method to set the DataSet (see page 10309) property.
	SetDataSource (see page 10305)	Sets the DataSource (see page 10309) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	StoreColumns (see page 10305)	Indicates whether the Columns (see page 10308) property is stored when the TDSTableProducer (see page 10290) is saved.
	TableCaption (see page 10306)	Returns the HTML <Caption (see page 10307)> tag that defines the caption for the HTML table.
	TableHeader (see page 10306)	Returns the HTML <Table> tag for the HTML table.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.

	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	DataLink (see page 10309)	Manages the link to the dataset.
	DataSource (see page 10309)	Represents the link to the DataSet (see page 10309) of the TDSTableProducer (see page 10290).
	InternalDataSource (see page 10311)	Represents the link to the dataset.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 10297)	Increments a counter that indicates the number of changes to the contents of the HTML table that have been initiated but not completed.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Content (see page 15106)	Returns the content produced by the content producer.
	ContentFromStream (see page 15107)	Returns the content produced in response to input read from a stream.
	ContentFromString (see page 15107)	Returns the content produced in response to an input string.
	Create (see page 10295)	Creates an instance of TDSTableProducer (see page 10290).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 10295)	Destroys an instance of TDSTableProducer (see page 10290).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 10301)	Decrements a counter that indicates the number of changes to the contents of the HTML table.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.

	GetAppDispatcher (see page 15220)	This is GetAppDispatcher, a member of class IGetAppDispatcher.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ProduceContent (see page 15224)	Returns the content that the producer creates.
	ProduceContentFromStream (see page 15225)	This is ProduceContentFromStream, a member of class IProduceContentFrom.
	ProduceContentFromString (see page 15226)	This is ProduceContentFromString, a member of class IProduceContentFrom.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetAppDispatcher (see page 15227)	This is SetAppDispatcher, a member of class ISetAppDispatcher.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
	Caption (see page 10307)	Specifies the caption string that appears with the HTML table.
	CaptionAlignment (see page 10308)	Specifies where the Caption (see page 10307) string should appear relative to the HTML table.
	Columns (see page 10308)	Describes the field bindings and display attributes of the columns in the HTML table.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DataSet (see page 10309)	Specifies the dataset from which the data in the HTML table is taken.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Dispatcher (see page 15109)	Provides access to the dispatcher for the Web server application that includes the TCustomContentProducer (see page 15102) object.
R	DispatcherComponent (see page 15110)	Provides access to the dispatcher component.

	Editor (see page 10310)	Writes changes made in the property editor at design time to the TDSTableProducer (see page 10290) object.
	Footer (see page 10310)	Specifies a set of HTML commands that appear in the HTML document following the HTML table.
	Header (see page 10311)	Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.
	MaxRows (see page 10312)	Specifies the maximum number of rows that appear in the HTML table.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	RowAttributes (see page 10312)	Specifies the display attributes of all the rows in the HTML table.
	TableAttributes (see page 10313)	Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer (see page 10290).
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

54.1.2.2 TDSTableProducer.Create Constructor

Creates an instance of TDSTableProducer (see page 10290).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDSTableProducer(TComponent * AOwner);
```

Description

Call Create to create a table producer from within the OnAction event handler of a TWebActionItem that needs to produce an HTML image of a dataset in response to an HTTP request message.

After calling the inherited constructor, Create allocates all the helper objects used by TDSTableProducer (see page 10290) and initializes the MaxRows (see page 10312) property to 20.

See Also

MaxRows (see page 10312)

Create (see page 2766)

54.1.2.3 TDSTableProducer.Destroy Destructor

Destroys an instance of TDSTableProducer (see page 10290).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDSTableProducer();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the TDSTableProducer (see page 10290) reference is not nil, and only then calls Destroy.

Destroy frees all the helper objects used by TDSTableProducer (see page 10290).

See Also

Free (see page 22300)

54.1.2.4 TDSTableProducer Methods

The methods of the TDSTableProducer class are listed here.

Protected Methods

	Name	Description
	AcquireLayoutLock (see page 10296)	Calls BeginLayout (see page 10297) when the HTML table is not currently being laid out.
	BeginLayout (see page 10297)	Increments a counter that indicates the number of times the computation of the column order was begun but not completed.
	ColumnHeader (see page 10298)	Returns the string of HTML <TH> tags that define the column headers for the table.
	DefineFieldMap (see page 10298)	Builds the Fields array in DataLink (see page 10309).
	DoCreateContent (see page 10299)	This is DoCreateContent, a member of class TDSTableProducer.
	DoFormatCell (see page 10299)	Generates an OnFormatCell (see page 10314) event.
	DoGetCaption (see page 10300)	Generates an OnGetCaption event.
	EndLayout (see page 10300)	Decrements a counter that indicates the number of times the computation of the column order has been begun but not completed.
	FormatCell (see page 10301)	Returns an HTML tag of a specified type that reflects a set of specified options.
A	GetDataSet (see page 10302)	Provides the abstract prototype of a method to access the DataSet (see page 10309) property.
	GetDataSource (see page 10302)	Returns the value of the DataSource (see page 10309) property.
	LayoutChanged (see page 10303)	Causes the Columns (see page 10308) property to be recomputed when the dataset changes or changes are made to individual column objects.
	LinkActive (see page 10303)	Recomputes the Columns (see page 10308) property when the dataset becomes active.
V	Notification (see page 10304)	Adjusts the properties of TDSTableProducer (see page 10290) when its helper objects are destroyed.
	RowHeader (see page 10304)	Returns the HTML <TR> tag that defines each row of the HTML table.
	SetColumns (see page 10304)	Sets the Columns (see page 10308) property.
A	SetDataSet (see page 10305)	Provides the abstract prototype of a method to set the DataSet (see page 10309) property.
	SetDataSource (see page 10305)	Sets the DataSource (see page 10309) property.
	StoreColumns (see page 10305)	Indicates whether the Columns (see page 10308) property is stored when the TDSTableProducer (see page 10290) is saved.
	TableCaption (see page 10306)	Returns the HTML <Caption (see page 10307)> tag that defines the caption for the HTML table.
	TableHeader (see page 10306)	Returns the HTML <Table> tag for the HTML table.

Public Methods

	Name	Description
	BeginUpdate (see page 10297)	Increments a counter that indicates the number of changes to the contents of the HTML table that have been initiated but not completed.
	EndUpdate (see page 10301)	Decrements a counter that indicates the number of changes to the contents of the HTML table.

54.1.2.4.1 TDSTableProducer.AcquireLayoutLock Method

Calls BeginLayout (see page 10297) when the HTML table is not currently being laid out.

Pascal

```
function AcquireLayoutLock: Boolean;
```

C++

```
__fastcall Boolean AcquireLayoutLock();
```

Description

Applications cannot call this protected method. AcquireLayoutLock is called before recomputing Columns (see page 10308) when the fields in the dataset change or when the Columns (see page 10308) property changes. AcquireLayoutLock returns true if the HTML table is not already being laid out, to indicate that the computation of Columns (see page 10308) should proceed. AcquireLayoutLock prevents the computation of Columns (see page 10308) from looping endlessly in response to the changes that occur during the computation.

See Also

BeginLayout (see page 10297)

Columns (see page 10308)

LayoutChanged (see page 10303)

54.1.2.4.2 TDSTableProducer.BeginLayout Method

Increments a counter that indicates the number of times the computation of the column order was begun but not completed.

Pascal

```
procedure BeginLayout;
```

C++

```
__fastcall BeginLayout();
```

Description

Applications cannot call this protected method. TDSTableProducer (see page 10290) calls BeginLayout internally before making changes to the Columns (see page 10308) property or any of the individual THTMLTableColumn (see page 10318) objects in Columns (see page 10308). Once the change is complete, TDSTableProducer (see page 10290) calls EndLayout (see page 10300).

When all BeginLayout calls have been matched by a corresponding call to EndLayout (see page 10300), the field mapping maintained by DataLink (see page 10309) for the fields in the dataset is updated to match both the field bindings of the Columns (see page 10308) property and the fields available in the dataset. The Columns (see page 10308) property is updated in turn to match the field bindings in DataLink (see page 10309). This ensures that the Columns (see page 10308) property matches both the specified column bindings and the fields available in the dataset.

See Also

AcquireLayoutLock (see page 10296)

BeginUpdate (see page 10297)

Columns (see page 10308)

DataLink (see page 10309)

DefineFieldMap (see page 10298)

EndLayout (see page 10300)

54.1.2.4.3 TDSTableProducer.BeginUpdate Method

Increments a counter that indicates the number of changes to the contents of the HTML table that have been initiated but not

completed.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

Applications should not call BeginUpdate. BeginUpdate is called internally before changes that affect the contents of the HTML table. Once a change is complete, EndUpdate (see page 10301) is called. BeginUpdate and EndUpdate (see page 10301) allow descendants of TDSTableProducer (see page 10290) to wait until changes to the dataset are complete before fetching records for the HTML image of the table.

See Also

BeginLayout (see page 10297)

DataSet (see page 10309)

EndUpdate (see page 10301)

54.1.2.4.4 TDSTableProducer.ColumnHeader Method

Returns the string of HTML <TH> tags that define the column headers for the table.

Pascal

```
function ColumnHeader: string; dynamic;
```

C++

```
__fastcall AnsiString ColumnHeader();
```

Description

The table producer uses this protected method when it assembles its HTML table. For each THTMLTableColumn (see page 10318) object listed in the Columns (see page 10308) property, ColumnHeader looks up the string that labels it (using its Title property or the display name for the field if there is no title caption). ColumnHeader then creates a table header (<TH>) tag that describes the column label, including all the properties specified by the THTMLTableColumn (see page 10318) object.

See Also

Columns (see page 10308)

RowHeader (see page 10304)

TableHeader (see page 10306)

Title (see page 10327)

54.1.2.4.5 TDSTableProducer.DefineFieldMap Method

Builds the Fields array in DataLink (see page 10309).

Pascal

```
procedure DefineFieldMap;
```

C++

```
__fastcall DefineFieldMap();
```

Description

Applications cannot call this protected method. DefineFieldMap rebuilds the field mapping for the dataset that is maintained by DataLink (see page 10309). This mapping reflects both the column bindings of the Columns (see page 10308) property and the fields available in the dataset. After calling DefineFieldMap, the Columns (see page 10308) property should be updated to match the field bindings in DataLink (see page 10309). This ensures that the Columns (see page 10308) property reflects any changes imposed by the dataset.

See Also

Columns (see page 10308)

DataSet (see page 10309)

EndLayout (see page 10300)

Fields (see page 10345)

54.1.2.4.6 TDSTableProducer.DoCreateContent Method

Pascal

```
function DoCreateContent: Boolean;
```

C++

```
__fastcall Boolean DoCreateContent();
```

Description

This is DoCreateContent, a member of class TDSTableProducer.

54.1.2.4.7 TDSTableProducer.DoFormatCell Method

Generates an OnFormatCell (see page 10314) event.

Pascal

```
procedure DoFormatCell(CellRow: Integer; CellColumn: Integer; var BgColor: THTMLBgColor; var
Align: THTMLAlign; var VAlign: THTMLVAlign; var CustomAttrs: string; var CellData: string);
dynamic;
```

C++

```
__fastcall DoFormatCell(int CellRow, int CellColumn, THTMLBgColor BgColor, THTMLAlign Align,
THTMLVAlign VAlign, AnsiString CustomAttrs, AnsiString CellData);
```

Description

Applications can't call this protected method. It is called internally by the Content method to allow the OnFormatCell (see page 10314) event handler to customize the contents or display attributes of any cell in the HTML table. CellRow and CellColumn indicate the cell about to be rendered as HTML, where CellRow for the table header is 0, and CellColumn for the first column is 0. BgColor, Align, VAlign, and CustomAttrs are the display attributes that can be changed. CellData is the text that goes in the cell.

Descendants of TDSTableProducer (see page 10290) can override DoFormatCell to make additional changes to the cells as they are rendered or to block the OnFormatCell (see page 10314) event.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

OnFormatCell (see page 10314)

54.1.2.4.8 TDSTableProducer.DoGetCaption Method

Generates an OnGetCaption event.

Pascal

```
procedure DoGetCaption(var TableCaption: string; var CaptionAlign: THTMLCaptionAlignment);
dynamic;
```

C++

```
__fastcall DoGetCaption(AnsiString TableCaption, THTMLCaptionAlignment CaptionAlign);
```

Description

Applications can't call this protected method. It is called internally by the Content method to let the OnGetTableCaption (see page 10314) event handler change the Caption (see page 10307) and CaptionAlignment (see page 10308) properties when the table caption is rendered as HTML.

Descendants of TDSTableProducer (see page 10290) can override DoCreateCaption to make additional changes when the caption is rendered or to block the OnCreateCaption event.

See Also

Caption (see page 10307)

CaptionAlignment (see page 10308)

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

OnGetTableCaption (see page 10314)

54.1.2.4.9 TDSTableProducer.EndLayout Method

Decrements a counter that indicates the number of times the computation of the column order has been begun but not completed.

Pascal

```
procedure EndLayout;
```

C++

```
__fastcall EndLayout();
```

Description

Applications can't call this protected method. TDSTableProducer (see page 10290) objects call EndLayout internally after making changes to the Columns (see page 10308) property or when changes are made to the fields in DataSet (see page 10309).

Each call to EndLayout should match a corresponding call to BeginLayout (see page 10297). If all BeginLayout (see page 10297) calls have been matched by an EndLayout call, EndLayout calls DefineFieldMap (see page 10298) to regenerate the field mapping for the dataset maintained by DataLink (see page 10309). The Columns (see page 10308) property is then updated to match the field map in DataLink (see page 10309). This ensures that the Columns (see page 10308) property matches both the specified column bindings and the fields available in the dataset.

See Also

BeginLayout (see page 10297)

Columns (see page 10308)

DataLink (see page 10309)

DefineFieldMap (see page 10298)

EndUpdate (see page 10301)

54.1.2.4.10 TDSTableProducer.EndUpdate Method

Decrements a counter that indicates the number of changes to the contents of the HTML table.

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Applications should not call EndUpdate. EndUpdate is called internally after changes to the column bindings or DataSet (see page 10309) of the TDSTableProducer (see page 10290). BeginUpdate (see page 10297) and EndUpdate allow descendants of TDSTableProducer (see page 10290) to wait until changes to the dataset are complete before fetching records for the HTML image of the table.

See Also

BeginUpdate (see page 10297)

Columns (see page 10308)

DataSet (see page 10309)

EndLayout (see page 10300)

54.1.2.4.11 TDSTableProducer.FormatCell Method

Returns an HTML tag of a specified type that reflects a set of specified options.

Pascal

```
function FormatCell(CellRow: Integer; CellColumn: Integer; CellData: string; const Tag:
string; const BgColor: THTMLBgColor; Align: THTMLAlign; VAlign: THTMLVAlign; const Custom:
string): string; dynamic;
```

C++

```
__fastcall AnsiString FormatCell(int CellRow, int CellColumn, AnsiString CellData, const
AnsiString Tag, const THTMLBgColor BgColor, THTMLAlign Align, THTMLVAlign VAlign, const
AnsiString Custom);
```

Description

The table producer uses this protected utility to assemble a set of properties into a single HTML tag. FormatCell first generates an OnFormatCell (see page 10314) event, so that the application can override any of the properties that control the tag options. Then it assembles the resulting values into the specified tag.

CellRow and CellColumn identify the table cell to be formatted. These parameters are passed to an OnFormatCell (see page 10314) event handler so that it can identify the cell.

CellData contains the text displayed in the cell (a data value or column header).

Tag indicates the type of HTML tag to generate (<TD> for data cells, <TH> for column headers).

BgColor specifies the background color of the cell. An OnFormatCell (see page 10314) event handler can override this value.

Align specifies the horizontal alignment of CellData within the cell. An OnFormatCell (see page 10314) event handler can override this value.

VAlign specifies the vertical alignment of CellData within the cell. An OnFormatCell (see page 10314) event handler can override this value.

Custom specifies any other options for the generated HTML tag. An OnFormatCell (see page 10314) event handler can override this value.

FormatCell returns a string with the generated HTML tag.

See Also

OnFormatCell (see page 10314)

54.1.2.4.12 TDSTableProducer.GetDataSet Method

Provides the abstract prototype of a method to access the DataSet (see page 10309) property.

Pascal

```
function GetDataSet: TDataSet; virtual; abstract;
```

C++

```
virtual __fastcall TDataSet GetDataSet() = 0;
```

Description

Descendants of TDSTableProducer (see page 10290) implement the GetDataSet method to access their specific implementation of the DataSet (see page 10309) property. Descendants of TDSTableProducer (see page 10290) restrict the DataSet (see page 10309) property to different classes of TDataSet objects.

See Also

DataSet (see page 10309)

SetDataSet (see page 10305)

54.1.2.4.13 TDSTableProducer.GetDataSource Method

Returns the value of the DataSource (see page 10309) property.

Pascal

```
function GetDataSource: TDataSource;
```

C++

```
__fastcall TDataSource GetDataSource();
```

Description

GetDataSource is exposed as a protected method so that descendants of TDSTableProducer (see page 10290) can override the implementation of the DataSource (see page 10309) property.

The DataSource (see page 10309) property for TDSTableProducer (see page 10290) is an internally generated TDataSource object, not an external component that can be shared with other objects. It is surfaced only for internal APIs that require a TDataSource object rather than working directly with TDataSet.

See Also

DataSource (see page 10309)

SetDataSource (see page 10305)

54.1.2.4.14 TDSTableProducer.LayoutChanged Method

Causes the Columns (see page 10308) property to be recomputed when the dataset changes or changes are made to individual column objects.

Pascal

```
procedure LayoutChanged;
```

C++

```
__fastcall LayoutChanged();
```

Description

Applications cannot call this protected method. It is called when the Columns (see page 10308) property changes or the fields in the dataset change. LayoutChanged recomputes the Columns (see page 10308) property after guarding against recursion from the changes to the Columns (see page 10308) property that arise in the computation.

LayoutChanged calls AcquireLayoutLock (see page 10296) to initiate the changes to Columns (see page 10308). If AcquireLayoutLock (see page 10296) does not indicate that the call to LayoutChanged is recursive, LayoutChanged calls EndLayout (see page 10300) to perform the actual computation.

See Also

AcquireLayoutLock (see page 10296)

Columns (see page 10308)

EndLayout (see page 10300)

54.1.2.4.15 TDSTableProducer.LinkActive Method

Recomputes the Columns (see page 10308) property when the dataset becomes active.

Pascal

```
procedure LinkActive(Value: Boolean);
```

C++

```
__fastcall LinkActive(Boolean Value);
```

Description

Applications cannot call this protected method. LinkActive is called when the DataSource (see page 10309) property changes or when the dataset becomes active. It recomputes Columns (see page 10308) to reflect any changes that may have occurred in the fields of the dataset when it was not active.

See Also

Columns (see page 10308)

DataSource (see page 10309)

LayoutChanged (see page 10303)

54.1.2.4.16 TDSTableProducer.Notification Method

Adjusts the properties of TDSTableProducer (see page 10290) when its helper objects are destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification overrides the inherited method to respond to messages that the DataSource (see page 10309) or one of its field objects is about to be destroyed. Notification sets the DataSource (see page 10309) property to nil (Delphi) or NULL (C++), or unbinds the column that references the field component.

See Also

DataSource (see page 10309)

Columns (see page 10308)

54.1.2.4.17 TDSTableProducer.RowHeader Method

Returns the HTML <TR> tag that defines each row of the HTML table.

Pascal

```
function RowHeader: string; dynamic;
```

C++

```
__fastcall AnsiString RowHeader();
```

Description

The table producer calls this protected method for each row when it assembles its HTML table. RowHeader generates an HTML table row tag (<TR>), using the RowAttributes (see page 10312) property to determine what options are added to the tag.

See Also

RowAttributes (see page 10312)

54.1.2.4.18 TDSTableProducer.SetColumns Method

Sets the Columns (see page 10308) property.

Pascal

```
procedure SetColumns(Value: THTMLTableColumns);
```

C++

```
__fastcall SetColumns(THTMLTableColumns Value);
```

Description

In Delphi, SetColumns is the protected method used to set the Columns (see page 10308) property. In C++, SetColumns is the protected implementation of the Columns (see page 10308) property. SetColumns calls the Assign method of the THTMLTableColumns (see page 10327) object stored internally by TDSTableProducer (see page 10290). Thus, the memory for any columns object assigned to the Columns (see page 10308) property is never owned or freed by TDSTableProducer (see page 10290).

See Also

Columns (see page 10308)

Assign (see page 2736)

AssignTo (see page 10322)

54.1.2.4.19 TDSTableProducer.SetDataSet Method

Provides the abstract prototype of a method to set the DataSet (see page 10309) property.

Pascal

```
procedure SetDataSet(ADataSet: TDataSet); virtual; abstract;
```

C++

```
virtual __fastcall SetDataSet(TDataSet ADataSet) = 0;
```

Description

Descendants of TDSTableProducer (see page 10290) override SetDataSet to ensure that the DataSet (see page 10309) property can only be set to an appropriate descendant of TDataSet.

See Also

DataSet (see page 10309)

GetDataSet (see page 10302)

54.1.2.4.20 TDSTableProducer.SetDataSource Method

Sets the DataSource (see page 10309) property.

Pascal

```
procedure SetDataSource(Value: TDataSource);
```

C++

```
__fastcall SetDataSource(TDataSource Value);
```

Description

SetDataSource is the protected implementation of the DataSource (see page 10309) property.

The DataSource (see page 10309) property for TDSTableProducer (see page 10290) is an internally generated TDataSource object, not an external component that can be shared with other objects. It is surfaced only for internal API calls that require a TDataSource object rather than working directly with TDataSet.

See Also

DataSource (see page 10309)

GetDataSource (see page 10302)

54.1.2.4.21 TDSTableProducer.StoreColumns Method

Indicates whether the Columns (see page 10308) property is stored when the TDSTableProducer (see page 10290) is saved.

Pascal

```
function StoreColumns: Boolean;
```

C++

```
__fastcall Boolean StoreColumns();
```

Description

StoreColumns causes the Columns (see page 10308) property to be stored only when the Columns (see page 10308) property has a State property of csCustom. The State property for Columns (see page 10308) indicates whether the columns represent default display attributes for all the fields in the dataset, or if the display attributes or field bindings of the columns have been customized programmatically or by the Columns (see page 10308) editor.

See Also

Columns (see page 10308)

State (see page 10335)

54.1.2.4.22 TDSTableProducer.TableCaption Method

Returns the HTML <Caption (see page 10307)> tag that defines the caption for the HTML table.

Pascal

```
function TableCaption: string; dynamic;
```

C++

```
__fastcall AnsiString TableCaption();
```

Description

The table producer calls this protected method when it assembles its HTML table. TableCaption generates an OnGetTableCaption (see page 10314) event to allow an event handler to override the Caption (see page 10307) and CaptionAlignment (see page 10308) properties. It then returns the HTML table caption tag (<caption>) with the resulting caption and alignment.

See Also

Caption (see page 10307)

OnGetTableCaption (see page 10314)

CaptionAlignment (see page 10308)

54.1.2.4.23 TDSTableProducer.TableHeader Method

Returns the HTML <Table> tag for the HTML table.

Pascal

```
function TableHeader: string; dynamic;
```

C++

```
__fastcall AnsiString TableHeader();
```

Description

The table producer calls this protected method when it assembles its HTML table. TableHeader generates an HTML table tag (<Table>), using the TableAttributes (see page 10313) property to determine what options are added to the tag.

See Also

TableAttributes (see page 10313)

54.1.2.5 TDSTableProducer Properties

The properties of the TDSTableProducer class are listed here.

Protected Properties

	Name	Description
R	DataLink (see page 10309)	Manages the link to the dataset.
	DataSource (see page 10309)	Represents the link to the DataSet (see page 10309) of the TDSTableProducer (see page 10290).
R	InternalDataSource (see page 10311)	Represents the link to the dataset.

Public Properties

	Name	Description
	Caption (see page 10307)	Specifies the caption string that appears with the HTML table.
	CaptionAlignment (see page 10308)	Specifies where the Caption (see page 10307) string should appear relative to the HTML table.
	Columns (see page 10308)	Describes the field bindings and display attributes of the columns in the HTML table.
	DataSet (see page 10309)	Specifies the dataset from which the data in the HTML table is taken.
	Editor (see page 10310)	Writes changes made in the property editor at design time to the TDSTableProducer (see page 10290) object.
	Footer (see page 10310)	Specifies a set of HTML commands that appear in the HTML document following the HTML table.
	Header (see page 10311)	Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.
	MaxRows (see page 10312)	Specifies the maximum number of rows that appear in the HTML table.
	RowAttributes (see page 10312)	Specifies the display attributes of all the rows in the HTML table.
	TableAttributes (see page 10313)	Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer (see page 10290).

54.1.2.5.1 TDSTableProducer.Caption Property

Specifies the caption string that appears with the HTML table.

Pascal

```
property Caption: string;
```

C++

```
__property AnsiString Caption;
```

Description

Set Caption to add a caption to the HTML table that represents the dataset. Caption indicates the text that should appear inside the HTML CAPTION tag.

See Also

CaptionAlignment (see page 10308)

OnGetTableCaption (see page 10314)

Embedding Tables in HTML Documents

54.1.2.5.2 TDSTableProducer.CaptionAlignment Property

Specifies where the Caption (see page 10307) string should appear relative to the HTML table.

Pascal

```
property CaptionAlignment: THTMLCaptionAlignment;
```

C++

```
__property THTMLCaptionAlignment CaptionAlignment;
```

Description

Set CaptionAlignment to specify whether the Caption (see page 10307) should appear above or below the HTML table.

CaptionAlignment is the value of the ALIGN option on the HTML CAPTION tag.

See Also

Caption (see page 10307)

Embedding Tables in HTML Documents

54.1.2.5.3 TDSTableProducer.Columns Property

Describes the field bindings and display attributes of the columns in the HTML table.

Pascal

```
property Columns: THTMLTableColumns;
```

C++

```
__property THTMLTableColumns Columns;
```

Description

Use Columns to read or set the field bindings and display attributes of the columns in the HTML table. Each THTMLTableColumn (see page 10318) object specifies the display attributes of the corresponding column. Each column object also specifies the name of the field the column represents. The field binding of a column designates a field within the dataset specified by the DataSet (see page 10309) property.

Columns can be set at design time through a property editor, or programmatically at runtime.

See Also

DataSet (see page 10309)

DefineFieldMap (see page 10298)

Editor (see page 10310)

RowAttributes (see page 10312)

SetColumns (see page 10304)

StoreColumns (see page 10305)

TableAttributes (see page 10313)

THTMLTableColumn (see page 10318)

THTMLTableColumns (see page 10327)

Specifying the Columns

54.1.2.5.4 TDSTableProducer.DataLink Property

Manages the link to the dataset.

Pascal

```
property DataLink: THTTPDataLink;
```

C++

```
__property THTTPDataLink DataLink;
```

Description

Applications cannot use the DataLink property. It is exposed as a protected property so that descendant HTML producers can customize their response to data events.

See Also

DataSet (see page 10309)

InternalDataSource (see page 10311)

54.1.2.5.5 TDSTableProducer.DataSet Property

Specifies the dataset from which the data in the HTML table is taken.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Set DataSet to specify where the TDSTableProducer (see page 10290) should look for the data it displays in the HTML table. The individual field bindings specified by the THTMLTableColumn (see page 10318) objects in the Columns (see page 10308) property refer to fields in DataSet.

Specify the data binding of a TDSTableProducer (see page 10290) using the DataSet property rather than through a DataSource (see page 10309) property. TDSTableProducer (see page 10290) objects do not use an external TDataSource object.

See Also

DataSource (see page 10309)

InternalDataSource (see page 10311)

Columns (see page 10308)

GetDataSet (see page 10302)

SetDataSet (see page 10305)

FieldName (see page 10326)

Using TDataSetTableProducer

54.1.2.5.6 TDSTableProducer.DataSource Property

Represents the link to the DataSet (see page 10309) of the TDSTableProducer (see page 10290).

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Do not use the DataSource property. The data source of a TDSTableProducer (see page 10290) object is an internally generated TDataSource object that is used for internal interfaces that do not work directly with a TDataSet object.

The InternalDataSource (see page 10311) property provides read-only access to the data source represented by DataSource.

See Also

DataSet (see page 10309)

GetDataSource (see page 10302)

InternalDataSource (see page 10311)

SetDataSource (see page 10305)

54.1.2.5.7 TDSTableProducer.Editor Property

Writes changes made in the property editor at design time to the TDSTableProducer (see page 10290) object.

Pascal

```
property Editor: TDSTableProducerEditor;
```

C++

```
__property TDSTableProducerEditor Editor;
```

Description

Descendants of TDSTableProducer (see page 10290) set the Editor property to the TDSTableProducer (see page 10290) Editor object that connects their implementation with a common property editor. Editor allows a single property editor to represent the properties of different table producers.

54.1.2.5.8 TDSTableProducer.Footer Property

Specifies a set of HTML commands that appear in the HTML document following the HTML table.

Pascal

```
property Footer: TStrings;
```

C++

```
__property TStrings Footer;
```

Description

Set Footer to embed the representation of DataSet (see page 10309) in a larger document. The Content method of TDSTableProducer (see page 10290) descendants returns any Header (see page 10311) commands, followed by the HTML table that represents the DataSet (see page 10309), followed by any Footer commands.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Header (see page 10311)

Embedding Tables in HTML Documents

54.1.2.5.9 TDSTableProducer.Header Property

Specifies a set of HTML commands that appear in the HTML document preceding the HTML table.

Pascal

```
property Header: TStrings;
```

C++

```
__property TStrings Header;
```

Description

Set Header to embed the representation of DataSet (see page 10309) in a larger document. The Content method of TDSTableProducer (see page 10290) descendants returns any Header commands, followed by the HTML table that represents the DataSet (see page 10309), followed by any Footer (see page 10310) commands.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Footer (see page 10310)

Embedding Tables in HTML Documents

54.1.2.5.10 TDSTableProducer.InternalDataSource Property

Represents the link to the dataset.

Pascal

```
property InternalDataSource: TDataSource;
```

C++

```
__property TDataSource InternalDataSource;
```

Description

Descendants of TDSTableProducer (see page 10290) read InternalDataSource to access the properties and methods of the data source. Unlike other data-aware components, TDSTableProducer (see page 10290) does not use an external TDataSource object.

See Also

DataSet (see page 10309)

54.1.2.5.11 TDSTableProducer.MaxRows Property

Specifies the maximum number of rows that appear in the HTML table.

Pascal

```
property MaxRows: Integer;
```

C++

```
__property int MaxRows;
```

Description

Set MaxRows to change the upper limit on the size of the HTML table produced to represent the DataSet (see page 10309). MaxRows is initialized to 20.

If DataSet (see page 10309) contains more than MaxRows records, only the first MaxRows records appear in the HTML commands produced by Content. If DataSet (see page 10309) contains fewer than MaxRows records, the HTML table produced by TDSTableProducer (see page 10290) will contain only enough rows to display all the records in DataSet (see page 10309).

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DataSet (see page 10309)

Specifying the Row Attributes

54.1.2.5.12 TDSTableProducer.RowAttributes Property

Specifies the display attributes of all the rows in the HTML table.

Pascal

```
property RowAttributes: THTMLTableRowAttributes;
```

C++

```
__property THTMLTableRowAttributes RowAttributes;
```

Description

Set RowAttributes to a THTMLTableRowAttributes object that describes the display attributes of the rows in the HTML table. Setting RowAttributes calls the Assign method of the THTMLTableRowAttributes object stored internally by TDSTableProducer (see page 10290). Thus, the memory for any row attributes object assigned to the RowAttributes property is never owned or freed by TDSTableProducer (see page 10290).

Note: Not all the properties of the row attributes object are copied when one row attributes object is assigned to another. To ensure that all the attributes represented by RowAttributes are set appropriately, read RowAttributes and set the individual properties of the THTMLTableRowAttributes object.

See Also

TableAttributes (see page 10313)

Title (see page 10327)

AssignTo (see page 15297)

Specifying the Row Attributes

54.1.2.5.13 TDSTableProducer.TableAttributes Property

Specifies the display attributes that pertain to the entire HTML table produced by TDSTableProducer (see page 10290).

Pascal

```
property TableAttributes: THTMLTableAttributes;
```

C++

```
__property THTMLTableAttributes TableAttributes;
```

Description

Set TableAttributes to a THTMLTableAttributes object that describes the display attributes for the HTML TABLE tag. Setting TableAttributes calls the Assign method of the THTMLTableAttributes object stored internally by TDSTableProducer (see page 10290). Thus, the memory for any table attributes object assigned to the TableAttributes property is never owned or freed by TDSTableProducer (see page 10290).

Note: Not all the properties of the table attributes object are copied when one table attributes object is assigned to another. To ensure that all the attributes represented by TableAttributes are set appropriately, read TableAttributes and set the individual properties of the THTMLTableAttributes object.

See Also

RowAttributes (see page 10312)

AssignTo (see page 15291)

Title (see page 10327)

Specifying the Table Attributes

54.1.2.6 TDSTableProducer Events

The events of the TDSTableProducer class are listed here.

Protected Events

	Name	Description
	OnCreateContent (see page 10313)	Occurs in descendants of TDSTableProducer (see page 10290) when the Content method needs to generate the HTML table image.
	OnFormatCell (see page 10314)	Occurs when the HTML for a specified cell specified is about to be generated.
	OnGetTableCaption (see page 10314)	Occurs when the HTML table producer is about to generate the HTML for the table caption.

54.1.2.6.1 TDSTableProducer.OnCreateContent Event

Occurs in descendants of TDSTableProducer (see page 10290) when the Content method needs to generate the HTML table image.

Pascal

```
property OnCreateContent: TCreateContentEvent;
```

C++

```
__property TCreateContentEvent OnCreateContent;
```

Description

Write an OnCreateContent event handler to conditionally prevent the Content method from producing any HTML commands. Set the Continue parameter to false to make Content return an empty string.

See Also

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

docreatecontent (see page 10299)

54.1.2.6.2 TDSTableProducer.OnFormatCell Event

Occurs when the HTML for a specified cell specified is about to be generated.

Pascal

```
property OnFormatCell: THTMLFormatCellEvent;
```

C++

```
__property THTMLFormatCellEvent OnFormatCell;
```

Description

Write an OnFormatCell event handler to change the appearance or contents of individual cells in the HTML table from the default values produced by TDSTableProducer (see page 10290).

See Also

Columns (see page 10308)

Content (see page 10282)

Content (see page 10847)

Content (see page 8157)

DoFormatCell (see page 10299)

DisplayText (see page 7162)

Align (see page 10324)

BgColor (see page 10325)

Custom (see page 10325)

VAlign (see page 10327)

54.1.2.6.3 TDSTableProducer.OnGetTableCaption Event

Occurs when the HTML table producer is about to generate the HTML for the table caption.

Pascal

```
property OnGetTableCaption: THTMLGetTableCaptionEvent;
```

C++

```
__property THTMLGetTableCaptionEvent OnGetTableCaption;
```

Description

Write an OnGetTableCaption event handler to change the value or placement of the HTML table caption. The Caption (see page 10307) and Alignment parameters are originally set to the values of the Caption (see page 10307) and CaptionAlignment (see page 10308) properties, respectively. The OnGetTableCaption event handler can change these values to alter the caption for the HTML table returned by the Content method.

See Also

Caption (see page 10307)

CaptionAlignment (see page 10308)

Content (see page 15106)

DoGetCaption (see page 10300)

54.1.3 TDSTableProducerEditor Class

TDSTableProducer (see page 10290) is the base class for the helper object used by TDSTableProducer (see page 10290) objects to communicate with a property editor at design time.

Class Hierarchy

Pascal

```
TDSTableProducerEditor = class;
```

C++

```
class TDSTableProducerEditor;
```

File

DBWeb

Description

Component writers can derive objects from TDSTableProducer (see page 10290) to enable new descendants of TDSTableProducer (see page 10290) to take advantage of the property editors in the IDE. TDSTableProducerEditor introduces methods to communicate changes between a TDSTableProducer (see page 10290) object and the property editor.

See Also

TDSTableProducer (see page 10290)

54.1.3.1 TDSTableProducerEditor Members

The following tables list the members exposed by TDSTableProducerEditor.

Public Methods

	Name	Description
	Changed (see page 10317)	Provides the interface for a method that responds to change notifications from the TDSTableProducer (see page 10290) object.
	Create (see page 10316)	Creates an instance of TDSTableProducerEditor (see page 10315).
	Destroy (see page 10316)	Destroys an instance of TDSTableProducerEditor (see page 10315).

	PostChange (see page 10317)	Provides an interface for a method that responds to update notifications from the columns of a TDSTableProducer (see page 10290) object.

Public Properties

	Name	Description
	DataSource (see page 10318)	Indicates the DataSource property of the associated TDSTableProducer (see page 10290).
	DSTableProducer (see page 10318)	Indicates the TDSTableProducer (see page 10290) object that uses TDSTableProducerEditor (see page 10315) to communicate with its property editor at design time.

54.1.3.2 TDSTableProducerEditor.Create Constructor

Creates an instance of TDSTableProducerEditor (see page 10315).

Pascal

```
constructor Create(DSTableProducer: TDSTableProducer);
```

C++

```
__fastcall TDSTableProducerEditor(TDSTableProducer DSTableProducer);
```

Description

Do not call Create directly in an application. A TDSTableProducerEditor (see page 10315) is created at design time when needed.

Create initializes the DSTableProducer (see page 10318) property, and sets the Editor property in the TDSTableProducer (see page 10290) object passed as the DSTableProducer (see page 10318) parameter.

See Also

DSTableProducer (see page 10318)

Editor (see page 10310)

54.1.3.3 TDSTableProducerEditor.Destroy Destructor

Destroys an instance of TDSTableProducerEditor (see page 10315).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDSTableProducerEditor();
```

Description

Do not call Destroy from an application. A TDSTableProducerEditor (see page 10315) object is freed automatically at design time. Destroy sets the Editor property of the associated TDSTableProducer (see page 10290) object to nil.

See Also

Free (see page 22300)

Editor (see page 10310)

54.1.3.4 TDSTableProducerEditor Methods

The methods of the TDSTableProducerEditor class are listed here.

Public Methods

	Name	Description
	Changed (see page 10317)	Provides the interface for a method that responds to change notifications from the TDSTableProducer (see page 10290) object.
	PostChange (see page 10317)	Provides an interface for a method that responds to update notifications from the columns of a TDSTableProducer (see page 10290) object.

54.1.3.4.1 TDSTableProducerEditor.Changed Method

Provides the interface for a method that responds to change notifications from the TDSTableProducer (see page 10290) object.

Pascal

```
procedure Changed; virtual;
```

C++

```
virtual __fastcall Changed();
```

Description

The Changed method for TDSTableProducerEditor (see page 10315) does nothing. It exists so that descendants of TDSTableProducerEditor (see page 10315) can perform any necessary updates when the TDSTableProducer (see page 10290) object changes. TDSTableProducer (see page 10290) calls Changed when any of its properties change.

See Also

PostChange (see page 10317)

TDSTableProducer (see page 10290)

54.1.3.4.2 TDSTableProducerEditor.PostChange Method

Provides an interface for a method that responds to update notifications from the columns of a TDSTableProducer (see page 10290) object.

Pascal

```
procedure PostChange; virtual;
```

C++

```
virtual __fastcall PostChange();
```

Description

The PostChange method for TDSTableProducerEditor (see page 10315) does nothing. It exists so that descendants of TDSTableProducerEditor (see page 10315) can perform any necessary updates when the columns of the TDSTableProducer (see page 10290) object change. THTMLTableColumns (see page 10327) calls PostChange when its columns are changed.

See Also

Changed (see page 10317)

THTMLTableColumns (see page 10327)

54.1.3.5 TDSTableProducerEditor Properties

The properties of the TDSTableProducerEditor class are listed here.

Public Properties

	Name	Description
	DataSource (see page 10318)	Indicates the DataSource property of the associated TDSTableProducer (see page 10290).
R	DSTableProducer (see page 10318)	Indicates the TDSTableProducer (see page 10290) object that uses TDSTableProducerEditor (see page 10315) to communicate with its property editor at design time.

54.1.3.5.1 TDSTableProducerEditor.DataSource Property

Indicates the DataSource property of the associated TDSTableProducer (see page 10290).

Pascal

```
property DataSource: TDataSource;
```

C++

```
__property TDataSource DataSource;
```

Description

Applications should not directly change the DataSource property. DataSource allows the property editor to read or change the internal data source of the TDSTableProducer (see page 10290) object.

See Also

DataSource (see page 10309)

54.1.3.5.2 TDSTableProducerEditor.DSTableProducer Property

Indicates the TDSTableProducer (see page 10290) object that uses TDSTableProducerEditor (see page 10315) to communicate with its property editor at design time.

Pascal

```
property DSTableProducer: TDSTableProducer;
```

C++

```
__property TDSTableProducer DSTableProducer;
```

Description

Read TDSTableProducer (see page 10290) to obtain direct access to the TDSTableProducer (see page 10290) object that uses TDSTableProducerEditor (see page 10315).

See Also

TDSTableProducer (see page 10290)

54.1.4 THTMLTableColumn Class

THTMLTableColumn represents the display attributes and field binding of a column in the HTML representation of a dataset.

Class Hierarchy

Pascal

```
THTMLTableColumn = class(TCollectionItem);
```

C++

```
class THTMLTableColumn : public TCollectionItem;
```

File

DBWeb

Description

Use THTMLTableColumn to specify the appearance or value of a column in a table produced by TDSTableProducer (see page 10290). Applications can set the properties of the columns programmatically at runtime, or use the Columns editor at design time.

See Also

THTMLTableColumns (see page 10327)

TDSTableProducer (see page 10290)

Specifying the Columns

54.1.4.1 THTMLTableColumn Members

The following tables list the members exposed by THTMLTableColumn.

Protected Methods

	Name	Description
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	GetDisplayName (see page 10322)	Returns the name of the collection item as it appears in the collection editor.
	GeTDSTableProducer (see page 10323)	This is GeTDSTableProducer, a member of class THTMLTableColumn.
V	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	IsStored (see page 10323)	This is IsStored, a member of class THTMLTableColumn.
V	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
V	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
V	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	AssignTo (see page 10322)	Copies the properties of a THTMLTableColumn (see page 10318) object to another THTMLTableColumn (see page 10318) object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 10320)	Creates an instance of THTMLTableColumn (see page 10318).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 10321)	Destroys an instance of THTMLTableColumn (see page 10318).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	RestoreDefaults (see page 10323)	Changes all properties of the attributes object back to their initial settings.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Update (see page 10324)	Ensures that the Field (see page 10326) property reflects the underlying dataset.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
R	DSTableProducer (see page 10325)	Indicates the table producer component that uses this column.
	Field (see page 10326)	Indicates the field component associated with the field binding of the column.
R	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

Published Properties

	Name	Description
	Align (see page 10324)	Specifies the horizontal alignment of the contents of the cells in the column.
	BgColor (see page 10325)	Specifies the background color of the cells in the column.
	Custom (see page 10325)	Specifies a tag option and its value in the HTML TD tags for the cells in the column.
	FieldName (see page 10326)	Specifies the name of the field to which the column is bound.
	Title (see page 10327)	Specifies the display attributes to be added to the header cell that appears at the top of the column.
	VAlign (see page 10327)	Specifies the vertical alignment of the contents of the cells in the column.

54.1.4.2 THTMLTableColumn.Create Constructor

Creates an instance of THTMLTableColumn (see page 10318).

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall THTMLTableColumn(TCollection Collection);
```

Description

Do not call Create to create and initialize a THTMLTableColumn (see page 10318) object. Columns created using the Columns editor at design time are created automatically. At runtime, create THTMLTableColumn (see page 10318) objects using the Add or Insert methods of the THTMLTableColumns (see page 10327) object that manages them.

After allocating the THTMLTableColumn (see page 10318) object, Create tells the associated TDSTableProducer (see page 10290) object to update its layout.

See Also

Create (see page 2757)

BeginLayout (see page 10297)

EndLayout (see page 10300)

54.1.4.3 THTMLTableColumn.Destroy Destructor

Destroys an instance of THTMLTableColumn (see page 10318).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THTMLTableColumn();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the THTMLTableColumn (see page 10318) reference is not nil, and only then calls Destroy. Do not explicitly free a THTMLTableColumn (see page 10318) that is included in a THTMLTableColumns (see page 10327) object. THTMLTableColumns (see page 10327) frees the individual column objects it manages.

See Also

Free (see page 22300)

THTMLTableColumns (see page 10327)

54.1.4.4 THTMLTableColumn Methods

The methods of the THTMLTableColumn class are listed here.

Protected Methods

	Name	Description
	GetDisplayName (see page 10322)	Returns the name of the collection item as it appears in the collection editor.
	GeTDSTableProducer (see page 10323)	This is GeTDSTableProducer, a member of class THTMLTableColumn.
	IsStored (see page 10323)	This is IsStored, a member of class THTMLTableColumn.

Public Methods

	Name	Description
	AssignTo (see page 10322)	Copies the properties of a THTMLTableColumn (see page 10318) object to another THTMLTableColumn (see page 10318) object.
	RestoreDefaults (see page 10323)	Changes all properties of the attributes object back to their initial settings.
	Update (see page 10324)	Ensures that the Field (see page 10326) property reflects the underlying dataset.

54.1.4.4.1 THTMLTableColumn.AssignTo Method

Copies the properties of a THTMLTableColumn (see page 10318) object to another THTMLTableColumn (see page 10318) object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Applications cannot call the AssignTo method. To assign the properties of a THTMLTableColumn (see page 10318) object to another object, use the Assign method of the destination object.

When the Assign method of another object specifies a THTMLTableColumn (see page 10318) object as the source of the assignment, the AssignTo method of the THTMLTableColumn (see page 10318) object is called. AssignTo checks whether the Dest parameter is another THTMLTableColumn (see page 10318) object, and if so, copies the values of all properties except Custom (see page 10325) and DisplayName. If Dest is any other class of object, the inherited method is called.

See Also

Custom (see page 10325)

Assign (see page 2930)

AssignTo (see page 2931)

54.1.4.4.2 THTMLTableColumn.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName (see page 2761)

GetNamePath (see page 2759)

54.1.4.4.3 THTMLTableColumn.GeTDSTableProducer Method

Pascal

```
function GeTDSTableProducer: TDSTableProducer;
```

C++

```
__fastcall TDSTableProducer GeTDSTableProducer();
```

Description

This is GeTDSTableProducer, a member of class THTMLTableColumn.

54.1.4.4.4 THTMLTableColumn.IsStored Method

Pascal

```
function IsStored: Boolean;
```

C++

```
__fastcall Boolean IsStored();
```

Description

This is IsStored, a member of class THTMLTableColumn.

54.1.4.4.5 THTMLTableColumn.RestoreDefaults Method

Changes all properties of the attributes object back to their initial settings.

Pascal

```
procedure RestoreDefaults;
```

C++

```
__fastcall RestoreDefaults();
```

Description

Call RestoreDefaults to undo any changes that were made to the table element attributes either programmatically, or using the Columns editor at design time. RestoreAttributes sets

Align (see page 10324) to haDefault, and VAlign (see page 10327) to haVDefault.

BgColor (see page 10325) to an empty string.

Custom (see page 10325) to an empty string.

It also restores the default settings for the THTMLTableHeaderAttributes object that represents the title of the column.

See Also

Align (see page 10324)

BgColor (see page 10325)

Custom (see page 10325)

RestoreDefaults (see page 15303)

VAlign (see page 10327)

54.1.4.4.6 THTMLTableColumn.Update Method

Ensures that the Field (see page 10326) property reflects the underlying dataset.

Pascal

```
procedure Update;
```

C++

```
__fastcall Update();
```

Description

Call Update to ensure that the Field (see page 10326) property reflects any changes to the fields in the underlying dataset.

See Also

Field (see page 10326)

54.1.4.5 THTMLTableColumn Properties

The properties of the THTMLTableColumn class are listed here.

Public Properties

	Name	Description
R	DSTableProducer (see page 10325)	Indicates the table producer component that uses this column.
	Field (see page 10326)	Indicates the field component associated with the field binding of the column.

Published Properties

	Name	Description
	Align (see page 10324)	Specifies the horizontal alignment of the contents of the cells in the column.
	BgColor (see page 10325)	Specifies the background color of the cells in the column.
	Custom (see page 10325)	Specifies a tag option and its value in the HTML TD tags for the cells in the column.
	FieldName (see page 10326)	Specifies the name of the field to which the column is bound.
	Title (see page 10327)	Specifies the display attributes to be added to the header cell that appears at the top of the column.
	VAlign (see page 10327)	Specifies the vertical alignment of the contents of the cells in the column.

54.1.4.5.1 THTMLTableColumn.Align Property

Specifies the horizontal alignment of the contents of the cells in the column.

Pascal

```
property Align: THTMLAlign;
```

C++

```
__property THTMLAlign Align;
```

Description

Set Align to indicate the desired horizontal alignment of text in the cells of the column. Align indicates the desired value of the Align option of the HTML TD tag.

The default value of Align is haDefault, which means the web browser that reads the HTML document horizontally positions the contents of cells wherever it wishes.

See Also

VAlign (see page 10327)

Align (see page 15292)

54.1.4.5.2 THTMLTableColumn.BgColor Property

Specifies the background color of the cells in the column.

Pascal

```
property BgColor: THTMLBgColor;
```

C++

```
__property THTMLBgColor BgColor;
```

Description

Use BgColor to indicate a value for the BgColor option of the HTML TD tag. The value of BgColor is the name of color. This can be one of the following strings:

Use the BgColor property of the THTMLTableAttributes object to set a background color for the entire table. Use the BgColor property of THTMLTableColumn (see page 10318) to make a column stand out from the rest of the table.

See Also

BgColor (see page 15293)

54.1.4.5.3 THTMLTableColumn.Custom Property

Specifies a tag option and its value in the HTML TD tags for the cells in the column.

Pascal

```
property Custom: string;
```

C++

```
__property AnsiString Custom;
```

Description

Use Custom to represent one or more options to be added to an HTML tag. Each option and its value should have the form

```
OPTIONNAME=Value
```

If Custom specifies more than one option, each object should be separated from the others by spaces.

See Also

Custom (see page 15307)

54.1.4.5.4 THTMLTableColumn.DSTableProducer Property

Indicates the table producer component that uses this column.

Pascal

```
property DSTableProducer: TDSTableProducer;
```

C++

```
__property TDSTableProducer DSTableProducer;
```

Description

Read DSTableProducer to obtain information about the component that uses this object to represent the attributes of a column in the HTML table it produces. For example, to access the dataset which contains the field for this column, use the Dataset property of DSTableProducer.

See Also

DataSet (see page 10309)

54.1.4.5.5 THTMLTableColumn.Field Property

Indicates the field component associated with the field binding of the column.

Pascal

```
property Field: TField;
```

C++

```
__property TField Field;
```

Description

Read Field to get direct access to the field component for the column. Usually, Field is a field component maintained by the dataset. In some cases, however, Field is maintained directly by THTMLTableColumn (see page 10318), such as when the column represents a calculated field. Do not set the Field property unless the TField object is obtained from the dataset of the TDSTableProducer (see page 10290) that uses this THTMLTableColumn (see page 10318) object, or is a calculated field based on that dataset.

Setting Field automatically updates the FieldName (see page 10326) property.

See Also

FieldName (see page 10326)

DataSet (see page 10309)

54.1.4.5.6 THTMLTableColumn.FieldName Property

Specifies the name of the field to which the column is bound.

Pascal

```
property FieldName: string;
```

C++

```
__property AnsiString FieldName;
```

Description

Set FieldName to specify the field binding for the column in the HTML table. FieldName identifies a particular field component in the dataset of the TDSTableProducer (see page 10290) object that uses this THTMLTableColumn (see page 10318) object.

Setting FieldName automatically updates the Field (see page 10326) property.

See Also

Field (see page 10326)

FieldName (see page 7164)

DataSet (see page 10309)

54.1.4.5.7 THTMLTableColumn.Title Property

Specifies the display attributes to be added to the header cell that appears at the top of the column.

Pascal

```
property Title: THTMLTableHeaderAttributes;
```

C++

```
__property THTMLTableHeaderAttributes Title;
```

Description

Set Title to a THTMLTableHeaderAttributes object that describes the display attributes for the HTML TH tag for the header cell at the top of the column. Setting Title calls the Assign method of the THTMLTableHeaderAttributes object stored internally by THTMLTableColumn (see page 10318). Thus, the memory for any table header attributes object assigned to the Title property is never owned or freed by the HTML table column.

Note: Not all the properties of the table header attributes object are copied when one table attributes object is assigned to another. To ensure that all the attributes represented by Title are set appropriately, read Title and set the individual properties of the THTMLTableHeaderAttributes object.

See Also

RowAttributes (see page 10312)

AssignTo (see page 15297)

54.1.4.5.8 THTMLTableColumn.VAlign Property

Specifies the vertical alignment of the contents of the cells in the column.

Pascal

```
property VAlign: THTMLVAlign;
```

C++

```
__property THTMLVAlign VAlign;
```

Description

Set VAlign to indicate the desired vertical alignment of text in the cells of the column. VAlign indicates the desired value of the VAlign option of the HTML <TD> tag.

The default value of VAlign is haVDefault, which means the web browser that reads the HTML document vertically positions the contents of cells wherever it wishes.

See Also

Align (see page 10324)

54.1.5 THTMLTableColumns Class

THTMLTableColumns is a collection of THTMLTableColumn (see page 10318) objects that describe the display attributes and field bindings of the columns in an HTML representation of tabular data.

Class Hierarchy

Pascal

```
THTMLTableColumns = class(TCollection);
```

C++

```
class THTMLTableColumns : public TCollection;
```

File

DBWeb

Description

THTMLTableColumns is tailored for use by TDSTableProducer (see page 10290). It stores and manages changes to the THTMLTableColumn (see page 10318) objects that describe the columns of the HTML table produced by TDSTableProducer (see page 10290). THTMLTableColumns informs the table producer of changes to the column bindings so the table producer can recompute its layout.

See Also

TDSTableProducer (see page 10290)

THTMLTableColumn (see page 10318)

54.1.5.1 THTMLTableColumns Members

The following tables list the members exposed by THTMLTableColumns.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
V	GetAttr (see page 10331)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
V	GetAttrCount (see page 10331)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
V	GetItemAttr (see page 10331)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 10332)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 10333)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 10330)	Adds a new column descriptor to the end of the Items (see page 10334) array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 10330)	This is Create, a member of class THTMLTableColumns.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
	Destroy (see page 2735)	Destroys the collection and each item in it.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
	RebuildColumns (see page 10332)	Replaces all the column descriptors in the Items (see page 10334) array with new column descriptors that exactly match the fields in the dataset of DSTableProducer (see page 10334).
	RestoreDefaults (see page 10333)	Restores the default properties of every column in the Items (see page 10334) property array.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.

R	DSTableProducer (see page 10334)	Indicates the table producer that uses THTMLTableColumns (see page 10327) to store and manage column descriptions.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 10334)	Lists the THTMLTableColumn (see page 10318) objects that THTMLTableColumns (see page 10327) stores and manages for its TDSTableProducer (see page 10290) object.
	State (see page 10335)	Indicates whether the individual column descriptors are generated dynamically or statically stored.

54.1.5.2 THTMLTableColumns.Create Constructor

Pascal

```
constructor Create(DSTableProducer: TDSTableProducer; ColumnClass: THTMLTableColumnClass);
```

C++

```
__fastcall THTMLTableColumns(TDSTableProducer DSTableProducer, THTMLTableColumnClass
ColumnClass);
```

Description

This is Create, a member of class THTMLTableColumns.

54.1.5.3 THTMLTableColumns Methods

The methods of the THTMLTableColumns class are listed here.

Protected Methods

	Name	Description
V	GetAttr (see page 10331)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
V	GetAttrCount (see page 10331)	Returns the number of custom attributes associated with items in the collection.
V	GetItemAttr (see page 10331)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 10332)	Returns the owner of an object.
V	Update (see page 10333)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 10330)	Adds a new column descriptor to the end of the Items (see page 10334) array.
	RebuildColumns (see page 10332)	Replaces all the column descriptors in the Items (see page 10334) array with new column descriptors that exactly match the fields in the dataset of DSTableProducer (see page 10334).
	RestoreDefaults (see page 10333)	Restores the default properties of every column in the Items (see page 10334) property array.

54.1.5.3.1 THTMLTableColumns.Add Method

Adds a new column descriptor to the end of the Items (see page 10334) array.

Pascal

```
function Add: THTMLTableColumn;
```

C++

```
__fastcall THTMLTableColumn Add();
```

Description

Call Add to add a column descriptor to the collection of columns shown in the HTML table generated by TDSTableProducer (

see page 10290). Applications should only call Add when the value of the State (see page 10335) property is csCustom.

See Also

State (see page 10335)

TDSTableProducer (see page 10290)

54.1.5.3.2 THTMLTableColumns.GetAttr Method

Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.

Pascal

```
function GetAttr(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetAttr(int Index);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. The GetAttr method returns the name of an attribute.

Index identifies the attribute whose name is requested. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

As implemented by TCollection, GetAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttrCount (see page 2744)

GetItemAttr (see page 2745)

54.1.5.3.3 THTMLTableColumns.GetAttrCount Method

Returns the number of custom attributes associated with items in the collection.

Pascal

```
function GetAttrCount: Integer; override;
```

C++

```
virtual __fastcall int GetAttrCount();
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetAttrCount returns the number of distinct attributes assigned to each item in the collection.

As implemented in TCollection, GetAttrCount always returns 0, because TCollection defines no custom attributes.

See Also

GetAttr (see page 2743)

GetItemAttr (see page 2745)

54.1.5.3.4 THTMLTableColumns.GetItemAttr Method

Returns the value of a custom attribute assigned to one of the collection's items.

Pascal

```
function GetItemAttr(Index: Integer; ItemIndex: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetItemAttr(int Index, int ItemIndex);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetItemAttr returns the value of one of these attributes for a specified item in the collection.

Index identifies which attribute's value is desired. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

ItemIndex identifies the item whose attribute value is desired. This is an index into the Items property array.

As implemented in TCollection, GetItemAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttr (see page 2743)

GetAttrCount (see page 2744)

54.1.5.3.5 THTMLTableColumns.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

54.1.5.3.6 THTMLTableColumns.RebuildColumns Method

Replaces all the column descriptors in the Items (see page 10334) array with new column descriptors that exactly match the fields in the dataset of DSTableProducer (see page 10334).

Pascal

```
procedure RebuildColumns;
```

C++

```
__fastcall RebuildColumns();
```

Description

Call RebuildColumns to set the collection of column descriptors to the default state which matches the order and number of fields in the dataset, and which imposes no special display attributes. RebuildColumns returns the collection of column descriptors to the state that is dynamically maintained when the State (see page 10335) property is csDefault.

See Also

DSTableProducer (see page 10334)

State (see page 10335)

DataSet (see page 10309)

54.1.5.3.7 THTMLTableColumns.RestoreDefaults Method

Restores the default properties of every column in the Items (see page 10334) property array.

Pascal

```
procedure RestoreDefaults;
```

C++

```
__fastcall RestoreDefaults();
```

Description

At design time, RestoreDefaults is called when the Restore defaults button is pressed in the Response editor.

See Also

Items (see page 10334)

RestoreDefaults (see page 10323)

54.1.5.3.8 THTMLTableColumns.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

See Also

Changed (see page 2740)

Changed (see page 2758)

54.1.5.4 THTMLTableColumns Properties

The properties of the THTMLTableColumns class are listed here.

Public Properties

	Name	Description
	DSTableProducer (see page 10334)	Indicates the table producer that uses THTMLTableColumns (see page 10327) to store and manage column descriptions.
	Items (see page 10334)	Lists the THTMLTableColumn (see page 10318) objects that THTMLTableColumns (see page 10327) stores and manages for its TDSTableProducer (see page 10290) object.
	State (see page 10335)	Indicates whether the individual column descriptors are generated dynamically or statically stored.

54.1.5.4.1 THTMLTableColumns.DSTableProducer Property

Indicates the table producer that uses THTMLTableColumns (see page 10327) to store and manage column descriptions.

Pascal

```
property DSTableProducer: TDSTableProducer;
```

C++

```
__property TDSTableProducer DSTableProducer;
```

Description

Read DSTableProducer to gain direct access to the table producer that uses the THTMLTableColumns (see page 10327) object. THTMLTableColumns (see page 10327) uses this property to inform the table producer of changes to the columns so that it can recompute its layout.

54.1.5.4.2 THTMLTableColumns.Items Property

Lists the THTMLTableColumn (see page 10318) objects that THTMLTableColumns (see page 10327) stores and manages for its TDSTableProducer (see page 10290) object.

Pascal

```
property Items [Index: Integer]: THTMLTableColumn;
```

C++

```
__property THTMLTableColumn Items[int Index];
```

Description

Use Items to access the individual column descriptors managed by THTMLTableColumns (see page 10327). Items is an indexed array, where the first column descriptor has index 0, the second column descriptor has index 1, and so on.

Note: In Delphi, Items is the default property of THTMLTableColumns (see page 10327). This means that applications do not need to specify the Items property name when referring to the elements of the Items array.

Note: In C++, you can use the [] operator to obtain an effect similar to using Items as the default property in Delphi.

See Also

Count (see page 2749)

Columns (see page 10308)

THTMLTableColumn (see page 10318)

operator_sb

54.1.5.4.3 THTMLTableColumns.State Property

Indicates whether the individual column descriptors are generated dynamically or statically stored.

Pascal

```
property State: THTMLColumnState;
```

C++

```
__property THTMLColumnState State;
```

Description

Set State to csDefault to indicate that the column descriptors should be generated dynamically. Dynamically generated column descriptors impose no special display attributes on the columns of the HTML table, and correspond exactly in order and number to the fields of the dataset. Setting State to csDefault replaces all the column descriptors in the collection with dynamically generated defaults.

Set State to csCustom before customizing the column descriptors by adding display attributes, reordering the fields, adding columns for calculated fields, or including only a subset of the fields in the dataset. When State is csCustom, the column descriptors are saved with the TDSTableProducer (see page 10290) object.

Note: Using the Columns editor to customize the column descriptors automatically sets State to csCustom.

See Also

RebuildColumns (see page 10332)

Fields (see page 7023)

StoreColumns (see page 10305)

54.1.6 THTTPDataLink Class

THTTPDataLink helps TDSTableProducer (see page 10290) manage its link to the data source.

Class Hierarchy

Pascal

```
THTTPDataLink = class(TDataLink);
```

C++

```
class THTTPDataLink : public TDataLink;
```

File

DBWeb

Description

THTTPDataLink is tailored to work with a TDSTableProducer (see page 10290) object. It should only be used by the TDSTableProducer (see page 10290) class.

See Also

TDataSource (see page 7070)

TDSTableProducer (see page 10290)

54.1.6.1 THTTPDataLink Members

The following tables list the members exposed by THTTPDataLink.

Protected Methods

	Name	Description
	ActiveChanged (see page 10339)	Informs the table producer when the Active property changes.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CheckBrowseMode (see page 6880)	Allows the data-aware object to respond just before an event that changes the dataset state.
	DataEvent (see page 6881)	Responds to various events that occur while working with data.
	DataSetChanged (see page 10340)	Informs the associated table producer of changes to the dataset.
	DataSetScrolled (see page 10340)	Ignores scrolling events on the dataset.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	EditingChanged (see page 10341)	Ignores changes to the editing state of the dataset.
	FocusControl (see page 10341)	Discards requests to set focus to the indicated field.
	GetActiveRecord (see page 6884)	This is GetActiveRecord, a member of class TDataLink.
	GetBOF (see page 6884)	This is GetBOF, a member of class TDataLink.
	GetBufferCount (see page 6884)	This is GetBufferCount, a member of class TDataLink.
	GetEOF (see page 6885)	This is GetEOF, a member of class TDataLink.
	GetMappedIndex (see page 10342)	Returns the index of the field component in the dataset that corresponds to the index of the field component within the Fields (see page 10345) array.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetRecordCount (see page 6885)	This is GetRecordCount, a member of class TDataLink.
	LayoutChanged (see page 10342)	Informs TDSTableProducer (see page 10290) of changes in the layout of columns at design time.
	MoveBy (see page 6885)	Repositions the dataset to another record relative to its active record.
	RecordChanged (see page 10343)	Ignores changes to the contents of the current record or field of the data source.
	SetActiveRecord (see page 6886)	This is SetActiveRecord, a member of class TDataLink.
	SetBufferCount (see page 6887)	This is SetBufferCount, a member of class TDataLink.
	UpdateData (see page 10343)	Discards requests to post changes to the dataset.

Protected Properties

	Name	Description
	VisualControl (see page 6894)	Indicates whether a visual control uses the datalink.

Public Methods

	Name	Description
	AddMapping (see page 10339)	Adds a field component to the end of the Fields (see page 10345) array.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClearMapping (see page 10340)	Empties the Fields (see page 10345) array and frees any associated memory.
	Create (see page 10338)	Creates an instance of THTTPDataLink (see page 10335).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 10338)	Destroys an instance of THTTPDataLink (see page 10335).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Edit (see page 6882)	Attempts to drive the data source into an editing state if it is not already in one.
	ExecuteAction (see page 6883)	Invokes an action with the datasource as its target.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Modified (see page 10342)	Tracks changes to the data which have not been written to the current record in the database.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Reset (see page 10343)	Cancels any pending edits to the dataset that have not been written to the current record in the database.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	UpdateAction (see page 6887)	Updates an action to reflect the current state of the TDataLink (see page 6876).
	UpdateRecord (see page 6888)	Responds to notifications that edits should be posted to the dataset.

Public Properties

	Name	Description
R	Active (see page 6888)	Specifies whether the dataset that TDataLink (see page 6876) manages is active.
	ActiveRecord (see page 6889)	Specifies the index of the current record within the internal record buffer maintained by the dataset for the Owner of the TDataLink (see page 6876) object.
R	BOF (see page 6889)	Indicates whether the first record in a dataset is active.
	BufferCount (see page 6890)	Specifies the number of records cached by the dataset for the Owner of the TDataLink (see page 6876) object.
R	DataSet (see page 6890)	Specifies the TDataSet (see page 6894) object that represents the data that this TDataLink (see page 6876) is tracking.
	DataSource (see page 6891)	Specifies the TDataSource (see page 7070) object that the Owner of the TDataLink (see page 6876) uses to connect to the dataset.
	DataSourceFixed (see page 6891)	Indicates whether the DataSource (see page 6891) property can be set.
R	DefaultFields (see page 10344)	Indicates whether the associated table producer uses dynamically generated field components.
R	Editing (see page 6892)	Indicates whether the DataSource (see page 6891) is in edit mode.
R	Eof (see page 6892)	Indicates whether the last record in a dataset is active.

R	FieldCount (see page 10344)	Specifies the number of entries in the Fields (see page 10345) array.
R	Fields (see page 10345)	Lists all the field components from the dataset that may be shown in the image of the datasource.
	ReadOnly (see page 6893)	Indicates whether the dataset for this TDataLink (see page 6876) can be modified.
R	RecordCount (see page 6893)	Indicates the number of records in the internal record buffer maintained by the dataset.
	SparseMap (see page 10345)	Indicates whether the associated table producer has customized the number or order of the fields that appear in the table.

54.1.6.2 THTTPDataLink.Create Constructor

Creates an instance of THTTPDataLink (see page 10335).

Pascal

```
constructor Create(DSTableProducer: TDSTableProducer);
```

C++

```
__fastcall THTTPDataLink(TDSTableProducer DSTableProducer);
```

Description

Applications should not create instances of THTTPDataLink (see page 10335). TDSTableProducer (see page 10290) instantiates a THTTPDataLink (see page 10335) object from its own constructor.

See Also

TDSTableProducer (see page 10290)

54.1.6.3 THTTPDataLink.Destroy Destructor

Destroys an instance of THTTPDataLink (see page 10335).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THTTPDataLink();
```

Description

Do not call Destroy directly in an application. The TDSTableProducer (see page 10290) object that owns the THTTPDataLink (see page 10335) frees the THTTPDataLink (see page 10335) from its own destructor.

Destroy frees up the memory used by the Fields (see page 10345) array before calling the inherited destructor.

See Also

Fields (see page 10345)

Free (see page 22300)

54.1.6.4 THTTPDataLink Methods

The methods of the THTTPDataLink class are listed here.

Protected Methods

	Name	Description
	ActiveChanged (see page 10339)	Informs the table producer when the Active property changes.
	DataSetChanged (see page 10340)	Informs the associated table producer of changes to the dataset.
	DataSetScrolled (see page 10340)	Ignores scrolling events on the dataset.
	EditingChanged (see page 10341)	Ignores changes to the editing state of the dataset.
	FocusControl (see page 10341)	Discards requests to set focus to the indicated field.
	GetMappedIndex (see page 10342)	Returns the index of the field component in the dataset that corresponds to the index of the field component within the Fields (see page 10345) array.
	LayoutChanged (see page 10342)	Informs TDSTableProducer (see page 10290) of changes in the layout of columns at design time.
	RecordChanged (see page 10343)	Ignores changes to the contents of the current record or field of the data source.
	UpdateData (see page 10343)	Discards requests to post changes to the dataset.

Public Methods

	Name	Description
	AddMapping (see page 10339)	Adds a field component to the end of the Fields (see page 10345) array.
	ClearMapping (see page 10340)	Empties the Fields (see page 10345) array and frees any associated memory.
	Modified (see page 10342)	Tracks changes to the data which have not been written to the current record in the database.
	Reset (see page 10343)	Cancels any pending edits to the dataset that have not been written to the current record in the database.

54.1.6.4.1 THTTPDataLink.ActiveChanged Method

Informs the table producer when the Active property changes.

Pascal

```
procedure ActiveChanged; override;
```

C++

```
virtual __fastcall ActiveChanged();
```

Description

Applications cannot call the ActiveChanged method directly. Changes in the Active property trigger this procedure. ActiveChanged calls the LinkActive method of the TDSTableProducer (see page 10290), which recomputes the layout for the table if the dataset has just become active.

See Also

Active (see page 6888)

LinkActive (see page 10303)

54.1.6.4.2 THTTPDataLink.AddMapping Method

Adds a field component to the end of the Fields (see page 10345) array.

Pascal

```
function AddMapping(const FieldName: string): Boolean;
```

C++

```
__fastcall Boolean AddMapping(const AnsiString FieldName);
```

Description

Applications should not call AddMapping directly, because this would cause the Fields (see page 10345) array to become out

of sync with the THTMLTableColumns (see page 10327) object used by TDSTableProducer (see page 10290). TDSTableProducer (see page 10290) calls AddMapping iteratively to set up the Fields (see page 10345) array so that it corresponds to the columns in the table image.

See Also

ClearMapping (see page 10340)

Fields (see page 10345)

TDSTableProducer (see page 10290)

THTMLTableColumns (see page 10327)

54.1.6.4.3 THTTPDataLink.ClearMapping Method

Empties the Fields (see page 10345) array and frees any associated memory.

Pascal

```
procedure ClearMapping;
```

C++

```
__fastcall ClearMapping();
```

Description

Applications should not call ClearMapping directly, because this would cause the Fields (see page 10345) array to become out of sync with the THTMLTableColumns (see page 10327) object used by TDSTableProducer (see page 10290). TDSTableProducer (see page 10290) calls ClearMapping before rebuilding the Fields (see page 10345) list, every time the column mapping changes.

See Also

AddMapping (see page 10339)

Fields (see page 10345)

THTMLTableColumns (see page 10327)

54.1.6.4.4 THTTPDataLink.DataSetChanged Method

Informs the associated table producer of changes to the dataset.

Pascal

```
procedure DataSetChanged; override;
```

C++

```
virtual __fastcall DataSetChanged();
```

Description

Applications can not call DataSetChanged directly. Changes to the contents of the dataset trigger this method automatically.

See Also

TDSTableProducer (see page 10290)

54.1.6.4.5 THTTPDataLink.DataSetScrolled Method

Ignores scrolling events on the dataset.

Pascal

```
procedure DataSetScrolled(Distance: Integer); override;
```

C++

```
virtual __fastcall DataSetScrolled(int Distance);
```

Description

Applications can not call DataSetScrolled directly. This method overrides the inherited method so that TDSTableProducer (see page 10290) can ignore scrolling events that would occur if the TDSTableProducer (see page 10290) were a visual control.

See Also

DataSetScrolled (see page 6882)

TDataSource (see page 7070)

TDSTableProducer (see page 10290)

54.1.6.4.6 THTTPDataLink.EditingChanged Method

Ignores changes to the editing state of the dataset.

Pascal

```
procedure EditingChanged; override;
```

C++

```
virtual __fastcall EditingChanged();
```

Description

Applications can not call EditingChanged directly. This method ignores changes to the editing state of the dataset, which are irrelevant to TDSTableProducer (see page 10290).

See Also

TDataSet (see page 6894)

TDSTableProducer (see page 10290)

54.1.6.4.7 THTTPDataLink.FocusControl Method

Discards requests to set focus to the indicated field.

Pascal

```
procedure FocusControl(Field: TFieldRef); override;
```

C++

```
virtual __fastcall FocusControl(TFieldRef Field);
```

Description

TDSTableProducer (see page 10290) does not support the concept of focus assigned to an individual field. FocusControl discards requests sent through the data source to assign focus to an individual field.

See Also

TDataSource (see page 7070)

TDSTableProducer (see page 10290)

54.1.6.4.8 THTTPDataLink.GetMappedIndex Method

Returns the index of the field component in the dataset that corresponds to the index of the field component within the Fields (see page 10345) array.

Pascal

```
function GetMappedIndex(ColIndex: Integer): Integer;
```

C++

```
__fastcall int GetMappedIndex(int ColIndex);
```

Description

Applications can not call GetMappedIndex directly. GetMappedIndex takes ColIndex, the index of a field component in the Fields (see page 10345) array, and returns the corresponding index of the field component in the dataset.

See Also

Fields (see page 10345)

Fields (see page 7023)

54.1.6.4.9 THTTPDataLink.LayoutChanged Method

Informs TDSTableProducer (see page 10290) of changes in the layout of columns at design time.

Pascal

```
procedure LayoutChanged; override;
```

C++

```
virtual __fastcall LayoutChanged();
```

Description

Applications can not call the LayoutChanged method directly. LayoutChanged is triggered automatically by changes to the layout of columns at design time. LayoutChanged instructs the TDSTableProducer (see page 10290) object to recompute the layout for the table.

See Also

LayoutChanged (see page 10303)

54.1.6.4.10 THTTPDataLink.Modified Method

Tracks changes to the data which have not been written to the current record in the database.

Pascal

```
procedure Modified;
```

C++

```
__fastcall Modified();
```

Description

Call Modified before changing the value of a field in the current record of the dataset. It is not necessary to call Modified if the changes are written directly to the field components indexed by the Fields (see page 10345) property.

See Also

Fields (see page 10345)

54.1.6.4.11 THTTPDataLink.RecordChanged Method

Ignores changes to the contents of the current record or field of the data source.

Pascal

```
procedure RecordChanged(Field: TField); override;
```

C++

```
virtual __fastcall RecordChanged(TField Field);
```

Description

Applications can not call RecordChanged directly. This method ignores changes to the contents of the current record in the data source, which are irrelevant to the TDSTableProducer (see page 10290).

See Also

DataSource (see page 6891)

TDSTableProducer (see page 10290)

54.1.6.4.12 THTTPDataLink.Reset Method

Cancels any pending edits to the dataset that have not been written to the current record in the database.

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

Applications can not call Reset directly. Descendants of TDSTableProducer (see page 10290) can implement a method or user interface that triggers the cancellation of pending edits.

See Also

TDSTableProducer (see page 10290)

54.1.6.4.13 THTTPDataLink.UpdateData Method

Discards requests to post changes to the dataset.

Pascal

```
procedure UpdateData; override;
```

C++

```
virtual __fastcall UpdateData();
```

Description

TDSTableProducer (see page 10290) produces an HTML image of a dataset. It is not a control that can be used to edit the data in the dataset. UpdateData discards requests sent through the data source to post edits to the dataset.

See Also

DataSource (see page 6891)

TDSTableProducer (see page 10290)

54.1.6.5 THTTPDataLink Properties

The properties of the THTTPDataLink class are listed here.

Public Properties

	Name	Description
R	DefaultFields (see page 10344)	Indicates whether the associated table producer uses dynamically generated field components.
R	FieldCount (see page 10344)	Specifies the number of entries in the Fields (see page 10345) array.
R	Fields (see page 10345)	Lists all the field components from the dataset that may be shown in the image of the datasource.
	SparseMap (see page 10345)	Indicates whether the associated table producer has customized the number or order of the fields that appear in the table.

54.1.6.5.1 THTTPDataLink.DefaultFields Property

Indicates whether the associated table producer uses dynamically generated field components.

Pascal

```
property DefaultFields: Boolean;
```

C++

```
__property Boolean DefaultFields;
```

Description

Read DefaultFields to determine whether the image of the table will display dynamically generated field components or persistent field components. If DefaultFields is true, the fields in the image of the table will represent dynamically allocated field components. If DefaultFields is false, the image will be built from persistent field components.

If the image of the datasource is built from persistent field components, it may not show all of the fields that are present in the underlying database table.

See Also

DataSource (see page 6891)

SparseMap (see page 10345)

54.1.6.5.2 THTTPDataLink.FieldCount Property

Specifies the number of entries in the Fields (see page 10345) array.

Pascal

```
property FieldCount: Integer;
```

C++

```
__property int FieldCount;
```

Description

Use FieldCount when iterating over all the field components in the Fields (see page 10345) property. FieldCount is the number of columns shown in the image of the datasource. The Fields (see page 10345) array can contain undefined field components, which correspond to field components that are not in the dataset, such as calculated fields.

See Also

DefaultFields (see page 10344)

Fields (see page 10345)

SparseMap (see page 10345)

54.1.6.5.3 THTTPDataLink.Fields Property

Lists all the field components from the dataset that may be shown in the image of the datasource.

Pascal

```
property Fields [I: Integer]: TField;
```

C++

```
__property TField Fields[int I];
```

Description

Use Fields to access field components by index. Fields[0] is the first field component, Fields[1] is the second field component, and so on. If the SparseMap (see page 10345) property is true, Fields may contain undefined field components. For these entries, Fields returns nil. NULL.

TDSTableProducer (see page 10290) uses Fields to keep track of all field components that are part of its dataset. Whenever necessary, TDSTableProducer (see page 10290) reconciles the field bindings of its columns with the field components in Fields.

AddMapping (see page 10339)

FieldCount (see page 10344)

SparseMap (see page 10345)

TField (see page 7115)

54.1.6.5.4 THTTPDataLink.SparseMap Property

Indicates whether the associated table producer has customized the number or order of the fields that appear in the table.

Pascal

```
property SparseMap: Boolean;
```

C++

```
__property Boolean SparseMap;
```

Description

Read SparseMap to determine whether Fields (see page 10345) is a simple reflection of the underlying dataset. TDSTableProducer (see page 10290) sets SparseMap when it builds the field map. SparseMap is false if TDSTableProducer (see page 10290) builds a default field map directly from the dataset. SparseMap is true if the number or order of the fields has been changed from the default. When SparseMap is true, the Fields (see page 10345) array may contain undefined fields.

AddMapping (see page 10339)

Fields (see page 10345)

54.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	HtmlTable (see page 10346)	Generates the HTML image of a dataset, using the properties and events of a table producer object.

54.2.1 DBWeb.HtmlTable Function

Generates the HTML image of a dataset, using the properties and events of a table producer object.

Pascal

```
function HtmlTable(DataSet: TDataSet; DataSetHandler: TDSTableProducer; MaxRows: Integer):
string;
```

C++

```
AnsiString HtmlTable(TDataSet DataSet, TDSTableProducer DataSetHandler, int MaxRows);
```

File

DBWeb

Description

Call HtmlTable to obtain a sequence of HTML commands that describe a dataset in tabular format. The DataSet parameter indicates the dataset whose records are converted into an HTML image. The DataSetHandler parameter is the table producer whose properties describe the attributes of the resulting image and whose event handlers respond to events that occur during the generation of the image. The MaxRows parameter is the maximum number of records from the dataset that will appear in the image.

Calling HtmlTable is equivalent to calling the Content method of the DataSetHandler parameter after setting its DataSet and MaxRows properties to the values given for the parameters of the same names.

54.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	THTMLCaptionAlignment (see page 10347)	This is record DBWeb.THTMLCaptionAlignment.
	THTMLColumnState (see page 10347)	This is record DBWeb.THTMLColumnState.

54.3.1 DBWeb.THTMLCaptionAlignment Enumeration

Pascal

```
THTMLCaptionAlignment = (
  caDefault,
  caTop,
  caBottom
);
```

C++

```
enum THTMLCaptionAlignment {
  caDefault,
  caTop,
  caBottom
};
```

File

DBWeb

Description

This is record DBWeb.THTMLCaptionAlignment.

54.3.2 DBWeb.THTMLColumnState Enumeration

Pascal

```
THTMLColumnState = (
  csDefault,
  csCustom
);
```

C++

```
enum THTMLColumnState {
  csDefault,
  csCustom
};
```

File

DBWeb

Description

This is record DBWeb.THTMLColumnState.

54.4 Types

The following table lists types in this documentation.

Types

Name	Description
TCreateContentEvent (see page 10349)	This is type DBWeb.TCreateContentEvent.
THTMLDataSetEmpty (see page 10349)	This is type DBWeb.THTMLDataSetEmpty.
THTMLFormatCellEvent (see page 10350)	This is type DBWeb.THTMLFormatCellEvent.
THTMLGetTableCaptionEvent (see page 10350)	This is type DBWeb.THTMLGetTableCaptionEvent.
THTMLTableColumnClass (see page 10350)	This is type DBWeb.THTMLTableColumnClass.

54.4.1 DBWeb.TCreateContentEvent Type

Pascal

```
TCreateContentEvent = procedure (Sender: TObject; var Continue: Boolean) of object;
```

C++

```
(Sender: TObject; var Continue: Boolean) ( TCreateContentEvent)();
```

File

DBWeb

Description

This is type DBWeb.TCreateContentEvent.

54.4.2 DBWeb.THTMLDataSetEmpty Type

Pascal

```
THTMLDataSetEmpty = procedure (Sender: TObject; var Continue: Boolean) of object;
```

C++

```
(Sender: TObject; var Continue: Boolean) ( THTMLDataSetEmpty)();
```

File

DBWeb

Description

This is type DBWeb.THTMLDataSetEmpty.

54.4.3 DBWeb.THTMLFormatCellEvent Type

Pascal

```
THTMLFormatCellEvent = procedure (Sender: TObject; CellRow, CellColumn: Integer; var BgColor:
THTMLBgColor; var Align: THTMLAlign; var VAlign: THTMLVAlign; var CustomAttrs, CellData:
string) of object;
```

C++

```
(Sender: TObject; CellRow, CellColumn: Integer; var BgColor: THTMLBgColor; var Align:
THTMLAlign; var VAlign: THTMLVAlign; var CustomAttrs, CellData: string) (
THTMLFormatCellEvent)();
```

File

DBWeb

Description

This is type DBWeb.THTMLFormatCellEvent.

54.4.4 DBWeb.THTMLGetTableCaptionEvent Type

Pascal

```
THTMLGetTableCaptionEvent = procedure (Sender: TObject; var Caption: string; var Alignment:
THTMLCaptionAlignment) of object;
```

C++

```
(Sender: TObject; var Caption: string; var Alignment: THTMLCaptionAlignment) (
THTMLGetTableCaptionEvent)();
```

File

DBWeb

Description

This is type DBWeb.THTMLGetTableCaptionEvent.

54.4.5 DBWeb.THTMLTableColumnClass Type

Pascal

```
THTMLTableColumnClass = class of THTMLTableColumn;
```

C++

```
THTMLTableColumn THTMLTableColumnClass;
```

File

DBWeb

Description

This is type DBWeb.THTMLTableColumnClass.

55 DBXCommon Namespace

This is namespace DBXCommon.

Topics

Name	Description
Classes (see page 10355)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 10668)	The following table lists structs, records, enums in this documentation.
Types (see page 10669)	The following table lists types in this documentation.
Constants (see page 10675)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDBXAnsiStringValue (see page 10356)	Implementation of writable ANSI string values.
	TDBXBcdValue (see page 10359)	Implementation of binary-compressed decimal values.
	TDBXBooleanValue (see page 10362)	Implementation of writable boolean values.
	TDBXByteArrayValue (see page 10364)	Implementation of writable byte array values.
	TDBXByteReader (see page 10368)	Allows for primitive retrieval of data using byte arrays.
	TDBXByteReaderEx (see page 10373)	This is class DBXCommon.TDBXByteReaderEx.
	TDBXByteStreamReader (see page 10374)	Used internally by driver implementations and TDBXStreamValue (see page 10608).
	TDBXCommand (see page 10378)	Class to execute SQL statements and stored procedures
	TDBXCommandEx (see page 10391)	Extension of TDBXCommand (see page 10378).
	TDBXCommandFactory (see page 10395)	This is class DBXCommon.TDBXCommandFactory.
	TDBXCommandTypes (see page 10396)	Type of command to be executed by a TDBXCommand (see page 10378)
	TDBXConnection (see page 10398)	Connection for the dbExpress driver framework
	TDBXConnectionBuilder (see page 10412)	Utility class used by driver writers when connections are created.
	TDBXConnectionEx (see page 10417)	Temporary extension of TDBXConnection (see page 10398) class.
	TDBXConnectionFactory (see page 10422)	Abstract base class used for creating new instances of TDBXConnection (see page 10398)
	TDBXContext (see page 10432)	Context information for a connection.
	TDBXCursorValue (see page 10438)	Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.CursorType.
	TDBXDatabaseMetaData (see page 10440)	Common database specific metadata.
	TDBXDatabaseMetaDataEx (see page 10444)	Temporary extension of TDBXDatabaseMetaData (see page 10440).
	TDBXDataTypes (see page 10447)	Data types supported by the dbExpress framework (TDBX).
	TDBXDataTypesEx (see page 10459)	Data types supported by dbExpress.
	TDBXDateValue (see page 10461)	Implementation of writable date type values.

	TDBXDelegateDriver (see page 10464)	Delegate driver base class.
	TDBXDelegateItem (see page 10468)	Used by driver implementors.
	TDBXDoubleValue (see page 10469)	Implementation of double-precision floating point values.
	TDBXDriver (see page 10472)	Driver class for DBX framework.
	TDBXDriverEx (see page 10477)	This is class DBXCommon.TDBXDriverEx.
	TDBXDriverHelp (see page 10480)	Used by driver implementors to access private or protected API.
	TDBXDriverHelpEx (see page 10482)	This is class DBXCommon.TDBXDriverHelpEx.
	TDBXDriverLoader (see page 10483)	Collection of parameters needed when loading a driver.
	TDBXDriverRegistry (see page 10485)	Registry (see page 18633) for TDBXDriverLoader (see page 10483) keyed by driver name.
	TDBXError (see page 10486)	Exception type for all dbExpress framework (TDBX) errors.
	TDBXErrorCodes (see page 10489)	Error codes for dbExpress framework (TDBX) exceptions
	TDBXIniFileConnectionFactory (see page 10501)	Creates new instances of TDBXConnection (see page 10398) from the dbxdrivers.ini and dbxconnections.ini files
	TDBXIniFileConnectionFactoryEx (see page 10504)	Extension of TDBXIniFileConnectionFactory (see page 10501).
	TDBXInt16Value (see page 10506)	Implementation of 16-byte integer values.
	TDBXInt32Value (see page 10508)	Implementation of writable 32-byte integer values.
	TDBXInt64Value (see page 10511)	Implementation of writable 64-byte integer values.
	TDBXIsolations (see page 10513)	Isolation levels supported by TDBXTransaction (see page 10623).
	TDBXLookAheadStreamReader (see page 10516)	Used internally by driver implementations and TDBXStreamValue (see page 10608).
	TDBXMemoryConnectionFactory (see page 10518)	Implementation of TDBXConnectionFactory (see page 10422) that does not load driver and connection properties.
	TDBXMetaDatabaseColumnNames (see page 10521)	Column names for metadata.
	TDBXMetaDataCommands (see page 10525)	List of available metadata commands to get metadata.
	TDBXMetaDataCommandsEx (see page 10531)	Temporary extension of TDBXMetaDataCommands (see page 10525) class.
	TDBXMetaDataKeyword (see page 10537)	Keyword for metadata.
	TDBXMetaDataProcedureTypes (see page 10538)	Constants passed to TDBXMetaDataCommands.GetProcedures metadata command.
	TDBXMetaDataTableTypes (see page 10540)	Constants for the GetTables metadata command
	TDBXMetaDataTableTypesEx (see page 10542)	Temporary extension of TDBXMetaDataTableTypes (see page 10540) class.
	TDBXNullValue (see page 10543)	This is class DBXCommon.TDBXNullValue.
	TDBXParameter (see page 10545)	Individual parameters for queries and stored commands.
	TDBXParameterDirections (see page 10549)	Parameter types supported by TDBXParameter (see page 10545)
	TDBXParameterEx (see page 10551)	Extension of TDBXParameter (see page 10545).
	TDBXParameterList (see page 10553)	A collection of TDBXParameter (see page 10545) instances that can be used to get and set parameters for a TDBXCommand (see page 10378).
	TDBXProperties (see page 10559)	Manages connection and driver level name/value pair property settings.
	TDBXPropertiesItem (see page 10564)	Contains a set of TDBXProperties (see page 10559).
	TDBXPropertyNames (see page 10566)	Property names for connections and drivers.
	TDBXPropertyNamesEx (see page 10574)	Temporary extension of TDBXPropertyNames (see page 10566) class.
	TDBXReader (see page 10576)	TDBXReader provides a unidirectional reader for a collection of database rows
	TDBXReaderByteReader (see page 10585)	Implementation of TDBXByteReader (see page 10368).
	TDBXRow (see page 10590)	Represents a row in a database.
	TDBXRowEx (see page 10600)	This is class DBXCommon.TDBXRowEx.
	TDBXStateItem (see page 10604)	This is class DBXCommon.TDBXStateItem.
	TDBXStateItemList (see page 10605)	This is class DBXCommon.TDBXStateItemList.
	TDBXStreamReader (see page 10607)	Used internally by driver implementations and TDBXStreamValue (see page 10608).
	TDBXStreamValue (see page 10608)	Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.ByteArrayType values.
	TDBXTimeStampValue (see page 10612)	Implementation of writable timestamp values.
	TDBXTimeValue (see page 10614)	Implementation of writable time values.
	TDBXTraceFlags (see page 10617)	Flags to indicate tracing type.
	TDBXTraceInfo (see page 10622)	Trace information for TDBXTraceEvent (see page 10672) handlers.
	TDBXTransaction (see page 10623)	Transaction management class.

	TDBXValue (see page 10626)	Gets and sets values for TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
	TDBXValueList (see page 10634)	Manage a list of TDBXValueType (see page 10636) instances.
	TDBXValueType (see page 10636)	Metadata for TDBXReader (see page 10576) columns and TDBXParameter (see page 10545) parameters.
	TDBXValueTypeEx (see page 10649)	Extension of TDBXValueType (see page 10636).
	TDBXValueTypeFlags (see page 10651)	Flags used by TDBXValueType (see page 10636).
	TDBXValueTypeFlagsEx (see page 10653)	Temporary extension of TDBXValueTypeFlags (see page 10651) class.
	TDBXWideCharsValue (see page 10655)	This is class DBXCommon.TDBXWideCharsValue.
	TDBXWideStringValue (see page 10658)	Implementation of writable wide string values.
	TDBXWritableValue (see page 10661)	Extension of TDBXValue (see page 10626) that adds the ability to set a value.

Constants

Name	Description
DBXDefaultRowSetSize (see page 10675)	This is constant DBXCommon.DBXDefaultRowSetSize.
DBXVersion25 (see page 10676)	This is constant DBXCommon.DBXVersion25.
DBXVersion30 (see page 10676)	This is constant DBXCommon.DBXVersion30.
DBXVersion40 (see page 10676)	This is constant DBXCommon.DBXVersion40.
SAlreadyPrepared (see page 10677)	This is constant DBXCommon.SAlreadyPrepared.
SConnectionFactoryInitFailed (see page 10677)	This is constant DBXCommon.SConnectionFactoryInitFailed.
SDefaultErrorMessage (see page 10677)	This is constant DBXCommon.SDefaultErrorMessage.
SDllLoadError (see page 10678)	This is constant DBXCommon.SDllLoadError.
SDllProcLoadError (see page 10678)	This is constant DBXCommon.SDllProcLoadError.
SDriverLoadError (see page 10678)	This is constant DBXCommon.SDriverLoadError.
SInvalidArgument (see page 10679)	This is constant DBXCommon.SInvalidArgument.
SInvalidDelegationDepth (see page 10679)	This is constant DBXCommon.SInvalidDelegationDepth.
SInvalidOrdinal (see page 10679)	This is constant DBXCommon.SInvalidOrdinal.
SInvalidTransaction (see page 10680)	This is constant DBXCommon.SInvalidTransaction.
SInvalidTypeAccess (see page 10680)	This is constant DBXCommon.SInvalidTypeAccess.
SNotImplemented (see page 10680)	This is constant DBXCommon.SNotImplemented.
SReaderClosed (see page 10681)	This is constant DBXCommon.SReaderClosed.
SReaderNew (see page 10681)	This is constant DBXCommon.SReaderNew.
SReadOnlyParameter (see page 10681)	This is constant DBXCommon.SReadOnlyParameter.
SReadOnlyType (see page 10682)	This is constant DBXCommon.SReadOnlyType.
SRequiredProperty (see page 10682)	This is constant DBXCommon.SRequiredProperty.
SSetFactoryOnce (see page 10682)	This is constant DBXCommon.SSetFactoryOnce.
SUnknownDriver (see page 10683)	This is constant DBXCommon.SUnknownDriver.
TDBXConnectionFile (see page 10683)	This is constant DBXCommon.TDBXConnectionFile.
TDBXDriverFile (see page 10683)	This is constant DBXCommon.TDBXDriverFile.
TDBXRegistryConnectionValue (see page 10684)	This is constant DBXCommon.TDBXRegistryConnectionValue.
TDBXRegistryDriverValue (see page 10684)	This is constant DBXCommon.TDBXRegistryDriverValue.
TDBXRegistryKey (see page 10684)	This is constant DBXCommon.TDBXRegistryKey.

Structs, Records, Enums

	Name	Description
	TDBXDriverDef (see page 10668)	Collection of parameters needed when loading a driver.

Types

Name	Description
TDBXChars (see page 10669)	This is type DBXCommon.TDBXChars.
TDBXCreateCommandEvent (see page 10669)	This is type DBXCommon.TDBXCreateCommandEvent.
TDBXDate (see page 10670)	This is type DBXCommon.TDBXDate.
TDBXDriverLoaderClass (see page 10670)	This is type DBXCommon.TDBXDriverLoaderClass.
TDBXErrorCode (see page 10670)	This is type DBXCommon.TDBXErrorCode.
TDBXErrorEvent (see page 10671)	Event handler for TDBXConnection.OnErrorEvent property.

TDBXIsolation (see page 10671)	This is type DBXCommon.TDBXIsolation.
TDBXParameterDirection (see page 10671)	This is type DBXCommon.TDBXParameterDirection.
TDBXTime (see page 10672)	This is type DBXCommon.TDBXTime.
TDBXTraceEvent (see page 10672)	Tracing information for drivers.
TDBXTraceFlag (see page 10673)	This is type DBXCommon.TDBXTraceFlag.
TDBXType (see page 10673)	Type for TDBXDataTypes (see page 10447).
TDBXValueArray (see page 10673)	This is type DBXCommon.TDBXValueArray.
TWideStringArray (see page 10674)	This is type DBXCommon.TWideStringArray.

55.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDBXAnsiStringValue (see page 10356)	Implementation of writable ANSI string values.
	TDBXBcdValue (see page 10359)	Implementation of binary-compressed decimal values.
	TDBXBooleanValue (see page 10362)	Implementation of writable boolean values.
	TDBXByteArrayValue (see page 10364)	Implementation of writable byte array values.
	TDBXByteReader (see page 10368)	Allows for primitive retrieval of data using byte arrays.
	TDBXByteReaderEx (see page 10373)	This is class DBXCommon.TDBXByteReaderEx.
	TDBXByteStreamReader (see page 10374)	Used internally by driver implementations and TDBXStreamValue (see page 10608).
	TDBXCommand (see page 10378)	Class to execute SQL statements and stored procedures
	TDBXCommandEx (see page 10391)	Extension of TDBXCommand (see page 10378).
	TDBXCommandFactory (see page 10395)	This is class DBXCommon.TDBXCommandFactory.
	TDBXCommandTypes (see page 10396)	Type of command to be executed by a TDBXCommand (see page 10378)
	TDBXConnection (see page 10398)	Connection for the dbExpress driver framework
	TDBXConnectionBuilder (see page 10412)	Utility class used by driver writers when connections are created.
	TDBXConnectionEx (see page 10417)	Temporary extension of TDBXConnection (see page 10398) class.
	TDBXConnectionFactory (see page 10422)	Abstract base class used for creating new instances of TDBXConnection (see page 10398)
	TDBXContext (see page 10432)	Context information for a connection.
	TDBXCursorValue (see page 10438)	Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.CursorType.
	TDBXDatabaseMetaData (see page 10440)	Common database specific metadata.
	TDBXDatabaseMetaDataEx (see page 10444)	Temporary extension of TDBXDatabaseMetaData (see page 10440).
	TDBXDataTypes (see page 10447)	Data types supported by the dbExpress framework (TDBX).
	TDBXDataTypesEx (see page 10459)	Data types supported by dbExpress.
	TDBXDateValue (see page 10461)	Implementation of writable date type values.
	TDBXDelegateDriver (see page 10464)	Delegate driver base class.
	TDBXDelegateItem (see page 10468)	Used by driver implementors.
	TDBXDoubleValue (see page 10469)	Implementation of double-precision floating point values.
	TDBXDriver (see page 10472)	Driver class for DBX framework.
	TDBXDriverEx (see page 10477)	This is class DBXCommon.TDBXDriverEx.
	TDBXDriverHelp (see page 10480)	Used by driver implementors to access private or protected API.
	TDBXDriverHelpEx (see page 10482)	This is class DBXCommon.TDBXDriverHelpEx.
	TDBXDriverLoader (see page 10483)	Collection of parameters needed when loading a driver.
	TDBXDriverRegistry (see page 10485)	Registry (see page 18633) for TDBXDriverLoader (see page 10483) keyed by driver name.
	TDBXError (see page 10486)	Exception type for all dbExpress framework (TDBX) errors.
	TDBXErrorCodes (see page 10489)	Error codes for dbExpress framework (TDBX) exceptions
	TDBXIniFileConnectionFactory (see page 10501)	Creates new instances of TDBXConnection (see page 10398) from the dbxdrivers.ini and dbxconnections.ini files
	TDBXIniFileConnectionFactoryEx (see page 10504)	Extension of TDBXIniFileConnectionFactory (see page 10501).
	TDBXInt16Value (see page 10506)	Implementation of 16-byte integer values.
	TDBXInt32Value (see page 10508)	Implementation of writable 32-byte integer values.
	TDBXInt64Value (see page 10511)	Implementation of writable 64-byte integer values.
	TDBXIsolations (see page 10513)	Isolation levels supported by TDBXTransaction (see page 10623).
	TDBXLookAheadStreamReader (see page 10516)	Used internally by driver implementations and TDBXStreamValue (see page 10608).

	TDBXMemoryConnectionFactory (see page 10518)	Implementation of TDBXConnectionFactory (see page 10422) that does not load driver and connection properties.
	TDBXMetaDatabaseColumnNames (see page 10521)	Column names for metadata.
	TDBXMetaDataCommands (see page 10525)	List of available metadata commands to get metadata.
	TDBXMetaDataCommandsEx (see page 10531)	Temporary extension of TDBXMetaDataCommands (see page 10525) class.
	TDBXMetaDataKeyword (see page 10537)	Keyword for metadata.
	TDBXMetaDataProcedureTypes (see page 10538)	Constants passed to TDBXMetaDataCommands.GetProcedures metadata command.
	TDBXMetaDataTableTypes (see page 10540)	Constants for the GetTables metadata command
	TDBXMetaDataTableTypesEx (see page 10542)	Temporary extension of TDBXMetaDataTableTypes (see page 10540) class.
	TDBXNullValue (see page 10543)	This is class DBXCommon.TDBXNullValue.
	TDBXParameter (see page 10545)	Individual parameters for queries and stored commands.
	TDBXParameterDirections (see page 10549)	Parameter types supported by TDBXParameter (see page 10545)
	TDBXParameterEx (see page 10551)	Extension of TDBXParameter (see page 10545).
	TDBXParameterList (see page 10553)	A collection of TDBXParameter (see page 10545) instances that can be used to get and set parameters for a TDBXCommand (see page 10378).
	TDBXProperties (see page 10559)	Manages connection and driver level name/value pair property settings.
	TDBXPropertiesItem (see page 10564)	Contains a set of TDBXProperties (see page 10559).
	TDBXPropertyNames (see page 10566)	Property names for connections and drivers.
	TDBXPropertyNamesEx (see page 10574)	Temporary extension of TDBXPropertyNames (see page 10566) class.
	TDBXReader (see page 10576)	TDBXReader provides a unidirectional reader for a collection of database rows
	TDBXReaderByteReader (see page 10585)	Implementation of TDBXByteReader (see page 10368).
	TDBXRow (see page 10590)	Represents a row in a database.
	TDBXRowEx (see page 10600)	This is class DBXCommon.TDBXRowEx.
	TDBXStateItem (see page 10604)	This is class DBXCommon.TDBXStateItem.
	TDBXStateItemList (see page 10605)	This is class DBXCommon.TDBXStateItemList.
	TDBXStreamReader (see page 10607)	Used internally by driver implementations and TDBXStreamValue (see page 10608).
	TDBXStreamValue (see page 10608)	Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.ByteArrayType values.
	TDBXTimeStampValue (see page 10612)	Implementation of writable timestamp values.
	TDBXTimeValue (see page 10614)	Implementation of writable time values.
	TDBXTraceFlags (see page 10617)	Flags to indicate tracing type.
	TDBXTransaction (see page 10623)	Transaction management class.
	TDBXValue (see page 10626)	Gets and sets values for TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
	TDBXValueList (see page 10634)	Manage a list of TDBXValueType (see page 10636) instances.
	TDBXValueType (see page 10636)	Metadata for TDBXReader (see page 10576) columns and TDBXParameter (see page 10545) parameters.
	TDBXValueTypeEx (see page 10649)	Extension of TDBXValueType (see page 10636).
	TDBXValueTypeFlags (see page 10651)	Flags used by TDBXValueType (see page 10636).
	TDBXValueTypeFlagsEx (see page 10653)	Temporary extension of TDBXValueTypeFlags (see page 10651) class.
	TDBXWideCharsValue (see page 10655)	This is class DBXCommon.TDBXWideCharsValue.
	TDBXWideStringValue (see page 10658)	Implementation of writable wide string values.
	TDBXWritableValue (see page 10661)	Extension of TDBXValue (see page 10626) that adds the ability to set a value.

Records

	Name	Description
	TDBXTraceInfo (see page 10622)	Trace information for TDBXTraceEvent (see page 10672) handlers.

55.1.1 TDBXAnsiStringValue Class

Implementation of writable ANSI string values.

Class Hierarchy

Pascal

```
TDBXAnsiStringValue = class(TDBXWritableValue);
```

C++

```
class TDBXAnsiStringValue : public TDBXWritableValue;
```

File

DBXCommon

Description

Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.AnsiStringType values.

55.1.1.1 TDBXAnsiStringValue Members

The following tables list the members exposed by TDBXAnsiStringValue.

Protected Methods

	Name	Description
	Create (see page 10358)	Creates an instance of TDBXAnsiStringValue (see page 10356)
	GetDbxContext (see page 10630)	Get context information for a connection associated with value.
V	SetPendingValue (see page 10666)	This is SetPendingValue, a member of class TDBXWritableValue.

Protected Properties

	Name	Description
R	DbxContext (see page 10633)	Context information for a connection associated with value.

Public Methods

	Name	Description
	CreateValue (see page 10628)	Creates values for both the TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
V	Destroy (see page 10358)	Destroys a TDBXAnsiStringValue (see page 10356) instance.
V	GetAnsiString (see page 10359)	Gets the string value for ANSI strings.
V	GetBcd (see page 10629)	Gets the BCD value for binary-compressed decimal data types.
V	GetBoolean (see page 10629)	Gets the boolean value for boolean data types.
V	GetBytes (see page 10629)	Gets the byte array value for byte array and blob types.
V	GetDate (see page 10630)	Gets the date value for date data types.
V	GetDouble (see page 10630)	Gets the double floating point value for double data types.
V	GetInt16 (see page 10631)	Gets the smallInt value for 16-byte integer data types.
V	GetInt32 (see page 10631)	Gets the 32-byte integer value for 32-byte integer data types.
V	GetInt64 (see page 10631)	Gets the 64-byte integer value for 64-byte integer data types.
V	GetTime (see page 10631)	Gets the time value for time data types.
V	GetTimeStamp (see page 10632)	Gets the timestamp value for timestamp data types.
V	GetValueSize (see page 10632)	Gets the size in bytes for values.
V	GetWideString (see page 10632)	Gets the wide string value for wide string data types.
V	IsNull (see page 10359)	Returns true if the value is **null**.
V	SetAnsiString (see page 10359)	Sets the string value for ANSI strings.
V	SetBcd (see page 10664)	Sets the BCD value for binary-compressed decimal data types.
V	SetBoolean (see page 10664)	Sets the boolean value for boolean data types..
V	SetDate (see page 10664)	Sets the date value for date data types..
V	SetDouble (see page 10664)	Sets the double floating point value for double data types.

	SetDynamicBytes (see page 10665)	Sets the dynamic array value for byte array and blob types.
	SetInt16 (see page 10665)	Sets the the smallInt value for 16-byte integer data types.
	SetInt32 (see page 10665)	Sets the 32-byte integer value for 32-byte integer data types.
	SetInt64 (see page 10665)	Sets the 64-byte integer value for 64-byte integer data types.
	SetNull (see page 10666)	Sets a writable value of any type to null.
	SetStaticBytes (see page 10666)	Sets the open array value for byte array and blob types
	SetTime (see page 10666)	Sets the time value for time data types.
	SetTimeStamp (see page 10667)	Sets the timestamp value for timestamp data types.
	SetWideString (see page 10667)	Sets the wide string value for wide string data types.

Public Properties

	Name	Description
	ValueType (see page 10633)	Gets the value type for this value.

55.1.1.2 TDBXAnsiStringValue.Create Constructor

Creates an instance of TDBXAnsiStringValue (see page 10356)

Pascal

```
constructor Create(ValueType: TDBXValueType);
```

C++

```
__fastcall TDBXAnsiStringValue(TDBXValueType ValueType);
```

Description

This constructor creates and initializes an instance of TDBXAnsiStringValue (see page 10356).

See Also

Destroy (see page 10358)

55.1.1.3 TDBXAnsiStringValue.Destroy Destructor

Destroys a TDBXAnsiStringValue (see page 10356) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXAnsiStringValue();
```

Description

This destructor destroys an instance of TDBXAnsiStringValue (see page 10356).

See Also

Create (see page 10358)

55.1.1.4 TDBXAnsiStringValue Methods

The methods of the TDBXAnsiStringValue class are listed here.

Public Methods

	Name	Description
	GetAnsiString (see page 10359)	Gets the string value for ANSI strings.
	IsNull (see page 10359)	Returns true if the value is **null**.
	SetAnsiString (see page 10359)	Sets the string value for ANSI strings.

55.1.1.4.1 TDBXAnsiStringValue.GetAnsiString Method

Gets the string value for ANSI strings.

Pascal

```
function GetAnsiString: String; override;
```

C++

```
virtual __fastcall AnsiString GetAnsiString();
```

Description

Gets the string value for TDBXValue (see page 10626) instances with a data type of AnsiStringType. Throws a TDBXError (see page 10486) exception if IsNull (see page 10359) is true.

55.1.1.4.2 TDBXAnsiStringValue.IsNull Method

Returns true if the value is **null**.

Pascal

```
function IsNull: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsNull();
```

Description

Returns true if the value is **null**. This method should be called before calling any of the Get methods. If the value is null, the Get methods throw a TDBXError (see page 10486) exception if they are called.

55.1.1.4.3 TDBXAnsiStringValue.SetAnsiString Method

Sets the string value for ANSI strings.

Pascal

```
procedure SetAnsiString(const Value: String); override;
```

C++

```
virtual __fastcall SetAnsiString(const AnsiString Value);
```

Description

Sets the string value for TDBXValue (see page 10626) instances with a data type of AnsiStringType.

55.1.2 TDBXBcdValue Class

Implementation of binary-compressed decimal values.

Class Hierarchy

Pascal

```
TDBXBcdValue = class(TDBXWritableValue);
```

C++

```
class TDBXBcdValue : public TDBXWritableValue;
```

File

DBXCommon

Description

Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.BcdType values.

55.1.2.1 TDBXBcdValue Members

The following tables list the members exposed by TDBXBcdValue.

Protected Methods

	Name	Description
	Create (see page 10627)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	Create (see page 10662)	Creates an instance of TDBXWritableValue (see page 10661)
	GetDbxContext (see page 10630)	Get context information for a connection associated with value.
V	SetPendingValue (see page 10666)	This is SetPendingValue, a member of class TDBXWritableValue.

Protected Properties

	Name	Description
R	DbxContext (see page 10633)	Context information for a connection associated with value.

Public Methods

	Name	Description
	CreateValue (see page 10628)	Creates values for both the TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
V	Destroy (see page 10627)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
V	Destroy (see page 10663)	Destroys a TDBXWritableValue (see page 10661) instance.
V	GetAnsiString (see page 10629)	Gets the string value for ANSI strings.
V	GetBcd (see page 10361)	Gets the BCD value for binary-compressed decimal data types.
V	GetBoolean (see page 10629)	Gets the boolean value for boolean data types.
V	GetBytes (see page 10629)	Gets the byte array value for byte array and blob types.
V	GetDate (see page 10630)	Gets the date value for date data types.
V	GetDouble (see page 10630)	Gets the double floating point value for double data types.
V	GetInt16 (see page 10631)	Gets the smallInt value for 16-byte integer data types.
V	GetInt32 (see page 10631)	Gets the 32-byte integer value for 32-byte integer data types.
V	GetInt64 (see page 10631)	Gets the 64-byte integer value for 64-byte integer data types.
V	GetTime (see page 10631)	Gets the time value for time data types.
V	GetTimeStamp (see page 10632)	Gets the timestamp value for timestamp data types.
V	GetValueSize (see page 10632)	Gets the size in bytes for values.
V	GetWideString (see page 10632)	Gets the wide string value for wide string data types.
V	IsNull (see page 10361)	Returns true if the value is **null**.
V	SetAnsiString (see page 10663)	Sets the string value for ANSI strings.

	SetBcd (see page 10362)	Sets the BCD value for binary-compressed decimal data types.
	SetBoolean (see page 10664)	Sets the boolean value for boolean data types..
	SetDate (see page 10664)	Sets the date value for date data types..
	SetDouble (see page 10664)	Sets the double floating point value for double data types.
	SetDynamicBytes (see page 10665)	Sets the dynamic array value for byte array and blob types.
	SetInt16 (see page 10665)	Sets the the smallInt value for 16-byte integer data types.
	SetInt32 (see page 10665)	Sets the 32-byte integer value for 32-byte integer data types.
	SetInt64 (see page 10665)	Sets the 64-byte integer value for 64-byte integer data types.
	SetNull (see page 10666)	Sets a writable value of any type to null.
	SetStaticBytes (see page 10666)	Sets the open array value for byte array and blob types
	SetTime (see page 10666)	Sets the time value for time data types.
	SetTimeStamp (see page 10667)	Sets the timestamp value for timestamp data types.
	SetWideString (see page 10667)	Sets the wide string value for wide string data types.

Public Properties

	Name	Description
	ValueType (see page 10633)	Gets the value type for this value.

55.1.2.2 TDBXBcdValue Methods

The methods of the TDBXBcdValue class are listed here.

Public Methods

	Name	Description
	GetBcd (see page 10361)	Gets the BCD value for binary-compressed decimal data types.
	IsNull (see page 10361)	Returns true if the value is **null**.
	SetBcd (see page 10362)	Sets the BCD value for binary-compressed decimal data types.

55.1.2.2.1 TDBXBcdValue.GetBcd Method

Gets the BCD value for binary-compressed decimal data types.

Pascal

```
function GetBcd: TBcd; override;
```

C++

```
virtual __fastcall TBcd GetBcd();
```

Description

Gets the TBcd value for TDBXValue (see page 10626) instances with a with a data type of BcdType. Throws a TDBXError (see page 10486) exception if IsNull (see page 10361) is true.

55.1.2.2.2 TDBXBcdValue.IsNull Method

Returns true if the value is **null**.

Pascal

```
function IsNull: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsNull();
```

Description

Returns true if the value is **null**. This method should be called before calling any of the Get methods. If the value is null, the Get methods will throw TDBXError (see page 10486) exception if they are called.

55.1.2.2.3 TDBXBcdValue.SetBcd Method

Sets the BCD value for binary-compressed decimal data types.

Pascal

```
procedure SetBcd(const Value: TBcd); override;
```

C++

```
virtual __fastcall SetBcd(const TBcd Value);
```

Description

Sets the TBcd value for TDBXValue (see page 10626) instances with a with a data type of BcdType.

55.1.3 TDBXBooleanValue Class

Implementation of writable boolean values.

Class Hierarchy

Pascal

```
TDBXBooleanValue = class(TDBXWritableValue);
```

C++

```
class TDBXBooleanValue : public TDBXWritableValue;
```

File

DBXCommon

Description

Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.BooleanType values.

55.1.3.1 TDBXBooleanValue Members

The following tables list the members exposed by TDBXBooleanValue.

Protected Methods

	Name	Description
	Create (see page 10627)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	Create (see page 10662)	Creates an instance of TDBXWritableValue (see page 10661)
	GetDbxContext (see page 10630)	Get context information for a connection associated with value.
V	SetPendingValue (see page 10666)	This is SetPendingValue, a member of class TDBXWritableValue.

Protected Properties

	Name	Description
R	DbxContext (see page 10633)	Context information for a connection associated with value.

Public Methods

	Name	Description
	CreateValue (see page 10628)	Creates values for both the TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
V	Destroy (see page 10627)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
V	Destroy (see page 10663)	Destroys a TDBXWritableValue (see page 10661) instance.
V	GetAnsiString (see page 10629)	Gets the string value for ANSI strings.
V	GetBcd (see page 10629)	Gets the BCD value for binary-compressed decimal data types.
V	GetBoolean (see page 10364)	Gets the boolean value for boolean data types.
V	GetBytes (see page 10629)	Gets the byte array value for byte array and blob types.
V	GetDate (see page 10630)	Gets the date value for date data types.
V	GetDouble (see page 10630)	Gets the double floating point value for double data types.
V	GetInt16 (see page 10631)	Gets the smallInt value for 16-byte integer data types.
V	GetInt32 (see page 10631)	Gets the 32-byte integer value for 32-byte integer data types.
V	GetInt64 (see page 10631)	Gets the 64-byte integer value for 64-byte integer data types.
V	GetTime (see page 10631)	Gets the time value for time data types.
V	GetTimeStamp (see page 10632)	Gets the timestamp value for timestamp data types.
V	GetValueSize (see page 10632)	Gets the size in bytes for values.
V	GetWideString (see page 10632)	Gets the wide string value for wide string data types.
V	IsNull (see page 10364)	Returns true if the value is **null**.
V	SetAnsiString (see page 10663)	Sets the string value for ANSI strings.
V	SetBcd (see page 10664)	Sets the BCD value for binary-compressed decimal data types.
V	SetBoolean (see page 10364)	Sets the boolean value for boolean data types..
V	SetDate (see page 10664)	Sets the date value for date data types..
V	SetDouble (see page 10664)	Sets the double floating point value for double data types.
V	SetDynamicBytes (see page 10665)	Sets the dynamic array value for byte array and blob types.
V	SetInt16 (see page 10665)	Sets the the smallInt value for 16-byte integer data types.
V	SetInt32 (see page 10665)	Sets the 32-byte integer value for 32-byte integer data types.
V	SetInt64 (see page 10665)	Sets the 64-byte integer value for 64-byte integer data types.
V	SetNull (see page 10666)	Sets a writable value of any type to null.
V	SetStaticBytes (see page 10666)	Sets the open array value for byte array and blob types
V	SetTime (see page 10666)	Sets the time value for time data types.
V	SetTimeStamp (see page 10667)	Sets the timestamp value for timestamp data types.
V	SetWideString (see page 10667)	Sets the wide string value for wide string data types.

Public Properties

	Name	Description
R	ValueType (see page 10633)	Gets the value type for this value.

55.1.3.2 TDBXBooleanValue Methods

The methods of the TDBXBooleanValue class are listed here.

Public Methods

	Name	Description
V	GetBoolean (see page 10364)	Gets the boolean value for boolean data types.
V	IsNull (see page 10364)	Returns true if the value is **null**.
V	SetBoolean (see page 10364)	Sets the boolean value for boolean data types..

55.1.3.2.1 TDBXBooleanValue.GetBoolean Method

Gets the boolean value for boolean data types.

Pascal

```
function GetBoolean: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetBoolean();
```

Description

Gets the boolean value for TDBXValue (see page 10626) instances with a data types of BooleanType. Throws a TDBXError (see page 10486) exception if IsNull (see page 10364) is true.

55.1.3.2.2 TDBXBooleanValue.IsNull Method

Returns true if the value is **null**.

Pascal

```
function IsNull: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsNull();
```

Description

Returns true if the value is **null**. This method should be called before calling any of the Get methods. If the value is null, the Get methods will throw TDBXError (see page 10486) exception if they are called.

55.1.3.2.3 TDBXBooleanValue.SetBoolean Method

Sets the boolean value for boolean data types..

Pascal

```
procedure SetBoolean(Value: Boolean); override;
```

C++

```
virtual __fastcall SetBoolean(Boolean Value);
```

Description

Sets the boolean value for TDBXValue (see page 10626) instances with a data types of BooleanType..

55.1.4 TDBXByteArrayValue Class

Implementation of writable byte array values.

Class Hierarchy

Pascal

```
TDBXByteArrayValue = class(TDBXWritableValue);
```

C++

```
class TDBXByteArrayValue : public TDBXWritableValue;
```

File

DBXCommon

Description

Implementation of TDBXWritableValue (see page 10661) for TDBXDataTypes.ByteArrayType values.

55.1.4.1 TDBXByteArrayValue Members

The following tables list the members exposed by TDBXByteArrayValue.

Protected Methods

	Name	Description
	Create (see page 10627)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	Create (see page 10662)	Creates an instance of TDBXWritableValue (see page 10661)
	GetDbxContext (see page 10630)	Get context information for a connection associated with value.
V	SetPendingValue (see page 10666)	This is SetPendingValue, a member of class TDBXWritableValue.

Protected Properties

	Name	Description
R	DbxContext (see page 10633)	Context information for a connection associated with value.

Public Methods

	Name	Description
	CreateValue (see page 10628)	Creates values for both the TDBXReader (see page 10576) and TDBXParameterList (see page 10553) classes.
V	Destroy (see page 10366)	Destroy a TDBXByteArrayValue (see page 10364) instance
V	GetAnsiString (see page 10629)	Gets the string value for ANSI strings.
V	GetBcd (see page 10629)	Gets the BCD value for binary-compressed decimal data types.
V	GetBoolean (see page 10629)	Gets the boolean value for boolean data types.
V	GetBytes (see page 10366)	Gets the byte array value for byte array and blob types.
V	GetDate (see page 10630)	Gets the date value for date data types.
V	GetDouble (see page 10630)	Gets the double floating point value for double data types.
V	GetInt16 (see page 10631)	Gets the smallInt value for 16-byte integer data types.
V	GetInt32 (see page 10631)	Gets the 32-byte integer value for 32-byte integer data types.
V	GetInt64 (see page 10631)	Gets the 64-byte integer value for 64-byte integer data types.
V	GetTime (see page 10631)	Gets the time value for time data types.
V	GetTimeStamp (see page 10632)	Gets the timestamp value for timestamp data types.
V	GetValueSize (see page 10367)	Gets the size in bytes for values.
V	GetWideString (see page 10632)	Gets the wide string value for wide string data types.
V	IsNull (see page 10367)	Returns true if the value is **null**.
V	SetAnsiString (see page 10663)	Sets the string value for ANSI strings.
V	SetBcd (see page 10664)	Sets the BCD value for binary-compressed decimal data types.
V	SetBoolean (see page 10664)	Sets the boolean value for boolean data types..
V	SetDate (see page 10664)	Sets the date value for date data types..
V	SetDouble (see page 10664)	Sets the double floating point value for double data types.
V	SetDynamicBytes (see page 10367)	Sets the dynamic array value for byte array and blob types.
V	SetInt16 (see page 10665)	Sets the the smallInt value for 16-byte integer data types.
V	SetInt32 (see page 10665)	Sets the 32-byte integer value for 32-byte integer data types.
V	SetInt64 (see page 10665)	Sets the 64-byte integer value for 64-byte integer data types.

	SetNull (see page 10666)	Sets a writable value of any type to null.
	SetStaticBytes (see page 10367)	Sets the open array value for byte array and blob types
	SetTime (see page 10666)	Sets the time value for time data types.
	SetTimeStamp (see page 10667)	Sets the timestamp value for timestamp data types.
	SetWideString (see page 10667)	Sets the wide string value for wide string data types.

Public Properties

	Name	Description
	ValueType (see page 10633)	Gets the value type for this value.

55.1.4.2 TDBXByteArrayValue.Destroy Destructor

Destroy a TDBXByteArrayValue (see page 10364) instance

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXByteArrayValue();
```

Description

This method destroys a TDBXByteArrayValue (see page 10364) instance.

55.1.4.3 TDBXByteArrayValue Methods

The methods of the TDBXByteArrayValue class are listed here.

Public Methods

	Name	Description
	GetBytes (see page 10366)	Gets the byte array value for byte array and blob types.
	GetValueSize (see page 10367)	Gets the size in bytes for values.
	IsNull (see page 10367)	Returns true if the value is **null**.
	SetDynamicBytes (see page 10367)	Sets the dynamic array value for byte array and blob types.
	SetStaticBytes (see page 10367)	Sets the open array value for byte array and blob types

55.1.4.3.1 TDBXByteArrayValue.GetBytes Method

Gets the byte array value for byte array and blob types.

Pascal

```
function GetBytes(Offset: Int64; const Buffer: TBytes; BufferOffset: Int64; Length: Int64):
Int64; override;
```

C++

```
virtual __fastcall Int64 GetBytes(Int64 Offset, const TBytes Buffer, Int64 BufferOffset, Int64
Length);
```

Description

Gets the byte array value for TDBXValue (see page 10626) instances with a data type of BytesType and .BlobType. Throws a TDBXError (see page 10486) exception if IsNull (see page 10367) is true.

55.1.4.3.2 TDBXByteArrayValue.GetValueSize Method

Gets the size in bytes for values.

Pascal

```
function GetValueSize: Int64; override;
```

C++

```
virtual __fastcall Int64 GetValueSize();
```

Description

Gets the size in bytes for a TDBXValue (see page 10626). For string data types the number of characters is returned. Throws a TDBXError (see page 10486) exception if IsNull (see page 10367) is true.

55.1.4.3.3 TDBXByteArrayValue.IsNull Method

Returns true if the value is **null**.

Pascal

```
function IsNull: Boolean; override;
```

C++

```
virtual __fastcall Boolean IsNull();
```

Description

Returns true if the value is **null**. This method should be called before calling any of the Get methods. If the value is null, the Get methods will throw TDBXError (see page 10486) exception if they are called.

55.1.4.3.4 TDBXByteArrayValue.SetDynamicBytes Method

Sets the dynamic array value for byte array and blob types.

Pascal

```
procedure SetDynamicBytes(Offset: Int64; const Buffer: TBytes; BufferOffset: Int64; Length:
Int64); override;
```

C++

```
virtual __fastcall SetDynamicBytes(Int64 Offset, const TBytes Buffer, Int64 BufferOffset,
Int64 Length);
```

Description

Sets the dynamic array value for TDBXValue (see page 10626) instances with a data type of BytesType and .BlobType.

55.1.4.3.5 TDBXByteArrayValue.SetStaticBytes Method

Sets the open array value for byte array and blob types

Pascal

```
procedure SetStaticBytes(Offset: Int64; const Buffer: array of Byte; BufferOffset: Int64;
Length: Int64); override;
```

C++

```
virtual __fastcall SetStaticBytes(Int64 Offset, const array of Byte Buffer, Int64
BufferOffset, Int64 Length);
```

Description

Sets the open array value for TDBXValue (see page 10626) instances with a data type of BytesType and .BlobType.

55.1.5 TDBXByteReader Class

Allows for primitive retrieval of data using byte arrays.

Class Hierarchy

DBXCommon.TDBXByteReader

Pascal

```
TDBXByteReader = class;
```

C++

```
class TDBXByteReader;
```

File

DBXCommon

Description

This class is used by dbExpress related TDataSet components. It allows for primitive retrieval of data using byte arrays. It is not for general usage.

See Also

TDataSet (see page 6894)

55.1.5.1 TDBXByteReader Members

The following tables list the members exposed by TDBXByteReader.

Protected Methods

	Name	Description
	Create (see page 10369)	Creates an instance of TDBXByteReader (see page 10368)

Public Methods

	Name	Description
	GetAnsiString (see page 10370)	This is GetAnsiString, a member of class TDBXByteReader.
	GetBcd (see page 10370)	This is GetBcd, a member of class TDBXByteReader.
	GetByteLength (see page 10370)	This is GetByteLength, a member of class TDBXByteReader.
	GetBytes (see page 10370)	This is GetBytes, a member of class TDBXByteReader.
	GetDate (see page 10371)	This is GetDate, a member of class TDBXByteReader.
	GetDouble (see page 10371)	This is GetDouble, a member of class TDBXByteReader.
	GetInt16 (see page 10371)	This is GetInt16, a member of class TDBXByteReader.
	GetInt32 (see page 10371)	This is GetInt32, a member of class TDBXByteReader.
	GetInt64 (see page 10372)	This is GetInt64, a member of class TDBXByteReader.
	GetTime (see page 10372)	This is GetTime, a member of class TDBXByteReader.
	GetTimeStamp (see page 10372)	This is GetTimeStamp, a member of class TDBXByteReader.
	GetWideString (see page 10372)	This is GetWideString, a member of class TDBXByteReader.

Strict protected Fields

	Name	Description
	FDBXContext (see page 10369)	This is FDBXContext, a member of class TDBXByteReader.

55.1.5.2 TDBXByteReader.Create Constructor

Creates an instance of TDBXByteReader (see page 10368)

Pascal

```
constructor Create(DBXContext: TDBXContext);
```

C++

```
__fastcall TDBXByteReader(TDBXContext DBXContext);
```

Description

This constructor creates and initializes an instance of TDBXByteReader (see page 10368).

55.1.5.3 TDBXByteReader Fields

The fields of the TDBXByteReader class are listed here.

Strict protected Fields

	Name	Description
	FDBXContext (see page 10369)	This is FDBXContext, a member of class TDBXByteReader.

55.1.5.3.1 TDBXByteReader.FDBXContext Field

Pascal

```
FDBXContext: TDBXContext;
```

C++

```
TDBXContext FDBXContext;
```

Description

This is FDBXContext, a member of class TDBXByteReader.

55.1.5.4 TDBXByteReader Methods

The methods of the TDBXByteReader class are listed here.

Public Methods

	Name	Description
	GetAnsiString (see page 10370)	This is GetAnsiString, a member of class TDBXByteReader.
	GetBcd (see page 10370)	This is GetBcd, a member of class TDBXByteReader.
	GetByteLength (see page 10370)	This is GetByteLength, a member of class TDBXByteReader.
	GetBytes (see page 10370)	This is GetBytes, a member of class TDBXByteReader.
	GetDate (see page 10371)	This is GetDate, a member of class TDBXByteReader.
	GetDouble (see page 10371)	This is GetDouble, a member of class TDBXByteReader.
	GetInt16 (see page 10371)	This is GetInt16, a member of class TDBXByteReader.
	GetInt32 (see page 10371)	This is GetInt32, a member of class TDBXByteReader.

	GetInt64 (see page 10372)	This is GetInt64, a member of class TDBXByteReader.
	GetTime (see page 10372)	This is GetTime, a member of class TDBXByteReader.
	GetTimeStamp (see page 10372)	This is GetTimeStamp, a member of class TDBXByteReader.
	GetWideString (see page 10372)	This is GetWideString, a member of class TDBXByteReader.

55.1.5.4.1 TDBXByteReader.GetAnsiString Method

Pascal

```
procedure GetAnsiString(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetAnsiString(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetAnsiString, a member of class TDBXByteReader.

55.1.5.4.2 TDBXByteReader.GetBcd Method

Pascal

```
procedure GetBcd(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull: LongBool);
virtual; abstract;
```

C++

```
virtual __fastcall GetBcd(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool IsNull)
= 0;
```

Description

This is GetBcd, a member of class TDBXByteReader.

55.1.5.4.3 TDBXByteReader.GetByteLength Method

Pascal

```
procedure GetByteLength(Ordinal: TInt32; var Length: Int64; var IsNull: LongBool); virtual;
abstract;
```

C++

```
virtual __fastcall GetByteLength(TInt32 Ordinal, Int64 Length, LongBool IsNull) = 0;
```

Description

This is GetByteLength, a member of class TDBXByteReader.

55.1.5.4.4 TDBXByteReader.GetBytes Method

Pascal

```
function GetBytes(Ordinal: TInt32; Offset: Int64; const Value: TBytes; ValueOffset: Int64;
Length: Int64; var IsNull: LongBool): Int64; virtual; abstract;
```

C++

```
virtual __fastcall Int64 GetBytes(TInt32 Ordinal, Int64 Offset, const TBytes Value, Int64
ValueOffset, Int64 Length, LongBool IsNull) = 0;
```

Description

This is GetBytes, a member of class TDBXByteReader.

55.1.5.4.5 TDBXByteReader.GetDate Method

Pascal

```
procedure GetDate(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull: LongBool);
virtual; abstract;
```

C++

```
virtual __fastcall GetDate(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool IsNull)
= 0;
```

Description

This is GetDate, a member of class TDBXByteReader.

55.1.5.4.6 TDBXByteReader.GetDouble Method

Pascal

```
procedure GetDouble(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetDouble(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetDouble, a member of class TDBXByteReader.

55.1.5.4.7 TDBXByteReader.GetInt16 Method

Pascal

```
procedure GetInt16(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetInt16(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetInt16, a member of class TDBXByteReader.

55.1.5.4.8 TDBXByteReader.GetInt32 Method

Pascal

```
procedure GetInt32(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetInt32(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetInt32, a member of class TDBXByteReader.

55.1.5.4.9 TDBXByteReader.GetInt64 Method

Pascal

```
procedure GetInt64(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetInt64(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetInt64, a member of class TDBXByteReader.

55.1.5.4.10 TDBXByteReader.GetTime Method

Pascal

```
procedure GetTime(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull: LongBool);
virtual; abstract;
```

C++

```
virtual __fastcall GetTime(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool IsNull)
= 0;
```

Description

This is GetTime, a member of class TDBXByteReader.

55.1.5.4.11 TDBXByteReader.GetTimeStamp Method

Pascal

```
procedure GetTimeStamp(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetTimeStamp(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetTimeStamp, a member of class TDBXByteReader.

55.1.5.4.12 TDBXByteReader.GetWideString Method

Pascal

```
procedure GetWideString(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual; abstract;
```

C++

```
virtual __fastcall GetWideString(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull) = 0;
```

Description

This is GetWideString, a member of class TDBXByteReader.

55.1.6 TDBXByteReaderEx Class

Class Hierarchy

Pascal

```
TDBXByteReaderEx = class(TDBXByteReader);
```

C++

```
class TDBXByteReaderEx : public TDBXByteReader;
```

File

DBXCommon

Description

This is class DBXCommon.TDBXByteReaderEx.

55.1.6.1 TDBXByteReaderEx Members

The following tables list the members exposed by TDBXByteReaderEx.

Protected Methods

	Name	Description
	Create (see page 10369)	Creates an instance of TDBXByteReader (see page 10368)

Public Methods

	Name	Description
	GetAnsiString (see page 10370)	This is GetAnsiString, a member of class TDBXByteReader.
	GetBcd (see page 10370)	This is GetBcd, a member of class TDBXByteReader.
	GetBoolean (see page 10374)	This is GetBoolean, a member of class TDBXByteReaderEx.
	GetByteLength (see page 10370)	This is GetByteLength, a member of class TDBXByteReader.
	GetBytes (see page 10370)	This is GetBytes, a member of class TDBXByteReader.
	GetDate (see page 10371)	This is GetDate, a member of class TDBXByteReader.
	GetDouble (see page 10371)	This is GetDouble, a member of class TDBXByteReader.
	GetInt16 (see page 10371)	This is GetInt16, a member of class TDBXByteReader.
	GetInt32 (see page 10371)	This is GetInt32, a member of class TDBXByteReader.
	GetInt64 (see page 10372)	This is GetInt64, a member of class TDBXByteReader.
	GetTime (see page 10372)	This is GetTime, a member of class TDBXByteReader.
	GetTimeStamp (see page 10372)	This is GetTimeStamp, a member of class TDBXByteReader.
	GetWideString (see page 10372)	This is GetWideString, a member of class TDBXByteReader.

Strict protected Fields

	Name	Description
	FDBXContext (see page 10369)	This is FDBXContext, a member of class TDBXByteReader.

55.1.6.2 TDBXByteReaderEx Methods

The methods of the TDBXByteReaderEx class are listed here.

Public Methods

	Name	Description
	GetBoolean (see page 10374)	This is GetBoolean, a member of class TDBXByteReaderEx.

55.1.6.2.1 TDBXByteReaderEx.GetBoolean Method

Pascal

```
procedure GetBoolean(Ordinal: TInt32; const Value: TBytes; Offset: TInt32; var IsNull:
LongBool); virtual;
```

C++

```
virtual __fastcall GetBoolean(TInt32 Ordinal, const TBytes Value, TInt32 Offset, LongBool
IsNull);
```

Description

This is GetBoolean, a member of class TDBXByteReaderEx.

55.1.7 TDBXByteStreamReader Class

Used internally by driver implementations and TDBXStreamValue (see page 10608).

Class Hierarchy

Pascal

```
TDBXByteStreamReader = class(TDBXStreamReader);
```

C++

```
class TDBXByteStreamReader : public TDBXStreamReader;
```

File

DBXCommon

Description

TDBXByteStreamReader is used internally by driver implementations and TDBXStreamValue (see page 10608).

See Also

TDBXStreamValue (see page 10608)

55.1.7.1 TDBXByteStreamReader Members

The following tables list the members exposed by TDBXByteStreamReader.

Public Fields

	Name	Description
	FBytes (see page 10376)	This is FBytes, a member of class TDBXByteStreamReader.
	FCount (see page 10376)	This is FCount, a member of class TDBXByteStreamReader.
	FEOS (see page 10376)	This is FEOS, a member of class TDBXByteStreamReader.
	FOffset (see page 10376)	This is FOffset, a member of class TDBXByteStreamReader.
	FPosition (see page 10376)	This is FPosition, a member of class TDBXByteStreamReader.

Public Methods

	Name	Description
	Create (see page 10375)	This is Create, a member of class TDBXByteStreamReader.
V	Destroy (see page 10375)	This is Destroy, a member of class TDBXByteStreamReader.
V	Eos (see page 10377)	This is Eos, a member of class TDBXByteStreamReader.
V	Read (see page 10377)	This is Read, a member of class TDBXByteStreamReader.
V	Size (see page 10377)	This is Size, a member of class TDBXByteStreamReader.

55.1.7.2 TDBXByteStreamReader.Create Constructor

Pascal

```
constructor Create(Bytes: TBytes; Offset: Integer; Count: Integer);
```

C++

```
__fastcall TDBXByteStreamReader(TBytes Bytes, int Offset, int Count);
```

Description

This is Create, a member of class TDBXByteStreamReader.

55.1.7.3 TDBXByteStreamReader.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXByteStreamReader();
```

Description

This is Destroy, a member of class TDBXByteStreamReader.

55.1.7.4 TDBXByteStreamReader Fields

The fields of the TDBXByteStreamReader class are listed here.

Public Fields

	Name	Description
	FBytes (see page 10376)	This is FBytes, a member of class TDBXByteStreamReader.
	FCount (see page 10376)	This is FCount, a member of class TDBXByteStreamReader.
	FEOS (see page 10376)	This is FEOS, a member of class TDBXByteStreamReader.
	FOffset (see page 10376)	This is FOffset, a member of class TDBXByteStreamReader.
	FPosition (see page 10376)	This is FPosition, a member of class TDBXByteStreamReader.

55.1.7.4.1 TDBXByteStreamReader.FBytes Field

Pascal

```
FBytes: TBytes;
```

C++

```
TBytes FBytes;
```

Description

This is FBytes, a member of class TDBXByteStreamReader.

55.1.7.4.2 TDBXByteStreamReader.FCount Field

Pascal

```
FCount: Integer;
```

C++

```
int FCount;
```

Description

This is FCount, a member of class TDBXByteStreamReader.

55.1.7.4.3 TDBXByteStreamReader.FEOS Field

Pascal

```
FEOS: Boolean;
```

C++

```
Boolean FEOS;
```

Description

This is FEOS, a member of class TDBXByteStreamReader.

55.1.7.4.4 TDBXByteStreamReader.FOffset Field

Pascal

```
FOffset: Integer;
```

C++

```
int FOffset;
```

Description

This is FOffset, a member of class TDBXByteStreamReader.

55.1.7.4.5 TDBXByteStreamReader.FPosition Field

Pascal

```
FPosition: Integer;
```

C++

```
int FPosition;
```

Description

This is FPosition, a member of class TDBXByteStreamReader.

55.1.7.5 TDBXByteStreamReader Methods

The methods of the TDBXByteStreamReader class are listed here.

Public Methods

	Name	Description
	Eos (see page 10377)	This is Eos, a member of class TDBXByteStreamReader.
	Read (see page 10377)	This is Read, a member of class TDBXByteStreamReader.
	Size (see page 10377)	This is Size, a member of class TDBXByteStreamReader.

55.1.7.5.1 TDBXByteStreamReader.Eos Method

Pascal

```
function Eos: Boolean; override;
```

C++

```
virtual __fastcall Boolean Eos();
```

Description

This is Eos, a member of class TDBXByteStreamReader.

55.1.7.5.2 TDBXByteStreamReader.Read Method

Pascal

```
function Read(const Buffer: TBytes; Offset: Integer; Count: Integer): Integer; override;
```

C++

```
virtual __fastcall int Read(const TBytes Buffer, int Offset, int Count);
```

Description

This is Read, a member of class TDBXByteStreamReader.

55.1.7.5.3 TDBXByteStreamReader.Size Method

Pascal

```
function Size: Int64; override;
```

C++

```
virtual __fastcall Int64 Size();
```

Description

This is Size, a member of class TDBXByteStreamReader.

55.1.8 TDBXCommand Class

Class to execute SQL statements and stored procedures

Class Hierarchy

DBXCommon.TDBXCommand

Pascal

```
TDBXCommand = class;
```

C++

```
class TDBXCommand;
```

File

DBXCommon

Description

The TDBXCommand class is typically used to execute SQL statements and stored procedures.

The TDBXCommand.Text (see page 10390) property is set to the desired command to execute.

Parameters (see page 10389) can be added and accessed through the TDBXCommand.Parameters (see page 10389) property. Parameters (see page 10389) can be created by calling the TDBXCommand.CreateParameter (see page 10382) method.

TDBXCommand can also execute other types of commands. The TDBXCommandTypes (see page 10396) class lists constants for common command types. Because the command type is represented as a `String`, driver implementations can use TDBXCommandTypes (see page 10396) as a namespace to create additional types of commands. For example, the TDBXPool delegate driver has a command type that allows a command to return a TDBXReader (see page 10576) with information on the active connection pools.

TDBXCommand instances can be created by calling one of the TDBXConnection.CreateCommandmethods. As soon as an application is finished using a command, the TDBXCommand.Free method must be called. This releases memory for the command and any associated resources.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXCommandTypes (see page 10396)

TDBXConnection (see page 10398)

TDBXReader (see page 10576)

Parameters (see page 10389)

Text (see page 10390)

CreateParameter (see page 10382)

CreateCommand (see page 10404)

55.1.8.1 TDBXCommand Members

The following tables list the members exposed by TDBXCommand.

Protected Fields

	Name	Description
	FDBXContext (see page 10381)	This is FDBXContext, a member of class TDBXCommand.

Protected Methods

	Name	Description
V	Close (see page 10382)	This is Close, a member of class TDBXCommand.
	Create (see page 10380)	Creates an instance of TDBXCommand (see page 10378)
V	CreateParameterRow (see page 10382)	This is CreateParameterRow, a member of class TDBXCommand.
V	CreateParameters (see page 10382)	This is CreateParameters, a member of class TDBXCommand.
A	DerivedClose (see page 10383)	This is DerivedClose, a member of class TDBXCommand.
A	DerivedExecuteQuery (see page 10383)	This is DerivedExecuteQuery, a member of class TDBXCommand.
A	DerivedExecuteUpdate (see page 10383)	This is DerivedExecuteUpdate, a member of class TDBXCommand.
A	DerivedGetNextReader (see page 10383)	This is DerivedGetNextReader, a member of class TDBXCommand.
A	DerivedOpen (see page 10384)	This is DerivedOpen, a member of class TDBXCommand.
A	DerivedPrepare (see page 10384)	This is DerivedPrepare, a member of class TDBXCommand.
V	GetCommandType (see page 10385)	This is GetCommandType, a member of class TDBXCommand.
V	GetErrorEvent (see page 10385)	This is GetErrorEvent, a member of class TDBXCommand.
V	GetParameters (see page 10385)	This is GetParameters, a member of class TDBXCommand.
A	GetRowsAffected (see page 10386)	This is GetRowsAffected, a member of class TDBXCommand.
V	GetText (see page 10386)	This is GetText, a member of class TDBXCommand.
V	Open (see page 10386)	This is Open, a member of class TDBXCommand.
V	SetCommandType (see page 10387)	This is SetCommandType, a member of class TDBXCommand.
A	SetMaxBlobSize (see page 10387)	This is SetMaxBlobSize, a member of class TDBXCommand.
A	SetRowSetSize (see page 10387)	This is SetRowSetSize, a member of class TDBXCommand.
V	SetText (see page 10387)	This is SetText, a member of class TDBXCommand.

Public Events

	Name	Description
R	OnErrorEvent (see page 10391)	Error handling event

Public Methods

	Name	Description
V	CreateParameter (see page 10382)	Create (see page 10380) a parameter
V	Destroy (see page 10380)	Destroy a command instance
V	ExecuteQuery (see page 10384)	Executes a command that returns an instance of TDBXReader (see page 10576)
V	ExecuteUpdate (see page 10384)	Executes an update command
V	GetNextReader (see page 10385)	Gets next instance of TDBXReader (see page 10576)
V	Prepare (see page 10386)	Prepare the command for execution

Public Properties

	Name	Description
	CommandType (see page 10388)	Command type
R	IsPrepared (see page 10388)	Is command prepared.
W	MaxBlobSize (see page 10389)	Maximum blob size
R	Parameters (see page 10389)	List of parameters
R	RowsAffected (see page 10389)	Number of rows updated
W	RowSetSize (see page 10390)	Row buffering property used to optimize reading data from TDBXReader (see page 10576) instances.

	Text (see page 10390)	Command to execute

Strict protected Fields

	Name	Description
	FParameters (see page 10381)	This is FParameters, a member of class TDBXCommand.

Strict protected Methods

	Name	Description
	NotImplemented (see page 10386)	This is NotImplemented, a member of class TDBXCommand.

55.1.8.2 TDBXCommand.Create Constructor

Creates an instance of TDBXCommand (see page 10378)

Pascal

```
constructor Create(DBXContext: TDBXContext);
```

C++

```
__fastcall TDBXCommand(TDBXContext DBXContext);
```

Description

This constructor creates and initializes an instance of TDBXCommand (see page 10378).

See Also

Destroy (see page 10380)

55.1.8.3 TDBXCommand.Destroy Destructor

Destroy a command instance

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXCommand();
```

Description

This method destroys a TDBXCommand (see page 10378) instance.

55.1.8.4 TDBXCommand Fields

The fields of the TDBXCommand class are listed here.

Protected Fields

	Name	Description
	FDBXContext (see page 10381)	This is FDBXContext, a member of class TDBXCommand.

Strict protected Fields

	Name	Description
	FParameters (see page 10381)	This is FParameters, a member of class TDBXCommand.

55.1.8.4.1 TDBXCommand.FDBXContext Field

Pascal

```
FDBXContext: TDBXContext;
```

C++

```
TDBXContext FDBXContext;
```

Description

This is FDBXContext, a member of class TDBXCommand.

55.1.8.4.2 TDBXCommand.FParameters Field

Pascal

```
FParameters: TDBXParameterList;
```

C++

```
TDBXParameterList FParameters;
```

Description

This is FParameters, a member of class TDBXCommand.

55.1.8.5 TDBXCommand Methods

The methods of the TDBXCommand class are listed here.

Protected Methods

	Name	Description
V	Close (see page 10382)	This is Close, a member of class TDBXCommand.
V	CreateParameterRow (see page 10382)	This is CreateParameterRow, a member of class TDBXCommand.
V	CreateParameters (see page 10382)	This is CreateParameters, a member of class TDBXCommand.
A	DerivedClose (see page 10383)	This is DerivedClose, a member of class TDBXCommand.
A	DerivedExecuteQuery (see page 10383)	This is DerivedExecuteQuery, a member of class TDBXCommand.
A	DerivedExecuteUpdate (see page 10383)	This is DerivedExecuteUpdate, a member of class TDBXCommand.
A	DerivedGetNextReader (see page 10383)	This is DerivedGetNextReader, a member of class TDBXCommand.
A	DerivedOpen (see page 10384)	This is DerivedOpen, a member of class TDBXCommand.
A	DerivedPrepare (see page 10384)	This is DerivedPrepare, a member of class TDBXCommand.
V	GetCommandType (see page 10385)	This is GetCommandType, a member of class TDBXCommand.
V	GetErrorEvent (see page 10385)	This is GetErrorEvent, a member of class TDBXCommand.
V	GetParameters (see page 10385)	This is GetParameters, a member of class TDBXCommand.
A	GetRowsAffected (see page 10386)	This is GetRowsAffected, a member of class TDBXCommand.
V	GetText (see page 10386)	This is GetText, a member of class TDBXCommand.
V	Open (see page 10386)	This is Open, a member of class TDBXCommand.
V	SetCommandType (see page 10387)	This is SetCommandType, a member of class TDBXCommand.
A	SetMaxBlobSize (see page 10387)	This is SetMaxBlobSize, a member of class TDBXCommand.
A	SetRowSetSize (see page 10387)	This is SetRowSetSize, a member of class TDBXCommand.
V	SetText (see page 10387)	This is SetText, a member of class TDBXCommand.

Public Methods

	Name	Description
V	CreateParameter (see page 10382)	Create (see page 10380) a parameter

	ExecuteQuery (see page 10384)	Executes a command that returns an instance of TDBXReader (see page 10576)
	ExecuteUpdate (see page 10384)	Executes an update command
	GetNextReader (see page 10385)	Gets next instance of TDBXReader (see page 10576)
	Prepare (see page 10386)	Prepare the command for execution

Strict protected Methods

	Name	Description
	NotImplemented (see page 10386)	This is NotImplemented, a member of class TDBXCommand.

55.1.8.5.1 TDBXCommand.Close Method

Pascal

```
procedure Close; virtual;
```

C++

```
virtual __fastcall Close();
```

Description

This is Close, a member of class TDBXCommand.

55.1.8.5.2 TDBXCommand.CreateParameter Method

Create (see page 10380) a parameter

Pascal

```
function CreateParameter: TDBXParameter; virtual;
```

C++

```
virtual __fastcall TDBXParameter CreateParameter();
```

Description

This method allocates a new instance of TDBXParameter (see page 10545), which can be added to the Parameterslist.

See Also

TDBXParameter (see page 10545)

55.1.8.5.3 TDBXCommand.CreateParameterRow Method

Pascal

```
function CreateParameterRow: TDBXRow; virtual;
```

C++

```
virtual __fastcall TDBXRow CreateParameterRow();
```

Description

This is CreateParameterRow, a member of class TDBXCommand.

55.1.8.5.4 TDBXCommand.CreateParameters Method

Pascal

```
procedure CreateParameters(Command: TDBXCommand); virtual;
```

C++

```
virtual __fastcall CreateParameters(TDBXCommand Command);
```

Description

This is CreateParameters, a member of class TDBXCommand.

55.1.8.5.5 TDBXCommand.DerivedClose Method

Pascal

```
procedure DerivedClose; virtual; abstract;
```

C++

```
virtual __fastcall DerivedClose() = 0;
```

Description

This is DerivedClose, a member of class TDBXCommand.

55.1.8.5.6 TDBXCommand.DerivedExecuteQuery Method

Pascal

```
function DerivedExecuteQuery: TDBXReader; virtual; abstract;
```

C++

```
virtual __fastcall TDBXReader DerivedExecuteQuery() = 0;
```

Description

This is DerivedExecuteQuery, a member of class TDBXCommand.

55.1.8.5.7 TDBXCommand.DerivedExecuteUpdate Method

Pascal

```
procedure DerivedExecuteUpdate; virtual; abstract;
```

C++

```
virtual __fastcall DerivedExecuteUpdate() = 0;
```

Description

This is DerivedExecuteUpdate, a member of class TDBXCommand.

55.1.8.5.8 TDBXCommand.DerivedGetNextReader Method

Pascal

```
function DerivedGetNextReader: TDBXReader; virtual; abstract;
```

C++

```
virtual __fastcall TDBXReader DerivedGetNextReader() = 0;
```

Description

This is DerivedGetNextReader, a member of class TDBXCommand.

55.1.8.5.9 TDBXCommand.DerivedOpen Method

Pascal

```
procedure DerivedOpen; virtual; abstract;
```

C++

```
virtual __fastcall DerivedOpen() = 0;
```

Description

This is DerivedOpen, a member of class TDBXCommand.

55.1.8.5.10 TDBXCommand.DerivedPrepare Method

Pascal

```
procedure DerivedPrepare; virtual; abstract;
```

C++

```
virtual __fastcall DerivedPrepare() = 0;
```

Description

This is DerivedPrepare, a member of class TDBXCommand.

55.1.8.5.11 TDBXCommand.ExecuteQuery Method

Executes a command that returns an instance of TDBXReader (see page 10576)

Pascal

```
function ExecuteQuery: TDBXReader; virtual;
```

C++

```
virtual __fastcall TDBXReader ExecuteQuery();
```

Description

This method executes a command that returns an instance of TDBXReader (see page 10576). Use a TDBXReader (see page 10576) instance to read database records and data.

Note: As soon as an application is done with a TDBXReader (see page 10576) instance, it should call TDBXReader.Free to free resources.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXReader (see page 10576)

Free

55.1.8.5.12 TDBXCommand.ExecuteUpdate Method

Executes an update command

Pascal

```
procedure ExecuteUpdate; virtual;
```

C++

```
virtual __fastcall ExecuteUpdate();
```

Description

This method executes a command that performs an update operation.

55.1.8.5.13 TDBXCommand.GetCommandType Method

Pascal

```
function GetCommandType: WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetCommandType();
```

Description

This is GetCommandType, a member of class TDBXCommand.

55.1.8.5.14 TDBXCommand.GetErrorEvent Method

Pascal

```
function GetErrorEvent: TDBXErrorEvent; virtual;
```

C++

```
virtual __fastcall TDBXErrorEvent GetErrorEvent();
```

Description

This is GetErrorEvent, a member of class TDBXCommand.

55.1.8.5.15 TDBXCommand.GetNextReader Method

Gets next instance of TDBXReader (see page 10576)

Pascal

```
function GetNextReader: TDBXReader; virtual;
```

C++

```
virtual __fastcall TDBXReader GetNextReader();
```

Description

For commands that return more then one reader, this method gets the next instance of TDBXReader (see page 10576). If there are no more TDBXReader (see page 10576) instances, it returns `nil`.

See Also

TDBXReader (see page 10576)

55.1.8.5.16 TDBXCommand.GetParameters Method

Pascal

```
function GetParameters: TDBXParameterList; virtual;
```

C++

```
virtual __fastcall TDBXParameterList GetParameters();
```

Description

This is GetParameters, a member of class TDBXCommand.

55.1.8.5.17 TDBXCommand.GetRowsAffected Method

Pascal

```
function GetRowsAffected: Int64; virtual; abstract;
```

C++

```
virtual __fastcall Int64 GetRowsAffected() = 0;
```

Description

This is GetRowsAffected, a member of class TDBXCommand.

55.1.8.5.18 TDBXCommand.GetText Method

Pascal

```
function GetText: WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetText();
```

Description

This is GetText, a member of class TDBXCommand.

55.1.8.5.19 TDBXCommand.NotImplemented Method

Pascal

```
procedure NotImplemented;
```

C++

```
__fastcall NotImplemented();
```

Description

This is NotImplemented, a member of class TDBXCommand.

55.1.8.5.20 TDBXCommand.Open Method

Pascal

```
procedure Open; virtual;
```

C++

```
virtual __fastcall Open();
```

Description

This is Open, a member of class TDBXCommand.

55.1.8.5.21 TDBXCommand.Prepare Method

Prepare the command for execution

Pascal

```
procedure Prepare; virtual;
```

C++

```
virtual __fastcall Prepare();
```

Description

This method prepares the command for execution.

Note: Prepare must be called before calling any of the TDBXCommand (see page 10378) Execute methods.

55.1.8.5.22 TDBXCommand.SetCommandType Method

Pascal

```
procedure SetCommandType(const CommandType: WideString); virtual;
```

C++

```
virtual __fastcall SetCommandType(const BSTR CommandType);
```

Description

This is SetCommandType, a member of class TDBXCommand.

55.1.8.5.23 TDBXCommand.SetMaxBlobSize Method

Pascal

```
procedure SetMaxBlobSize(const MaxBlobSize: Int64); virtual; abstract;
```

C++

```
virtual __fastcall SetMaxBlobSize(const Int64 MaxBlobSize) = 0;
```

Description

This is SetMaxBlobSize, a member of class TDBXCommand.

55.1.8.5.24 TDBXCommand.SetRowSetSize Method

Pascal

```
procedure SetRowSetSize(const RowSetSize: Int64); virtual; abstract;
```

C++

```
virtual __fastcall SetRowSetSize(const Int64 RowSetSize) = 0;
```

Description

This is SetRowSetSize, a member of class TDBXCommand.

55.1.8.5.25 TDBXCommand.SetText Method

Pascal

```
procedure SetText(const Value: WideString); virtual;
```

C++

```
virtual __fastcall SetText(const BSTR Value);
```

Description

This is SetText, a member of class TDBXCommand.

55.1.8.6 TDBXCommand Properties

The properties of the TDBXCommand class are listed here.

Public Properties

	Name	Description
	CommandType (see page 10388)	Command type
R	IsPrepared (see page 10388)	Is command prepared.
W	MaxBlobSize (see page 10389)	Maximum blob size
R	Parameters (see page 10389)	List of parameters
R	RowsAffected (see page 10389)	Number of rows updated
W	RowSetSize (see page 10390)	Row buffering property used to optimize reading data from TDBXReader (see page 10576) instances.
	Text (see page 10390)	Command to execute

55.1.8.6.1 TDBXCommand.CommandType Property

Command type

Pascal

```
property CommandType: WideString;
```

C++

```
__property BSTR CommandType;
```

Description

This property contains the command type, which is typically set to one of the constant strings in the TDBXCommandTypes (see page 10396) class. However, driver implementors can use this property as a namespace to create new types of commands.

See Also

TDBXCommandTypes (see page 10396)

55.1.8.6.2 TDBXCommand.IsPrepared Property

Is command prepared.

Pascal

```
property IsPrepared: Boolean;
```

C++

```
__property Boolean IsPrepared;
```

Description

This property is true if the command has been prepared and false otherwise.

See Also

Prepare (see page 10386)

55.1.8.6.3 TDBXCommand.MaxBlobSize Property

Maximum blob size

Pascal

```
property MaxBlobSize: Int64;
```

C++

```
__property Int64 MaxBlobSize;
```

Description

This property holds the maximum blob size allowed for TDBXReader (see page 10576) instances returned from ExecuteQuery (see page 10384).

See Also

TDBXReader (see page 10576)

ExecuteQuery (see page 10384)

55.1.8.6.4 TDBXCommand.Parameters Property

List of parameters

Pascal

```
property Parameters: TDBXParameterList;
```

C++

```
__property TDBXParameterList Parameters;
```

Description

This property contains a TDBXParametersList list of parameters used to get and set parameters for Text (see page 10390) property commands that contain '?' parameter markers.

See Also

TDBXParametersList

Text (see page 10390)

55.1.8.6.5 TDBXCommand.RowsAffected Property

Number of rows updated

Pascal

```
property RowsAffected: Int64;
```

C++

```
__property Int64 RowsAffected;
```

Description

This property holds the number of rows updated from the last call to ExecuteUpdate (see page 10384).

See Also

ExecuteUpdate (see page 10384)

55.1.8.6.6 TDBXCommand.RowSetSize Property

Row buffering property used to optimize reading data from TDBXReader (see page 10576) instances.

Pascal

```
property RowSetSize: Int64;
```

C++

```
__property Int64 RowSetSize;
```

Description

RowSetSize is a row buffering property used to optimize reading data from TDBXReader (see page 10576) instances returned from ExecuteQuery (see page 10384). It only takes affect for database vendors that return true for the TDBXDataBaseMetadata.SupportsRowSetSize property.

See Also

TDBXReader (see page 10576)

SupportsRowSetSize (see page 10443)

ExecuteQuery (see page 10384)

55.1.8.6.7 TDBXCommand.Text Property

Command to execute

Pascal

```
property Text: WideString;
```

C++

```
__property BSTR Text;
```

Description

This property contains the text of the command to execute. When CommandType (see page 10388) is set to TDBXCommandTypes.SQLStatement, Text can be set to SQL statements such as `select`, `insert`, `update`, and `delete`.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXCommandTypes (see page 10396)

CommandType (see page 10388)

Text

55.1.8.7 TDBXCommand Events

The events of the TDBXCommand class are listed here.

Public Events

	Name	Description
R	OnErrorEvent (see page 10391)	Error handling event

55.1.8.7.1 TDBXCommand.OnErrorEvent Event

Error handling event

Pascal

```
property OnErrorEvent: TDBXErrorEvent;
```

C++

```
__property TDBXErrorEvent OnErrorEvent;
```

Description

This property contains the error handling event provided by the TDBXConnection (see page 10398) that created this command. This event is a TDBXErrorEvent (see page 10671) that is called just before any dbExpress TDBXError (see page 10486) exception is raised.

See Also

TDBXConnection (see page 10398)

TDBXError (see page 10486)

TDBXErrorEvent (see page 10671)

55.1.9 TDBXCommandEx Class

Extension of TDBXCommand (see page 10378).

Class Hierarchy

Pascal

```
TDBXCommandEx = class(TDBXCommand);
```

C++

```
class TDBXCommandEx : public TDBXCommand;
```

File

DBXCommon

Description

TDBXCommandEx is an extension of TDBXCommand (see page 10378).

Note: Classes (see page 2685) ending in “Ex” are temporary classes that exist to avoid breaking interfaces. Their contents will be migrated to their base class in the next release.

See Also

TDBXCommand (see page 10378)

55.1.9.1 TDBXCommandEx Members

The following tables list the members exposed by TDBXCommandEx.

Protected Fields

	Name	Description
	FDBXContext (see page 10381)	This is FDBXContext, a member of class TDBXCommand.

Protected Methods

	Name	Description
V	Close (see page 10382)	This is Close, a member of class TDBXCommand.
	Create (see page 10380)	Creates an instance of TDBXCommand (see page 10378)
V	CreateParameterRow (see page 10382)	This is CreateParameterRow, a member of class TDBXCommand.
V	CreateParameters (see page 10382)	This is CreateParameters, a member of class TDBXCommand.
A	DerivedClose (see page 10383)	This is DerivedClose, a member of class TDBXCommand.
A	DerivedExecuteQuery (see page 10383)	This is DerivedExecuteQuery, a member of class TDBXCommand.
A	DerivedExecuteUpdate (see page 10383)	This is DerivedExecuteUpdate, a member of class TDBXCommand.
A	DerivedGetNextReader (see page 10383)	This is DerivedGetNextReader, a member of class TDBXCommand.
A	DerivedOpen (see page 10384)	This is DerivedOpen, a member of class TDBXCommand.
A	DerivedPrepare (see page 10384)	This is DerivedPrepare, a member of class TDBXCommand.
V	GetCommandTimeout (see page 10393)	This is GetCommandTimeout, a member of class TDBXCommandEx.
V	GetCommandType (see page 10385)	This is GetCommandType, a member of class TDBXCommand.
V	GetErrorEvent (see page 10385)	This is GetErrorEvent, a member of class TDBXCommand.
V	GetParameters (see page 10385)	This is GetParameters, a member of class TDBXCommand.
A	GetRowsAffected (see page 10386)	This is GetRowsAffected, a member of class TDBXCommand.
V	GetText (see page 10386)	This is GetText, a member of class TDBXCommand.
V	Open (see page 10386)	This is Open, a member of class TDBXCommand.
V	SetCommandTimeout (see page 10393)	This is SetCommandTimeout, a member of class TDBXCommandEx.
V	SetCommandType (see page 10387)	This is SetCommandType, a member of class TDBXCommand.
A	SetMaxBlobSize (see page 10387)	This is SetMaxBlobSize, a member of class TDBXCommand.
A	SetRowSetSize (see page 10387)	This is SetRowSetSize, a member of class TDBXCommand.
V	SetText (see page 10387)	This is SetText, a member of class TDBXCommand.

Public Events

	Name	Description
R	OnErrorEvent (see page 10391)	Error handling event

Public Methods

	Name	Description
V	CreateParameter (see page 10382)	Create (see page 10380) a parameter
V	Destroy (see page 10380)	Destroy a command instance
V	ExecuteQuery (see page 10384)	Executes a command that returns an instance of TDBXReader (see page 10576)
V	ExecuteUpdate (see page 10384)	Executes an update command
V	GetNextReader (see page 10385)	Gets next instance of TDBXReader (see page 10576)
V	Prepare (see page 10386)	Prepare the command for execution

Public Properties

	Name	Description
	CommandTimeout (see page 10394)	Time-out value for the execution of a command.
	CommandType (see page 10388)	Command type
R	IsPrepared (see page 10388)	Is command prepared.
W	MaxBlobSize (see page 10389)	Maximum blob size
R	Parameters (see page 10389)	List of parameters
R	RowsAffected (see page 10389)	Number of rows updated
W	RowSetSize (see page 10390)	Row buffering property used to optimize reading data from TDBXReader (see page 10576) instances.
	Text (see page 10390)	Command to execute

Strict protected Fields

	Name	Description
	FParameters (see page 10381)	This is FParameters, a member of class TDBXCommand.

Strict protected Methods

	Name	Description
	NotImplemented (see page 10386)	This is NotImplemented, a member of class TDBXCommand.
	SetLastReader (see page 10394)	This is SetLastReader, a member of class TDBXCommandEx.

Strict protected Properties

	Name	Description
W	LastReader (see page 10394)	This is LastReader, a member of class TDBXCommandEx.

55.1.9.2 TDBXCommandEx Methods

The methods of the TDBXCommandEx class are listed here.

Protected Methods

	Name	Description
V	GetCommandTimeout (see page 10393)	This is GetCommandTimeout, a member of class TDBXCommandEx.
V	SetCommandTimeout (see page 10393)	This is SetCommandTimeout, a member of class TDBXCommandEx.

Strict protected Methods

	Name	Description
	SetLastReader (see page 10394)	This is SetLastReader, a member of class TDBXCommandEx.

55.1.9.2.1 TDBXCommandEx.GetCommandTimeout Method

Pascal

```
function GetCommandTimeout: Integer; virtual;
```

C++

```
virtual __fastcall int GetCommandTimeout();
```

Description

This is GetCommandTimeout, a member of class TDBXCommandEx.

55.1.9.2.2 TDBXCommandEx.SetCommandTimeout Method

Pascal

```
procedure SetCommandTimeout(Timeout: Integer); virtual;
```

C++

```
virtual __fastcall SetCommandTimeout(int Timeout);
```

Description

This is SetCommandTimeout, a member of class TDBXCommandEx.

55.1.9.2.3 TDBXCommandEx.SetLastReader Method

Pascal

```
procedure SetLastReader(Reader: TDBXReader);
```

C++

```
__fastcall SetLastReader(TDBXReader Reader);
```

Description

This is SetLastReader, a member of class TDBXCommandEx.

55.1.9.3 TDBXCommandEx Properties

The properties of the TDBXCommandEx class are listed here.

Public Properties

	Name	Description
	CommandTimeout (see page 10394)	Time-out value for the execution of a command.

Strict protected Properties

	Name	Description
	LastReader (see page 10394)	This is LastReader, a member of class TDBXCommandEx.

55.1.9.3.1 TDBXCommandEx.CommandTimeout Property

Time-out value for the execution of a command.

Pascal

```
property CommandTimeout: Integer;
```

C++

```
__property int CommandTimeout;
```

Description

Time-out value for the execution of a command. Not all drivers support this. Time in seconds to wait for a command to execute.

55.1.9.3.2 TDBXCommandEx.LastReader Property

Pascal

```
property LastReader: TDBXReader;
```

C++

```
__property TDBXReader LastReader;
```

Description

This is LastReader, a member of class TDBXCommandEx.

55.1.10 TDBXCommandFactory Class

Class Hierarchy

DBXCommon.TDBXCommandFactory

Pascal

```
TDBXCommandFactory = class;
```

C++

```
class TDBXCommandFactory;
```

File

DBXCommon

Description

This is class DBXCommon.TDBXCommandFactory.

55.1.10.1 TDBXCommandFactory Members

The following tables list the members exposed by TDBXCommandFactory.

Public Methods

	Name	Description
	CreateCommand (see page 10395)	This is CreateCommand, a member of class TDBXCommandFactory.

55.1.10.2 TDBXCommandFactory Methods

The methods of the TDBXCommandFactory class are listed here.

Public Methods

	Name	Description
	CreateCommand (see page 10395)	This is CreateCommand, a member of class TDBXCommandFactory.

55.1.10.2.1 TDBXCommandFactory.CreateCommand Method

Pascal

```
function CreateCommand(DbxContext: TDBXContext; Connection: TDBXConnection; MorphicCommand:
TDBXCommand): TDBXCommand; virtual; abstract;
```

C++

```
virtual __fastcall TDBXCommand CreateCommand(TDBXContext DbxContext, TDBXConnection
Connection, TDBXCommand MorphicCommand) = 0;
```

Description

This is CreateCommand, a member of class TDBXCommandFactory.

55.1.11 TDBXCommandTypes Class

Type of command to be executed by a TDBXCommand (see page 10378)

Class Hierarchy

DBXCommon.TDBXCommandTypes

Pascal

```
TDBXCommandTypes = class;
```

C++

```
class TDBXCommandTypes;
```

File

DBXCommon

Description

This class provides the types of commands that can be executed against a database using an instance of TDBXCommand (see page 10378).

This table lists the commands.

Constant	Description
DbxSQL (see page 10398)	Used for any SQL statement including selects, inserts, updates, deletes, and so on.
DbxStoredProcedure (see page 10398)	Used for any stored procedure.
DbxTable (see page 10398)	Used to retrieve all rows and columns of a table.
DbxMetaData (see page 10397)	Used to retrieve metadata objects such as tables and columns that are accessible from a TDBXConnection (see page 10398).
DbxCommand (see page 10397)	Deprecated. Do not use.
DbxPool (see page 10397)	Command type for TDBXPool delegate driver commands.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXCommand (see page 10378)

TDBXConnection (see page 10398)

55.1.11.1 TDBXCommandTypes Members

The following tables list the members exposed by TDBXCommandTypes.

Public Constants

	Name	Description
	DbxCommand (see page 10397)	This is DbxCommand, a member of class TDBXCommandTypes.
	DbxMetaData (see page 10397)	This is DbxMetaData, a member of class TDBXCommandTypes.
	DbxPool (see page 10397)	This is DbxPool, a member of class TDBXCommandTypes.
	DbxSQL (see page 10398)	This is DbxSQL, a member of class TDBXCommandTypes.
	DbxStoredProcedure (see page 10398)	This is DbxStoredProcedure, a member of class TDBXCommandTypes.
	DbxTable (see page 10398)	This is DbxTable, a member of class TDBXCommandTypes.

55.1.11.2 TDBXCommandTypes Constants

The constants of the TDBXCommandTypes class are listed here.

Public Constants

	Name	Description
	DbxCommand (see page 10397)	This is DbxCommand, a member of class TDBXCommandTypes.
	DbxMetaData (see page 10397)	This is DbxMetaData, a member of class TDBXCommandTypes.
	DbxPool (see page 10397)	This is DbxPool, a member of class TDBXCommandTypes.
	DbxSQL (see page 10398)	This is DbxSQL, a member of class TDBXCommandTypes.
	DbxStoredProcedure (see page 10398)	This is DbxStoredProcedure, a member of class TDBXCommandTypes.
	DbxTable (see page 10398)	This is DbxTable, a member of class TDBXCommandTypes.

55.1.11.2.1 TDBXCommandTypes.DbxCommand Constant

Pascal

```
const DbxCommand = 'Dbx.Command';
```

C++

```
DbxCommand = 'Dbx.Command';
```

Description

This is DbxCommand, a member of class TDBXCommandTypes.

55.1.11.2.2 TDBXCommandTypes.DbxMetaData Constant

Pascal

```
const DbxMetaData = 'Dbx.MetaData';
```

C++

```
DbxMetaData = 'Dbx.MetaData';
```

Description

This is DbxMetaData, a member of class TDBXCommandTypes.

55.1.11.2.3 TDBXCommandTypes.DbxPool Constant

Pascal

```
const DbxPool = 'Dbx.Pool';
```

C++

```
DbxPool = 'Dbx.Pool';
```

Description

This is DbxPool, a member of class TDBXCommandTypes.

55.1.11.2.4 TDBXCommandTypes.DbxSQL Constant

Pascal

```
const DbxSQL = 'Dbx.SQL';
```

C++

```
DbxSQL = 'Dbx.SQL';
```

Description

This is DbxSQL, a member of class TDBXCommandTypes.

55.1.11.2.5 TDBXCommandTypes.DbxStoredProcedure Constant

Pascal

```
const DbxStoredProcedure = 'Dbx.StoredProcedure';
```

C++

```
DbxStoredProcedure = 'Dbx.StoredProcedure';
```

Description

This is DbxStoredProcedure, a member of class TDBXCommandTypes.

55.1.11.2.6 TDBXCommandTypes.DbxTable Constant

Pascal

```
const DbxTable = 'Dbx.Table';
```

C++

```
DbxTable = 'Dbx.Table';
```

Description

This is DbxTable, a member of class TDBXCommandTypes.

55.1.12 TDBXConnection Class

Connection for the dbExpress driver framework

Class Hierarchy

Pascal

```
TDBXConnection = class;
```

C++

```
class TDBXConnection;
```

File

DBXCommon

Description

This class represents a connection for the dbExpress driver framework. It provides support for creating commands, retrieving database records and related metadata, and transaction management.

Use the TDBXConnection.CreateCommand (see page 10404) to create a TDBXReader (see page 10576) object to read database records.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXReader (see page 10576)

55.1.12.1 TDBXConnection Members

The following tables list the members exposed by TDBXConnection.

Protected Fields

	Name	Description
	FConnectionProperties (see page 10401)	This is FConnectionProperties, a member of class TDBXConnection.
	FDBXContext (see page 10401)	This is FDBXContext, a member of class TDBXConnection.

Protected Methods

	Name	Description
V	Close (see page 10403)	Closes the TDBXConnection (see page 10398)
A	Commit (see page 10403)	Commits work for a transaction
	Create (see page 10400)	Creates an instance of TDBXConnection (see page 10398)
A	CreateAndBeginTransaction (see page 10404)	This is CreateAndBeginTransaction, a member of class TDBXConnection.
A	DerivedCreateCommand (see page 10405)	This is DerivedCreateCommand, a member of class TDBXConnection.
A	DerivedGetCommands (see page 10405)	This is DerivedGetCommands, a member of class TDBXConnection.
A	DerivedGetCommandTypes (see page 10405)	This is DerivedGetCommandTypes, a member of class TDBXConnection.
A	DerivedOpen (see page 10405)	This is DerivedOpen, a member of class TDBXConnection.
V	GetConnectionProperties (see page 10406)	This is GetConnectionProperties, a member of class TDBXConnection.
V	GetDatabaseMetaData (see page 10406)	This is GetDatabaseMetaData, a member of class TDBXConnection.
V	GetErrorEvent (see page 10407)	This is GetErrorEvent, a member of class TDBXConnection.
V	GetIsOpen (see page 10407)	This is GetIsOpen, a member of class TDBXConnection.
V	GetTraceFlags (see page 10407)	This is GetTraceFlags, a member of class TDBXConnection.
V	GetTraceInfoEvent (see page 10407)	This is GetTraceInfoEvent, a member of class TDBXConnection.
V	Open (see page 10407)	Opens a connection
A	Rollback (see page 10408)	This is Rollback, a member of class TDBXConnection.
V	SetConnectionProperties (see page 10409)	This is SetConnectionProperties, a member of class TDBXConnection.
V	SetErrorEvent (see page 10409)	This is SetErrorEvent, a member of class TDBXConnection.
V	SetTraceFlags (see page 10409)	This is SetTraceFlags, a member of class TDBXConnection.
V	SetTraceInfoEvent (see page 10410)	This is SetTraceInfoEvent, a member of class TDBXConnection.

Public Events

	Name	Description
	OnErrorEvent (see page 10411)	Error handling event called before any exception is raised
	OnTrace (see page 10412)	Event handler for receiving trace events

Public Methods

	Name	Description
	BeginTransaction (see page 10402)	This is the overview for the BeginTransaction method overload.
	CommitFreeAndNil (see page 10404)	Commits work for a transaction
	CreateCommand (see page 10404)	Returns a TDBXCommand (see page 10378) instance to execute commands.
	Destroy (see page 10400)	Destroys a TDBXConnection (see page 10398) instance.
	GetCommands (see page 10406)	Gets list of known commands for command type.
	GetCommandTypes (see page 10406)	Gets list of supported command types for connection.
	RollbackFreeAndNil (see page 10408)	Rollbacks the work for a transaction
	RollbackIncompleteFreeAndNil (see page 10408)	Rollbacks a transaction without throwing an exception for invalid transaction.

Public Properties

	Name	Description
	ConnectionProperties (see page 10410)	Connection properties
	DatabaseMetaData (see page 10410)	Database metadata for connection
	IsOpen (see page 10411)	Indicates if connection open
	TraceFlags (see page 10411)	Trace flags to enable or disable tracing categories

Strict protected Fields

	Name	Description
	FIsolationLevel (see page 10401)	This is FIsolationLevel, a member of class TDBXConnection.

55.1.12.2 TDBXConnection.Create Constructor

Creates an instance of TDBXConnection (see page 10398)

Pascal

```
constructor Create(ConnectionBuilder: TDBXConnectionBuilder);
```

C++

```
__fastcall TDBXConnection(TDBXConnectionBuilder ConnectionBuilder);
```

Description

This constructor creates and initializes an instance of TDBXConnection (see page 10398).

See Also

Destroy (see page 10400)

55.1.12.3 TDBXConnection.Destroy Destructor

Destroys a TDBXConnection (see page 10398) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXConnection();
```

Description

This destructor destroys an instance of TDBXConnection (see page 10398).

See Also

Create (see page 10400)

55.1.12.4 TDBXConnection Fields

The fields of the TDBXConnection class are listed here.

Protected Fields

	Name	Description
	FConnectionProperties (see page 10401)	This is FConnectionProperties, a member of class TDBXConnection.
	FDBXContext (see page 10401)	This is FDBXContext, a member of class TDBXConnection.

Strict protected Fields

	Name	Description
	FIsolationLevel (see page 10401)	This is FIsolationLevel, a member of class TDBXConnection.

55.1.12.4.1 TDBXConnection.FConnectionProperties Field

Pascal

```
FConnectionProperties: TDBXProperties;
```

C++

```
TDBXProperties FConnectionProperties;
```

Description

This is FConnectionProperties, a member of class TDBXConnection.

55.1.12.4.2 TDBXConnection.FDBXContext Field

Pascal

```
FDBXContext: TDBXContext;
```

C++

```
TDBXContext FDBXContext;
```

Description

This is FDBXContext, a member of class TDBXConnection.

55.1.12.4.3 TDBXConnection.FIsolationLevel Field

Pascal

```
FIsolationLevel: TDBXIsolation;
```

C++

```
TDBXIsolation FIsolationLevel;
```

Description

This is FIsolationLevel, a member of class TDBXConnection.

55.1.12.5 TDBXConnection Methods

The methods of the TDBXConnection class are listed here.

Protected Methods

	Name	Description
V	Close (see page 10403)	Closes the TDBXConnection (see page 10398)
A	Commit (see page 10403)	Commits work for a transaction
A	CreateAndBeginTransaction (see page 10404)	This is CreateAndBeginTransaction, a member of class TDBXConnection.
A	DerivedCreateCommand (see page 10405)	This is DerivedCreateCommand, a member of class TDBXConnection.
A	DerivedGetCommands (see page 10405)	This is DerivedGetCommands, a member of class TDBXConnection.
A	DerivedGetCommandTypes (see page 10405)	This is DerivedGetCommandTypes, a member of class TDBXConnection.
A	DerivedOpen (see page 10405)	This is DerivedOpen, a member of class TDBXConnection.
V	GetConnectionProperties (see page 10406)	This is GetConnectionProperties, a member of class TDBXConnection.
V	GetDatabaseMetaData (see page 10406)	This is GetDatabaseMetaData, a member of class TDBXConnection.
V	GetErrorEvent (see page 10407)	This is GetErrorEvent, a member of class TDBXConnection.
V	GetIsOpen (see page 10407)	This is GetIsOpen, a member of class TDBXConnection.
V	GetTraceFlags (see page 10407)	This is GetTraceFlags, a member of class TDBXConnection.
V	GetTraceInfoEvent (see page 10407)	This is GetTraceInfoEvent, a member of class TDBXConnection.
V	Open (see page 10407)	Opens a connection
A	Rollback (see page 10408)	This is Rollback, a member of class TDBXConnection.
V	SetConnectionProperties (see page 10409)	This is SetConnectionProperties, a member of class TDBXConnection.
V	SetErrorEvent (see page 10409)	This is SetErrorEvent, a member of class TDBXConnection.
V	SetTraceFlags (see page 10409)	This is SetTraceFlags, a member of class TDBXConnection.
V	SetTraceInfoEvent (see page 10410)	This is SetTraceInfoEvent, a member of class TDBXConnection.

Public Methods

	Name	Description
V	BeginTransaction (see page 10402)	This is the overview for the BeginTransaction method overload.
V	CommitFreeAndNil (see page 10404)	Commits work for a transaction
V	CreateCommand (see page 10404)	Returns a TDBXCommand (see page 10378) instance to execute commands.
	GetCommands (see page 10406)	Gets list of known commands for command type.
	GetCommandTypes (see page 10406)	Gets list of supported command types for connection.
V	RollbackFreeAndNil (see page 10408)	Rollbacks the work for a transaction
V	RollbackIncompleteFreeAndNil (see page 10408)	Rollbacks a transaction without throwing an exception for invalid transaction.

55.1.12.5.1 BeginTransaction Method

This is the overview for the BeginTransaction method overload.

Overload List

	Name	Description
V	TDBXConnection.BeginTransaction () (see page 10402)	Returns a TDBXTransaction (see page 10623) instance
V	TDBXConnection.BeginTransaction (TDBXIsolation) (see page 10402)	Returns a TDBXTransaction (see page 10623) instance

55.1.12.5.1.1 TDBXConnection.BeginTransaction Method ()

Returns a TDBXTransaction (see page 10623) instance

Pascal

```
function BeginTransaction(Isolation: TDBXIsolation): TDBXTransaction; virtual; overload;
function BeginTransaction: TDBXTransaction; virtual; overload;
```

C++

```
virtual __fastcall TDBXTransaction BeginTransaction(TDBXIsolation Isolation);
virtual __fastcall TDBXTransaction BeginTransaction();
```

Description

This method gest a TDBXTransaction (see page 10623) instance for a new transaction.

Note: When the work for the transaction is complete, call either CommitFreeAndNil (see page 10404), RollbackFreeAndNil (see page 10408), or RollbackIncompleteFreeAndNil (see page 10408).

See Also

TDBXTransaction (see page 10623)

CommitFreeAndNil (see page 10404)

RollbackFreeAndNil (see page 10408)

RollbackIncompleteFreeAndNil (see page 10408)

55.1.12.5.2 TDBXConnection.Close Method

Closes the TDBXConnection (see page 10398)

Pascal

```
procedure Close; virtual;
```

C++

```
virtual __fastcall Close();
```

Description

This method closes the TDBXConnection (see page 10398), making it unavailable.

See Also

Open (see page 10407)

55.1.12.5.3 TDBXConnection.Commit Method

Commits work for a transaction

Pascal

```
procedure Commit(Transaction: TDBXTransaction); virtual; abstract;
```

C++

```
virtual __fastcall Commit(TDBXTransaction Transaction) = 0;
```

Description

This method commits the work for the specified TDBXTransaction (see page 10623).

Note: This method raises an exception if Transaction

is not an active transaction.

See Also

TDBXTransaction (see page 10623)

55.1.12.5.4 TDBXConnection.CommitFreeAndNil Method

Commits work for a transaction

Pascal

```
procedure CommitFreeAndNil(var Transaction: TDBXTransaction); virtual;
```

C++

```
virtual __fastcall CommitFreeAndNil(TDBXTransaction Transaction);
```

Description

This method commits the work for the specified TDBXTransaction (see page 10623). Any active transactions that were begun after this transaction are freed and effectively committed as well. The variable **Transaction** instance is set to `nil`.

Note: This method raises an exception if Transaction

is not an active transaction.

See Also

TDBXTransaction (see page 10623)

55.1.12.5.5 TDBXConnection.CreateAndBeginTransaction Method

Pascal

```
function CreateAndBeginTransaction(Isolation: TDBXIsolation): TDBXTransaction; virtual;
abstract;
```

C++

```
virtual __fastcall TDBXTransaction CreateAndBeginTransaction(TDBXIsolation Isolation) = 0;
```

Description

This is CreateAndBeginTransaction, a member of class TDBXConnection.

55.1.12.5.6 TDBXConnection.CreateCommand Method

Returns a TDBXCommand (see page 10378) instance to execute commands.

Pascal

```
function CreateCommand: TDBXCommand; virtual; overload;
```

C++

```
virtual __fastcall TDBXCommand CreateCommand();
```

Description

This method returns a TDBXCommand (see page 10378) instance to execute commands. The TDBXCommand.CommandType property specifies the type of command. Command types are specified in the TDBXCommandTypes (see page 10396) class. The default CommandType property setting is TDBXCommandTypes.SQLStatement., an SQL command.

Note: Call TDBXCommand.Free when the TDBXCommand (see page 10378) is no longer needed.

See Also

Connecting to a Database using the dbExpress Driver Framework

TDBXCommand (see page 10378)

TDBXCommandTypes (see page 10396)

Free

55.1.12.5.7 TDBXConnection.DerivedCreateCommand Method

Pascal

```
function DerivedCreateCommand: TDBXCommand; virtual; abstract;
```

C++

```
virtual __fastcall TDBXCommand DerivedCreateCommand() = 0;
```

Description

This is DerivedCreateCommand, a member of class TDBXConnection.

55.1.12.5.8 TDBXConnection.DerivedGetCommands Method

Pascal

```
procedure DerivedGetCommands(CommandType: WideString; List: TWideStrings); virtual; abstract;
```

C++

```
virtual __fastcall DerivedGetCommands(BSTR CommandType, TWideStrings List) = 0;
```

Description

This is DerivedGetCommands, a member of class TDBXConnection.

55.1.12.5.9 TDBXConnection.DerivedGetCommandTypes Method

Pascal

```
procedure DerivedGetCommandTypes(List: TWideStrings); virtual; abstract;
```

C++

```
virtual __fastcall DerivedGetCommandTypes(TWideStrings List) = 0;
```

Description

This is DerivedGetCommandTypes, a member of class TDBXConnection.

55.1.12.5.10 TDBXConnection.DerivedOpen Method

Pascal

```
procedure DerivedOpen; virtual; abstract;
```

C++

```
virtual __fastcall DerivedOpen() = 0;
```

Description

This is DerivedOpen, a member of class TDBXConnection.

55.1.12.5.11 TDBXConnection.GetCommands Method

Gets list of known commands for command type.

Pascal

```
procedure GetCommands(const CommandType: WideString; List: TWideStrings); overload;
```

C++

```
__fastcall GetCommands(const BSTR CommandType, TWideStrings List);
```

Description

This method populates a list with the known commands for **CommandType**.

55.1.12.5.12 TDBXConnection.GetCommandTypes Method

Gets list of supported command types for connection.

Pascal

```
procedure GetCommandTypes(List: TWideStrings); overload;
```

C++

```
__fastcall GetCommandTypes(TWideStrings List);
```

Description

This method populates a list with the supported command types for this connection. TDBXCommandTypes (see page 10396) provides constant names for the most common command types.

See Also

TDBXCommandTypes (see page 10396)

55.1.12.5.13 TDBXConnection.GetConnectionProperties Method

Pascal

```
function GetConnectionProperties: TDBXProperties; virtual;
```

C++

```
virtual __fastcall TDBXProperties GetConnectionProperties();
```

Description

This is GetConnectionProperties, a member of class TDBXConnection.

55.1.12.5.14 TDBXConnection.GetDatabaseMetaData Method

Pascal

```
function GetDatabaseMetaData: TDBXDatabaseMetaData; virtual;
```

C++

```
virtual __fastcall TDBXDatabaseMetaData GetDatabaseMetaData();
```

Description

This is GetDatabaseMetaData, a member of class TDBXConnection.

55.1.12.5.15 TDBXConnection.GetErrorEvent Method

Pascal

```
function GetErrorEvent: TDBXErrorEvent; virtual;
```

C++

```
virtual __fastcall TDBXErrorEvent GetErrorEvent();
```

Description

This is GetErrorEvent, a member of class TDBXConnection.

55.1.12.5.16 TDBXConnection.GetIsOpen Method

Pascal

```
function GetIsOpen: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetIsOpen();
```

Description

This is GetIsOpen, a member of class TDBXConnection.

55.1.12.5.17 TDBXConnection.GetTraceFlags Method

Pascal

```
function GetTraceFlags: TDBXTraceFlag; virtual;
```

C++

```
virtual __fastcall TDBXTraceFlag GetTraceFlags();
```

Description

This is GetTraceFlags, a member of class TDBXConnection.

55.1.12.5.18 TDBXConnection.GetTraceInfoEvent Method

Pascal

```
function GetTraceInfoEvent: TDBXTraceEvent; virtual;
```

C++

```
virtual __fastcall TDBXTraceEvent GetTraceInfoEvent();
```

Description

This is GetTraceInfoEvent, a member of class TDBXConnection.

55.1.12.5.19 TDBXConnection.Open Method

Opens a connection

Pascal

```
procedure Open; virtual;
```

C++

```
virtual __fastcall Open();
```

Description

This method opens a connection. A TDBXConnection (see page 10398) object provides support for creating commands and managing transactions.

Note: Attempting to use a TDBXConnection (see page 10398) instance before calling Open raises an exception

See Also

Connecting to a Database using the dbExpress Driver Framework

55.1.12.5.20 TDBXConnection.Rollback Method

Pascal

```
procedure Rollback(Transaction: TDBXTransaction); virtual; abstract;
```

C++

```
virtual __fastcall Rollback(TDBXTransaction Transaction) = 0;
```

Description

This is Rollback, a member of class TDBXConnection.

55.1.12.5.21 TDBXConnection.RollbackFreeAndNil Method

Rollbacks the work for a transaction

Pascal

```
procedure RollbackFreeAndNil(var Transaction: TDBXTransaction); virtual;
```

C++

```
virtual __fastcall RollbackFreeAndNil(TDBXTransaction Transaction);
```

Description

This method rollbacks the work for the TDBXTransaction (see page 10623). Any active transactions that were begun after this transaction are freed and effectively rolled back as well. The variable **Transaction** instance is set to `nil`.

Note: RollbackFreeAndNil raises an exception if Transaction

is not an active transaction.

See Also

TDBXTransaction (see page 10623)

55.1.12.5.22 TDBXConnection.RollbackIncompleteFreeAndNil Method

Rollbacks a transaction without throwing an exception for invalid transaction.

Pascal

```
procedure RollbackIncompleteFreeAndNil(var Transaction: TDBXTransaction); virtual;
```

C++

```
virtual __fastcall RollbackIncompleteFreeAndNil(TDBXTransaction Transaction);
```

Description

This method rolls back the work for the TDBXTransaction (see page 10623). Any active transactions that were begun after this transaction are freed and effectively rolled back as well. The variable **Transaction** instance is set to `nil`.

Unlike the RollbackFreeAndNil (see page 10408) procedure, this procedure does not throw an exception if **Transaction** is invalid or set to `nil`. This method is ideally used in a `finally` (or `except`) block. The `try` block uses either CommitFreeAndNil (see page 10404) or RollbackFreeAndNil (see page 10408), and the **Transaction** has already been completed, freed, and set to `nil`. If an exception is not raised in the `try` block, a call to RollbackIncompleteFreeAndNil in the `finally` block does nothing, because the **Transaction** instance is no longer valid. If an exception is raised, a call to RollbackIncompleteFreeAndNil in the `finally` block rolls back, frees, and sets the **Transaction** instance to `nil`.

See Also

TDBXTransaction (see page 10623)

CommitFreeAndNil

RollbackFreeAndNil

55.1.12.5.23 TDBXConnection.SetConnectionProperties Method

Pascal

```
procedure SetConnectionProperties(const Value: TDBXProperties); virtual;
```

C++

```
virtual __fastcall SetConnectionProperties(const TDBXProperties Value);
```

Description

This is SetConnectionProperties, a member of class TDBXConnection.

55.1.12.5.24 TDBXConnection.SetErrorEvent Method

Pascal

```
procedure SetErrorEvent(ErrorEvent: TDBXErrorEvent); virtual;
```

C++

```
virtual __fastcall SetErrorEvent(TDBXErrorEvent ErrorEvent);
```

Description

This is SetErrorEvent, a member of class TDBXConnection.

55.1.12.5.25 TDBXConnection.SetTraceFlags Method

Pascal

```
procedure SetTraceFlags(TraceFlags: TDBXTraceFlag); virtual;
```

C++

```
virtual __fastcall SetTraceFlags(TDBXTraceFlag TraceFlags);
```

Description

This is SetTraceFlags, a member of class TDBXConnection.

55.1.12.5.26 TDBXConnection.SetTraceInfoEvent Method

Pascal

```
procedure SetTraceInfoEvent(TraceInfoEvent: TDBXTraceEvent); virtual;
```

C++

```
virtual __fastcall SetTraceInfoEvent(TDBXTraceEvent TraceInfoEvent);
```

Description

This is SetTraceInfoEvent, a member of class TDBXConnection.

55.1.12.6 TDBXConnection Properties

The properties of the TDBXConnection class are listed here.

Public Properties

	Name	Description
	ConnectionProperties (see page 10410)	Connection properties
R	DatabaseMetaData (see page 10410)	Database metadata for connection
R	IsOpen (see page 10411)	Indicates if connection open
	TraceFlags (see page 10411)	Trace flags to enable or disable tracing categories

55.1.12.6.1 TDBXConnection.ConnectionProperties Property

Connection properties

Pascal

```
property ConnectionProperties: TDBXProperties;
```

C++

```
__property TDBXProperties ConnectionProperties;
```

Description

This property contains a TDBXProperties (see page 10559) instance specifying connection properties used to create this connection.

See Also

TDBXProperties (see page 10559)

55.1.12.6.2 TDBXConnection.DatabaseMetaData Property

Database metadata for connection

Pascal

```
property DatabaseMetaData: TDBXDatabaseMetaData;
```

C++

```
__property TDBXDatabaseMetaData DatabaseMetaData;
```

Description

This property contains a TDBXDatabaseMetaData (see page 10440) instance for this connection.

See Also

TDBXDatabaseMetaData (see page 10440)

55.1.12.6.3 TDBXConnection.IsOpen Property

Indicates if connection open

Pascal

```
property IsOpen: Boolean;
```

C++

```
__property Boolean IsOpen;
```

Description

This property is true if the connection is open and false otherwise.

55.1.12.6.4 TDBXConnection.TraceFlags Property

Trace flags to enable or disable tracing categories

Pascal

```
property TraceFlags: TDBXTraceFlag;
```

C++

```
__property TDBXTraceFlag TraceFlags;
```

Description

This property contains trace flags to enable or disable tracing categories. This value is a logical OR of the trace flags in the TDBXTraceFlags (see page 10617) class.

See Also

TDBXTraceFlags (see page 10617)

55.1.12.7 TDBXConnection Events

The events of the TDBXConnection class are listed here.

Public Events

	Name	Description
	OnErrorEvent (see page 10411)	Error handling event called before any exception is raised
	OnTrace (see page 10412)	Event handler for receiving trace events

55.1.12.7.1 TDBXConnection.OnErrorEvent Event

Error handling event called before any exception is raised

Pascal

```
property OnErrorEvent: TDBXErrorEvent;
```

C++

```
__property TDBXErrorEvent OnErrorEvent;
```

Description

This property contains an error handling event TDBXErrorEvent (see page 10671) that is called just before any dbExpress TDBXError (see page 10486) exception is raised.

See Also

TDBXError (see page 10486)

TDBXErrorEvent (see page 10671)

55.1.12.7.2 TDBXConnection.OnTrace Event

Event handler for receiving trace events

Pascal

```
property OnTrace: TDBXTraceEvent;
```

C++

```
__property TDBXTraceEvent OnTrace;
```

Description

This property contains an event handler TDBXTraceEvent (see page 10672) used for receiving trace events.

See Also

TDBXTraceEvent (see page 10672)

55.1.13 TDBXConnectionBuilder Class

Utility class used by driver writers when connections are created.

Class Hierarchy

Pascal

```
TDBXConnectionBuilder = class;
```

C++

```
class TDBXConnectionBuilder;
```

File

DBXCommon

Description

This utility class is used by driver writers when connections are created. It is particularly important for chaining delegate connections in front of a database connection.

55.1.13.1 TDBXConnectionBuilder Members

The following tables list the members exposed by TDBXConnectionBuilder.

Protected Methods

	Name	Description
	Create (see page 10413)	This is the overview for the Create constructor overload.

Public Methods

	Name	Description
	CreateDelegateeConnection (see page 10414)	Request creation of the connection the delegate connection delegates to.
V	Destroy (see page 10414)	Destroys an instance of TDBXConnectionBuilder (see page 10412).

Public Properties

	Name	Description
R	ConnectionProperties (see page 10415)	TDBXConnection (see page 10398) properties of current delegate or database connection being created.
R	DbxContext (see page 10415)	TDBXContext (see page 10432) used for the database connection.
R	DelegationSignature (see page 10415)	List of the delegate drivers and database driver used to create a connection.
R	InputConnectionName (see page 10416)	Connection name when connection first requested.
R	InputConnectionProperties (see page 10416)	TDBXProperties (see page 10559) when connection first requested.
R	InputPassword (see page 10416)	Database password when connection first requested.
R	InputUserName (see page 10417)	User name when connection first requested.

55.1.13.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TDBXConnectionBuilder.Create () (see page 10413)	Creates an instance of TDBXConnectionBuilder (see page 10412)
	TDBXConnectionBuilder.Create (TDBXConnectionBuilder) (see page 10413)	Creates an instance of TDBXConnectionBuilder (see page 10412)

55.1.13.2.1 TDBXConnectionBuilder.Create Constructor ()

Creates an instance of TDBXConnectionBuilder (see page 10412)

Pascal

```
constructor Create; overload;
constructor Create(Source: TDBXConnectionBuilder); overload;
```

C++

```
__fastcall TDBXConnectionBuilder();
__fastcall TDBXConnectionBuilder(TDBXConnectionBuilder Source);
```

Description

This constructor creates and initializes an instance of TDBXConnectionBuilder (see page 10412).

See Also

Destroy (see page 10414)

55.1.13.3 TDBXConnectionBuilder.Destroy Destructor

Destroys an instance of TDBXConnectionBuilder (see page 10412).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXConnectionBuilder();
```

Description

This destructor destroys an instance of TDBXConnectionBuilder (see page 10412).

55.1.13.4 TDBXConnectionBuilder Methods

The methods of the TDBXConnectionBuilder class are listed here.

Public Methods

	Name	Description
	CreateDelegateeConnection (see page 10414)	Request creation of the connection the delegate connection delegates to.

55.1.13.4.1 TDBXConnectionBuilder.CreateDelegateeConnection Method

Request creation of the connection the delegate connection delegates to.

Pascal

```
function CreateDelegateeConnection: TDBXConnection;
```

C++

```
__fastcall TDBXConnection CreateDelegateeConnection();
```

Description

Delegate driver implementations use this to request the creation of the connection the delegate connection delegates to.

55.1.13.5 TDBXConnectionBuilder Properties

The properties of the TDBXConnectionBuilder class are listed here.

Public Properties

	Name	Description
R	ConnectionProperties (see page 10415)	TDBXConnection (see page 10398) properties of current delegate or database connection being created.
R	DbxContext (see page 10415)	TDBXContext (see page 10432) used for the database connection.
R	DelegationSignature (see page 10415)	List of the delegate drivers and database driver used to create a connection.
R	InputConnectionName (see page 10416)	Connection name when connection first requested.
R	InputConnectionProperties (see page 10416)	TDBXProperties (see page 10559) when connection first requested.
R	InputPassword (see page 10416)	Database password when connection first requested.
R	InputUserName (see page 10417)	User name when connection first requested.

55.1.13.5.1 TDBXConnectionBuilder.ConnectionProperties Property

TDBXConnection (see page 10398) properties of current delegate or database connection being created.

Pascal

```
property ConnectionProperties: TDBXProperties;
```

C++

```
__property TDBXProperties ConnectionProperties;
```

Description

This property contains a TDBXProperties (see page 10559) instance describing the TDBXConnection (see page 10398) properties provided by the current delegate or database connection being created.

See Also

TDBXConnection (see page 10398)

TDBXProperties (see page 10559)

55.1.13.5.2 TDBXConnectionBuilder.DbxContext Property

TDBXContext (see page 10432) used for the database connection.

Pascal

```
property DbxContext: TDBXContext;
```

C++

```
__property TDBXContext DbxContext;
```

Description

This TDBXContext (see page 10432) instance is used for the database connection.

Note: Delegate connections should not use this instance of TDBXContext (see page 10432). They should create their own instead.

See Also

TDBXContext (see page 10432)

55.1.13.5.3 TDBXConnectionBuilder.DelegationSignature Property

List of the delegate drivers and database driver used to create a connection.

Pascal

```
property DelegationSignature: WideString;
```

C++

```
__property BSTR DelegationSignature;
```

Description

This property holds a slash ('/') separated list of the delegate drivers and the database driver used to create a connection by this TDBXConnectionBuilder (see page 10412) instance.

55.1.13.5.4 TDBXConnectionBuilder.InputConnectionName Property

Connection name when connection first requested.

Pascal

```
property InputConnectionName: WideString;
```

C++

```
__property BSTR InputConnectionName;
```

Description

This property contains the database connection name from when a connection was first requested from a TDBXConnectionFactory (see page 10422).

See Also

InputConnectionProperties

InputPassword

InputUserName

55.1.13.5.5 TDBXConnectionBuilder.InputConnectionProperties Property

TDBXProperties (see page 10559) when connection first requested.

Pascal

```
property InputConnectionProperties: TDBXProperties;
```

C++

```
__property TDBXProperties InputConnectionProperties;
```

Description

This property contains a database TDBXProperties (see page 10559) instance from when a connection was first requested from a TDBXConnectionFactory (see page 10422).

See Also

TDBXProperties (see page 10559)

InputConnectionName

InputPassword

InputUserName

55.1.13.5.6 TDBXConnectionBuilder.InputPassword Property

Database password when connection first requested.

Pascal

```
property InputPassword: WideString;
```

C++

```
__property BSTR InputPassword;
```

Description

This property contains the database password from when a connection was first requested from a TDBXConnectionFactory (

see page 10422).

See Also

InputConnectionName

InputConnectionProperties

InputUserName

55.1.13.5.7 TDBXConnectionBuilder.InputUserName Property

User name when connection first requested.

Pascal

```
property InputUserName: WideString;
```

C++

```
__property BSTR InputUserName;
```

Description

This property contains the database user name when a connection was first requested from a TDBXConnectionFactory (see page 10422).

See Also

InputConnectionName

InputConnectionProperties

InputPassword

55.1.14 TDBXConnectionEx Class

Temporary extension of TDBXConnection (see page 10398) class.

Class Hierarchy

Pascal

```
TDBXConnectionEx = class(TDBXConnection);
```

C++

```
class TDBXConnectionEx : public TDBXConnection;
```

File

DBXCommon

Description

TDBXConnectionEx is an extension of TDBXConnection (see page 10398).

Note: Classes (see page 2685) ending in “Ex” are temporary classes that exist to avoid breaking interfaces. Their contents will be migrated to their base class in the next release.

See Also

TDBXConnection (see page 10398)

55.1.14.1 TDBXConnectionEx Members

The following tables list the members exposed by TDBXConnectionEx.

Protected Fields

	Name	Description
	FConnectionProperties (see page 10401)	This is FConnectionProperties, a member of class TDBXConnection.
	FDBXContext (see page 10401)	This is FDBXContext, a member of class TDBXConnection.

Protected Methods

	Name	Description
V	Close (see page 10403)	Closes the TDBXConnection (see page 10398)
A	Commit (see page 10403)	Commits work for a transaction
	Create (see page 10400)	Creates an instance of TDBXConnection (see page 10398)
A	CreateAndBeginTransaction (see page 10404)	This is CreateAndBeginTransaction, a member of class TDBXConnection.
V	CreateMorphCommand (see page 10419)	This is CreateMorphCommand, a member of class TDBXConnectionEx.
A	DerivedCreateCommand (see page 10405)	This is DerivedCreateCommand, a member of class TDBXConnection.
A	DerivedGetCommands (see page 10405)	This is DerivedGetCommands, a member of class TDBXConnection.
A	DerivedGetCommandTypes (see page 10405)	This is DerivedGetCommandTypes, a member of class TDBXConnection.
A	DerivedOpen (see page 10405)	This is DerivedOpen, a member of class TDBXConnection.
V	GetConnectionProperties (see page 10406)	This is GetConnectionProperties, a member of class TDBXConnection.
V	GetConnectionProperty (see page 10420)	This is GetConnectionProperty, a member of class TDBXConnectionEx.
V	GetDatabaseMetaData (see page 10406)	This is GetDatabaseMetaData, a member of class TDBXConnection.
V	GetErrorEvent (see page 10407)	This is GetErrorEvent, a member of class TDBXConnection.
V	GetIsOpen (see page 10407)	This is GetIsOpen, a member of class TDBXConnection.
V	GetProductName (see page 10420)	This is GetProductName, a member of class TDBXConnectionEx.
V	GetProductVersion (see page 10420)	This is GetProductVersion, a member of class TDBXConnectionEx.
V	GetTraceFlags (see page 10407)	This is GetTraceFlags, a member of class TDBXConnection.
V	GetTraceInfoEvent (see page 10407)	This is GetTraceInfoEvent, a member of class TDBXConnection.
V	Open (see page 10407)	Opens a connection
A	Rollback (see page 10408)	This is Rollback, a member of class TDBXConnection.
V	SetConnectionProperties (see page 10409)	This is SetConnectionProperties, a member of class TDBXConnection.
V	SetErrorEvent (see page 10409)	This is SetErrorEvent, a member of class TDBXConnection.
V	SetTraceFlags (see page 10409)	This is SetTraceFlags, a member of class TDBXConnection.
V	SetTraceInfoEvent (see page 10410)	This is SetTraceInfoEvent, a member of class TDBXConnection.

Public Events

	Name	Description
	OnErrorEvent (see page 10411)	Error handling event called before any exception is raised
	OnTrace (see page 10412)	Event handler for receiving trace events

Public Methods

	Name	Description
V	BeginTransaction (see page 10402)	This is the overview for the BeginTransaction method overload.
V	CommitFreeAndNil (see page 10404)	Commits work for a transaction
V	CreateCommand (see page 10404)	Returns a TDBXCommand (see page 10378) instance to execute commands.
V	Destroy (see page 10419)	Destroy a TDBXConnectionEx (see page 10417) instance
	GetCommands (see page 10406)	Gets list of known commands for command type.
	GetCommandTypes (see page 10406)	Gets list of supported command types for connection.
V	GetVendorProperty (see page 10420)	This is GetVendorProperty, a member of class TDBXConnectionEx.
V	RollbackFreeAndNil (see page 10408)	Rollbacks the work for a transaction
V	RollbackIncompleteFreeAndNil (see page 10408)	Rollbacks a transaction without throwing an exception for invalid transaction.

Public Properties

	Name	Description
	ConnectionProperties (see page 10410)	Connection properties
R	ConnectionProperty (see page 10421)	Connection properties.
R	DatabaseMetaData (see page 10410)	Database metadata for connection
R	IsOpen (see page 10411)	Indicates if connection open
	MetaDataReader (see page 10421)	This is MetaDataReader, a member of class TDBXConnectionEx.
R	ProductName (see page 10421)	Provide product name if supported.
R	ProductVersion (see page 10421)	Product version.
	TraceFlags (see page 10411)	Trace flags to enable or disable tracing categories

Strict protected Fields

	Name	Description
	FIsolationLevel (see page 10401)	This is FIsolationLevel, a member of class TDBXConnection.

55.1.14.2 TDBXConnectionEx.Destroy Destructor

Destroy a TDBXConnectionEx (see page 10417) instance

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDBXConnectionEx();
```

Description

This method destroys a TDBXConnectionEx (see page 10417) instance.

55.1.14.3 TDBXConnectionEx Methods

The methods of the TDBXConnectionEx class are listed here.

Protected Methods

	Name	Description
V	CreateMorphCommand (see page 10419)	This is CreateMorphCommand, a member of class TDBXConnectionEx.
V	GetConnectionProperty (see page 10420)	This is GetConnectionProperty, a member of class TDBXConnectionEx.
V	GetProductName (see page 10420)	This is GetProductName, a member of class TDBXConnectionEx.
V	GetProductVersion (see page 10420)	This is GetProductVersion, a member of class TDBXConnectionEx.

Public Methods

	Name	Description
V	GetVendorProperty (see page 10420)	This is GetVendorProperty, a member of class TDBXConnectionEx.

55.1.14.3.1 TDBXConnectionEx.CreateMorphCommand Method

Pascal

```
function CreateMorphCommand(MorphicCommand: TDBXCommand): TDBXCommand; virtual;
```

C++

```
virtual __fastcall TDBXCommand CreateMorphCommand(TDBXCommand MorphicCommand);
```

Description

This is CreateMorphCommand, a member of class TDBXConnectionEx.

55.1.14.3.2 TDBXConnectionEx.GetConnectionProperty Method

Pascal

```
function GetConnectionProperty(const Name: WideString): WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetConnectionProperty(const BSTR Name);
```

Description

This is GetConnectionProperty, a member of class TDBXConnectionEx.

55.1.14.3.3 TDBXConnectionEx.GetProductName Method

Pascal

```
function GetProductName: WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetProductName();
```

Description

This is GetProductName, a member of class TDBXConnectionEx.

55.1.14.3.4 TDBXConnectionEx.GetProductVersion Method

Pascal

```
function GetProductVersion: WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetProductVersion();
```

Description

This is GetProductVersion, a member of class TDBXConnectionEx.

55.1.14.3.5 TDBXConnectionEx.GetVendorProperty Method

Pascal

```
function GetVendorProperty(const Name: WideString): WideString; virtual;
```

C++

```
virtual __fastcall BSTR GetVendorProperty(const BSTR Name);
```

Description

This is GetVendorProperty, a member of class TDBXConnectionEx.

55.1.14.4 TDBXConnectionEx Properties

The properties of the TDBXConnectionEx class are listed here.

Public Properties

	Name	Description
R	ConnectionProperty (see page 10421)	Connection properties.
	MetaDataReader (see page 10421)	This is MetaDataReader, a member of class TDBXConnectionEx.
R	ProductName (see page 10421)	Provide product name if supported.
R	ProductVersion (see page 10421)	Product version.

55.1.14.4.1 TDBXConnectionEx.ConnectionProperty Property

Connection properties.

Pascal

```
property ConnectionProperty [const Name: WideString]: WideString;
```

C++

```
__property BSTR ConnectionProperty[BSTR const Name];
```

Description

ConnectionProperty holds connection properties. It can be indexed by property name.

55.1.14.4.2 TDBXConnectionEx.MetaDataReader Property

Pascal

```
property MetaDataReader: TObject;
```

C++

```
__property TObject * MetaDataReader;
```

Description

This is MetaDataReader, a member of class TDBXConnectionEx.

55.1.14.4.3 TDBXConnectionEx.ProductName Property

Provide product name if supported.

Pascal

```
property ProductName: WideString;
```

C++

```
__property BSTR ProductName;
```

Description

Provide product name if supported. The default implementation tries to use the TDBXPropertyNamesEx.ProductName driver first. It calls **GetVendorProperty (see page 10420)** second. The TDBXPropertyNames.DriverName is used as a last resort.

See Also

TDBXPropertyNames (see page 10566)

TDBXPropertyNamesEx (see page 10574)
