	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
V	Create (see page 13179)	Creates an instance of TShape (see page 13172).
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 13180)	Destroys of an instance of TShape (see page 13172).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.

	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.

R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnContextPopup (see page 13194)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 13195)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13197)	Occurs when the user drags an object over a control.
	OnEndDock (see page 13199)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 13200)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 13201)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13202)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13204)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13204)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13205)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13207)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 13209)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 13210)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Methods

	Name	Description
	StyleChanged (see page 13181)	This is StyleChanged, a member of class TShape.

Published Properties

	Name	Description
	Align (see page 13181)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13185)	Specifies how the control is anchored to its parent.
	Brush (see page 13185)	Specifies the color and pattern used for filling the shape control.
	Constraints (see page 13186)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 13186)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 13187)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 13187)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13189)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentShowHint (see page 13189)	Determines where a control looks to find out if its Help Hint should be shown.
	Pen (see page 13190)	Specifies the pen used to outline the shape control.
	Shape (see page 13190)	Specifies the shape of the control.
	ShowHint (see page 13191)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13192)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

68.1.34.2 TShape.Create Constructor

Creates an instance of TShape (see page 13172).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TShape(TComponent * AOwner);
```

Description

Call TShape (see page 13172) indirectly, using the new keyword, to instantiate a TShape (see page 13172) object at runtime. Shapes added to a form at design time are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the shape object.

See Also

Owner (see page 2807)

68.1.34.3 TShape.Destroy Destructor

Destroys of an instance of TShape (see page 13172).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TShape();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the object is not nil before it calls Destroy.

See Also

Free (see page 22300)

68.1.34.4 TShape Methods

The methods of the TShape class are listed here.

Protected Methods

	Name	Description
	Paint (see page 13180)	Render control surface.

Published Methods

	Name	Description
	StyleChanged (see page 13181)	This is StyleChanged, a member of class TShape.

68.1.34.4.1 TShape.Paint Method

Render control surface.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when a lightweight control needs update its display area. Code in the Paint method uses the Canvas property to render the control surface.

As implemented in TGraphicControl, Paint does nothing. Specific rendering logic is provided by Paint methods in descendant control classes.

See Also

Canvas (see page 6053)

68.1.34.4.2 TShape.StyleChanged Method

Pascal

```
procedure StyleChanged(Sender: TObject);
```

C++

```
__fastcall StyleChanged(TObject * Sender);
```

Description

This is StyleChanged, a member of class TShape.

68.1.34.5 TShape Properties

The properties of the TShape class are listed here.

Published Properties

	Name	Description
	Align (see page 13181)	Determines how the control aligns within its container (parent control).
	Anchors (see page 13185)	Specifies how the control is anchored to its parent.
	Brush (see page 13185)	Specifies the color and pattern used for filling the shape control.
	Constraints (see page 13186)	Specifies the size constraints for the control.
	DragCursor (see page 13186)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 13187)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 13187)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13189)	Controls whether the control responds to mouse, keyboard, and timer events.
	ParentShowHint (see page 13189)	Determines where a control looks to find out if its Help Hint should be shown.
	Pen (see page 13190)	Specifies the pen used to outline the shape control.
	Shape (see page 13190)	Specifies the shape of the control.
	ShowHint (see page 13191)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Visible (see page 13192)	Determines whether the component appears onscreen.

68.1.34.5.1 TShape.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
```

```
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);

  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

68.1.34.5.2 TShape.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

68.1.34.5.3 TShape.Brush Property

Specifies the color and pattern used for filling the shape control.

Pascal

```
property Brush: TBrush;
```

C++

```
__property TBrush Brush;
```

Description

Brush is a TBrush object that represents the color and pattern that fill the interior of the shape. Use the properties and methods of TBrush to change the color or pattern of the shape object:

```
Shape1.Brush.Color := clWhite;
Shape1->Brush->Color = clWhite;
```

Note: Setting the Brush property assigns the properties of another TBrush object to the shape's brush. The shape object does not take ownership of the assigned object.

See Also

Pen (see page 13190)

TBrush (see page 14430)

68.1.34.5.4 TShape.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

68.1.34.5.5 TShape.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

68.1.34.5.6 TShape.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

68.1.34.5.7 TShape.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
```

```
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

68.1.34.5.8 TShape.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

68.1.34.5.9 TShape.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

68.1.34.5.10 TShape.Pen Property

Specifies the pen used to outline the shape control.

Pascal

```
property Pen: TPen;
```

C++

```
__property TPen Pen;
```

Description

Read Pen to obtain the TPen object that represents the color and style of the line used to outline the shape. Use the properties of Pen to change the color or style.

Pen is a TPen object that represents the color and style of the line used to outline the shape. Use the properties and methods of TPen to change the color or pattern of the shape object:

Shape1.Pen.Width := 1;

Shape1.Pen.Color := Red;

Shape1->Pen->Width = 1;

Shape1->Pen->Color = clRed;

Note: Setting the Pen property assigns the properties of another TPen object to the shape's pen. The shape object does not take ownership of the assigned object.

See Also

Brush (see page 13185)

TPen (see page 14571)

68.1.34.5.11 TShape.Shape Property

Specifies the shape of the control.

Pascal

```
property Shape: TShapeType;
```

C++

```
__property TShapeType Shape;
```

Description

Set Shape to the geometric shape that should be drawn on the form. The Shape property has these possible values:

Value	Meaning
stCircle	The shape is a circle.
stEllipse	The shape is an ellipse.
stRectangle	The shape is a rectangle. (Default)
stRoundRect	The shape is a rectangle with rounded corners.
stRoundSquare	The shape is a square with rounded corners.

stSquare	The shape is a square.

68.1.34.5.12 TShape.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
```

```
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

68.1.34.5.13 TShape.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
```

```
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

68.1.34.6 TShape Events

The events of the TShape class are listed here.

Published Events

	Name	Description
	OnContextPopup (see page 13194)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 13195)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13197)	Occurs when the user drags an object over a control.
	OnEndDock (see page 13199)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 13200)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 13201)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13202)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13204)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13204)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13205)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13207)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 13209)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 13210)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

68.1.34.6.1 TShape.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result,

when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

See Also

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

68.1.34.6.2 TShape.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
```

```
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
```

```
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

68.1.34.6.3 TShape.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

68.1.34.6.4 TShape.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

68.1.34.6.5 TShape.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
```

```
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;
```

68.1.34.6.6 TShape.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

68.1.34.6.7 TShape.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}
```

```
// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{

68.1.34.6.8 TShape.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

68.1.34.6.9 TShape.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

68.1.34.6.10 TShape.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

68.1.34.6.11 TShape.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

68.1.34.6.12 TShape.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

68.1.34.6.13 TShape.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

68.1.35 TSplitter Class

TSplitter divides the client area of a form into resizable panes.

Class Hierarchy

Pascal

```
TSplitter = class(TGraphicControl);
```

C++

```
class TSplitter : public TGraphicControl;
```

File

ExtCtrls

Description

Add a splitter to a form between two aligned controls to allow users to resize the controls at runtime. The splitter sits between a control aligned to one edge of the form and the controls that fill up the rest of the client area. Give the splitter the same alignment as the control that is anchored to the edge of the form. When the user moves the splitter, it resizes the anchored control. This, in turn, changes the client area of the form, and the controls that fill up the rest of the client area resize accordingly.

Use each control on the form as a separate pane. After each pane is placed, place a splitter with the same alignment to allow that pane to be resized. The last pane to be placed on the form should be client-aligned, so that it resizes automatically to fill up the remaining space after all other panes are resized.

TForm (see page 13992)

Splitter Controls

68.1.35.1 TSplitter Members

The following tables list the members exposed by TSplitter.

Protected Events

	Name	Description
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.

	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanResize (see page 13220)	Determines how the splitter responds to mouse moves.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DoCanResize (see page 13221)	Generates an OnCanResize (see page 13240) event and enforces the MinSize (see page 13235) property.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.

	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 13221)	Dynamically locates the control that can be resized by the splitter.
V	MouseMove (see page 13222)	Provides visual feedback of how the neighboring control would be resized.
V	MouseUp (see page 13222)	Resizes the neighboring control when the user releases the mouse.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Paint (see page 13222)	Draws the image of the splitter.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	RequestAlign (see page 13223)	Changes the cursor when the alignment of the splitter changes.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.

	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	StopSizing (see page 13223)	Cleans up after the splitter has resized its neighboring control.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.

	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Create (see page 13218)	Creates an instance of TSplitter (see page 13210).
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 13220)	Frees the memory associated with the splitter.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
	Canvas (see page 13228)	Provides the drawing surface used by the graphic control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCanResize (see page 13240)	Occurs when the user tries to move the splitter with the mouse.
	OnMoved (see page 13240)	Occurs after the user has retiled the form using the splitter.
	OnPaint (see page 13241)	Occurs when the splitter needs to draw itself.

Published Properties

	Name	Description
	Align (see page 13224)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AutoSnap (see page 13228)	Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 13235).
	Beveled (see page 13228)	Determines whether the splitter looks beveled along the edge that moves.
	Color (see page 13231)	Specifies the background color of the control.
	Constraints (see page 13231)	Specifies the size constraints for the control.
	Cursor (see page 13232)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	MinSize (see page 13235)	Specifies the minimum size, in pixels, of the panes on either side of the splitter.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 13236)	Determines where a control looks for its color information.
	ResizeStyle (see page 13237)	Specifies the effect of moving the splitter.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13237)	Determines whether the component appears onscreen.
	Width (see page 13239)	Specifies the horizontal size of the control or form in pixels.

68.1.35.2 TSplitter.Create Constructor

Creates an instance of TSplitter (see page 13210).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSplitter(TComponent * AOwner);
```

Description

Call Create to instantiate a splitter at runtime. TSplitter (see page 13210) objects placed on forms at design time are created automatically.

AOwner specifies the form whose surface the splitter divides.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form’s width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

See Also

Owner (see page 2807)

68.1.35.3 TSplitter.Destroy Destructor

Frees the memory associated with the splitter.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSplitter();
```

Description

Do not call Destroy directly. Instead,call Free, which checks that the splitter is not nil before calling Destroy.

See Also

Free (see page 22300)

68.1.35.4 TSplitter Methods

The methods of the TSplitter class are listed here.

Protected Methods

	Name	Description
	CanResize (see page 13220)	Determines how the splitter responds to mouse moves.
	DoCanResize (see page 13221)	Generates an OnCanResize (see page 13240) event and enforces the MinSize (see page 13235) property.
	MouseDown (see page 13221)	Dynamically locates the control that can be resized by the splitter.
	MouseMove (see page 13222)	Provides visual feedback of how the neighboring control would be resized.
	MouseUp (see page 13222)	Resizes the neighboring control when the user releases the mouse.
	Paint (see page 13222)	Draws the image of the splitter.
	RequestAlign (see page 13223)	Changes the cursor when the alignment of the splitter changes.
	StopSizing (see page 13223)	Cleans up after the splitter has resized its neighboring control.

68.1.35.4.1 TSplitter.CanResize Method

Determines how the splitter responds to mouse moves.

Pascal

```
function CanResize(var NewSize: Integer): Boolean; virtual; reintroduce;
```

C++

```
virtual __fastcall Boolean CanResize(int NewSize);
```

Description

CanResize is called by the DoCanResize (see page 13221) method to generate an OnCanResize (see page 13240) event. The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. CanResize returns a boolean value that indicates whether the value specified by NewSize should be applied by redrawing the line (when ResizeStyle (see page 13237) is rsLine) or resizing the associated control (when ResizeStyle (see page 13237) is rsUpdate);

Unless an OnCanResize (see page 13240) event handler sets the value of NewSize and the return value, CanResize returns true without changing the NewSize parameter.

Note: CanResize is not called if the value of ResizeStyle (see page 13237) is rsNone when the user presses the mouse button.

See Also

OnCanResize (see page 13240)

ResizeStyle (see page 13237)

DoCanResize (see page 13221)

68.1.35.4.2 TSplitter.DoCanResize Method

Generates an OnCanResize (see page 13240) event and enforces the MinSize (see page 13235) property.

Pascal

```
function DoCanResize(var NewSize: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoCanResize(int NewSize);
```

Description

DoCanResize is called automatically when the user moves the mouse after pressing the mouse button on the splitter. The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. DoCanResize returns a boolean value that indicates whether the value specified by NewSize should be applied by redrawing the line (when ResizeStyle (see page 13237) is rsLine) or resizing the associated control (when ResizeStyle (see page 13237) is rsUpdate).

DoCanResize calls CanResize (see page 13220) to generate an OnCanResize (see page 13240) event. If, after calling the event handler, NewSize is less than the value of MinSize (see page 13235), NewSize is changed to zero.

Note: DoCanResize is not called if the value of ResizeStyle (see page 13237) is rsNone when the user presses the mouse button.

68.1.35.4.3 TSplitter.MouseDown Method

Dynamically locates the control that can be resized by the splitter.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

After calling the parent class's method, MouseDown locates the control that it is about to resize. Because this control is located dynamically, an application can delete or add aligned controls beside a splitter at runtime and the splitter will resize whichever control is currently beside it.

See Also

MouseDown (see page 5773)

MouseMove (see page 13222)

MouseUp (see page 13222)

68.1.35.4.4 TSplitter.MouseMove Method

Provides visual feedback of how the neighboring control would be resized.

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

After calling the inherited method, MouseMove computes the new boundaries of the neighboring control and draws a line where the new edge would be. The control is not actually resized until the mouse is released.

See Also

OnCanResize (see page 13240)

ResizeStyle (see page 13237)

CanResize (see page 13220)

MinSize (see page 13235)

MouseMove (see page 5773)

MouseDown (see page 13221)

MouseUp (see page 13222)

68.1.35.4.5 TSplitter.MouseUp Method

Resizes the neighboring control when the user releases the mouse.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

After calling the inherited method, MouseUp resizes the neighboring control that was located when the mouse went down. After the control is resized, MouseUp generates an OnMoved (see page 13240) event.

See Also

MouseUp (see page 5774)

MouseDown (see page 13221)

MouseMove (see page 13222)

68.1.35.4.6 TSplitter.Paint Method

Draws the image of the splitter.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when the splitter receives WM_PAINT messages from its Parent. Paint draws the background color of the splitter, and if Beveled (see page 13228) is true, draws a bevel along the movable edges. After drawing the background and bevel, Paint generates an OnPaint (see page 13241) event.

See Also

Beveled (see page 13228)

Color (see page 5812)

Parent (see page 5832)

OnPaint (see page 13241)

68.1.35.4.7 TSplitter.RequestAlign Method

Changes the cursor when the alignment of the splitter changes.

Pascal

```
procedure RequestAlign; override;
```

C++

```
virtual __fastcall RequestAlign();
```

Description

RequestAlign changes the cursor from crHSplit to crVSplit when the Align (see page 13224) property changes to alBottom or alTop. It changes the cursor from crVSplit to crHSplit when the Align (see page 13224) property changes to any other value.

If the Cursor (see page 13232) property is not crHSplit or crVSplit, RequestAlign has no effect.

Override RequestAlign to suppress the automatic cursor change or to implement a different association between alignment and the splitter's cursor.

See Also

Align (see page 5798)

Cursor (see page 5815)

68.1.35.4.8 TSplitter.StopSizing Method

Cleans up after the splitter has resized its neighboring control.

Pascal

```
procedure StopSizing; dynamic;
```

C++

```
__fastcall StopSizing();
```

Description

This protected procedure is called when the user releases the mouse or hits the Escape key while using the splitter to resize a

control. StopSizing makes sure that the resize line is no longer visible and generates an OnMoved (see page 13240) event.

See Also

OnMoved (see page 13240)

68.1.35.5 TSplitter Properties

The properties of the TSplitter class are listed here.

Public Properties

	Name	Description
	Canvas (see page 13228)	Provides the drawing surface used by the graphic control.

Published Properties

	Name	Description
	Align (see page 13224)	Determines how the control aligns within its container (parent control).
	AutoSnap (see page 13228)	Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 13235).
	Beveled (see page 13228)	Determines whether the splitter looks beveled along the edge that moves.
	Color (see page 13231)	Specifies the background color of the control.
	Constraints (see page 13231)	Specifies the size constraints for the control.
	Cursor (see page 13232)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	MinSize (see page 13235)	Specifies the minimum size, in pixels, of the panes on either side of the splitter.
	ParentColor (see page 13236)	Determines where a control looks for its color information.
	ResizeStyle (see page 13237)	Specifies the effect of moving the splitter.
	Visible (see page 13237)	Determines whether the component appears onscreen.
	Width (see page 13239)	Specifies the horizontal size of the control or form in pixels.

68.1.35.5.1 TSplitter.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls

into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
```

```
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Parent (see page 5832)

Anchors (see page 5802)

68.1.35.5.2 TSplitter.AutoSnap Property

Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 13235).

Pascal

```
property AutoSnap: Boolean;
```

C++

```
__property Boolean AutoSnap;
```

Description

Set AutoSnap to false to prevent the splitter from resizing neighboring objects to zero when the user tries to make them smaller than MinSize (see page 13235). When AutoSnap is false, such resize attempts are simply blocked, leaving the neighboring object with a size of MinSize (see page 13235). The default value of AutoSnap is true.

See Also

MinSize (see page 13235)

68.1.35.5.3 TSplitter.Beveled Property

Determines whether the splitter looks beveled along the edge that moves.

Pascal

```
property Beveled: Boolean;
```

C++

```
__property Boolean Beveled;
```

Description

Set Beveled to false to remove the beveled edges from the splitter. Set Beveled to true to give the edge a 3D beveled look.

The bevel on a splitter runs in a single direction only: along the edges the user moves to resize neighboring objects. Thus, if the Align (see page 13224) property is alLeft or alRight, the vertical edges of the splitter are beveled. If the Align (see page 13224) property is alTop or alBottom, the horizontal edges of the splitter are beveled. The default value of Beveled is false.

See Also

Align (see page 5798)

68.1.35.5.4 TSplitter.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl instance does not have its own Windows screen object, it obtains its device context from its parent control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = (TLabel *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

68.1.35.5.5 TSplitter.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

68.1.35.5.6 TSplitter.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

68.1.35.5.7 TSplitter.Cursor Property

Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.

Pascal

```
property Cursor: TCursor;
```

C++

```
__property TCursor Cursor;
```

Description

Change the value of Cursor to provide feedback to the user when the mouse pointer enters the control. The value of Cursor is the index of the cursor in the list of cursors maintained by the global variable, Screen. In addition to the built-in cursors provided by TScreen, applications can add custom cursors to the list.

C++ Examples:

```
/*
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
*/
Graphics::TBitmap *bmpMask, *bmpColor;
TIconInfo *iconInfo;

const crMyCursor = 5;

  void __fastcall TForm1::Button2Click(TObject *Sender)
{
  bmpMask = new Graphics::TBitmap();
```

```
  bmpColor = new Graphics::TBitmap();
  iconInfo = new TIconInfo();

  bmpMask->LoadFromFile("../SquareMask.bmp");
  bmpColor->LoadFromFile("../Square.bmp");

  iconInfo->fIcon = false;
  iconInfo->xHotspot = 15;
  iconInfo->yHotspot = 15;
  iconInfo->hbmMask = bmpMask->Handle;
  iconInfo->hbmColor = bmpColor->Handle;

  Screen->Cursors[crMyCursor] = CreateIconIndirect(iconInfo);

  Screen->Cursor = crMyCursor;

  delete bmpMask;
  delete bmpColor;
  delete iconInfo;
}
```

Delphi Examples:

```
{
This example uses a splitter and two image controls to
create a "slide show" effect.  The example displays an image
(the current "slide"), which can be hidden behind a screen
that looks like a venetian blind. When the blind is pulled
down to completely cover the current slide, the slide changes
to a different image.  When the blind is raised, the new
image appears.
To prepare this example, follow these steps:
1. Place an image control on the form.
Set the picture property to a bitmap of a venetian blind,
Set the Stretch property to True.
Set the Align property to alTop.
2. Add a splitter control to the form.
Set the Align property to alTop.
Set the Cursor property to crVSplit.
Set the OnMoved event handler to the code that appears below.
Set the MinSize property to 1.
3. Add a second image control to the form.
Set the Align property to alClient.
Set the Stretch property to True.
4. Select the form and add the OnCreate and OnDestroy event
   handlers that appear below.
5. Add the global variables below to the unit.
}
var
  CurImage: Integer;
  BMPs: Array[1..5] of TBitmap;

procedure TForm1.Splitter1Moved(Sender: TObject);
begin
  { check if the blind is closed }
  if Image2.Height <= 1 then
  begin
    { the blind is closed, change the current slide }
    CurImage := CurImage + 1;
    if CurImage = 6 then
       CurImage := 1;
    Image2.Picture.Bitmap := BMPs[CurImage];
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    { Initialize the array of slides.
      These must be freed in the OnDestroy event handler. }
    BMPs[1] := TBitmap.Create;
    BMPs[1].LoadFromFile('Factory.bmp');
    BMPs[2] := TBitmap.Create;
    BMPs[2].LoadFromFile('Rhododendron.bmp');
    BMPs[3] := TBitmap.Create;
    BMPs[3].LoadFromFile('littleB_64.bmp');
    BMPs[4] := TBitmap.Create;
    BMPs[4].LoadFromFile('Soap bubbles.bmp');
    BMPs[5] := TBitmap.Create;
    BMPs[5].LoadFromFile('Gone Fishing.bmp');
    CurImage := 1;
    Image2.Picture.Bitmap := BMPs[1];
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    { clean up }
    for I := 1 to 5 do
      BMPs[I].Free;
  end;
  {
  This example shows how to add custom cursors to an
  application.  The following code makes this cursor available
  to the application via the constant crMyCursor, and sets it
  as the global cursor to the application.
  }
  var
    bmpMask : TBitmap;
    bmpColor : TBitmap;
    iconInfo : TIconInfo;
  const
    crMyCursor = 5;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    bmpMask := TBitmap.Create;
    bmpColor := TBitmap.Create;

    bmpMask.LoadFromFile('SquareMask.bmp');
    bmpColor.LoadFromFile('Square.bmp');

    with iconInfo do
    begin
      fIcon := false;
      xHotspot := 15;
      yHotspot := 15;
      hbmMask := bmpMask.Handle;
      hbmColor := bmpColor.Handle;
    end;

    Screen.Cursors[crMyCursor] := CreateIconIndirect(iconInfo);

    Screen.Cursor := crMyCursor;

    bmpMask.Free;
    bmpColor.Free;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    DestroyIcon(Screen.Cursors[crMyCursor]);
  end;
```

68.1.35.5.8 TSplitter.MinSize Property

Specifies the minimum size, in pixels, of the panes on either side of the splitter.

Pascal

```
property MinSize: NaturalNumber;
```

C++

```
__property NaturalNumber MinSize;
```

Description

Set MinSize to provide a minimum size the splitter must leave when resizing its neighboring control. For example, if the Align (see page 13224) property is alLeft or alRight, the splitter cannot resize the regions to its left or right any smaller than MinSize pixels. If the Align (see page 13224) property is alTop or alBottom, the splitter cannot resize the regions above or below it any smaller than MinSize pixels. The default value of MinSize is 30.

Note: Always set MinSize to a value less than half the client width of its parent. When MinSize is half the client width of the splitter's parent, the splitter cannot move because to do so would be to resize one of the panes less than MinSize pixels.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.
```

```
    // Each pane must be at least one quarter of the form's width.
    ps->MinSize = Form1->ClientWidth/4;

    // Finally, create the last pane - a file list box.
    pflb->Parent = Form1;
    pflb->Align = alClient;
    pdlb->FileList = pflb; // Link the file list box to the directory list box.
  }
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form’s width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

See Also

Align (see page 5798)

68.1.35.5.9 TSplitter.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its

own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

68.1.35.5.10 TSplitter.ResizeStyle Property

Specifies the effect of moving the splitter.

Pascal

```
property ResizeStyle: TResizeStyle;
```

C++

```
__property TResizeStyle ResizeStyle;
```

Description

Use ResizeStyle to determine what happens when the user moves the splitter with the mouse.

ResizeStyle can have one of the values in the following table:

Value	Meaning
rsNone	Moving the splitter with the mouse has no effect.
rsLine	A line is drawn indicating the new position of the splitter that would result if the user released the mouse at the current position. The splitter does not actually move and no controls are resized.
rsUpdate	The control against which the splitter is aligned is resized based on the current mouse position, and the splitter is moved to that position.
rsPattern	A pattern is drawn indicating the new position of the splitter that would result if the user released the mouse at the current position. The splitter does not actually move and no controls are resized. This is the default value for ResizeStyle.

See Also

OnCanResize (see page 13240)

OnMoved (see page 13240)

68.1.35.5.11 TSplitter.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
```

```
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

VisibleChanging (see page 5791)

68.1.35.5.12 TSplitter.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

See Also

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

68.1.35.6 TSplitter Events

The events of the TSplitter class are listed here.

Published Events

	Name	Description
	OnCanResize (see page 13240)	Occurs when the user tries to move the splitter with the mouse.
	OnMoved (see page 13240)	Occurs after the user has retiled the form using the splitter.
	OnPaint (see page 13241)	Occurs when the splitter needs to draw itself.

68.1.35.6.1 TSplitter.OnCanResize Event

Occurs when the user tries to move the splitter with the mouse.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Write an OnCanResize event handler to conditionally prevent the user from resizing neighboring components using the splitter.

The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. This value can be changed if the attempted resize can be partially allowed. The Accept parameter indicates whether the resize should be permitted at all. Set Accept to false to disallow any movement of the splitter.

See Also

OnMoved (see page 13240)

ResizeStyle (see page 13237)

68.1.35.6.2 TSplitter.OnMoved Event

Occurs after the user has retiled the form using the splitter.

Pascal

```
property OnMoved: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMoved;
```

Description

Write an OnMoved event handler to take specific action when the user finishes dragging the edge of the neighboring control using the splitter. For example, after resizing a control on the edge of the form, use an OnMoved event handler to update the layout of the new client area of the form. Use the ClientRect property of the form to determine the new size remaining.

Delphi Examples:

```
{
This example uses a splitter and two image controls to
create a "slide show" effect.  The example displays an image
(the current "slide"), which can be hidden behind a screen
that looks like a venetian blind. When the blind is pulled
down to completely cover the current slide, the slide changes
to a different image.  When the blind is raised, the new
image appears.
To prepare this example, follow these steps:
1. Place an image control on the form.
Set the picture property to a bitmap of a venetian blind,
Set the Stretch property to True.
Set the Align property to alTop.
2. Add a splitter control to the form.
Set the Align property to alTop.
Set the Cursor property to crVSplit.
Set the OnMoved event handler to the code that appears below.
Set the MinSize property to 1.
3. Add a second image control to the form.
Set the Align property to alClient.
```

```
  Set the Stretch property to True.
  4. Select the form and add the OnCreate and OnDestroy event
     handlers that appear below.
  5. Add the global variables below to the unit.
  }
  var
    CurImage: Integer;
    BMPs: Array[1..5] of TBitmap;

  procedure TForm1.Splitter1Moved(Sender: TObject);
  begin
    { check if the blind is closed }
    if Image2.Height <= 1 then
    begin
      { the blind is closed, change the current slide }
      CurImage := CurImage + 1;
      if CurImage = 6 then
         CurImage := 1;
      Image2.Picture.Bitmap := BMPs[CurImage];
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    { Initialize the array of slides.
      These must be freed in the OnDestroy event handler. }
    BMPs[1] := TBitmap.Create;
    BMPs[1].LoadFromFile('Factory.bmp');
    BMPs[2] := TBitmap.Create;
    BMPs[2].LoadFromFile('Rhododendron.bmp');
    BMPs[3] := TBitmap.Create;
    BMPs[3].LoadFromFile('littleB_64.bmp');
    BMPs[4] := TBitmap.Create;
    BMPs[4].LoadFromFile('Soap bubbles.bmp');
    BMPs[5] := TBitmap.Create;
    BMPs[5].LoadFromFile('Gone Fishing.bmp');
    CurImage := 1;
    Image2.Picture.Bitmap := BMPs[1];
  end;

68.1.35.6.3 TSplitter.OnPaint Event

Occurs when the splitter needs to draw itself.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Write an OnPaint event handler to customize the appearance of the splitter. For example, use an OnPaint event handler to give a splitter the appearance of the splitters that appear in cool bar objects. Use the Canvas (see page 13228) property as a drawing surface for painting the splitter. Use the ClientRect property to determine the coordinates of the canvas on which to paint the splitter.

When a splitter object receives a WM_PAINT message, it paints its background before generating the OnPaint event. If the Beveled (see page 13228) property is true, the beveled appearance will also be added before the OnPaint event. Most applications set Beveled (see page 13228) to false when using the OnPaint event to customize the appearance of the splitter.

68.1.36 TTimer Class

TTimer encapsulates the Windows API timer functions.

Class Hierarchy

Pascal

```
TTimer = class(TComponent);
```

C++

```
class TTimer : public TComponent;
```

File

ExtCtrls

Description

TTimer is used to simplify calling the Windows API timer functions SetTimer and KillTimer, and to simplify processing the WM_TIMER messages. Use one timer component for each timer in the application.

The execution of the timer occurs through its OnTimer (see page 13251) event. TTimer has an Interval (see page 13249) property that determines how often the timer's OnTimer (see page 13251) event occurs. Interval (see page 13249) corresponds to the parameter for the Windows API SetTimer function.

Warning: Caution:Limitations on the total number of timers system-wide are system dependent.

68.1.36.1 TTimer Members

The following tables list the members exposed by TTimer.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Timer (see page 13246)	This is Timer, a member of class TTimer.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.

	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 13245)	Instantiates a timer object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 13245)	Disposes of a timer object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.

V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnTimer (see page 13251)	Occurs when a specified amount of time, determined by the Interval (see page 13249) property, has passed.

Published Properties

	Name	Description
	Enabled (see page 13246)	Controls (see page 5711) whether the timer generates OnTimer (see page 13251) events periodically.
	Interval (see page 13249)	Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 13251) event.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

68.1.36.2 TTimer.Create Constructor

Instantiates a timer object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTimer(TComponent * AOwner);
```

Description

Call Create to instantiate a timer at runtime. Timers added to forms or data modules at design time are created automatically.

AOwner specifies the component, typically a form or data module, that is responsible for freeing the timer.

See Also

Owner (see page 2807)

68.1.36.3 TTimer.Destroy Destructor

Disposes of a timer object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTimer();
```

Description

Do not call Destroy directly in an application. Instead, an application should call Free. Free verifies that the timer is not nil before it calls Destroy.

Destroy deactivates the timer by setting Enabled (see page 13246) to False before freeing the resources required by the timer.

See Also

Create (see page 13245)

68.1.36.4 TTimer Methods

The methods of the TTimer class are listed here.

Protected Methods

	Name	Description
	Timer (see page 13246)	This is Timer, a member of class TTimer.

68.1.36.4.1 TTimer.Timer Method

Pascal

```
procedure Timer; dynamic;
```

C++

```
__fastcall Timer();
```

Description

This is Timer, a member of class TTimer.

68.1.36.5 TTimer Properties

The properties of the TTimer class are listed here.

Published Properties

	Name	Description
	Enabled (see page 13246)	Controls (see page 5711) whether the timer generates OnTimer (see page 13251) events periodically.
	Interval (see page 13249)	Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 13251) event.

68.1.36.5.1 TTimer.Enabled Property

Controls (see page 5711) whether the timer generates OnTimer (see page 13251) events periodically.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to enable or disable the timer. If Enabled is true, the timer responds normally. If Enabled is false, the timer does not generate OnTimer (see page 13251) events. The default is true.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
/*
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
*/

Word TimeOver;

void __fastcall TForm1::FormClick(TObject *Sender)
{
  MediaPlayer1->DeviceType = dtCDAudio;
  MediaPlayer1->Open();
  MediaPlayer1->Play();
  Timer1->Enabled = true;
  TimeOver = 0;
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  if (TimeOver == 10)
  {
    MediaPlayer1->Eject();
    MediaPlayer1->Close();
    // disable the timer, as we are done
    Timer1->Enabled = false;
  }
```

```
  else
    TimeOver++;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
{
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
}
var
  TimerOver: Word;

procedure TForm1.FormClick(Sender: TObject);
begin
  MediaPlayer1.DeviceType := dtCDAudio;
  MediaPlayer1.Open;
  MediaPlayer1.Play;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  if TimeOver = 10 then
  begin
    MediaPlayer1.Eject;
    MediaPlayer1.Close;
    { disable the timer, as we are done }
    Timer1.Enabled := False;
  end
  else
    if (MediaPlayer1.Mode = mpOpen) then
     Inc(TimeOver);
end;
```

See Also

OnTimer (see page 13251)

68.1.36.5.2 TTimer.Interval Property

Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 13251) event.

Pascal

```
property Interval: Cardinal;
```

C++

```
__property unsigned Interval;
```

Description

Interval determines how frequently the OnTimer (see page 13251) event occurs. Each time the specified interval passes, the OnTimer (see page 13251) event occurs.

Use Interval to specify any cardinal value as the interval between OnTimer (see page 13251) events. The default value is 1000 (one second).

Note: A 0 value is valid, however the timer will not call an OnTimer (see page 13251) event for a value of 0.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
/*
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
reappears:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Timer1->Enabled = true;
  Hide();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Visible = true;
  Timer1->Enabled = false;
}
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
```

```
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
{
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
reappears:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Timer1.Interval := StrtoInt(MaskEdit1.Text);
  Timer1.Enabled := True;
  Hide;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Visible := True;
  Timer1.Enabled := False;
end;
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
```

```
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

See Also

OnTimer (see page 13251)

68.1.36.6 TTimer Events

The events of the TTimer class are listed here.

Published Events

	Name	Description
	OnTimer (see page 13251)	Occurs when a specified amount of time, determined by the Interval (see page 13249) property, has passed.

68.1.36.6.1 TTimer.OnTimer Event

Occurs when a specified amount of time, determined by the Interval (see page 13249) property, has passed.

Pascal

```
property OnTimer: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTimer;
```

Description

Write an OnTimer event handler to execute an action at regular intervals.

The Interval (see page 13249) property of a timer determines how frequently the OnTimer event occurs. Each time the specified interval passes, the OnTimer event occurs.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
```

```
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

68.1.37 TTrayIcon Class

Creates an icon in the system tray next to the clock.

Class Hierarchy

Pascal

```
TTrayIcon = class(TCustomTrayIcon);
```

C++

```
class TTrayIcon : public TCustomTrayIcon;
```

File

ExtCtrls

Description

Use the TTrayIcon component to create an icon in the system tray next to the clock. TTrayIcon has events for mouse clicks, properties for menus and animation of the icon, and methods for showing balloon hints.

68.1.37.1 TTrayIcon Members

The following tables list the members exposed by TTrayIcon.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.

	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoOnAnimate (see page 12569)	This is DoOnAnimate, a member of class TCustomTrayIcon.
	GetAnimateInterval (see page 12569)	This is GetAnimateInterval, a member of class TCustomTrayIcon.
	GetBalloonTimeout (see page 12569)	This is GetBalloonTimeout, a member of class TCustomTrayIcon.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAnimate (see page 12570)	This is SetAnimate, a member of class TCustomTrayIcon.
	SetAnimateInterval (see page 12570)	This is SetAnimateInterval, a member of class TCustomTrayIcon.
	SetBalloonHint (see page 12571)	This is SetBalloonHint, a member of class TCustomTrayIcon.
	SetBalloonTimeout (see page 12571)	This is SetBalloonTimeout, a member of class TCustomTrayIcon.
	SetBalloonTitle (see page 12571)	This is SetBalloonTitle, a member of class TCustomTrayIcon.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetHint (see page 12571)	This is SetHint, a member of class TCustomTrayIcon.
	SetIcon (see page 12572)	This is SetIcon, a member of class TCustomTrayIcon.
V	SetIconIndex (see page 12572)	This is SetIconIndex, a member of class TCustomTrayIcon.
	SetIconList (see page 12572)	This is SetIconList, a member of class TCustomTrayIcon.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetVisible (see page 12572)	This is SetVisible, a member of class TCustomTrayIcon.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WindowProc (see page 12573)	This is WindowProc, a member of class TCustomTrayIcon.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	Data (see page 12575)	This is Data, a member of class TCustomTrayIcon.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 12568)	Creates and initializes a TCustomTrayIcon (see page 12564) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 12568)	Frees the memory associated with the TCustomTrayIcon (see page 12564) object.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 12570)	This is the overview for the Refresh method overload.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetDefaultIcon (see page 12571)	Sets the tray icon to the default application icon.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
V	ShowBalloonHint (see page 12573)	Displays the balloon hint.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnAnimate (see page 13260)	Occurs each time the icon changes when the tray icon is animating.
	OnClick (see page 13260)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 13260)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 13260)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 13261)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 13261)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Published Properties

	Name	Description
	Animate (see page 13256)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 13256)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 13257)	Specifies an icon for the balloon hint.
	BalloonHint (see page 13257)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 13257)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 13257)	Specifies the text that appears as the balloon title.
	Hint (see page 13258)	Specifies the text that appears when the user moves the mouse over the control.

	Icon (see page 13258)	Specifies the default icon shown in the system tray.
	IconIndex (see page 13258)	This is an index into the Icons image list which is the icon currently being displayed in the system tray.
	Icons (see page 13258)	Specifies the list of images to be displayed for the icon in the system tray.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PopupMenu (see page 13259)	Identifies the pop-up menu associated with the tray icon.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Visible (see page 13259)	Determines whether the icon appears in the system tray.

68.1.37.2 TTrayIcon Properties

The properties of the TTrayIcon class are listed here.

Published Properties

	Name	Description
	Animate (see page 13256)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 13256)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 13257)	Specifies an icon for the balloon hint.
	BalloonHint (see page 13257)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 13257)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 13257)	Specifies the text that appears as the balloon title.
	Hint (see page 13258)	Specifies the text that appears when the user moves the mouse over the control.
	Icon (see page 13258)	Specifies the default icon shown in the system tray.
	IconIndex (see page 13258)	This is an index into the Icons image list which is the icon currently being displayed in the system tray.
	Icons (see page 13258)	Specifies the list of images to be displayed for the icon in the system tray.
	PopupMenu (see page 13259)	Identifies the pop-up menu associated with the tray icon.
	Visible (see page 13259)	Determines whether the icon appears in the system tray.

68.1.37.2.1 TTrayIcon.Animate Property

Specifies whether the icon in the system tray is static or animated.

Pascal

```
property Animate: Boolean;
```

C++

```
__property Boolean Animate;
```

Description

When set to True, the icon shown in the system tray displays, in sequence, the images in the image list specified by the Icons property. The images change only if the specified image list contains images. The images change on a rotating basis by the interval set by the AnimateInterval property. When set to False the animation stops.

68.1.37.2.2 TTrayIcon.AnimateInterval Property

Controls the length of time between image changes for the tray icon image.

Pascal

```
property AnimateInterval: Cardinal;
```

C++

```
__property unsigned AnimateInterval;
```

Description

Use AnimateInterval to specify the length of time between image changes in the tray icon. The default interval is 1000 ms (1 second).

68.1.37.2.3 TTrayIcon.BalloonFlags Property

Specifies an icon for the balloon hint.

Pascal

```
property BalloonFlags: TBalloonFlags;
```

C++

```
__property TBalloonFlags BalloonFlags;
```

Description

The following values specify an icon to be displayed in the balloon hint:

- bfNone
- bfInfo
- bfWarning
- bfError

68.1.37.2.4 TTrayIcon.BalloonHint Property

Specifies the text within a balloon hint.

Pascal

```
property BalloonHint: string;
```

C++

```
__property AnsiString BalloonHint;
```

Description

Use BalloonHint to specify the text string that appears when a balloon hint is shown.

68.1.37.2.5 TTrayIcon.BalloonTimeout Property

Specifies the length of time that the balloon displays.

Pascal

```
property BalloonTimeout: Integer;
```

C++

```
__property int BalloonTimeout;
```

Description

Use BalloonTimeout to set the length of time that a balloon displays. By default, this value is set to 3000 ms (3 seconds).

68.1.37.2.6 TTrayIcon.BalloonTitle Property

Specifies the text that appears as the balloon title.

Pascal

```
property BalloonTitle: string;
```

C++

```
__property AnsiString BalloonTitle;
```

Description

Specifies the text that appears as the balloon title.

68.1.37.2.7 TTrayIcon.Hint Property

Specifies the text that appears when the user moves the mouse over the control.

Pascal

```
property Hint: string;
```

C++

```
__property AnsiString Hint;
```

Description

Specifies the text that appears when the user moves the mouse over the control.

68.1.37.2.8 TTrayIcon.Icon Property

Specifies the default icon shown in the system tray.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Use the Icon property to set the default icon to be shown in the system tray. If you do not specify a value, the application icon is used.

68.1.37.2.9 TTrayIcon.IconIndex Property

This is an index into the Icons image list which is the icon currently being displayed in the system tray.

Pascal

```
property IconIndex: Integer;
```

C++

```
__property int IconIndex;
```

Description

This is an index into the Icons image list which is the icon currently being displayed in the system tray.

68.1.37.2.10 TTrayIcon.Icons Property

Specifies the list of images to be displayed for the icon in the system tray.

Pascal

```
property Icons: TImageList;
```

C++

```
__property TImageList Icons;
```

Description

Use this property to specify the list of images used for the icon in the system tray. These images are displayed when the Animate property is set to True.

68.1.37.2.11 TTrayIcon.PopupMenu Property

Identifies the pop-up menu associated with the tray icon.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Use PopupMenuOn to specify when the menu is displayed.

68.1.37.2.12 TTrayIcon.Visible Property

Determines whether the icon appears in the system tray.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Determines whether the icon appears in the system tray.

68.1.37.3 TTrayIcon Events

The events of the TTrayIcon class are listed here.

Published Events

	Name	Description
	OnAnimate (see page 13260)	Occurs each time the icon changes when the tray icon is animating.
	OnClick (see page 13260)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 13260)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 13260)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 13261)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 13261)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

68.1.37.3.1 TTrayIcon.OnAnimate Event

Occurs each time the icon changes when the tray icon is animating.

Pascal

```
property OnAnimate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAnimate;
```

Description

Occurs each time the icon changes when the tray icon is animating.

68.1.37.3.2 TTrayIcon.OnClick Event

Occurs when the user clicks the tray icon.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Occurs when the user clicks the tray icon.

68.1.37.3.3 TTrayIcon.OnDblClick Event

Occurs when the user double clicks the tray icon.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Occurs when the user double clicks the tray icon.

68.1.37.3.4 TTrayIcon.OnMouseDown Event

Occurs when the user presses a mouse button while the mouse pointer is over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Occurs when the user presses a mouse button while the mouse pointer is over a control.

68.1.37.3.5 TTrayIcon.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

68.1.37.3.6 TTrayIcon.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

68.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Frame3D (see page 13262)	Draws a three dimensional frame on a canvas.
	NotebookHandlesNeeded (see page 13263)	This is function ExtCtrls.NotebookHandlesNeeded.

68.2.1 ExtCtrls.Frame3D Function

Draws a three dimensional frame on a canvas.

Pascal

```
procedure Frame3D(Canvas: TCanvas; var Rect: TRect; TopColor: TColor; BottomColor: TColor;
Width: Integer);
```

C++

```
Frame3D(TCanvas Canvas, TRect Rect, TColor TopColor, TColor BottomColor, int Width);
```

File

ExtCtrls

Description

Use Frame3D to create three-dimensional effects when drawing directly on a canvas.

The Canvas parameter is the canvas to draw on.

The Rect parameter specifies the position on the canvas where the three-dimensional rectangle should appear. It returns the dimensions of the rectangle that lies inside the frame.

The TopColor and BottomColor parameters indicate the colors that appear on the left and top or the right and bottom of the rectangle respectively.

The Width parameter specifies the width of the frame.

To create a raised effect, the TopColor should be a light color and the BottomColor should be a shadow color. To create a depressed effect, the TopColor should be the shadow color and the BottomColor should be the light color. To create a beveled effect, draw a frame immediately inside another frame with the colors reversed.

TFrameControl

68.2.2 ExtCtrls.NotebookHandlesNeeded Function

Pascal

```
procedure NotebookHandlesNeeded(Notebook: TNotebook);
```

C++

```
NotebookHandlesNeeded(TNotebook Notebook);
```

File

ExtCtrls

Description

This is function ExtCtrls.NotebookHandlesNeeded.

68.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBalloonFlags (see page 13264)	A type specified when showing a balloon hint that puts one of the default icons on the balloon message.
	TBandDrawingStyle (see page 13265)	This is record ExtCtrls.TBandDrawingStyle.
	TBandPaintOption (see page 13265)	TBandPaintOption and TBandPaintOptions (see page 13274) specify which parts of a band are painted.
	TBevelShape (see page 13266)	TBevelShape determines the overall shape of a bevel control.
	TBevelStyle (see page 13267)	TBevelStyle indicates whether a bevel appears raised or lowered.
	TColorBoxStyles (see page 13267)	This is record ExtCtrls.TColorBoxStyles.
	TCornerEdge (see page 13268)	The size of the cornering for the edge of the bands in a TControlBar (see page 12316).
	TExpandStyle (see page 13268)	Specifies how a grid panel expands.
	TFlowStyle (see page 13269)	This is record ExtCtrls.TFlowStyle.
	TLabelPosition (see page 13269)	TLabelPosition specifies the position of the label in a labeled edit control.
	TResizeStyle (see page 13270)	This is record ExtCtrls.TResizeStyle.
	TShapeType (see page 13270)	TShapeType determines the shape of a TShape (see page 13172) control.
	TSizeStyle (see page 13271)	This is record ExtCtrls.TSizeStyle.

68.3.1 ExtCtrls.TBalloonFlags Enumeration

A type specified when showing a balloon hint that puts one of the default icons on the balloon message.

Pascal

```
TBalloonFlags = (
  bfNone = NIIF_NONE,
  bfInfo = NIIF_INFO,
  bfWarning = NIIF_WARNING,
  bfError = NIIF_ERROR
);
```

C++

```
enum TBalloonFlags {
  bfNone = NIIF_NONE,
  bfInfo = NIIF_INFO,
  bfWarning = NIIF_WARNING,
  bfError = NIIF_ERROR
};
```

File

ExtCtrls

Description

You can set TBalloonFlags to one of the following values:

- bfNone
- bfInfo

- bfWarning
- bfError

68.3.2 ExtCtrls.TBandDrawingStyle Enumeration

Pascal

```
TBandDrawingStyle = (
  dsNormal,
  dsGradient
);
```

C++

```
enum TBandDrawingStyle {
  dsNormal,
  dsGradient
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TBandDrawingStyle.

68.3.3 ExtCtrls.TBandPaintOption Enumeration

TBandPaintOption and TBandPaintOptions (see page 13274) specify which parts of a band are painted.

Pascal

```
TBandPaintOption = (
  bpoGrabber,
  bpoFrame,
  bpoGradient,
  bpoRoundRect
);
```

C++

```
enum TBandPaintOption {
  bpoGrabber,
  bpoFrame,
  bpoGradient,
  bpoRoundRect
};
```

File

ExtCtrls

Description

TBandPaintOptions (see page 13274) has one or more of the following values:

Value	Meaning
bpoGrabber	The grabber is painted.

bpoFrame	The frame is painted.
bpoGradient	The gradient is painted.
bpoRoundRect	The round rectangle is painted.

68.3.4 ExtCtrls.TBevelShape Enumeration

TBevelShape determines the overall shape of a bevel control.

Pascal

```
TBevelShape = (
  bsBox,
  bsFrame,
  bsTopLine,
  bsBottomLine,
  bsLeftLine,
  bsRightLine,
  bsSpacer
);
```

C++

```
enum TBevelShape {
  bsBox,
  bsFrame,
  bsTopLine,
  bsBottomLine,
  bsLeftLine,
  bsRightLine,
  bsSpacer
};
```

File

ExtCtrls

Description

These are the possible values of the TBevelShape type:

Value	Meaning
bsBox	The entire client area appears raised or lowered.
bsFrame	The client area is outlined by a raised or lowered frame.
bsTopLine	The bevel displays a line at the top of the client area.
bsBottomLine	The bevel displays a line at the bottom of the client area.
bsLeftLine	The bevel displays a line at the left side of the client area.
bsRightLine	The bevel displays a line at the right side of the client area.
bsSpacer	The bevel is an empty space.

68.3.5 ExtCtrls.TBevelStyle Enumeration

TBevelStyle indicates whether a bevel appears raised or lowered.

Pascal

```
TBevelStyle = (
  bsLowered,
  bsRaised
);
```

C++

```
enum TBevelStyle {
  bsLowered,
  bsRaised
};
```

File

ExtCtrls

Description

These are the possible values of the TBevelStyle type:

Value	Meaning
bsLowered	The bevel is lowered.
bsRaised	The bevel is raised.

68.3.6 ExtCtrls.TColorBoxStyles Enumeration

Pascal

```
TColorBoxStyles = (
  cbStandardColors,
  cbExtendedColors,
  cbSystemColors,
  cbIncludeNone,
  cbIncludeDefault,
  cbCustomColor,
  cbPrettyNames,
  cbCustomColors
);
```

C++

```
enum TColorBoxStyles {
  cbStandardColors,
  cbExtendedColors,
  cbSystemColors,
  cbIncludeNone,
  cbIncludeDefault,
  cbCustomColor,
  cbPrettyNames,
  cbCustomColors
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TColorBoxStyles.

68.3.7 ExtCtrls.TCornerEdge Enumeration

The size of the cornering for the edge of the bands in a TControlBar (see page 12316).

Pascal

```
TCornerEdge = (
  ceNone,
  ceSmall,
  ceMedium,
  ceLarge
);
```

C++

```
enum TCornerEdge {
  ceNone,
  ceSmall,
  ceMedium,
  ceLarge
};
```

File

ExtCtrls

Description

This type contains the size of the cornering for the edge of the bands in a TControlBar (see page 12316).

68.3.8 ExtCtrls.TExpandStyle Enumeration

Specifies how a grid panel expands.

Pascal

```
TExpandStyle = (
  emAddRows,
  emAddColumns,
  emFixedSize
);
```

C++

```
enum TExpandStyle {
  emAddRows,
  emAddColumns,
  emFixedSize
};
```

File

ExtCtrls

Description

Use TExpandStyle to specify whether a grid panel adds rows or columns when new controls are added.

68.3.9 ExtCtrls.TFlowStyle Enumeration

Pascal

```
TFlowStyle = (
  fsLeftRightTopBottom,
  fsRightLeftTopBottom,
  fsLeftRightBottomTop,
  fsRightLeftBottomTop,
  fsTopBottomLeftRight,
  fsBottomTopLeftRight,
  fsTopBottomRightLeft,
  fsBottomTopRightLeft
);
```

C++

```
enum TFlowStyle {
  fsLeftRightTopBottom,
  fsRightLeftTopBottom,
  fsLeftRightBottomTop,
  fsRightLeftBottomTop,
  fsTopBottomLeftRight,
  fsBottomTopLeftRight,
  fsTopBottomRightLeft,
  fsBottomTopRightLeft
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TFlowStyle.

68.3.10 ExtCtrls.TLabelPosition Enumeration

TLabelPosition specifies the position of the label in a labeled edit control.

Pascal

```
TLabelPosition = (
  lpAbove,
  lpBelow,
  lpLeft,
  lpRight
);
```

C++

```
enum TLabelPosition {
  lpAbove,
  lpBelow,
  lpLeft,
  lpRight
```

```
};
```

File

ExtCtrls

Description

The following are possible values of TLabelPosition:

Value	Meaning
lpAbove	The label appears above the edit control.
lpBelow	The label appears below the edit control.
lpLeft	The label appears to the left of the edit control.
lpRight	The label appears to the right of the edit control.

68.3.11 ExtCtrls.TResizeStyle Enumeration

Pascal

```
TResizeStyle = (
  rsNone,
  rsLine,
  rsUpdate,
  rsPattern
);
```

C++

```
enum TResizeStyle {
  rsNone,
  rsLine,
  rsUpdate,
  rsPattern
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TResizeStyle.

68.3.12 ExtCtrls.TShapeType Enumeration

TShapeType determines the shape of a TShape (see page 13172) control.

Pascal

```
TShapeType = (
  stRectangle,
  stSquare,
  stRoundRect,
  stRoundSquare,
  stEllipse,
  stCircle
```

```
);
```

C++

```
enum TShapeType {
  stRectangle,
  stSquare,
  stRoundRect,
  stRoundSquare,
  stEllipse,
  stCircle
};
```

File

ExtCtrls

Description

These are the possible values of the TShapeType type:

Value	Meaning
stCircle	The shape is a circle.
stEllipse	The shape is an ellipse.
stRectangle	The shape is a rectangle. (Default)
stRoundRect	The shape is a rectangle with rounded corners.
stRoundSquare	The shape is a square with rounded corners.
stSquare	The shape is a square.

68.3.13 ExtCtrls.TSizeStyle Enumeration

Pascal

```
TSizeStyle = (
  ssAbsolute,
  ssPercent,
  ssAuto
);
```

C++

```
enum TSizeStyle {
  ssAbsolute,
  ssPercent,
  ssAuto
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TSizeStyle.

68.4 Types

The following table lists types in this documentation.

Types

Name	Description
NaturalNumber (see page 13272)	This is type ExtCtrls.NaturalNumber.
TBandDragEvent (see page 13272)	This is type ExtCtrls.TBandDragEvent.
TBandInfoEvent (see page 13273)	This is type ExtCtrls.TBandInfoEvent.
TBandMoveEvent (see page 13273)	This is type ExtCtrls.TBandMoveEvent.
TBandPaintEvent (see page 13273)	This is type ExtCtrls.TBandPaintEvent.
TBandPaintOptions (see page 13274)	This is type ExtCtrls.TBandPaintOptions.
TBeginBandMoveEvent (see page 13274)	This is type ExtCtrls.TBeginBandMoveEvent.
TCanResizeEvent (see page 13274)	This is type ExtCtrls.TCanResizeEvent.
TCellSpan (see page 13275)	This is type ExtCtrls.TCellSpan.
TColorBoxStyle (see page 13275)	TColorBoxStyle and TColorBoxStyles (see page 13267) specify how a color box control displays its selections.
TEndBandMoveEvent (see page 13276)	This is type ExtCtrls.TEndBandMoveEvent.
TGetColorsEvent (see page 13276)	This is type ExtCtrls.TGetColorsEvent.
TLBGetColorsEvent (see page 13276)	This is type ExtCtrls.TLBGetColorsEvent.
TPanelBevel (see page 13277)	TPanelBevel specifies a bevel's cut.
TRowSize (see page 13277)	This is type ExtCtrls.TRowSize.
TSectionEvent (see page 13278)	TSectionEvent is the type of event handlers that respond when a section of a THeader (see page 12744) control is resized.
TSplitterCanResizeEvent (see page 13278)	This is type ExtCtrls.TSplitterCanResizeEvent.

68.4.1 ExtCtrls.NaturalNumber Type

Pascal

```
NaturalNumber = 1..High(Integer);
```

C++

```
1..High(Integer) NaturalNumber;
```

File

ExtCtrls

Description

This is type ExtCtrls.NaturalNumber.

68.4.2 ExtCtrls.TBandDragEvent Type

Pascal

```
TBandDragEvent = procedure (Sender: TObject; Control: TControl; var Drag: Boolean) of object;
```

C++

```
(Sender: TObject; Control: TControl; var Drag: Boolean) ( TBandDragEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandDragEvent.

68.4.3 ExtCtrls.TBandInfoEvent Type

Pascal

```
TBandInfoEvent = procedure (Sender: TObject; Control: TControl; var Insets: TRect; var
PreferredSize, RowCount: Integer) of object;
```

C++

```
(Sender: TObject; Control: TControl; var Insets: TRect; var PreferredSize, RowCount: Integer)
( TBandInfoEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandInfoEvent.

68.4.4 ExtCtrls.TBandMoveEvent Type

Pascal

```
TBandMoveEvent = procedure (Sender: TObject; Control: TControl; var ARect: TRect) of object;
```

C++

```
(Sender: TObject; Control: TControl; var ARect: TRect) ( TBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandMoveEvent.

68.4.5 ExtCtrls.TBandPaintEvent Type

Pascal

```
TBandPaintEvent = procedure (Sender: TObject; Control: TControl; Canvas: TCanvas; var ARect:
TRect; var Options: TBandPaintOptions) of object;
```

C++

```
(Sender: TObject; Control: TControl; Canvas: TCanvas; var ARect: TRect; var Options:
TBandPaintOptions) ( TBandPaintEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandPaintEvent.

68.4.6 ExtCtrls.TBandPaintOptions Type

Pascal

```
TBandPaintOptions = set of TBandPaintOption;
```

C++

```
TBandPaintOption TBandPaintOptions;
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandPaintOptions.

68.4.7 ExtCtrls.TBeginBandMoveEvent Type

Pascal

```
TBeginBandMoveEvent = procedure (Sender: TObject; Control: TControl; var AllowMove: Boolean)
of object;
```

C++

```
(Sender: TObject; Control: TControl; var AllowMove: Boolean) ( TBeginBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBeginBandMoveEvent.

68.4.8 ExtCtrls.TCanResizeEvent Type

Pascal

```
TCanResizeEvent = TSplitterCanResizeEvent;
```

C++

```
TSplitterCanResizeEvent TCanResizeEvent;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCanResizeEvent.

68.4.9 ExtCtrls.TCellSpan Type

Pascal

```
TCellSpan = 1..MaxInt;
```

C++

```
1..MaxInt TCellSpan;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCellSpan.

68.4.10 ExtCtrls.TColorBoxStyle Type

TColorBoxStyle and TColorBoxStyles (see page 13267) specify how a color box control displays its selections.

Pascal

```
TColorBoxStyle = set of TColorBoxStyles;
```

C++

```
TColorBoxStyles TColorBoxStyle;
```

File

ExtCtrls

Description

TColorBoxStyle is a set of TColorBoxStyles (see page 13267) values. The possible values of TColorBoxStyles (see page 13267) are

Style	Meaning when included
cbStandardColors	The color box lists the first 16 color constants from the Graphics (see page 14387) unit. These are the constants such as clRed or clBlack, that represent fixed RGB values.
cbExtendedColors	The color box includes clMoneyGreen, clSkyBlue, clCream, and clMedGray.
cbSystemColors	The color box includes the symbolic color constants that reflect the values specified in the Windows control panel.
cbIncludeNone	The color box includes clNone. This option only has an effect if Style includes cbSystemColors.
cbIncludeDefault	The color box includes clNone. This option only has an effect if Style includes cbSystemColors.

cbCustomColor	The first entry in the color box represents a custom color. When the user selects the Custom entry, the color box displays the Color selection dialog, where the user can specify a custom color.
cbPrettyNames	The color box lists the names as words rather than as the color constant strings. (for example 'Black' rather than 'clBlack').

68.4.11 ExtCtrls.TEndBandMoveEvent Type

Pascal

```
TEndBandMoveEvent = procedure (Sender: TObject; Control: TControl) of object;
```

C++

```
(Sender: TObject; Control: TControl) ( TEndBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TEndBandMoveEvent.

68.4.12 ExtCtrls.TGetColorsEvent Type

Pascal

```
TGetColorsEvent = procedure (Sender: TCustomColorBox; Items: TStrings) of object;
```

C++

```
(Sender: TCustomColorBox; Items: TStrings) ( TGetColorsEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TGetColorsEvent.

68.4.13 ExtCtrls.TLBGetColorsEvent Type

Pascal

```
TLBGetColorsEvent = procedure (Sender: TCustomColorListBox; Items: TStrings) of object;
```

C++

```
(Sender: TCustomColorListBox; Items: TStrings) ( TLBGetColorsEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TLBGetColorsEvent.

68.4.14 ExtCtrls.TPanelBevel Type

TPanelBevel specifies a bevel's cut.

Pascal

```
TPanelBevel = TBevelCut;
```

C++

```
TBevelCut TPanelBevel;
```

File

ExtCtrls

Description

TPanelBevel can have one of the following values:

Value	Meaning
bvNone	The bevel does not exist.
bvLowered	The bevel appears lowered.
bvRaised	The bevel appears raised.
bvSpace	The bevel appears as a space if its kind is not bkTile. Otherwise, the bevel appears raised.

See Also

TWinControl

TWinControl

68.4.15 ExtCtrls.TRowSize Type

Pascal

```
TRowSize = 1..MaxInt;
```

C++

```
1..MaxInt TRowSize;
```

File

ExtCtrls

Description

This is type ExtCtrls.TRowSize.

68.4.16 ExtCtrls.TSectionEvent Type

TSectionEvent is the type of event handlers that respond when a section of a THeader (see page 12744) control is resized.

Pascal

```
TSectionEvent = procedure (Sender: TObject; ASection, AWidth: Integer) of object;
```

C++

```
(Sender: TObject; ASection, AWidth: Integer) ( TSectionEvent)();
```

File

ExtCtrls

Description

Sender is the header control.

ASection is the index of the section that was resized.

AWidth is the width of the section.

68.4.17 ExtCtrls.TSplitterCanResizeEvent Type

Pascal

```
TSplitterCanResizeEvent = procedure (Sender: TObject; var NewSize: Integer; var Accept:
Boolean) of object;
```

C++

```
(Sender: TObject; var NewSize: Integer; var Accept: Boolean) ( TSplitterCanResizeEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TSplitterCanResizeEvent.

68.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
NoColorSelected (see page 13279)	This is constant ExtCtrls.NoColorSelected.
WM_SYSTEM_TRAY_MESSAGE (see page 13279)	This is constant ExtCtrls.WM_SYSTEM_TRAY_MESSAGE.

68.5.1 ExtCtrls.NoColorSelected Constant

Pascal

```
NoColorSelected = TColor($FF000000);
```

C++

```
NoColorSelected = TColor($FF000000);
```

File

ExtCtrls

Description

This is constant ExtCtrls.NoColorSelected.

68.5.2 ExtCtrls.WM_SYSTEM_TRAY_MESSAGE Constant

Pascal

```
WM_SYSTEM_TRAY_MESSAGE = WM_USER + 1;
```

C++

```
WM_SYSTEM_TRAY_MESSAGE = WM_USER + 1;
```

File

ExtCtrls

Description

This is constant ExtCtrls.WM_SYSTEM_TRAY_MESSAGE.

69 ExtDlgs Namespace

This is namespace ExtDlgs.

Topics

Name	Description
Classes (see page 13282)	The following table lists classes in this documentation.
Constants (see page 13310)	The following table lists constants in this documentation.

Classes

	Name	Description
	TOpenPictureDialog (see page 13282)	TOpenPictureDialog displays a graphics-file selection dialog.
	TOpenTextFileDialog (see page 13292)	This is class ExtDlgs.TOpenTextFileDialog.
	TSavePictureDialog (see page 13300)	TSavePictureDialog displays a "Save As" dialog for saving graphics files.
	TSaveTextFileDialog (see page 13305)	This is class ExtDlgs.TSaveTextFileDialog.

Constants

Name	Description
DefaultEncodingNames (see page 13310)	This is constant ExtDlgs.DefaultEncodingNames.

69.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TOpenPictureDialog (see page 13282)	TOpenPictureDialog displays a graphics-file selection dialog.
	TOpenTextFileDialog (see page 13292)	This is class ExtDlgs.TOpenTextFileDialog.
	TSavePictureDialog (see page 13300)	TSavePictureDialog displays a "Save As" dialog for saving graphics files.
	TSaveTextFileDialog (see page 13305)	This is class ExtDlgs.TSaveTextFileDialog.

69.1.1 TOpenPictureDialog Class

TOpenPictureDialog displays a graphics-file selection dialog.

Class Hierarchy

Pascal

```
TOpenPictureDialog = class(TOpenDialog);
```

C++

```
class TOpenPictureDialog : public TOpenDialog;
```

File

ExtDlgs

Description

TOpenPictureDialog displays a modal Windows dialog box for selecting and opening graphics files. This component is just like TOpenDialog, except that it includes a rectangular preview region. If the selected image can be read by TPicture, it is displayed in the preview region; supported file types include bitmap (.BMP), icon (.ICO), Windows metafile (.WMF), and enhanced Windows metafile (.EMF). If the selected image cannot be displayed, "(None)" appears in the preview region.

If the user selects a file of an unrecognized type, TPicture raises an EInvalidGraphic exception.

See Also

EInvalidGraphic (see page 14395)

TOpenDialog (see page 11407)

TPicture (see page 14584)

TSavePictureDialog (see page 13300)

GraphicFilter

69.1.1.1 TOpenPictureDialog Members

The following tables list the members exposed by TOpenPictureDialog.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CanClose (see page 11413)	This is CanClose, a member of class TOpenDialog.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 11413)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoCanClose (see page 11413)	This is DoCanClose, a member of class TOpenDialog.
V	DoClose (see page 13287)	Generates an OnClose event.
	DoExecute (see page 11413)	This is the overview for the DoExecute method overload.
	DoFolderChange (see page 11414)	This is DoFolderChange, a member of class TOpenDialog.
	DoIncludeItem (see page 11414)	This is DoIncludeItem, a member of class TOpenDialog.
V	DoSelectionChange (see page 13287)	This is DoSelectionChange, a member of class TOpenPictureDialog.
V	DoShow (see page 13287)	Generates an OnShow event.
	DoTypeChange (see page 11415)	This is DoTypeChange, a member of class TOpenDialog.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetFileNames (see page 11417)	This is GetFileNames, a member of class TOpenDialog.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetStaticRect (see page 11417)	Returns the coordinates of the reserved area of the dialog box.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	MessageHook (see page 11284)	Provides special Windows message processing for the dialog.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	PreviewClick (see page 13288)	This is PreviewClick, a member of class TOpenPictureDialog.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.

	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	TaskModalDialog (see page 11284)	Ensures that Windows messages are properly routed when the dialog executes.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WndProc (see page 11285)	Responds to Windows messages sent to the dialog.
V	WndProc (see page 11420)	Responds to Windows messages sent to the dialog.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ImageCtrl (see page 13292)	This is ImageCtrl, a member of class TOpenPictureDialog.
R	PictureLabel (see page 13292)	This is PictureLabel, a member of class TOpenPictureDialog.
	Template (see page 11287)	Points to a custom template for the dialog.
	TemplateModule (see page 11287)	This is TemplateModule, a member of class TCommonDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 13286)	Creates and initializes a TOpenPictureDialog (see page 13282) instance.
V	DefaultHandler (see page 11282)	Sends unhandled messages to Windows for processing.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 11281)	Destroys the TCommonDialog (see page 11277) instance and frees its memory.
V	Destroy (see page 11412)	Destroys the TOpenDialog (see page 11407) and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

V	Execute (see page 13288)	Displays the file-selection dialog.
V	Execute (see page 11283)	This is the overview for the Execute method overload.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	FileEditStyle (see page 11423)	Determines the style of the file-selection dialog. (Obsolete.)
R	Files (see page 11429)	List of selected file names.
R	Handle (see page 11286)	Specifies the window handle of the dialog.

	HistoryList (see page 11436)	Maintains a list of previously selected files. (Obsolete.)
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCanClose (see page 11439)	Occurs when the user tries to close the dialog without canceling.
	OnClose (see page 11287)	Occurs when the dialog closes.
	OnFolderChange (see page 11440)	Occurs when a directory is opened or closed from the dialog.
	OnIncludeItem (see page 11440)	Occurs before the dialog adds a file to the file list box.
	OnSelectionChange (see page 11441)	Occurs when file names displayed in the dialog are changed.
	OnShow (see page 11288)	Occurs when the dialog opens.
	OnTypeChange (see page 11441)	Occurs when the file types displayed in the dialog are changed.

Published Properties

	Name	Description
	Ctl3D (see page 11285)	Determines whether the dialog has a three-dimensional look.
	DefaultExt (see page 11421)	Specifies a default file extension.
	FileName (see page 11424)	Indicates the name and directory path of the last file selected.
	Filter (see page 13289)	Determines the file masks (filters) available in the dialog.
	FilterIndex (see page 11434)	Determines which filter is selected by default when the dialog opens.
	HelpContext (see page 11286)	Specifies the context number for online Help.
	InitialDir (see page 11436)	Determines the current directory when the dialog opens.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 11436)	Determines the appearance and behavior of the file-selection dialog.
	OptionsEx (see page 11438)	Augments the Options (see page 11436) property with additional flags that determine the appearance and behavior of the file-selection dialog.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Title (see page 11438)	Specifies the text in the dialog's title bar.

69.1.1.2 TOpenPictureDialog.Create Constructor

Creates and initializes a TOpenPictureDialog (see page 13282) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOpenPictureDialog(TComponent * AOwner);
```

Description

The Create method generates a TOpenPictureDialog (see page 13282) instance, but the dialog does not appear at runtime until the Execute (see page 13288) method is called. Create initializes the Filter (see page 13289) property by defining a filter for each file type that TPicture supports.

See Also

Execute (see page 13288)

Filter (see page 11431)

TPicture (see page 14584)

69.1.1.3 TOpenPictureDialog Methods

The methods of the TOpenPictureDialog class are listed here.

Protected Methods

	Name	Description
	DoClose (see page 13287)	Generates an OnClose event.
	DoSelectionChange (see page 13287)	This is DoSelectionChange, a member of class TOpenPictureDialog.
	DoShow (see page 13287)	Generates an OnShow event.
	PreviewClick (see page 13288)	This is PreviewClick, a member of class TOpenPictureDialog.

Public Methods

	Name	Description
	Execute (see page 13288)	Displays the file-selection dialog.

69.1.1.3.1 TOpenPictureDialog.DoClose Method

Generates an OnClose event.

Pascal

```
procedure DoClose; override;
```

C++

```
virtual __fastcall DoClose();
```

Description

DoClose is called automatically when the user closes the dialog. Override this method to provide additional processing other than calling the OnClose event handler. For example, to perform shutdown operations that use protected methods of the dialog class, override DoClose rather than writing an OnClose event handler (which can access only public methods).

See Also

OnClose (see page 11287)

69.1.1.3.2 TOpenPictureDialog.DoSelectionChange Method

Pascal

```
procedure DoSelectionChange; override;
```

C++

```
virtual __fastcall DoSelectionChange();
```

Description

This is DoSelectionChange, a member of class TOpenPictureDialog.

69.1.1.3.3 TOpenPictureDialog.DoShow Method

Generates an OnShow event.

Pascal

```
procedure DoShow; override;
```

C++

```
virtual __fastcall DoShow();
```

Description

DoShow is called automatically when the dialog is first displayed. Override this method to provide additional processing other than calling the OnShow event handler. For example, to perform initializations that use protected methods of the dialog class, override DoShow rather than writing an OnShow event handler (which can access only public methods).

See Also

OnShow (see page 11288)

69.1.1.3.4 TOpenPictureDialog.Execute Method

Displays the file-selection dialog.

Pascal

```
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the file-selection dialog, returning true when the user selects a file and clicks Open. If the user clicks Cancel, Execute returns false.

69.1.1.3.5 TOpenPictureDialog.PreviewClick Method

Pascal

```
procedure PreviewClick(Sender: TObject); virtual;
```

C++

```
virtual __fastcall PreviewClick(TObject * Sender);
```

Description

This is PreviewClick, a member of class TOpenPictureDialog.

69.1.1.4 TOpenPictureDialog Properties

The properties of the TOpenPictureDialog class are listed here.

Protected Properties

	Name	Description
R	ImageCtrl (see page 13292)	This is ImageCtrl, a member of class TOpenPictureDialog.
R	PictureLabel (see page 13292)	This is PictureLabel, a member of class TOpenPictureDialog.

Published Properties

	Name	Description
	Filter (see page 13289)	Determines the file masks (filters) available in the dialog.

69.1.1.4.1 TOpenPictureDialog.Filter Property

Determines the file masks (filters) available in the dialog.

Pascal

```
property Filter: string;
```

C++

```
__property AnsiString Filter;
```

Description

The file-selection dialog includes a drop-down list of file types under the edit box. When the user picks a file type from the list, only files of the selected type are displayed in the dialog.

To configure file masks at design time, click on the ellipsis marks (...) to the right of the Filter property in the Object Inspector. This opens the Filter editor. In the left column of the Filter editor, under Filter Name, type a brief description of each file type that will be available at runtime. In the right column, under Filter, type the file mask corresponding to each description. For example, the description "Text files" might appear to the left of the mask "*.txt", and the description "Pascal source files" might appear to the left of the mask "*.pas". Since the description appears in the drop-down list at runtime, it is often helpful to show the mask explicitly in the description (for example, "Text files (*.txt)").

To create file masks in program code, assign a value to the Filter property that consists of a description and a mask separated by a vertical bar (pipe) character. Do not include spaces around the vertical bar. For example,

```
OpenDialog1.Filter := 'Text files (*.txt)|*.TXT';
OpenDialog1->Filter = "Text files (*.txt)|*.TXT";
```

Multiple filters should be separated by vertical bars. For example,

```
OpenDialog1.Filter := 'Text files (*.txt)|*.TXT|Pascal files (*.pas)|*.PAS';
OpenDialog1->Filter = "Text files (*.txt)|*.TXT|Pascal files (*.pas)|*.PAS";
```

To include multiple masks in a single filter, separate the masks with semicolons. This works both in the Object Inspector and in program code. For example,

```
OpenDialog1.Filter := 'Pascal files|*.PAS;*.DPK;*.DPR';
OpenDialog1->Filter = "Pascal files|*.PAS;*.DPK;*.DPR";
```

If no value is assigned to Filter, the dialog displays all file types.

C++ Examples:

```
/*
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString NewFileName, OldFileName;
  TFileStream *NewFile, *OldFile;
  SavePictureDialog1->DefaultExt = GraphicExtension(__classid(Graphics::TBitmap));
  SavePictureDialog1->Filter = GraphicFilter(__classid(Graphics::TBitmap));
  OldFileName = "factory.bmp";
  if (SavePictureDialog1->Execute())
  {
    NewFileName = SavePictureDialog1->FileName;
    OldFile = new TFileStream(OldFileName, (fmOpenRead | fmShareDenyWrite));
    try
    {
```

```
        NewFile = new TFileStream(NewFileName, (fmCreate | fmShareDenyRead));
        try
        {
          NewFile->CopyFrom(OldFile, OldFile->Size);
        }
        __finally
        {
          FreeAndNil(&NewFile);
        };
      }
      __finally
      {
        FreeAndNil(&OldFile);
      };
    };
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Image1->Picture->LoadFromFile("../factory.bmp");
  }
  /*
  The following code allows the user to use a dialog box to
  redefine the icon for the application at run time. When the
  user clicks Button1, OpenDialog1 executes and the user
  specifies an icon filename. The Icon is then assigned to the
  application.  At runtime, click Button1 to select the icon,
  then minimize the application to see the icon.
  */
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
    OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
    OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
    OpenPictureDialog1->Options.Clear();
    OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
    while (true)
    {
      if (OpenPictureDialog1->Execute())
      {
        if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
        {
          Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
          break;
        }
        else // reset Options to remove ofExtensionDifferent
        {
          OpenPictureDialog1->Options.Clear();
          OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
        }
      }
      else // user cancelled
        break;
    }
  }
```

Delphi Examples:

```
  {
  This code displays a Save Picture dialog box with the
  TBitmap default extension that is added automatically to
  files that are given no extension. Confirm that the
  bitmap file has been saved under the filename and path
  specified.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var NewFileName, OldFileName: string;
```

```
    NewFile, OldFile: TFileStream;
begin
  SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
  SavePictureDialog1.Filter := GraphicFilter(TBitmap);
  OldFileName := 'factory.bmp';
  if SavePictureDialog1.Execute then
  begin
    NewFileName := SavePictureDialog1.FileName;
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Picture.LoadFromFile('factory.bmp');
end;
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
```

FilterIndex (see page 11434)

GraphicFilter (see page 14624)

69.1.1.4.2 TOpenPictureDialog.ImageCtrl Property

Pascal

```
property ImageCtrl: TImage;
```

C++

```
__property TImage ImageCtrl;
```

Description

This is ImageCtrl, a member of class TOpenPictureDialog.

69.1.1.4.3 TOpenPictureDialog.PictureLabel Property

Pascal

```
property PictureLabel: TLabel;
```

C++

```
__property TLabel PictureLabel;
```

Description

This is PictureLabel, a member of class TOpenPictureDialog.

69.1.2 TOpenTextFileDialog Class

Class Hierarchy

Pascal

```
TOpenTextFileDialog = class(TOpenDialog);
```

C++

```
class TOpenTextFileDialog : public TOpenDialog;
```

File

ExtDlgs

Description

This is class ExtDlgs.TOpenTextFileDialog.

69.1.2.1 TOpenTextFileDialog Members

The following tables list the members exposed by TOpenTextFileDialog.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CanClose (see page 11413)	This is CanClose, a member of class TOpenDialog.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 11413)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoCanClose (see page 11413)	This is DoCanClose, a member of class TOpenDialog.
V	DoClose (see page 13297)	Generates an OnClose event.
	DoExecute (see page 11413)	This is the overview for the DoExecute method overload.
	DoFolderChange (see page 11414)	This is DoFolderChange, a member of class TOpenDialog.
	DoIncludeItem (see page 11414)	This is DoIncludeItem, a member of class TOpenDialog.
	DoSelectionChange (see page 11415)	This is DoSelectionChange, a member of class TOpenDialog.
V	DoShow (see page 13297)	Generates an OnShow event.
	DoTypeChange (see page 11415)	This is DoTypeChange, a member of class TOpenDialog.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetFileNames (see page 11417)	This is GetFileNames, a member of class TOpenDialog.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetStaticRect (see page 11417)	Returns the coordinates of the reserved area of the dialog box.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	MessageHook (see page 11284)	Provides special Windows message processing for the dialog.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	TaskModalDialog (see page 11284)	Ensures that Windows messages are properly routed when the dialog executes.

	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WndProc (see page 11285)	Responds to Windows messages sent to the dialog.
V	WndProc (see page 11420)	Responds to Windows messages sent to the dialog.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	Template (see page 11287)	Points to a custom template for the dialog.
	TemplateModule (see page 11287)	This is TemplateModule, a member of class TCommonDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 13296)	Creates and initializes a TOpenDialog instance.
V	DefaultHandler (see page 11282)	Sends unhandled messages to Windows for processing.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 13296)	Destroys the TOpenDialog and frees its memory.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Execute (see page 13298)	Displays the file-selection dialog.
V	Execute (see page 11283)	This is the overview for the Execute method overload.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	FileEditStyle (see page 11423)	Determines the style of the file-selection dialog. (Obsolete.)
R	Files (see page 11429)	List of selected file names.
R	Handle (see page 11286)	Specifies the window handle of the dialog.
	HistoryList (see page 11436)	Maintains a list of previously selected files. (Obsolete.)
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCanClose (see page 11439)	Occurs when the user tries to close the dialog without canceling.
	OnClose (see page 11287)	Occurs when the dialog closes.
	OnFolderChange (see page 11440)	Occurs when a directory is opened or closed from the dialog.
	OnIncludeItem (see page 11440)	Occurs before the dialog adds a file to the file list box.
	OnSelectionChange (see page 11441)	Occurs when file names displayed in the dialog are changed.
	OnShow (see page 11288)	Occurs when the dialog opens.

	OnTypeChange (see page 11441)	Occurs when the file types displayed in the dialog are changed.

Published Properties

	Name	Description
	Ctl3D (see page 11285)	Determines whether the dialog has a three-dimensional look.
	DefaultExt (see page 11421)	Specifies a default file extension.
	EncodingIndex (see page 13300)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 13300)	This is Encodings, a member of class TOpenTextFileDialog.
	FileName (see page 11424)	Indicates the name and directory path of the last file selected.
	Filter (see page 11431)	Determines the file masks (filters) available in the dialog.
	FilterIndex (see page 11434)	Determines which filter is selected by default when the dialog opens.
	HelpContext (see page 11286)	Specifies the context number for online Help.
	InitialDir (see page 11436)	Determines the current directory when the dialog opens.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 11436)	Determines the appearance and behavior of the file-selection dialog.
	OptionsEx (see page 11438)	Augments the Options (see page 11436) property with additional flags that determine the appearance and behavior of the file-selection dialog.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Title (see page 11438)	Specifies the text in the dialog's title bar.

69.1.2.2 TOpenTextFileDialog.Create Constructor

Creates and initializes a TOpenDialog instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOpenTextFileDialog(TComponent * AOwner);
```

Description

Create generates a TOpenDialog instance, but the new dialog does not appear on the form at runtime until the Execute method is called.

AOwner is the component that is responsible for freeing the TOpenDialog instance. It becomes the value of the Owner property.

See Also

Execute (see page 11415)

Owner (see page 2807)

Destroy (see page 11412)

69.1.2.3 TOpenTextFileDialog.Destroy Destructor

Destroys the TOpenDialog and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOpenTextFileDialog();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the TOpenDialog reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Create (see page 11411)

69.1.2.4 TOpenTextFileDialog Methods

The methods of the TOpenTextFileDialog class are listed here.

Protected Methods

	Name	Description
	DoClose (see page 13297)	Generates an OnClose event.
	DoShow (see page 13297)	Generates an OnShow event.

Public Methods

	Name	Description
	Execute (see page 13298)	Displays the file-selection dialog.

69.1.2.4.1 TOpenTextFileDialog.DoClose Method

Generates an OnClose event.

Pascal

```
procedure DoClose; override;
```

C++

```
virtual __fastcall DoClose();
```

Description

DoClose is called automatically when the user closes the dialog. Override this method to provide additional processing other than calling the OnClose event handler. For example, to perform shutdown operations that use protected methods of the dialog class, override DoClose rather than writing an OnClose event handler (which can access only public methods).

See Also

OnClose (see page 11287)

69.1.2.4.2 TOpenTextFileDialog.DoShow Method

Generates an OnShow event.

Pascal

```
procedure DoShow; override;
```

C++

```
virtual __fastcall DoShow();
```

Description

DoShow is called automatically when the dialog is first displayed. Override this method to provide additional processing other

than calling the OnShow event handler. For example, to perform initializations that use protected methods of the dialog class, override DoShow rather than writing an OnShow event handler (which can access only public methods).

See Also

OnShow (see page 11288)

69.1.2.4.3 TOpenTextFileDialog.Execute Method

Displays the file-selection dialog.

Pascal

```
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the file-selection dialog, returning true when the user selects a file and clicks Open. If the user clicks Cancel, Execute returns false.

```
if OpenDialog1.Execute then
  Memo1.Lines.LoadFromFile(OpenDialog1.FileName)
else
  Memo1.Lines.Clear;
if (OpenDialog1->Execute())
  Memo1->Lines->LoadFromFile(OpenDialog1->FileName);
else
  Memo1->Clear();
```

C++ Examples:

```
/*
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
  OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
  OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
  OpenPictureDialog1->Options.Clear();
  OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
  while (true)
  {
    if (OpenPictureDialog1->Execute())
    {
      if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
      {
        Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
        break;
      }
      else // reset Options to remove ofExtensionDifferent
      {
        OpenPictureDialog1->Options.Clear();
        OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
      }
    }
    else // user cancelled
      break;
```

```
  }
}
```

Delphi Examples:

```
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
{
Use a TOpenDialog to select a file.  Place the first line of
the file into a TEdit.
}
procedure TForm1.Edit1Click(Sender: TObject);
var
  F: TextFile;
  S: string;
begin
  if OpenDialog1.Execute then            { Display Open dialog box }
  begin
    AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
    Reset(F);
    Readln(F, S);                        { Read first line of file }
    Edit1.Text := S;                     { Put string in a TEdit control }
    CloseFile(F);
  end;
end;
```

69.1.2.5 TOpenTextFileDialog Properties

The properties of the TOpenTextFileDialog class are listed here.

Published Properties

	Name	Description
	EncodingIndex (see page 13300)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 13300)	This is Encodings, a member of class TOpenTextFileDialog.

69.1.2.5.1 TOpenTextFileDialog.EncodingIndex Property

Pascal

```
property EncodingIndex: Integer;
```

C++

```
__property int EncodingIndex;
```

Description

This is EncodingIndex, a member of class TOpenTextFileDialog.

69.1.2.5.2 TOpenTextFileDialog.Encodings Property

Pascal

```
property Encodings: TStrings;
```

C++

```
__property TStrings Encodings;
```

Description

This is Encodings, a member of class TOpenTextFileDialog.

69.1.3 TSavePictureDialog Class

TSavePictureDialog displays a "Save As" dialog for saving graphics files.

Class Hierarchy

Pascal

```
TSavePictureDialog = class(TOpenPictureDialog);
```

C++

```
class TSavePictureDialog : public TOpenPictureDialog;
```

File

ExtDlgs

Description

TSavePictureDialog displays a modal Windows dialog box for selecting file names and saving graphics files. This component is just like TSaveDialog, except that it includes a rectangular preview region. If the selected image can be read by TPicture, it is displayed in the preview region; supported file types include bitmap (.BMP), icon (.ICO), Windows metafile (.WMF), and enhanced Windows metafile (.EMF). If the selected image cannot be displayed, "(None)" appears in the preview region.

See Also

TOpenPictureDialog (see page 13282)

TPicture (see page 14584)

TSaveDialog (see page 11489)

69.1.3.1 TSavePictureDialog Members

The following tables list the members exposed by TSavePictureDialog.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CanClose (see page 11413)	This is CanClose, a member of class TOpenDialog.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 11413)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoCanClose (see page 11413)	This is DoCanClose, a member of class TOpenDialog.
	DoClose (see page 11282)	Generates an OnClose (see page 11287) event.
V	DoClose (see page 13287)	Generates an OnClose event.
	DoExecute (see page 11413)	This is the overview for the DoExecute method overload.
	DoFolderChange (see page 11414)	This is DoFolderChange, a member of class TOpenDialog.
	DoIncludeItem (see page 11414)	This is DoIncludeItem, a member of class TOpenDialog.
	DoSelectionChange (see page 11415)	This is DoSelectionChange, a member of class TOpenDialog.
V	DoSelectionChange (see page 13287)	This is DoSelectionChange, a member of class TOpenPictureDialog.
	DoShow (see page 11283)	Generates an OnShow (see page 11288) event.
V	DoShow (see page 13287)	Generates an OnShow event.
	DoTypeChange (see page 11415)	This is DoTypeChange, a member of class TOpenDialog.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetFileNames (see page 11417)	This is GetFileNames, a member of class TOpenDialog.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

V	GetStaticRect (see page 11417)	Returns the coordinates of the reserved area of the dialog box.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	MessageHook (see page 11284)	Provides special Windows message processing for the dialog.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	PreviewClick (see page 13288)	This is PreviewClick, a member of class TOpenPictureDialog.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	TaskModalDialog (see page 11284)	Ensures that Windows messages are properly routed when the dialog executes.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WndProc (see page 11285)	Responds to Windows messages sent to the dialog.
V	WndProc (see page 11420)	Responds to Windows messages sent to the dialog.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
R	ImageCtrl (see page 13292)	This is ImageCtrl, a member of class TOpenPictureDialog.
R	PictureLabel (see page 13292)	This is PictureLabel, a member of class TOpenPictureDialog.
	Template (see page 11287)	Points to a custom template for the dialog.
	TemplateModule (see page 11287)	This is TemplateModule, a member of class TCommonDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 11281)	Creates and initializes a TCommonDialog (see page 11277) instance.
V	Create (see page 11411)	Creates and initializes a TOpenDialog (see page 11407) instance.
V	Create (see page 13286)	Creates and initializes a TOpenPictureDialog (see page 13282) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 11282)	Sends unhandled messages to Windows for processing.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 11281)	Destroys the TCommonDialog (see page 11277) instance and frees its memory.
V	Destroy (see page 11412)	Destroys the TOpenDialog (see page 11407) and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Execute (see page 13305)	Displays the Save As dialog box.
V	Execute (see page 11283)	This is the overview for the Execute method overload.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.

	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	FileEditStyle (see page 11423)	Determines the style of the file-selection dialog. (Obsolete.)
R	Files (see page 11429)	List of selected file names.
R	Handle (see page 11286)	Specifies the window handle of the dialog.
	HistoryList (see page 11436)	Maintains a list of previously selected files. (Obsolete.)
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCanClose (see page 11439)	Occurs when the user tries to close the dialog without canceling.
	OnClose (see page 11287)	Occurs when the dialog closes.
	OnFolderChange (see page 11440)	Occurs when a directory is opened or closed from the dialog.
	OnIncludeItem (see page 11440)	Occurs before the dialog adds a file to the file list box.
	OnSelectionChange (see page 11441)	Occurs when file names displayed in the dialog are changed.
	OnShow (see page 11288)	Occurs when the dialog opens.
	OnTypeChange (see page 11441)	Occurs when the file types displayed in the dialog are changed.

Published Properties

	Name	Description
	Ctl3D (see page 11285)	Determines whether the dialog has a three-dimensional look.
	DefaultExt (see page 11421)	Specifies a default file extension.
	FileName (see page 11424)	Indicates the name and directory path of the last file selected.
	Filter (see page 11431)	Determines the file masks (filters) available in the dialog.
	Filter (see page 13289)	Determines the file masks (filters) available in the dialog.
	FilterIndex (see page 11434)	Determines which filter is selected by default when the dialog opens.
	HelpContext (see page 11286)	Specifies the context number for online Help.
	InitialDir (see page 11436)	Determines the current directory when the dialog opens.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 11436)	Determines the appearance and behavior of the file-selection dialog.
	OptionsEx (see page 11438)	Augments the Options (see page 11436) property with additional flags that determine the appearance and behavior of the file-selection dialog.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Title (see page 11438)	Specifies the text in the dialog's title bar.

69.1.3.2 TSavePictureDialog Methods

The methods of the TSavePictureDialog class are listed here.

Public Methods

	Name	Description
	Execute (see page 13305)	Displays the Save As dialog box.

69.1.3.2.1 TSavePictureDialog.Execute Method

Displays the Save As dialog box.

Pascal

```
function Execute: Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute();
```

Description

Execute opens the Save As dialog, returning true when the user selects a file name and clicks Save.

69.1.4 TSaveTextFileDialog Class

Class Hierarchy

Pascal

```
TSaveTextFileDialog = class(TOpenTextFileDialog);
```

C++

```
class TSaveTextFileDialog : public TOpenTextFileDialog;
```

File

ExtDlgs

Description

This is class ExtDlgs.TSaveTextFileDialog.

69.1.4.1 TSaveTextFileDialog Members

The following tables list the members exposed by TSaveTextFileDialog.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	CanClose (see page 11413)	This is CanClose, a member of class TOpenDialog.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 11413)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DoCanClose (see page 11413)	This is DoCanClose, a member of class TOpenDialog.
	DoClose (see page 11282)	Generates an OnClose (see page 11287) event.
V	DoClose (see page 13297)	Generates an OnClose event.
	DoExecute (see page 11413)	This is the overview for the DoExecute method overload.
	DoFolderChange (see page 11414)	This is DoFolderChange, a member of class TOpenDialog.
	DoIncludeItem (see page 11414)	This is DoIncludeItem, a member of class TOpenDialog.
	DoSelectionChange (see page 11415)	This is DoSelectionChange, a member of class TOpenDialog.
	DoShow (see page 11283)	Generates an OnShow (see page 11288) event.
V	DoShow (see page 13297)	Generates an OnShow event.
	DoTypeChange (see page 11415)	This is DoTypeChange, a member of class TOpenDialog.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetFileNames (see page 11417)	This is GetFileNames, a member of class TOpenDialog.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetStaticRect (see page 11417)	Returns the coordinates of the reserved area of the dialog box.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	MessageHook (see page 11284)	Provides special Windows message processing for the dialog.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	TaskModalDialog (see page 11284)	Ensures that Windows messages are properly routed when the dialog executes.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.

	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WndProc (see page 11285)	Responds to Windows messages sent to the dialog.
	WndProc (see page 11420)	Responds to Windows messages sent to the dialog.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	Template (see page 11287)	Points to a custom template for the dialog.
	TemplateModule (see page 11287)	This is TemplateModule, a member of class TCommonDialog.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 11281)	Creates and initializes a TCommonDialog (see page 11277) instance.
	Create (see page 11411)	Creates and initializes a TOpenDialog (see page 11407) instance.
	Create (see page 13296)	Creates and initializes a TOpenDialog instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 11282)	Sends unhandled messages to Windows for processing.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 11281)	Destroys the TCommonDialog (see page 11277) instance and frees its memory.
	Destroy (see page 11412)	Destroys the TOpenDialog (see page 11407) and frees its memory.
	Destroy (see page 13296)	Destroys the TOpenDialog and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Execute (see page 13309)	Displays the dialog box.
	Execute (see page 11283)	This is the overview for the Execute method overload.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	FileEditStyle (see page 11423)	Determines the style of the file-selection dialog. (Obsolete.)
R	Files (see page 11429)	List of selected file names.
R	Handle (see page 11286)	Specifies the window handle of the dialog.
	HistoryList (see page 11436)	Maintains a list of previously selected files. (Obsolete.)
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Events

	Name	Description
	OnCanClose (see page 11439)	Occurs when the user tries to close the dialog without canceling.
	OnClose (see page 11287)	Occurs when the dialog closes.
	OnFolderChange (see page 11440)	Occurs when a directory is opened or closed from the dialog.
	OnIncludeItem (see page 11440)	Occurs before the dialog adds a file to the file list box.
	OnSelectionChange (see page 11441)	Occurs when file names displayed in the dialog are changed.
	OnShow (see page 11288)	Occurs when the dialog opens.
	OnTypeChange (see page 11441)	Occurs when the file types displayed in the dialog are changed.

Published Properties

	Name	Description
	Ctl3D (see page 11285)	Determines whether the dialog has a three-dimensional look.
	DefaultExt (see page 11421)	Specifies a default file extension.
	EncodingIndex (see page 13300)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 13300)	This is Encodings, a member of class TOpenTextFileDialog.
	FileName (see page 11424)	Indicates the name and directory path of the last file selected.
	Filter (see page 11431)	Determines the file masks (filters) available in the dialog.
	FilterIndex (see page 11434)	Determines which filter is selected by default when the dialog opens.
	HelpContext (see page 11286)	Specifies the context number for online Help.
	InitialDir (see page 11436)	Determines the current directory when the dialog opens.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 11436)	Determines the appearance and behavior of the file-selection dialog.
	OptionsEx (see page 11438)	Augments the Options (see page 11436) property with additional flags that determine the appearance and behavior of the file-selection dialog.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Title (see page 11438)	Specifies the text in the dialog's title bar.

69.1.4.2 TSaveTextFileDialog Methods

The methods of the TSaveTextFileDialog class are listed here.

Public Methods

	Name	Description
	Execute (see page 13309)	Displays the dialog box.

69.1.4.2.1 TSaveTextFileDialog.Execute Method

Displays the dialog box.

Pascal

```
function Execute: Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute();
```

Description

TCommonDialog introduces the abstract Execute method, which descendant classes use to open the dialog instance at runtime. Generally, Execute returns true when the user makes a selection and clicks OK, and returns false when the user closes the dialog without making a selection.

TaskModalDialog (see page 11284)

69.2 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DefaultEncodingNames (see page 13310)	This is constant ExtDlgs.DefaultEncodingNames.

69.2.1 ExtDlgs.DefaultEncodingNames Constant

Pascal

```
DefaultEncodingNames: array[0..5] of string = (SANSIEncoding, SASCIIEncoding,
SUnicodeEncoding, SBigEndianEncoding, SUTF8Encoding, SUTF7Encoding);
```

C++

```
array[0..5] of string DefaultEncodingNames = (SANSIEncoding, SASCIIEncoding, SUnicodeEncoding,
SBigEndianEncoding, SUTF8Encoding, SUTF7Encoding);
```

File

ExtDlgs

Description

This is constant ExtDlgs.DefaultEncodingNames.

70 FileCtrl Namespace

This is namespace FileCtrl.

Topics

Name	Description
Classes (see page 13313)	The following table lists classes in this documentation.
Functions (see page 13616)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 13620)	The following table lists structs, records, enums in this documentation.
Types (see page 13624)	The following table lists types in this documentation.
Constants (see page 13626)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDirectoryListBox (see page 13313)	TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.
	TDriveComboBox (see page 13396)	TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.
	TFileListBox (see page 13465)	TFileListBox is a specialized list box that lists all the files in a specified directory.
	TFilterComboBox (see page 13547)	TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

Constants

Name	Description
WNTYPE_DRIVE (see page 13626)	This is constant FileCtrl.WNTYPE_DRIVE.

Functions

	Name	Description
	DirectoryExists (see page 13616)	Determines whether a specified directory exists.
	ForceDirectories (see page 13617)	Creates a new directory, including the creation of parent directories as needed.
	MinimizeName (see page 13617)	Shortens a fully qualified path name so that it can be drawn with a specified length limit.
	ProcessPath (see page 13618)	Parses a file name into its constituent parts.
	SelectDirectory (see page 13619)	Brings up a dialog to allow the user to enter a directory name.
	SelectDirectory (see page 13619)	Brings up a dialog to allow the user to enter a directory name.

Structs, Records, Enums

	Name	Description
	TDriveType (see page 13620)	This is record FileCtrl.TDriveType.
	TFileAttr (see page 13620)	TFileAttr and TFileType (see page 13624) determine which files a file list box displays.
	TSelectDirExtOpt (see page 13621)	This is record FileCtrl.TSelectDirExtOpt.
	TSelectDirOpt (see page 13622)	TSelectDirOpt and TSelectDirOpts (see page 13625) determine how a directory selection dialog responds when the user enters a nonexistent directory.
	TTextCase (see page 13623)	TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

Types

Name	Description
TFileType (see page 13624)	TFileType describes possible combinations of file attributes.
TSelectDirExtOpts (see page 13624)	This is type FileCtrl.TSelectDirExtOpts.
TSelectDirOpts (see page 13625)	This is type FileCtrl.TSelectDirOpts.

70.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDirectoryListBox (see page 13313)	TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.
	TDriveComboBox (see page 13396)	TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.
	TFileListBox (see page 13465)	TFileListBox is a specialized list box that lists all the files in a specified directory.
	TFilterComboBox (see page 13547)	TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

70.1.1 TDirectoryListBox Class

TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.

Class Hierarchy

Pascal

```
TDirectoryListBox = class(TCustomListBox);
```

C++

```
class TDirectoryListBox : public TCustomListBox;
```

File

FileCtrl

Description

TDirectoryListBox implements the generic behavior introduced in TCustomListBox. TDirectoryListBox publishes many of the properties inherited from TCustomListBox and introduces new behavior to let the user change directories or drives.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
```

```
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

TFilterComboBox (see page 13547)

TCustomListBox (see page 21308)

70.1.1.1 TDirectoryListBox Members

The following tables list the members exposed by TDirectoryListBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnData (see page 21357)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 21357)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 21358)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDrawItem (see page 21358)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMeasureItem (see page 21360)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.

	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	ClosedBMP (see page 13327)	This is ClosedBMP, a member of class TDirectoryListBox.
	CurrentBMP (see page 13327)	This is CurrentBMP, a member of class TDirectoryListBox.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDirectory (see page 13327)	This is FDirectory, a member of class TDirectoryListBox.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FMoving (see page 21321)	This is FMoving, a member of class TCustomListBox.
	FMultiSelect (see page 5956)	This is FMultiSelect, a member of class TCustomMultiSelectListControl.
	FOnChange (see page 13328)	This is FOnChange, a member of class TDirectoryListBox.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	OpenedBMP (see page 13328)	This is OpenedBMP, a member of class TDirectoryListBox.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BuildList (see page 13329)	This is BuildList, a member of class TDirectoryListBox.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.

	Change (see page 13329)	This is Change, a member of class TDirectoryListBox.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 21324)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 13329)	Creates a Windows control corresponding to the list box component.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 13330)	OnDblClick event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DeleteString (see page 21326)	Deletes a string from the list box.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21326)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFindData (see page 21326)	Returns the index of a string in the list box.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoGetData (see page 21327)	Returns a string in the list box given its index.
	DoGetDataObject (see page 21327)	Returns the object associated with an item in a virtual list box.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.

	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
V	DragCanceled (see page 21328)	Sends a mouse message canceling the drag-and-drop operation.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
V	DrawItem (see page 13330)	Generates an OnDrawItem event.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetCount (see page 21329)	Returns the value of the Count (see page 21346) property.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetItemData (see page 21329)	Returns a 32-bit value associated with the specified item in a list box.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetItemIndex (see page 21329)	Returns the value of the ItemIndex property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
A	GetSelCount (see page 5956)	Returns the value of the SelCount (see page 5957) property.
V	GetSelCount (see page 21330)	Returns the number of selected items.
	GetSelected (see page 21330)	Indicates whether a particular item is selected.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event

	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InternalGetItemData (see page 21330)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 21330)	Associates an integer with a specified item in the list box.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
V	KeyPress (see page 13331)	Responds when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	LoadRecreateItems (see page 21334)	This is LoadRecreateItems, a member of class TCustomListBox.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
V	MeasureItem (see page 21335)	Generates an OnMeasureItem (see page 21360) event.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 13332)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadBitmaps (see page 13333)	This is ReadBitmaps, a member of class TDirectoryListBox.
	ReadDirectoryNames (see page 13333)	This is ReadDirectoryNames, a member of class TDirectoryListBox.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetContent (see page 21335)	Removes all of the items from a list box.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	SaveRecreateItems (see page 21336)	This is SaveRecreateItems, a member of class TCustomListBox.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.

	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetItemData (see page 21336)	Sets the 32-bit value associated with the specified item in a list box.
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
V	SetItemIndex (see page 21336)	Gives focus to the item with a specified index.
A	SetMultiSelect (see page 5956)	Sets the value of the MultiSelect (see page 5957) property.
V	SetMultiSelect (see page 21337)	Sets the MultiSelect property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.

	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WndProc (see page 21337)	Handles Windows messages.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 21343)	Determines whether the list box has a border.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	ExtendedSelect (see page 21346)	This is ExtendedSelect, a member of class TCustomListBox.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Sorted (see page 21353)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 21354)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 21355)	Specifies the size of the tabs in the list box.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddItem (see page 5940)	Adds an item to the list control.
	AddItem (see page 21322)	Adds an item to the list box
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 5940)	Deletes all of the items from the list control.
V	Clear (see page 21322)	Deletes all items from the list box.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
V	ClearSelection (see page 21323)	Deselects all selected items in the list box, if possible.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
V	CopySelection (see page 21323)	Copies the selected items to another list-type control
V	Create (see page 13326)	Creates and initializes a directory list box.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	DeleteSelected (see page 21325)	Deletes the selected items from the list box
V	Destroy (see page 13326)	Disposes of an instance of a directory list box.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DisplayCase (see page 13330)	Preserves or converts the case of the string passed to it.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FileCompareText (see page 13331)	Compares two strings, taking into account the case-sensitivity of the file system.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.

	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetItemPath (see page 13331)	This is GetItemPath, a member of class TDirectoryListBox.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ItemAtPos (see page 21331)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 21333)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MoveSelection (see page 5942)	Moves all selected items to another list control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	OpenCurrent (see page 13332)	Opens the selected directory.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)

V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.
V	SelectAll (see page 21336)	Selects the entire block of text in the list box.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Update (see page 13333)	Refreshes the directory list.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	AutoCompleteDelay (see page 21342)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 21343)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 21358) event of an owner-draw list box.
R	CaseSensitive (see page 13342)	Indicates whether the system supports case-sensitive directory information.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.

	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Count (see page 21346)	Indicates the number of items in the list box.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	Directory (see page 13344)	Determines the current directory for the directory list box control.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Drive (see page 13349)	Determines the drive for which the list box displays the directory structure.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	Items (see page 21348)	Contains the strings that appear in the list box.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	MultiSelect (see page 5957)	Specifies whether the user can select more than one item.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	PreserveCase (see page 13362)	Indicates whether the file system preserves the case of file names when writing to disk.
	ScrollWidth (see page 21351)	Specifies the width, in pixels, by which the list box can scroll horizontally.
R	SelCount (see page 5957)	Indicates the number of selected items.
	Selected (see page 21351)	Indicates whether a particular item is selected.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopIndex (see page 21356)	Specifies the index number of the item that appears at the top of the list box.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 13367)	Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.
	OnClick (see page 13369)	Occurs when the user clicks the control.
	OnContextPopup (see page 13371)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13371)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

	OnDragDrop (see page 13372)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13374)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 13376)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13377)	Occurs when a control receives the input focus.
	OnExit (see page 13380)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13381)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13384)	Occurs when a key is pressed.
	OnKeyUp (see page 13385)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13387)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13388)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13390)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13391)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13391)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13393)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 13395)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 13336)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13339)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13340)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 13340)	Specifies which edges of the control are beveled.
	BevelInner (see page 13340)	Specifies the cut of the inner bevel.
	BevelKind (see page 13341)	Specifies the control's bevel style.
	BevelOuter (see page 13341)	Specifies the cut of the outer bevel.
	Color (see page 13342)	Specifies the background color of the control.
	Columns (see page 13343)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 13343)	Specifies the size constraints for the control.
	Ctl3D (see page 13344)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DirLabel (see page 13346)	Provides a simple way to display the current directory as the caption of a label control.
	DragCursor (see page 13347)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13347)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13350)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 13350)	Provides a simple way to connect a directory list box with a file list box.
	Font (see page 13353)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 13354)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13354)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 13355)	Determines whether the list box displays the partial items.

	ItemHeight (see page 13355)	Specifies the height in pixels of an item in an owner-draw list box.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 13356)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13356)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13357)	Determines where a control looks for its font information.
	ParentShowHint (see page 13357)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13358)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13363)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13364)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13365)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13365)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

70.1.1.2 TDirectoryListBox.Create Constructor

Creates and initializes a directory list box.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDirectoryListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a directory list box at runtime. For directory list boxes created at design time, Create is called automatically.

See Also

Create (see page 21320)

Sorted (see page 21353)

Style (see page 21354)

ParentWindow (see page 6210)

70.1.1.3 TDirectoryListBox.Destroy Destructor

Disposes of an instance of a directory list box.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDirectoryListBox();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free checks that the list box reference is not nil before it calls Destroy.

Destroy frees the bitmaps used for the Open, Close and Current folders, and then calls the inherited Destroy method.

See Also

Destroy (see page 21320)

70.1.1.4 TDirectoryListBox Fields

The fields of the TDirectoryListBox class are listed here.

Protected Fields

	Name	Description
	ClosedBMP (see page 13327)	This is ClosedBMP, a member of class TDirectoryListBox.
	CurrentBMP (see page 13327)	This is CurrentBMP, a member of class TDirectoryListBox.
	FDirectory (see page 13327)	This is FDirectory, a member of class TDirectoryListBox.
	FOnChange (see page 13328)	This is FOnChange, a member of class TDirectoryListBox.
	OpenedBMP (see page 13328)	This is OpenedBMP, a member of class TDirectoryListBox.

70.1.1.4.1 TDirectoryListBox.ClosedBMP Field

Pascal

```
ClosedBMP: TBitmap;
```

C++

```
TBitmap ClosedBMP;
```

Description

This is ClosedBMP, a member of class TDirectoryListBox.

70.1.1.4.2 TDirectoryListBox.CurrentBMP Field

Pascal

```
CurrentBMP: TBitmap;
```

C++

```
TBitmap CurrentBMP;
```

Description

This is CurrentBMP, a member of class TDirectoryListBox.

70.1.1.4.3 TDirectoryListBox.FDirectory Field

Pascal

```
FDirectory: string;
```

C++

```
AnsiString FDirectory;
```

Description

This is FDirectory, a member of class TDirectoryListBox.

70.1.1.4.4 TDirectoryListBox.FOnChange Field

Pascal

```
FOnChange: TNotifyEvent;
```

C++

```
TNotifyEvent FOnChange;
```

Description

This is FOnChange, a member of class TDirectoryListBox.

70.1.1.4.5 TDirectoryListBox.OpenedBMP Field

Pascal

```
OpenedBMP: TBitmap;
```

C++

```
TBitmap OpenedBMP;
```

Description

This is OpenedBMP, a member of class TDirectoryListBox.

70.1.1.5 TDirectoryListBox Methods

The methods of the TDirectoryListBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 13329)	This is BuildList, a member of class TDirectoryListBox.
	Change (see page 13329)	This is Change, a member of class TDirectoryListBox.
	CreateWnd (see page 13329)	Creates a Windows control corresponding to the list box component.
	DblClick (see page 13330)	OnDblClick event dispatcher.
	DrawItem (see page 13330)	Generates an OnDrawItem event.
	KeyPress (see page 13331)	Responds when the user presses a key.
	Notification (see page 13332)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 13333)	This is ReadBitmaps, a member of class TDirectoryListBox.
	ReadDirectoryNames (see page 13333)	This is ReadDirectoryNames, a member of class TDirectoryListBox.

Public Methods

	Name	Description
	DisplayCase (see page 13330)	Preserves or converts the case of the string passed to it.
	FileCompareText (see page 13331)	Compares two strings, taking into account the case-sensitivity of the file system.
	GetItemPath (see page 13331)	This is GetItemPath, a member of class TDirectoryListBox.
	OpenCurrent (see page 13332)	Opens the selected directory.
	Update (see page 13333)	Refreshes the directory list.

70.1.1.5.1 TDirectoryListBox.BuildList Method

Pascal

```
procedure BuildList; virtual;
```

C++

```
virtual __fastcall BuildList();
```

Description

This is BuildList, a member of class TDirectoryListBox.

70.1.1.5.2 TDirectoryListBox.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TDirectoryListBox.

70.1.1.5.3 TDirectoryListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns (see page 21346)

CreateHandle (see page 6135)

CreateParams (see page 21324)

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

ItemIndex

Items (see page 21348)

TabWidth (see page 21355)

TopIndex (see page 21356)

70.1.1.5.4 TDirectoryListBox.DblClick Method

OnDblClick event dispatcher.

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

DblClick calls any event handler attached to the OnDblClick event. Override DblClick to provide other responses in addition to the inherited event-handler call when the user double-clicks the control.

The DblClick method is triggered by left mouse-button double-click message (WM_LBUTTONDBLCLK) from Windows.

See Also

Click (see page 5743)

OnDblClick (see page 5854)

70.1.1.5.5 TDirectoryListBox.DisplayCase Method

Preserves or converts the case of the string passed to it.

Pascal

```
function DisplayCase(const S: String): String;
```

C++

```
__fastcall AnsiString DisplayCase(const AnsiString S);
```

Description

DisplayCase converts S to all-lower-case (using the currently installed language driver) if neither PreserveCase (see page 13362) nor CaseSensitive (see page 13342) is true. Otherwise, it returns S unmodified.

See Also

CaseSensitive (see page 13342)

PreserveCase (see page 13362)

70.1.1.5.6 TDirectoryListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight (see page 21347)

MeasureItem (see page 21335)

OnDrawItem (see page 21358)

OnMeasureItem (see page 21360)

Style (see page 21354)

70.1.1.5.7 TDirectoryListBox.FileCompareText Method

Compares two strings, taking into account the case-sensitivity of the file system.

Pascal

```
function FileCompareText(const A: String; const B: String): Integer;
```

C++

```
__fastcall int FileCompareText(const AnsiString A, const AnsiString B);
```

Description

If CaseSensitive (see page 13342) is false, FileCompareText compares the strings passed to it case-insensitively. Otherwise, it uses AnsiCompareStr to compare the strings.

See Also

AnsiCompareStr (see page 22789)

CaseSensitive (see page 13342)

70.1.1.5.8 TDirectoryListBox.GetItemPath Method

Pascal

```
function GetItemPath(Index: Integer): string;
```

C++

```
__fastcall AnsiString GetItemPath(int Index);
```

Description

This is GetItemPath, a member of class TDirectoryListBox.

70.1.1.5.9 TDirectoryListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress (see page 6227)

70.1.1.5.10 TDirectoryListBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

70.1.1.5.11 TDirectoryListBox.OpenCurrent Method

Opens the selected directory.

Pascal

```
procedure OpenCurrent;
```

C++

```
__fastcall OpenCurrent();
```

Description

OpenCurrent opens the directory selected in the directory list box, as if the user had double-clicked the directory.

C++ Examples:

```
/*
This example uses a directory list box, a button, and a
label on a form. When the user selects a directory in the
directory list box and clicks the button, the selected
directory opens, and the path of the second directory
displayed in the list box appears as the caption of the
label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DirectoryListBox1->OpenCurrent();
  Label1->Caption = DirectoryListBox1->GetItemPath(1);
}
```

Delphi Examples:

```
{
This example uses a directory list box, a button, and a
label on a form. When the user selects a directory in the
directory list box and clicks the button, the selected
directory opens, and the path of the second directory
displayed in the list box appears as the caption of the
label.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DirectoryListBox1.OpenCurrent;
  Label1.Caption := DirectoryListBox1.GetItemPath(1);
end;
```

70.1.1.5.12 TDirectoryListBox.ReadBitmaps Method

Pascal

```
procedure ReadBitmaps; virtual;
```

C++

```
virtual __fastcall ReadBitmaps();
```

Description

This is ReadBitmaps, a member of class TDirectoryListBox.

70.1.1.5.13 TDirectoryListBox.ReadDirectoryNames Method

Pascal

```
function ReadDirectoryNames(const ParentDirectory: string; DirectoryList: TStringList):
Integer;
```

C++

```
__fastcall int ReadDirectoryNames(const AnsiString ParentDirectory, TStringList DirectoryList);
```

Description

This is ReadDirectoryNames, a member of class TDirectoryListBox.

70.1.1.5.14 TDirectoryListBox.Update Method

Refreshes the directory list.

Pascal

```
procedure Update; reintroduce;
```

C++

```
__fastcall Update();
```

Description

Call Update to refresh the directory list after new directories have been created or existing directories deleted.

C++ Examples:

```
/*
The following sample code sets the directory of
DirectoryListBox1 to c:\\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
c:\\WINDOWS\\mytemp is added, but note that it is not updated
in DirectoryListBox1 until Button2 is pressed and Update is
called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current directory to see the magic happen.  Also,
capitalization matters in C++ and the file spearators must
be "\\".
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ForceDirectories(Edit1->Text);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  DirectoryListBox1->Update();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  DirectoryListBox1->Directory = "c:\\WINDOWS";
}
```

Delphi Examples:

```
{
The following sample code sets the directory of
DirectoryListBox1 to C:\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
mytemp is added to C:\WINDOWS, but note that it is not
updated in DirectoryListBox1 until Button2 is pressed
and Update is called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current path to see the magic happen.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  MkDir(Edit1.Text);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  DirectoryListBox1.Update;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
  DirectoryListBox1.Directory := 'c:\WINDOWS';
end;
```

70.1.1.6 TDirectoryListBox Properties

The properties of the TDirectoryListBox class are listed here.

Public Properties

	Name	Description
R	CaseSensitive (see page 13342)	Indicates whether the system supports case-sensitive directory information.
	Directory (see page 13344)	Determines the current directory for the directory list box control.
	Drive (see page 13349)	Determines the drive for which the list box displays the directory structure.
R	PreserveCase (see page 13362)	Indicates whether the file system preserves the case of file names when writing to disk.

Published Properties

	Name	Description
	Align (see page 13336)	Determines how the control aligns within its container (parent control).
	Anchors (see page 13339)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13340)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 13340)	Specifies which edges of the control are beveled.
	BevelInner (see page 13340)	Specifies the cut of the inner bevel.
	BevelKind (see page 13341)	Specifies the control's bevel style.
	BevelOuter (see page 13341)	Specifies the cut of the outer bevel.
	Color (see page 13342)	Specifies the background color of the control.
	Columns (see page 13343)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 13343)	Specifies the size constraints for the control.
	Ctl3D (see page 13344)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirLabel (see page 13346)	Provides a simple way to display the current directory as the caption of a label control.
	DragCursor (see page 13347)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13347)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13350)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 13350)	Provides a simple way to connect a directory list box with a file list box.
	Font (see page 13353)	Controls the attributes of text written on or in the control.
	ImeMode (see page 13354)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13354)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 13355)	Determines whether the list box displays the partial items.
	ItemHeight (see page 13355)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 13356)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13356)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13357)	Determines where a control looks for its font information.
	ParentShowHint (see page 13357)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13358)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13363)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13364)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13365)	Determines if the user can tab to a control.
	Visible (see page 13365)	Determines whether the component appears onscreen.

70.1.1.6.1 TDirectoryListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
```

```
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
```

```
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

70.1.1.6.2 TDirectoryListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

70.1.1.6.3 TDirectoryListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

70.1.1.6.4 TDirectoryListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

70.1.1.6.5 TDirectoryListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

70.1.1.6.6 TDirectoryListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

70.1.1.6.7 TDirectoryListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

70.1.1.6.8 TDirectoryListBox.CaseSensitive Property

Indicates whether the system supports case-sensitive directory information.

Pascal

```
property CaseSensitive: Boolean;
```

C++

```
__property Boolean CaseSensitive;
```

Description

Read CaseSensitive to ascertain whether the current file system supports case-sensitive file names. CaseSensitive returns true if it does and false if it does not.

See Also

DisplayCase (see page 13330)

FileCompareText (see page 13331)

PreserveCase (see page 13362)

70.1.1.6.9 TDirectoryListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

70.1.1.6.10 TDirectoryListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 21347)

Width (see page 5849)

70.1.1.6.11 TDirectoryListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

70.1.1.6.12 TDirectoryListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

70.1.1.6.13 TDirectoryListBox.Directory Property

Determines the current directory for the directory list box control.

Pascal

```
property Directory: string;
```

C++

```
__property AnsiString Directory;
```

Description

The directory list box displays the value of the Directory property as the current directory in the list box. The example shows how a directory list box and a file list box can work together through their Directory properties.

If the form contains a file list box, you can set the FileList (see page 13350) property to have the file list box automatically display the files from the directory specified by the Directory property.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

DirLabel (see page 13346)

Drive (see page 13349)

FileList (see page 13350)

70.1.1.6.14 TDirectoryListBox.DirLabel Property

Provides a simple way to display the current directory as the caption of a label control.

Pascal

```
property DirLabel: TLabel;
```

C++

```
__property TLabel DirLabel;
```

Description

Use DirLabel to specify a label. When the current directory changes in the directory list box, the change is reflected in the caption of the label.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
```

```
    FilterComboBox1.FileList := FileListBox1;
    DirectoryListBox1.FileList := FileListBox1;
    DirectoryListBox1.DirLabel := Label1;
    DriveComboBox1.DirList := DirectoryListBox1;
    Button1.Default := True;
  end;
```

70.1.1.6.15 TDirectoryListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

70.1.1.6.16 TDirectoryListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
```

```
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

70.1.1.6.17 TDirectoryListBox.Drive Property

Determines the drive for which the list box displays the directory structure.

Pascal

```
property Drive: Char;
```

C++

```
__property Char Drive;
```

Description

When the value of Drive changes, the Directory (see page 13344) value changes to the current directory on the specified drive.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
```

```
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

70.1.1.6.18 TDirectoryListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Enabling Mouse

70.1.1.6.19 TDirectoryListBox.FileList Property

Provides a simple way to connect a directory list box with a file list box.

Pascal

```
property FileList: TFileListBox;
```

C++

```
__property TFileListBox FileList;
```

Description

Use FileList to specify a file list box in which to display the files of the current directory.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

70.1.1.6.20 TDirectoryListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

70.1.1.6.21 TDirectoryListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

70.1.1.6.22 TDirectoryListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector

provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

Imes (see page 14227)

70.1.1.6.23 TDirectoryListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 21347)

Items (see page 21348)

Style (see page 21354)

Using TDBListBox and TDBComboBox

70.1.1.6.24 TDirectoryListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

See Also

Using TDBListBox and TDBComboBox

70.1.1.6.25 TDirectoryListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

70.1.1.6.26 TDirectoryListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

70.1.1.6.27 TDirectoryListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

70.1.1.6.28 TDirectoryListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

70.1.1.6.29 TDirectoryListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
```

```
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
```

```
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
```

```
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

Popup (see page 16174)

OnContextPopup (see page 5854)

70.1.1.6.30 TDirectoryListBox.PreserveCase Property

Indicates whether the file system preserves the case of file names when writing to disk.

Pascal

```
property PreserveCase: Boolean;
```

C++

```
__property Boolean PreserveCase;
```

Description

Read PreserveCase to ascertain whether the current file system preserves the case of file names. PreserveCase returns true if it does and false if it does not.

See Also

CaseSensitive (see page 13342)

DisplayCase (see page 13330)

70.1.1.6.31 TDirectoryListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

ShowHint (see page 13721)

Displaying Fly-over Help

70.1.1.6.32 TDirectoryListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

70.1.1.6.33 TDirectoryListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

70.1.1.6.34 TDirectoryListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
```

```
    PageControl1Change(Sender);
end;
```

70.1.1.7 TDirectoryListBox Events

The events of the TDirectoryListBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 13367)	Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.
	OnClick (see page 13369)	Occurs when the user clicks the control.
	OnContextPopup (see page 13371)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13371)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13372)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13374)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 13376)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13377)	Occurs when a control receives the input focus.
	OnExit (see page 13380)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13381)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13384)	Occurs when a key is pressed.
	OnKeyUp (see page 13385)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13387)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13388)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13390)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13391)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13391)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13393)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 13395)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

70.1.1.7.1 TDirectoryListBox.OnChange Event

Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to perform an action whenever a new directory is selected.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
```

```
    FileListBox1.Drive := DriveComboBox1.Drive;
    FileListBox1.Directory := DirectoryListBox1.Directory;
  end;
  {
  This example uses a file list box, a directory list box, and
  a label on a form. When the user uses the directory list box
  to change directories, a message appears and the color of
  the form changes if the file AUTOEXEC.BAT is in the new
  directory. The code is written in the OnChange event of the
  directory list box:
  }
  procedure TForm1.DirectoryListBox1Change(Sender: TObject);
  begin
    FileListBox1.Directory := DirectoryListBox1.Directory;
    if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
    begin
      Color := clYellow;
      Label1.Caption := 'You are in the root directory!';
    end
    else
    begin
      Color := clBtnFace;
      Label1.Caption := '';
    end;
  end;
```

70.1.1.7.2 TDirectoryListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
```

```
    PageControl1Change(Sender);
end;
```

70.1.1.7.3 TDirectoryListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

70.1.1.7.4 TDirectoryListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

70.1.1.7.5 TDirectoryListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
```

```
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.
```

```
procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.1.7.6 TDirectoryListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
```

```
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
```

```
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.1.7.7 TDirectoryListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

70.1.1.7.8 TDirectoryListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
```

```
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also

70.1.1.7.9 TDirectoryListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
```

```
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

OnEnter (see page 6219)

ActiveControl (see page 13896)

70.1.1.7.10 TDirectoryListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
```

```
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var

70.1.1.7.11 TDirectoryListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an

OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

70.1.1.7.12 TDirectoryListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
```

```
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;

70.1.1.7.13 TDirectoryListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level

form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

70.1.1.7.14 TDirectoryListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
```

```
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {

70.1.1.7.15 TDirectoryListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

70.1.1.7.16 TDirectoryListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

70.1.1.7.17 TDirectoryListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

70.1.1.7.18 TDirectoryListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
```

```
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
```

```
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

Responding to a Mouse-up Action

70.1.1.7.19 TDirectoryListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it

contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

70.1.2 TDriveComboBox Class

TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.

Class Hierarchy

Pascal

```
TDriveComboBox = class(TCustomComboBox);
```

C++

```
class TDriveComboBox : public TCustomComboBox;
```

File

FileCtrl

Description

Add TDriveComboBox to a form to allow users to select a drive. Use TDriveComboBox along with TFileListBox (see page 13465), TFilterComboBox (see page 13547), and TDirectoryListBox (see page 13313) to add full file selection capabilities to a form.

To add a standard Windows 95 file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

TOpenDialog (see page 11407)

TSaveDialog (see page 11489)

70.1.2.1 TDriveComboBox Members

The following tables list the members exposed by TDriveComboBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCloseUp (see page 21199)	Occurs when the drop-down list closes up due to some user action.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDrawItem (see page 21224)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMeasureItem (see page 21225)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnSelect (see page 21201)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	CDROMBMP (see page 13410)	This is CDROMBMP, a member of class TDriveComboBox.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDefEditProc (see page 21167)	This is FDefEditProc, a member of class TCustomCombo.
	FDefListProc (see page 21167)	This is FDefListProc, a member of class TCustomCombo.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FDropHandle (see page 21168)	This is FDropHandle, a member of class TCustomCombo.
	FDroppingDown (see page 21168)	This is FDroppingDown, a member of class TCustomCombo.

	FEditHandle (see page 21168)	This is FEditHandle, a member of class TCustomCombo.
	FEditInstance (see page 21168)	This is FEditInstance, a member of class TCustomCombo.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFocusChanged (see page 21168)	This is FFocusChanged, a member of class TCustomCombo.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FIsFocused (see page 21169)	This is FIsFocused, a member of class TCustomCombo.
	FixedBMP (see page 13410)	This is FixedBMP, a member of class TDriveComboBox.
	FListHandle (see page 21169)	This is FListHandle, a member of class TCustomCombo.
	FListInstance (see page 21169)	This is FListInstance, a member of class TCustomCombo.
	FloppyBMP (see page 13410)	This is FloppyBMP, a member of class TDriveComboBox.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveIndex (see page 21169)	This is FSaveIndex, a member of class TCustomCombo.
	NetworkBMP (see page 13410)	This is NetworkBMP, a member of class TDriveComboBox.
	RAMBMP (see page 13411)	This is RAMBMP, a member of class TDriveComboBox.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustDropDown (see page 21171)	Adjusts the size and position of the drop down list.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BuildList (see page 13411)	This is BuildList, a member of class TDriveComboBox.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 21171)	Generates an OnChange (see page 21197) event.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
V	Click (see page 13411)	Respond to user click.
	CloseUp (see page 21172)	Generates an OnCloseUp (see page 21199) event.
V	ComboWndProc (see page 21173)	Responds to Windows messages sent to the edit control or drop-down list.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.

	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 21215)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 13412)	Creates the Windows control that represents the combo box.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 21174)	Destroys all of the windows controls that implement the combo box.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21215)	Destroys the Windows control that represents the combo box.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	DrawItem (see page 13412)	Generates an OnDrawItem event.

	DropDown (see page 21175)	Generates an OnDropDown (see page 21199) event.
V	EditWndProc (see page 21175)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetCount (see page 21176)	Returns the value of the ItemCount (see page 21186) property.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetDroppedDown (see page 21176)	Returns the value of the DroppedDown (see page 21185) property.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
A	GetItemCount (see page 21176)	Returns the value of the ItemCount (see page 21186) property.
V	GetItemCount (see page 21216)	Returns the number of items in the Items (see page 21187) property list.
A	GetItemHt (see page 21177)	Returns the value of the ItemHeight (see page 21186) property.
V	GetItemHt (see page 21216)	Returns the value of the ItemHeight (see page 21186) property.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetItemIndex (see page 21177)	Returns the value of the ItemIndex property.
A	GetItemsClass (see page 21177)	Indicates the class that implements the Items (see page 21187) property.
V	GetItemsClass (see page 21217)	Returns the class used to implement the Items (see page 21187) property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSelLength (see page 21178)	Returns the value of the SelLength (see page 21190) property.
	GetSelStart (see page 21178)	Returns the value of the SelStart (see page 21193) property.
	GetSelText (see page 21217)	Returns the value of the SelText (see page 21222) property.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.

	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyPress (see page 21217)	Responds to WM_CHAR messages sent to the combo box.
	KeyUp (see page 6164)	Respond to released key.
	ListWndProc (see page 21178)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	Loaded (see page 21179)	Initializes the combo box after its form is loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MeasureItem (see page 21218)	Generates an OnMeasureItem (see page 21225) event.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 13413)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	Select (see page 21179)	Generates an OnSelect (see page 21201) event.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectItem (see page 21218)	Selects a specified item from the drop-down list.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.

	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetDropDownCount (see page 21180)	Sets the value of the DropDownCount (see page 21185) property.
	SetDroppedDown (see page 21180)	Sets the value of the DroppedDown (see page 21185) property.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetItemHeight (see page 21181)	Sets the value of the ItemHeight (see page 21186) property.
	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
	SetItemIndex (see page 21181)	Sets the value of the ItemIndex property.
	SetItems (see page 21181)	Sets the value of the Items (see page 21187) property.
	SetMaxLength (see page 21182)	Sets the value of the MaxLength (see page 21189) property.
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetSelLength (see page 21182)	Sets the value of the SelLength (see page 21190) property.
	SetSelStart (see page 21182)	Sets the value of the SelStart (see page 21193) property.
	SetStyle (see page 21219)	Sets the Style (see page 21224) property.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.

V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 21183)	Processes messages received by the combo box.
V	WndProc (see page 21219)	Processes messages received by the combo box.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DropDownCount (see page 21185)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 21185)	Returns the window handle for the edit portion of the combo box.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	ItemCount (see page 21186)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 21186)	Specifies the height, in pixels, of the items in the drop-down list.
R	ListHandle (see page 21189)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 21189)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Sorted (see page 21222)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 21224)	Determines the display style of the combo box.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
A	AddItem (see page 5940)	Adds an item to the list control.
V	AddItem (see page 21170)	Adds an item to the drop-down list of items.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 5940)	Deletes all of the items from the list control.
V	Clear (see page 21172)	Deletes all text from the edit box and all items from the Items (see page 21187) list.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
V	ClearSelection (see page 21172)	Deselects any selected items in the drop-down list.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
V	CopySelection (see page 21173)	Copies the selected item in the drop-down list to another list control.
V	Create (see page 13409)	Creates and initializes an instance of TDriveComboBox (see page 13396).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	DeleteSelected (see page 21174)	Deletes the selected item from the drop-down list.
V	Destroy (see page 13409)	Destroys an instance of TDriveComboBox (see page 13396).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
V	Focused (see page 21175)	Indicates whether the combo box has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MoveSelection (see page 5942)	Moves all selected items to another list control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.

V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.
V	SelectAll (see page 21180)	Selects the entire block of text in the edit box.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	AutoCloseUp (see page 21220)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoCompleteDelay (see page 21220)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 21184)	Provides access to the drawing surface of the combo box.
	CharCase (see page 21221)	Determines the case of the text in the combo box.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.

R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Drive (see page 13426)	Indicates the currently selected drive displayed in the edit portion of the combo box.
	DroppedDown (see page 21185)	Indicates whether the drop-down list is currently displayed.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	Items (see page 21187)	Provides access to the list of items (strings) in the list portion of the combo box.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelLength (see page 21190)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 21193)	Specifies the position of the first selected character in the edit portion of the combo box.
	SelText (see page 21222)	Represents the selected text in the edit region.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	Text (see page 13438)	Contains a text string associated with the control.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 13442)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 13444)	Occurs when the user clicks the control.
	OnContextPopup (see page 13446)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13446)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13447)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13449)	Occurs when the user drags an object over a control.
	OnDropDown (see page 13451)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 13453)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnEnter (see page 13454)	Occurs when a control receives the input focus.
	OnExit (see page 13456)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13458)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13461)	Occurs when a key is pressed.
	OnKeyUp (see page 13462)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 13464)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13464)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 13464)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 13414)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13417)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13418)	Positions to matching list items as you type.
	AutoDropDown (see page 13418)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 13419)	Specifies which edges of the control are beveled.
	BevelInner (see page 13419)	Specifies the cut of the inner bevel.
	BevelKind (see page 13420)	Specifies the control's bevel style.
	BevelOuter (see page 13420)	Specifies the cut of the outer bevel.
	Color (see page 13420)	Specifies the background color of the control.
	Constraints (see page 13421)	Specifies the size constraints for the control.
	Ctl3D (see page 13422)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DirList (see page 13422)	Connects the drive combo box to a directory list box.
	DragCursor (see page 13424)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13424)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13427)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 13427)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 13428)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13429)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 13429)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13430)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13430)	Determines where a control looks for its font information.
	ParentShowHint (see page 13431)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13431)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13436)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13437)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13438)	Determines if the user can tab to a control.

	Tag (see page 2808)	Stores an integer value as part of a component.
	TextCase (see page 13439)	Determines if the volume name in the Text (see page 13438) property appears in uppercase or lowercase.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13440)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

70.1.2.2 TDriveComboBox.Create Constructor

Creates and initializes an instance of TDriveComboBox (see page 13396).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDriveComboBox(TComponent * AOwner);
```

Description

Call Create to create a TDriveComboBox (see page 13396) object at runtime. Drive (see page 13426) combo boxes placed on a form at design time are created automatically.

After allocating the memory for the combo box, Create fills the combo box with all the drives on the system, and initializes the Drive (see page 13426) property to the current drive.

See Also

Drive (see page 13426)

Create (see page 21214)

70.1.2.3 TDriveComboBox.Destroy Destructor

Destroys an instance of TDriveComboBox (see page 13396).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDriveComboBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the drive combo box reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

70.1.2.4 TDriveComboBox Fields

The fields of the TDriveComboBox class are listed here.

Protected Fields

	Name	Description
	CDROMBMP (see page 13410)	This is CDROMBMP, a member of class TDriveComboBox.
	FixedBMP (see page 13410)	This is FixedBMP, a member of class TDriveComboBox.
	FloppyBMP (see page 13410)	This is FloppyBMP, a member of class TDriveComboBox.
	NetworkBMP (see page 13410)	This is NetworkBMP, a member of class TDriveComboBox.
	RAMBMP (see page 13411)	This is RAMBMP, a member of class TDriveComboBox.

70.1.2.4.1 TDriveComboBox.CDROMBMP Field

Pascal

```
CDROMBMP: TBitmap;
```

C++

```
TBitmap CDROMBMP;
```

Description

This is CDROMBMP, a member of class TDriveComboBox.

70.1.2.4.2 TDriveComboBox.FixedBMP Field

Pascal

```
FixedBMP: TBitmap;
```

C++

```
TBitmap FixedBMP;
```

Description

This is FixedBMP, a member of class TDriveComboBox.

70.1.2.4.3 TDriveComboBox.FloppyBMP Field

Pascal

```
FloppyBMP: TBitmap;
```

C++

```
TBitmap FloppyBMP;
```

Description

This is FloppyBMP, a member of class TDriveComboBox.

70.1.2.4.4 TDriveComboBox.NetworkBMP Field

Pascal

```
NetworkBMP: TBitmap;
```

C++

```
TBitmap NetworkBMP;
```

Description

This is NetworkBMP, a member of class TDriveComboBox.

70.1.2.4.5 TDriveComboBox.RAMBMP Field

Pascal

```
RAMBMP: TBitmap;
```

C++

```
TBitmap RAMBMP;
```

Description

This is RAMBMP, a member of class TDriveComboBox.

70.1.2.5 TDriveComboBox Methods

The methods of the TDriveComboBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 13411)	This is BuildList, a member of class TDriveComboBox.
	Click (see page 13411)	Respond to user click.
	CreateWnd (see page 13412)	Creates the Windows control that represents the combo box.
	DrawItem (see page 13412)	Generates an OnDrawItem event.
	Notification (see page 13413)	Responds to notifications that components are being created or destroyed.

70.1.2.5.1 TDriveComboBox.BuildList Method

Pascal

```
procedure BuildList; virtual;
```

C++

```
virtual __fastcall BuildList();
```

Description

This is BuildList, a member of class TDriveComboBox.

70.1.2.5.2 TDriveComboBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action (see page 5797)

OnExecute (see page 2716)

Execute (see page 2712)

DblClick (see page 5747)

OnClick (see page 5851)

70.1.2.5.3 TDriveComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle (see page 6135)

70.1.2.5.4 TDriveComboBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

When Style is csOwnerDrawFixed or csOwnerDrawVariable, DrawItem is called whenever an item in the list needs to be drawn. If an OnDrawItem event handler is assigned, DrawItem generates an OnDrawItem event, passing the Index, Rect, and State parameters to the event handler. Otherwise, OnDrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item, ignoring the State parameter.

Override DrawItem to provide class-specific drawing code for the items in the list.

See Also

OnDrawItem (see page 21224)

Style (see page 21224)

70.1.2.5.5 TDriveComboBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

70.1.2.6 TDriveComboBox Properties

The properties of the TDriveComboBox class are listed here.

Public Properties

	Name	Description
	Drive (see page 13426)	Indicates the currently selected drive displayed in the edit portion of the combo box.
	Text (see page 13438)	Contains a text string associated with the control.

Published Properties

	Name	Description
	Align (see page 13414)	Determines how the control aligns within its container (parent control).
	Anchors (see page 13417)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13418)	Positions to matching list items as you type.
	AutoDropDown (see page 13418)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 13419)	Specifies which edges of the control are beveled.
	BevelInner (see page 13419)	Specifies the cut of the inner bevel.
	BevelKind (see page 13420)	Specifies the control's bevel style.
	BevelOuter (see page 13420)	Specifies the cut of the outer bevel.
	Color (see page 13420)	Specifies the background color of the control.
	Constraints (see page 13421)	Specifies the size constraints for the control.
	Ctl3D (see page 13422)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirList (see page 13422)	Connects the drive combo box to a directory list box.
	DragCursor (see page 13424)	Indicates the image used to represent the mouse pointer when the control is being dragged.

	DragMode (see page 13424)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13427)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 13427)	Controls the attributes of text written on or in the control.
	ImeMode (see page 13428)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13429)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 13429)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13430)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13430)	Determines where a control looks for its font information.
	ParentShowHint (see page 13431)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13431)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13436)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13437)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13438)	Determines if the user can tab to a control.
	TextCase (see page 13439)	Determines if the volume name in the Text (see page 13438) property appears in uppercase or lowercase.
	Visible (see page 13440)	Determines whether the component appears onscreen.

70.1.2.6.1 TDriveComboBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
```

```
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {

  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

70.1.2.6.2 TDriveComboBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

70.1.2.6.3 TDriveComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay milliseconds between the characters typed and the autocomplete operation.

See Also

AutoCompleteDelay (see page 21220)

70.1.2.6.4 TDriveComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown: Boolean;
```

C++

```
__property Boolean AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

autocomplete (see page 21220)

OnDropDown (see page 21199)

DroppedDown (see page 21185)

70.1.2.6.5 TDriveComboBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

70.1.2.6.6 TDriveComboBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

70.1.2.6.7 TDriveComboBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

70.1.2.6.8 TDriveComboBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

70.1.2.6.9 TDriveComboBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

70.1.2.6.10 TDriveComboBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

70.1.2.6.11 TDriveComboBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

70.1.2.6.12 TDriveComboBox.DirList Property

Connects the drive combo box to a directory list box.

Pascal

```
property DirList: TDirectoryListBox;
```

C++

```
__property TDirectoryListBox DirList;
```

Description

Set DirList to a directory list box control that should update when the user changes the drive. When a new drive is selected in the drive combo box, the specified directory list box updates to display the directory structure and the current directory on the new drive.

Note: If the form contains a file list box as well, it can be updated automatically using the FileList property of the directory list box object.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

TDirectoryListBox (see page 13313)

TFileListBox (see page 13465)

70.1.2.6.13 TDriveComboBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

70.1.2.6.14 TDriveComboBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
```

```
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

70.1.2.6.15 TDriveComboBox.Drive Property

Indicates the currently selected drive displayed in the edit portion of the combo box.

Pascal

```
property Drive: Char;
```

C++

```
__property Char Drive;
```

Description

Set Drive to initialize the combo box to a particular drive. Read Drive to obtain the drive that was selected by the user.

When the user uses the drive combo box to select a new drive, the selected drive becomes the value of the Drive property. The value of the Text (see page 13438) property also changes to the new volume name when the Drive property value changes.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
```

```
end;
```

See Also

Text (see page 5842)

70.1.2.6.16 TDriveComboBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

EnableControls (see page 6934)

Enabling Mouse

70.1.2.6.17 TDriveComboBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}
```

```
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

70.1.2.6.18 TDriveComboBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

70.1.2.6.19 TDriveComboBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

70.1.2.6.20 TDriveComboBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

70.1.2.6.21 TDriveComboBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

70.1.2.6.22 TDriveComboBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

70.1.2.6.23 TDriveComboBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

70.1.2.6.24 TDriveComboBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
```

```
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.

```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and

70.1.2.6.25 TDriveComboBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
```

```
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

70.1.2.6.26 TDriveComboBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

70.1.2.6.27 TDriveComboBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

70.1.2.6.28 TDriveComboBox.Text Property

Contains a text string associated with the control.

Pascal

```
property Text: TCaption;
```

C++

```
__property TCaption Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
```

```
  copies the text in an edit box into a null-terminated string, and
  puts this string in another edit box when the user clicks the
  button on the form.
  */
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    int Size = Edit1->GetTextLen(); //Get length of string in Edit1
    Size++;                        //Add room for null character
    char *Buffer = new char[Size];  //Creates Buffer dynamic variable
    Edit1->GetTextBuf(Buffer,Size); //Puts Edit1->Text into Buffer
    Edit2->Text = Buffer;
    delete [] Buffer;
  }
  /*
  Note: the same thing could be accomplished more simply as follows:
  */
  void __fastcall TForm1::Button2Click(TObject *Sender)
  {
    Edit2->Text = Edit1->Text;
  }
```

Delphi Examples:

```
  {
  This example requires two edit boxes and a button.  This example
  copies the text in an edit box into a null-terminated string, and
  puts this string in another edit box when the user clicks the
  button on the form.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    Buffer: PChar;
    Size: Byte;
  begin
    Size := Edit1.GetTextLen;       {Get length of string in Edit1}
    Inc(Size);                      {Add room for null character}
    GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
    Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
    Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
    FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
  end;

  {
  Note: the same thing could be accomplished more simply as follows:
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    Edit2.Text := Edit1.Text;
  end;
```

Caption (see page 5806)

Lines (see page 21380)

70.1.2.6.29 TDriveComboBox.TextCase Property

Determines if the volume name in the Text (see page 13438) property appears in uppercase or lowercase.

Pascal

```
  property TextCase: TTextCase;
```

C++

```
  __property TTextCase TextCase;
```

Description

Set TextCase to the case that should be used to represent the drive letter that is the value of the Text (see page 13438) property.

Note: Changes made to the TextCase property at design time don't appear until the application runs.

See Also

Drive (see page 13426)

Text (see page 5842)

70.1.2.6.30 TDriveComboBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

70.1.2.7 TDriveComboBox Events

The events of the TDriveComboBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 13442)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 13444)	Occurs when the user clicks the control.
	OnContextPopup (see page 13446)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13446)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13447)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13449)	Occurs when the user drags an object over a control.
	OnDropDown (see page 13451)	Occurs when the user opens the drop-down list.

	OnEndDrag (see page 13453)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13454)	Occurs when a control receives the input focus.
	OnExit (see page 13456)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13458)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13461)	Occurs when a key is pressed.
	OnKeyUp (see page 13462)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 13464)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13464)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 13464)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

70.1.2.7.1 TDriveComboBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)

70.1.2.7.2 TDriveComboBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

70.1.2.7.3 TDriveComboBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

70.1.2.7.4 TDriveComboBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

70.1.2.7.5 TDriveComboBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
```

```
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

70.1.2.7.6 TDriveComboBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
```

```
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.2.7.7 TDriveComboBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if (((TForm1 *)Screen->CustomForms[i])->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
```

```
      end;
      Items.EndUpdate; {reenable painting }
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ComboBox1.Sorted := True; { make sure the form names are sorted }
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Form2.Show;
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    Form3.Show;
  end;
```

See Also

DroppedDown (see page 21185)

70.1.2.7.8 TDriveComboBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
```

```
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;
```

70.1.2.7.9 TDriveComboBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
```

```
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.2.7.10 TDriveComboBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
```

```
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.2.7.11 TDriveComboBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
```

```
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
  {
  The following code aborts a print job if the user presses
  Esc. Note that you should set KeyPreview to true to ensure
  that the OnKeyDown event handler of Form1 is called.
  }

  uses Printers;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, X, Y: Integer;
    Memo1 : TMemo;
    r: TRect;
  begin
    Memo1 := TMemo.Create(Form1);
    Memo1.Parent := Form1;
    Memo1.Visible := True;
    Memo1.Width := 700;
    if (OpenDialog1.Execute) then
    begin
      Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
     KeyPreview := True;
  end;

  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
  if (Key=VK_ESCAPE) and Printer.Printing then
    begin
```

```
    Printer.Abort;
    MessageDlg('Printing aborted', mtInformation, [mbOK],0);
    end;
  end;
```

70.1.2.7.12 TDriveComboBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
```

```
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

70.1.2.7.13 TDriveComboBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/

      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
```

```
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
```

OnKeyDown (see page 6225)

OnKeyPress (see page 6227)

70.1.2.7.14 TDriveComboBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

70.1.2.7.15 TDriveComboBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

70.1.2.7.16 TDriveComboBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these

controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

70.1.3 TFileListBox Class

TFileListBox is a specialized list box that lists all the files in a specified directory.

Class Hierarchy

Pascal

```
TFileListBox = class(TCustomListBox);
```

C++

```
class TFileListBox : public TCustomListBox;
```

File

FileCtrl

Description

Add TFileListBox to a form to allow users to select a file. Use TFileListBox along with TDriveComboBox (see page 13396), TFilterComboBox (see page 13547), and TDirectoryListBox (see page 13313) to add full file selection capabilities to a form.

Note: To add a standard Windows file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

70.1.3.1 TFileListBox Members

The following tables list the members exposed by TFileListBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnData (see page 21357)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 21357)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 21358)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDrawItem (see page 21358)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMeasureItem (see page 21360)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.

	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DirBMP (see page 13479)	This is DirBMP, a member of class TFileListBox.
	ExeBMP (see page 13480)	This is ExeBMP, a member of class TFileListBox.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDirectory (see page 13480)	This is FDirectory, a member of class TFileListBox.
	FDirList (see page 13480)	This is FDirList, a member of class TFileListBox.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFileEdit (see page 13480)	This is FFileEdit, a member of class TFileListBox.
	FFileType (see page 13480)	This is FFileType, a member of class TFileListBox.
	FFilterCombo (see page 13481)	This is FFilterCombo, a member of class TFileListBox.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FLastSel (see page 13481)	This is FLastSel, a member of class TFileListBox.
	FMask (see page 13481)	This is FMask, a member of class TFileListBox.
	FMoving (see page 21321)	This is FMoving, a member of class TCustomListBox.
	FMultiSelect (see page 5956)	This is FMultiSelect, a member of class TCustomMultiSelectListControl.
	FOnChange (see page 13481)	This is FOnChange, a member of class TFileListBox.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FShowGlyphs (see page 13482)	This is FShowGlyphs, a member of class TFileListBox.
	UnknownBMP (see page 13482)	This is UnknownBMP, a member of class TFileListBox.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.

	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 13484)	This is Change, a member of class TFileListBox.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 13484)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 21324)	Initializes the window-creation parameter record passed in the Params parameter.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 13484)	Creates a Windows control corresponding to the list box component.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DeleteString (see page 21326)	Deletes a string from the list box.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21326)	Saves the list box items in a string list before freeing the underlying Windows control.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFindData (see page 21326)	Returns the index of a string in the list box.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoGetData (see page 21327)	Returns a string in the list box given its index.
	DoGetDataObject (see page 21327)	Returns the object associated with an item in a virtual list box.

	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
V	DragCanceled (see page 21328)	Sends a mouse message canceling the drag-and-drop operation.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
V	DrawItem (see page 13485)	Generates an OnDrawItem event.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetCount (see page 21329)	Returns the value of the Count (see page 21346) property.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFilePath (see page 13486)	This is GetFilePath, a member of class TFileListBox.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetItemData (see page 21329)	Returns a 32-bit value associated with the specified item in a list box.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetItemIndex (see page 21329)	Returns the value of the ItemIndex property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.

	GetSelCount (see page 5956)	Returns the value of the SelCount (see page 5957) property.
	GetSelCount (see page 21330)	Returns the number of selected items.
	GetSelected (see page 21330)	Indicates whether a particular item is selected.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InternalGetItemData (see page 21330)	Retrieves the data associated with an item in the list box.
	InternalSetItemData (see page 21330)	Associates an integer with a specified item in the list box.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyPress (see page 21334)	Responds when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	LoadRecreateItems (see page 21334)	This is LoadRecreateItems, a member of class TCustomListBox.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MeasureItem (see page 21335)	Generates an OnMeasureItem (see page 21360) event.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 13486)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadBitmaps (see page 13486)	This is ReadBitmaps, a member of class TFileListBox.
	ReadFileNames (see page 13487)	This is ReadFileNames, a member of class TFileListBox.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetContent (see page 21335)	Removes all of the items from a list box.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.

	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	SaveRecreateItems (see page 21336)	This is SaveRecreateItems, a member of class TCustomListBox.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetItemData (see page 21336)	Sets the 32-bit value associated with the specified item in a list box.
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
V	SetItemIndex (see page 21336)	Gives focus to the item with a specified index.
A	SetMultiSelect (see page 5956)	Sets the value of the MultiSelect (see page 5957) property.
V	SetMultiSelect (see page 21337)	Sets the MultiSelect property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed

	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 21337)	Handles Windows messages.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 21343)	Determines whether the list box has a border.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Columns (see page 21346)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Sorted (see page 21353)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 21354)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabWidth (see page 21355)	Specifies the size of the tabs in the list box.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
A	AddItem (see page 5940)	Adds an item to the list control.
V	AddItem (see page 21322)	Adds an item to the list box
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	ApplyFilePath (see page 13482)	Updates the file list box to represent a fully qualified file name.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 5940)	Deletes all of the items from the list control.
V	Clear (see page 21322)	Deletes all items from the list box.
A	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
V	ClearSelection (see page 21323)	Deselects all selected items in the list box, if possible.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
A	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
V	CopySelection (see page 21323)	Copies the selected items to another list-type control
V	Create (see page 13478)	Creates an instance of TFileListBox (see page 13465).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
A	DeleteSelected (see page 5941)	Deletes all the selected items.
V	DeleteSelected (see page 21325)	Deletes the selected items from the list box
V	Destroy (see page 13479)	Destroys an instance of TFileListBox (see page 13465).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ItemAtPos (see page 21331)	Returns the index of the list box item indicated by the coordinates of a point on the control.
	ItemRect (see page 21333)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	MoveSelection (see page 5942)	Moves all selected items to another list control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
A	SelectAll (see page 5943)	Selects all items or all text in the selected item.
V	SelectAll (see page 21336)	Selects the entire block of text in the list box.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Update (see page 13487)	Refreshes the directory list for the file list box.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	AutoCompleteDelay (see page 21342)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 21343)	Provides a drawing surface when implementing a handler for the OnDrawItem (see page 21358) event of an owner-draw list box.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.

R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Count (see page 21346)	Indicates the number of items in the list box.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	Directory (see page 13496)	Specifies the directory that contains all the files listed in the file list box.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Drive (see page 13499)	Specifies the drive which contains the files listed in the list box.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
	FileName (see page 13502)	Indicates the name of the selected file in the list box, including the path name.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	Items (see page 21348)	Contains the strings that appear in the list box.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ScrollWidth (see page 21351)	Specifies the width, in pixels, by which the list box can scroll horizontally.
R	SelCount (see page 5957)	Indicates the number of selected items.
	Selected (see page 21351)	Indicates whether a particular item is selected.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopIndex (see page 21356)	Specifies the index number of the item that appears at the top of the list box.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 13519)	Occurs immediately after the user changes the selected file in the list.
	OnClick (see page 13520)	Occurs when the user clicks the control.
	OnContextPopup (see page 13521)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 13522)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13522)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13525)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 13527)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13528)	Occurs when a control receives the input focus.
	OnExit (see page 13531)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13532)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13535)	Occurs when a key is pressed.
	OnKeyUp (see page 13536)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13538)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13539)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13541)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13541)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13541)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13544)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 13546)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 13488)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13492)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13492)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 13493)	Specifies which edges of the control are beveled.
	BevelInner (see page 13493)	Specifies the cut of the inner bevel.
	BevelKind (see page 13493)	Specifies the control's bevel style.
	BevelOuter (see page 13494)	Specifies the cut of the outer bevel.
	Color (see page 13494)	Specifies the background color of the control.
	Constraints (see page 13495)	Specifies the size constraints for the control.
	Ctl3D (see page 13496)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 13497)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13498)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13500)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 13501)	This is ExtendedSelect, a member of class TFileListBox.
	FileEdit (see page 13501)	Links the directory list box to an edit control that displays the currently selected file.
	FileType (see page 13503)	Determines which files are displayed in the file list box based on the attributes of the files.
	Font (see page 13503)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 13504)	Determines the behavior of the input method editor (IME).

	ImeName (see page 13505)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 13505)	Determines whether the list box displays the partial items.
	ItemHeight (see page 13506)	Specifies the height in pixels of an item in an owner-draw list box.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Mask (see page 13506)	Limits which files are displayed in the file list box.
	MultiSelect (see page 13507)	Specifies whether the user can select more than one item.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 13508)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13508)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13509)	Determines where a control looks for its font information.
	ParentShowHint (see page 13509)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13510)	Identifies the pop-up menu associated with the control.
	ShowGlyphs (see page 13514)	Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.
	ShowHint (see page 13515)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13516)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13517)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13517)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

70.1.3.2 TFileListBox.Create Constructor

Creates an instance of TFileListBox (see page 13465).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFileListBox(TComponent * AOwner);
```

Description

Call Create to create a TFileListBox (see page 13465) object at runtime. File list boxes placed on a form at design time are created automatically.

See Also

Directory (see page 13496)

Drive (see page 13499)

FileType (see page 13503)

Mask (see page 13506)

MultiSelect

Sorted (see page 21353)

Create (see page 21320)

Width (see page 5849)

70.1.3.3 TFileListBox.Destroy Destructor

Destroys an instance of TFileListBox (see page 13465).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFileListBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the file list box reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

70.1.3.4 TFileListBox Fields

The fields of the TFileListBox class are listed here.

Protected Fields

	Name	Description
	DirBMP (see page 13479)	This is DirBMP, a member of class TFileListBox.
	ExeBMP (see page 13480)	This is ExeBMP, a member of class TFileListBox.
	FDirectory (see page 13480)	This is FDirectory, a member of class TFileListBox.
	FDirList (see page 13480)	This is FDirList, a member of class TFileListBox.
	FFileEdit (see page 13480)	This is FFileEdit, a member of class TFileListBox.
	FFileType (see page 13480)	This is FFileType, a member of class TFileListBox.
	FFilterCombo (see page 13481)	This is FFilterCombo, a member of class TFileListBox.
	FLastSel (see page 13481)	This is FLastSel, a member of class TFileListBox.
	FMask (see page 13481)	This is FMask, a member of class TFileListBox.
	FOnChange (see page 13481)	This is FOnChange, a member of class TFileListBox.
	FShowGlyphs (see page 13482)	This is FShowGlyphs, a member of class TFileListBox.
	UnknownBMP (see page 13482)	This is UnknownBMP, a member of class TFileListBox.

70.1.3.4.1 TFileListBox.DirBMP Field

Pascal

```
DirBMP: TBitmap;
```

C++

```
TBitmap DirBMP;
```

Description

This is DirBMP, a member of class TFileListBox.

70.1.3.4.2 TFileListBox.ExeBMP Field

Pascal

```
ExeBMP: TBitmap;
```

C++

```
TBitmap ExeBMP;
```

Description

This is ExeBMP, a member of class TFileListBox.

70.1.3.4.3 TFileListBox.FDirectory Field

Pascal

```
FDirectory: string;
```

C++

```
AnsiString FDirectory;
```

Description

This is FDirectory, a member of class TFileListBox.

70.1.3.4.4 TFileListBox.FDirList Field

Pascal

```
FDirList: TDirectoryListBox;
```

C++

```
TDirectoryListBox FDirList;
```

Description

This is FDirList, a member of class TFileListBox.

70.1.3.4.5 TFileListBox.FFileEdit Field

Pascal

```
FFileEdit: TEdit;
```

C++

```
TEdit FFileEdit;
```

Description

This is FFileEdit, a member of class TFileListBox.

70.1.3.4.6 TFileListBox.FFileType Field

Pascal

```
FFileType: TFileType;
```

C++

```
TFileType FFileType;
```

Description

This is FFileType, a member of class TFileListBox.

70.1.3.4.7 TFileListBox.FFilterCombo Field

Pascal

```
FFilterCombo: TFilterComboBox;
```

C++

```
TFilterComboBox FFilterCombo;
```

Description

This is FFilterCombo, a member of class TFileListBox.

70.1.3.4.8 TFileListBox.FLastSel Field

Pascal

```
FLastSel: Integer;
```

C++

```
int FLastSel;
```

Description

This is FLastSel, a member of class TFileListBox.

70.1.3.4.9 TFileListBox.FMask Field

Pascal

```
FMask: string;
```

C++

```
AnsiString FMask;
```

Description

This is FMask, a member of class TFileListBox.

70.1.3.4.10 TFileListBox.FOnChange Field

Pascal

```
FOnChange: TNotifyEvent;
```

C++

```
TNotifyEvent FOnChange;
```

Description

This is FOnChange, a member of class TFileListBox.

70.1.3.4.11 TFileListBox.FShowGlyphs Field

Pascal

```
FShowGlyphs: Boolean;
```

C++

```
Boolean FShowGlyphs;
```

Description

This is FShowGlyphs, a member of class TFileListBox.

70.1.3.4.12 TFileListBox.UnknownBMP Field

Pascal

```
UnknownBMP: TBitmap;
```

C++

```
TBitmap UnknownBMP;
```

Description

This is UnknownBMP, a member of class TFileListBox.

70.1.3.5 TFileListBox Methods

The methods of the TFileListBox class are listed here.

Protected Methods

	Name	Description
	Change (see page 13484)	This is Change, a member of class TFileListBox.
	Click (see page 13484)	Respond to user click.
	CreateWnd (see page 13484)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 13485)	Generates an OnDrawItem event.
	GetFilePath (see page 13486)	This is GetFilePath, a member of class TFileListBox.
	Notification (see page 13486)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 13486)	This is ReadBitmaps, a member of class TFileListBox.
	ReadFileNames (see page 13487)	This is ReadFileNames, a member of class TFileListBox.

Public Methods

	Name	Description
	ApplyFilePath (see page 13482)	Updates the file list box to represent a fully qualified file name.
	Update (see page 13487)	Refreshes the directory list for the file list box.

70.1.3.5.1 TFileListBox.ApplyFilePath Method

Updates the file list box to represent a fully qualified file name.

Pascal

```
procedure ApplyFilePath(const EditText: string); virtual;
```

C++

```
virtual __fastcall ApplyFilePath(const AnsiString EditText);
```

Description

Call ApplyFilePath to change the Directory (see page 13496), Drive (see page 13499), FileName (see page 13502), and Mask (see page 13506) properties so that they match the values implied by the EditText parameter. For example, if an edit control is linked to the file list box using the FileEdit (see page 13501) property, call ApplyFilePath from the OnChange (see page 13519) event handler of the edit control to update the file list box whenever the user types a value in the edit control.

ApplyFilePath updates the Mask (see page 13506) property only if the EditText parameter includes wildcards. If the form contains a TDirectoryListBox (see page 13313) object that specifies this file list box object in its FileList property, the Directory (see page 13496) and Drive (see page 13499) properties of the directory list box object are updated as well. If the form also includes a TDriveComboBox (see page 13396) object that specifies the directory list box in its DirList property, the Drive (see page 13499) property of the drive combo box will also be updated. However, the Mask (see page 13506) property of any TFilterComboBox (see page 13547) will not be updated.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

TDirectoryListBox (see page 13313)

TDriveComboBox (see page 13396)

TFilterComboBox (see page 13547)

70.1.3.5.2 TFileListBox.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TFileListBox.

70.1.3.5.3 TFileListBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action (see page 5797)

OnExecute (see page 2716)

Execute (see page 2712)

DblClick (see page 5747)

OnClick (see page 5851)

70.1.3.5.4 TFileListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns (see page 21346)

CreateHandle (see page 6135)

CreateParams (see page 21324)

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

ItemIndex

Items (see page 21348)

TabWidth (see page 21355)

TopIndex (see page 21356)

70.1.3.5.5 TFileListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight (see page 21347)

MeasureItem (see page 21335)

OnDrawItem (see page 21358)

OnMeasureItem (see page 21360)

Style (see page 21354)

70.1.3.5.6 TFileListBox.GetFilePath Method

Pascal

```
function GetFilePath: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetFilePath();
```

Description

This is GetFilePath, a member of class TFileListBox.

70.1.3.5.7 TFileListBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

70.1.3.5.8 TFileListBox.ReadBitmaps Method

Pascal

```
procedure ReadBitmaps; virtual;
```

C++

```
virtual __fastcall ReadBitmaps();
```

Description

This is ReadBitmaps, a member of class TFileListBox.

70.1.3.5.9 TFileListBox.ReadFileNames Method

Pascal

```
procedure ReadFileNames; virtual;
```

C++

```
virtual __fastcall ReadFileNames();
```

Description

This is ReadFileNames, a member of class TFileListBox.

70.1.3.5.10 TFileListBox.Update Method

Refreshes the directory list for the file list box.

Pascal

```
procedure Update; reintroduce;
```

C++

```
__fastcall Update();
```

Description

Call Update whenever the files listed by the file list box may be out of date. For example, if an application creates, renames, or deletes files, calling Update will ensure that those changes are reflected in the file list box.

The list box is updated automatically when the Drive (see page 13499), Directory (see page 13496), FileType (see page 13503), or Mask (see page 13506) property is changed.

See Also

Directory (see page 13496)

Drive (see page 13499)

FileType (see page 13503)

Mask (see page 13506)

70.1.3.6 TFileListBox Properties

The properties of the TFileListBox class are listed here.

Public Properties

	Name	Description
	Directory (see page 13496)	Specifies the directory that contains all the files listed in the file list box.
	Drive (see page 13499)	Specifies the drive which contains the files listed in the list box.
	FileName (see page 13502)	Indicates the name of the selected file in the list box, including the path name.

Published Properties

	Name	Description
	Align (see page 13488)	Determines how the control aligns within its container (parent control).
	Anchors (see page 13492)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13492)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 13493)	Specifies which edges of the control are beveled.

	BevelInner (see page 13493)	Specifies the cut of the inner bevel.
	BevelKind (see page 13493)	Specifies the control's bevel style.
	BevelOuter (see page 13494)	Specifies the cut of the outer bevel.
	Color (see page 13494)	Specifies the background color of the control.
	Constraints (see page 13495)	Specifies the size constraints for the control.
	Ctl3D (see page 13496)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 13497)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13498)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13500)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 13501)	This is ExtendedSelect, a member of class TFileListBox.
	FileEdit (see page 13501)	Links the directory list box to an edit control that displays the currently selected file.
	FileType (see page 13503)	Determines which files are displayed in the file list box based on the attributes of the files.
	Font (see page 13503)	Controls the attributes of text written on or in the control.
	ImeMode (see page 13504)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13505)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 13505)	Determines whether the list box displays the partial items.
	ItemHeight (see page 13506)	Specifies the height in pixels of an item in an owner-draw list box.
	Mask (see page 13506)	Limits which files are displayed in the file list box.
	MultiSelect (see page 13507)	Specifies whether the user can select more than one item.
	ParentColor (see page 13508)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13508)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13509)	Determines where a control looks for its font information.
	ParentShowHint (see page 13509)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13510)	Identifies the pop-up menu associated with the control.
	ShowGlyphs (see page 13514)	Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.
	ShowHint (see page 13515)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13516)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13517)	Determines if the user can tab to a control.
	Visible (see page 13517)	Determines whether the component appears onscreen.

70.1.3.6.1 TFileListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
```

```
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
```

```
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    ProgressBar: TProgressBar;
  begin
    ProgressBar := TProgressBar.Create(Self);
    with ProgressBar do
    begin
      Parent := Self;
      Align := alBottom;
    end;
  end;
  {
  This example dynamically creates a Page Control, then a
  series of Tab Sheets on the Page Control.
  }
  var
    PageControl1: TPageControl;
    pts: array[0..3] of TTabSheet;
  const
    TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

  procedure TForm1.FormCreate(Sender: TObject);
  const
    colorpalette: Array[0..11] of TColor = (
      clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
      clNavy, clMaroon, clLime, clOlive, clPurple);
  var
    i: Integer;
  begin
    PageControl1 := TPageControl.Create(Self);
    PageControl1.Parent := Self;
    PageControl1.Align := alClient;
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i]:= TTabSheet.Create(PageControl1);
      with pts[i] do
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    i: Integer;
```

```
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

70.1.3.6.2 TFileListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

70.1.3.6.3 TFileListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes

longer.

See Also

ItemIndex

70.1.3.6.4 TFileListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

70.1.3.6.5 TFileListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

70.1.3.6.6 TFileListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

70.1.3.6.7 TFileListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

70.1.3.6.8 TFileListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

70.1.3.6.9 TFileListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict,

the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

70.1.3.6.10 TFileListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

70.1.3.6.11 TFileListBox.Directory Property

Specifies the directory that contains all the files listed in the file list box.

Pascal

```
property Directory: string;
```

C++

```
__property AnsiString Directory;
```

Description

Set Directory to update the file list box so that it displays the files in a new directory. If the form includes a TDirectoryListBox (see page 13313) object, set the FileList property of the directory list box to have the Directory property updated automatically when the user selects a new directory.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
```

```
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

See Also

Drive (see page 13499)

Directory (see page 13344)

FileList (see page 13350)

70.1.3.6.12 TFileListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

70.1.3.6.13 TFileListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

OnStartDrag (see page 5871)

DragKind (see page 5819)

Arranging the Order of Persistent Columns

70.1.3.6.14 TFileListBox.Drive Property

Specifies the drive which contains the files listed in the list box.

Pascal

```
property Drive: char;
```

C++

```
__property char Drive;
```

Description

Set the value of Drive to the drive that contains the files that the list box should display. When the value of Drive changes, the

Directory (see page 13496) value also changes to the current directory on the specified drive.

If the form includes a TDirectoryListBox (see page 13313) object, set the FileList property of the directory list box to have the Drive property updated automatically when the Drive property of the directory list box changes.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

See Also

Directory (see page 13496)

Drive (see page 13349)

FileList (see page 13350)

70.1.3.6.15 TFileListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

70.1.3.6.16 TFileListBox.ExtendedSelect Property

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

This is ExtendedSelect, a member of class TFileListBox.

70.1.3.6.17 TFileListBox.FileEdit Property

Links the directory list box to an edit control that displays the currently selected file.

Pascal

```
property FileEdit: TEdit;
```

C++

```
__property TEdit FileEdit;
```

Description

Set FileEdit to an edit control that displays the selected file from the file list box, as is commonly done in Open and Save dialog boxes. If no file is selected in the file list box, the text of the edit control is the current value of the file list box's Mask (see page 13506) property.

Note: If the user changes the text of the edit control, the results are not automatically reflected in the file list box. Use the ApplyFilePath (see page 13482) method to update the file list box when the edit control's text changes.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
```

```
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

ApplyFilePath (see page 13482)

FileName (see page 13502)

Mask (see page 13506)

70.1.3.6.18 TFileListBox.FileName Property

Indicates the name of the selected file in the list box, including the path name.

Pascal

```
property FileName: string;
```

C++

```
__property AnsiString FileName;
```

Description

Set FileName to initialize the file list box to a particular file. Read FileName to obtain the name of the file the user selected.

If the FileEdit (see page 13501) property is set, the linked edit control displays the value of FileName whenever the FileName

property changes.

See Also

FileEdit (see page 13501)

FileType (see page 13503)

70.1.3.6.19 TFileListBox.FileType Property

Determines which files are displayed in the file list box based on the attributes of the files.

Pascal

```
property FileType: TFileType;
```

C++

```
__property TFileType FileType;
```

Description

Set FileType to the type of files the list box should display. FileType can specify more than one type of file. For example, if the value of FileType is a set containing the values ftReadOnly and ftHidden, files that have either the read-only or the hidden attributes are displayed in the list box.

To set the FileType property using the Object Inspector, click the FileType property to see the attribute values. Then set each value to True or False true or false to specify whether it is included in the FileType set.

Note: The files that are listed can also be limited by the form of their names. To restrict the files to particular names, use the Mask (see page 13506) property or include a TFilterComboBox (see page 13547) on the form.

See Also

Mask (see page 13506)

TFilterComboBox (see page 13547)

70.1.3.6.20 TFileListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

70.1.3.6.21 TFileListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

70.1.3.6.22 TFileListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

70.1.3.6.23 TFileListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 21347)

Items (see page 21348)

Style (see page 21354)

Using TDBListBox and TDBComboBox

70.1.3.6.24 TFileListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

See Also

DrawItem (see page 21328)

IntegralHeight (see page 21347)

Items (see page 21348)

MeasureItem (see page 21335)

OnDrawItem (see page 21358)

OnMeasureItem (see page 21360)

Style (see page 21354)

Using TDBListBox and TDBComboBox

70.1.3.6.25 TFileListBox.Mask Property

Limits which files are displayed in the file list box.

Pascal

```
property Mask: string;
```

C++

```
__property AnsiString Mask;
```

Description

Set Mask to a regular expression to limit the list box to files that match the mask. The value of the mask is a file name that may include wildcards. The asterisk (*) is a wildcard which matches any number of arbitrary characters. The question mark (?) is a wildcard which matches a single arbitrary character. The file mask *.* displays all files, which is the default value.

To specify multiple file masks, separate the file mask specifications with semicolons. For example, *.DLL;*.EXE.

If the form includes a TFilterComboBox (see page 13547) object, set the FileList property of the filter combo box to have the Mask property updated automatically when the Mask property of the filter combo box changes.

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

See Also

FileEdit (see page 13501)

FileName (see page 13502)

FileList (see page 13574)

Mask (see page 13579)

70.1.3.6.26 TFileListBox.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect: Boolean;
```

C++

```
__property Boolean MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount property indicates the number of selected items. When MultiSelect is false, the user can only select one item, which is indicated by the ItemIndex property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl descendant, override the protected SetMultiSelect method.

See Also

SelCount (see page 5957)

ItemIndex (see page 5944)

70.1.3.6.27 TFileListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

70.1.3.6.28 TFileListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

70.1.3.6.29 TFileListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

70.1.3.6.30 TFileListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

70.1.3.6.31 TFileListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.

```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
```

```
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.

70.1.3.6.32 TFileListBox.ShowGlyphs Property

Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.

Pascal

```
property ShowGlyphs: Boolean;
```

C++

```
__property Boolean ShowGlyphs;
```

Description

Set ShowGlyphs to true to display icons next to the files in the list that indicate the file type. Set ShowGlyphs to false to list only the file names.

70.1.3.6.33 TFileListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

70.1.3.6.34 TFileListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

70.1.3.6.35 TFileListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

70.1.3.6.36 TFileListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
```

```
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

70.1.3.7 TFileListBox Events

The events of the TFileListBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 13519)	Occurs immediately after the user changes the selected file in the list.
	OnClick (see page 13520)	Occurs when the user clicks the control.
	OnContextPopup (see page 13521)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13522)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13522)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13525)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 13527)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13528)	Occurs when a control receives the input focus.
	OnExit (see page 13531)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13532)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13535)	Occurs when a key is pressed.
	OnKeyUp (see page 13536)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13538)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13539)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13541)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13541)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13541)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13544)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 13546)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

70.1.3.7.1 TFileListBox.OnChange Event

Occurs immediately after the user changes the selected file in the list.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action when the FileName (see page 13502) property changes. If the FileEdit (see page 13501) property has been set, the edit control is updated before the OnChange event.

See Also

FileEdit (see page 13501)

FileName (see page 13502)

70.1.3.7.2 TFileListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

70.1.3.7.3 TFileListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

70.1.3.7.4 TFileListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

70.1.3.7.5 TFileListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
```

```
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.3.7.6 TFileListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
```

```
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.3.7.7 TFileListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
```

```
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

70.1.3.7.8 TFileListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.3.7.9 TFileListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.3.7.10 TFileListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly

fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
```

```
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

70.1.3.7.11 TFileListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/
```

```
void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

70.1.3.7.12 TFileListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
```

```
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
```

```
    WriteLn(ComboBox1.Text);
  end;
end;

70.1.3.7.13 TFileListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

70.1.3.7.14 TFileListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
```

```
      {
        StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
        StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
      }
      else
      {
        StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
        StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
      }
      if (X > StartX)
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
      }
      else
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
      }
    }
  }
```

Delphi Examples:

```
{

70.1.3.7.15 TFileListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

70.1.3.7.16 TFileListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

70.1.3.7.17 TFileListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

70.1.3.7.18 TFileListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*

70.1.3.7.19 TFileListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

OnEndDrag (see page 5860)

TDragControlObjectEx (see page 6007)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDragDrop (see page 5855)

70.1.4 TFilterComboBox Class

TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

Class Hierarchy

Pascal

```
TFilterComboBox = class(TCustomComboBox);
```

C++

```
class TFilterComboBox : public TCustomComboBox;
```

File

FileCtrl

Description

Add a filter combo box to a form that includes a file selection control to provide a set of predefined file filters. Use TFilterComboBox along with TDriveComboBox (see page 13396), TDirectoryListBox (see page 13313), and TFileListBox (see page 13465) to add full file selection capabilities to a form.

To add a standard Win32 file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

See Also

TDirectoryListBox (see page 13313)

TDriveComboBox (see page 13396)

TFileListBox (see page 13465)

70.1.4.1 TFilterComboBox Members

The following tables list the members exposed by TFilterComboBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCloseUp (see page 21199)	Occurs when the drop-down list closes up due to some user action.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDrawItem (see page 21224)	Occurs when an item in an owner-draw combo box needs to be displayed.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.

	OnMeasureItem (see page 21225)	Occurs when an item in a csOwnerDrawVariable combo box needs to be redisplayed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnSelect (see page 21201)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDefEditProc (see page 21167)	This is FDefEditProc, a member of class TCustomCombo.
	FDefListProc (see page 21167)	This is FDefListProc, a member of class TCustomCombo.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FDropHandle (see page 21168)	This is FDropHandle, a member of class TCustomCombo.
	FDroppingDown (see page 21168)	This is FDroppingDown, a member of class TCustomCombo.
	FEditHandle (see page 21168)	This is FEditHandle, a member of class TCustomCombo.
	FEditInstance (see page 21168)	This is FEditInstance, a member of class TCustomCombo.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFocusChanged (see page 21168)	This is FFocusChanged, a member of class TCustomCombo.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FIsFocused (see page 21169)	This is FIsFocused, a member of class TCustomCombo.
	FListHandle (see page 21169)	This is FListHandle, a member of class TCustomCombo.
	FListInstance (see page 21169)	This is FListInstance, a member of class TCustomCombo.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveIndex (see page 21169)	This is FSaveIndex, a member of class TCustomCombo.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustDropDown (see page 21171)	Adjusts the size and position of the drop down list.

	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BuildList (see page 13560)	This is BuildList, a member of class TFilterComboBox.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 13560)	Generates an OnChange event.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 13561)	Respond to user click.
	CloseUp (see page 21172)	Generates an OnCloseUp (see page 21199) event.
	ComboWndProc (see page 21173)	Responds to Windows messages sent to the edit control or drop-down list.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 21215)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 13561)	Creates the Windows control that represents the combo box.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 21174)	Destroys all of the windows controls that implement the combo box.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21215)	Destroys the Windows control that represents the combo box.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.

	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
V	DrawItem (see page 21216)	Generates an OnDrawItem (see page 21224) event.
	DropDown (see page 21175)	Generates an OnDropDown (see page 21199) event.
V	EditWndProc (see page 21175)	Responds to Windows messages that are sent to the edit control portion of the combo box.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
A	GetCount (see page 5942)	Returns the number of items in the list.
V	GetCount (see page 21176)	Returns the value of the ItemCount (see page 21186) property.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetDroppedDown (see page 21176)	Returns the value of the DroppedDown (see page 21185) property.

V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
A	GetItemCount (see page 21176)	Returns the value of the ItemCount (see page 21186) property.
V	GetItemCount (see page 21216)	Returns the number of items in the Items (see page 21187) property list.
A	GetItemHt (see page 21177)	Returns the value of the ItemHeight (see page 21186) property.
V	GetItemHt (see page 21216)	Returns the value of the ItemHeight (see page 21186) property.
A	GetItemIndex (see page 5942)	Returns the value of the ItemIndex (see page 5944) property.
V	GetItemIndex (see page 21177)	Returns the value of the ItemIndex property.
A	GetItemsClass (see page 21177)	Indicates the class that implements the Items (see page 21187) property.
V	GetItemsClass (see page 21217)	Returns the class used to implement the Items (see page 21187) property.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSelLength (see page 21178)	Returns the value of the SelLength (see page 21190) property.
	GetSelStart (see page 21178)	Returns the value of the SelStart (see page 21193) property.
	GetSelText (see page 21217)	Returns the value of the SelText (see page 21222) property.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
V	KeyPress (see page 21217)	Responds to WM_CHAR messages sent to the combo box.
	KeyUp (see page 6164)	Respond to released key.
	ListWndProc (see page 21178)	Responds to Windows messages that are sent to the drop-down list portion of the combo box.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 21179)	Initializes the combo box after its form is loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
V	MeasureItem (see page 21218)	Generates an OnMeasureItem (see page 21225) event.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 13562)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.

V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	Select (see page 21179)	Generates an OnSelect (see page 21201) event.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectItem (see page 21218)	Selects a specified item from the drop-down list.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetDropDownCount (see page 21180)	Sets the value of the DropDownCount (see page 21185) property.
	SetDroppedDown (see page 21180)	Sets the value of the DroppedDown (see page 21185) property.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetItemHeight (see page 21181)	Sets the value of the ItemHeight (see page 21186) property.
A	SetItemIndex (see page 5943)	Sets the value of the ItemIndex (see page 5944) property.
V	SetItemIndex (see page 21181)	Sets the value of the ItemIndex property.
V	SetItems (see page 21181)	Sets the value of the Items (see page 21187) property.
	SetMaxLength (see page 21182)	Sets the value of the MaxLength (see page 21189) property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.

	SetSelLength (see page 21182)	Sets the value of the SelLength (see page 21190) property.
	SetSelStart (see page 21182)	Sets the value of the SelStart (see page 21193) property.
V	SetStyle (see page 21219)	Sets the Style (see page 21224) property.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 21183)	Processes messages received by the combo box.
V	WndProc (see page 21219)	Processes messages received by the combo box.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DropDownCount (see page 21185)	Specifies the maximum number of items displayed in the drop-down list.
R	EditHandle (see page 21185)	Returns the window handle for the edit portion of the combo box.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	ItemCount (see page 21186)	Specifies the number of items in the drop-down list.
	ItemHeight (see page 21186)	Specifies the height, in pixels, of the items in the drop-down list.
R	ListHandle (see page 21189)	Provides access to the window handle of the list of items in the combo box.
	MaxLength (see page 21189)	Specifies the maximum number of characters the user can type into the edit portion of the combo box.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.

	Sorted (see page 21222)	Determines whether the list portion of the combo box is alphabetized.
	Style (see page 21224)	Determines the display style of the combo box.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AddItem (see page 5940)	Adds an item to the list control.
	AddItem (see page 21170)	Adds an item to the drop-down list of items.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 5940)	Deletes all of the items from the list control.
	Clear (see page 21172)	Deletes all text from the edit box and all items from the Items (see page 21187) list.
	ClearSelection (see page 5940)	Removes the selection, leaving all items unselected.
	ClearSelection (see page 21172)	Deselects any selected items in the drop-down list.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	CopySelection (see page 5941)	Copies the selected item or items to another TCustomListControl (see page 5928) descendant.
	CopySelection (see page 21173)	Copies the selected item in the drop-down list to another list control.
	Create (see page 13559)	Creates and initializes an instance of TFilterComboBox (see page 13547).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DeleteSelected (see page 5941)	Deletes all the selected items.
	DeleteSelected (see page 21174)	Deletes the selected item from the drop-down list.
	Destroy (see page 13560)	Destroys an instance of TFilterComboBox (see page 13547).
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
V	Focused (see page 21175)	Indicates whether the combo box has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.

	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	MoveSelection (see page 5942)	Moves all selected items to another list control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SelectAll (see page 5943)	Selects all items or all text in the selected item.
	SelectAll (see page 21180)	Selects the entire block of text in the edit box.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Update (see page 5789)	Processes any pending paint messages immediately.
	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	AutoCloseUp (see page 21220)	Specifies whether the drop-down closes up automatically when the user selects an item.
	AutoCompleteDelay (see page 21220)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 21184)	Provides access to the drawing surface of the combo box.
	CharCase (see page 21221)	Determines the case of the text in the combo box.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DroppedDown (see page 21185)	Indicates whether the drop-down list is currently displayed.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemIndex (see page 5944)	Specifies the index of the selected item.
	Items (see page 21187)	Provides access to the list of items (strings) in the list portion of the combo box.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	Mask (see page 13579)	Specifies the mask associated with the string selected in the filter combo box.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.

R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelLength (see page 21190)	Specifies the length, in characters, of the selected text in the edit portion of the combo box.
	SelStart (see page 21193)	Specifies the position of the first selected character in the edit portion of the combo box.
	SelText (see page 21222)	Represents the selected text in the edit region.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	Text (see page 13588)	Contains a text string associated with the control.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 13592)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 13594)	Occurs when the user clicks the control.
	OnContextPopup (see page 13596)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13596)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13597)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13599)	Occurs when the user drags an object over a control.
	OnDropDown (see page 13601)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 13603)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 13604)	Occurs when a control receives the input focus.
	OnExit (see page 13606)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13608)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13611)	Occurs when a key is pressed.
	OnKeyUp (see page 13612)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 13614)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13614)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 13614)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 13563)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13567)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13567)	Positions to matching list items as you type.
	AutoDropDown (see page 13567)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 13568)	Specifies which edges of the control are beveled.
	BevelInner (see page 13568)	Specifies the cut of the inner bevel.
	BevelKind (see page 13569)	Specifies the control's bevel style.
	BevelOuter (see page 13569)	Specifies the cut of the outer bevel.
	Color (see page 13570)	Specifies the background color of the control.
	Constraints (see page 13570)	Specifies the size constraints for the control.

	Ctl3D (see page 13571)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 13571)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13572)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13573)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 13574)	Links the filter combo box to a file list box control.
	Filter (see page 13575)	Contains all the file masks displayed in the filter combo box.
	Font (see page 13576)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 13577)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13578)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentColor (see page 13580)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13580)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13580)	Determines where a control looks for its font information.
	ParentShowHint (see page 13581)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13581)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13586)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13587)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13588)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 13590)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

70.1.4.2 TFilterComboBox.Create Constructor

Creates and initializes an instance of TFilterComboBox (see page 13547).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFilterComboBox(TComponent * AOwner);
```

Description

Call Create to create a TFilterComboBox (see page 13547) objectat runtime. Filter (see page 13575) combo boxes placed on a form at design time are created automatically.

See Also

Mask (see page 13579)

Style (see page 21224)

Create (see page 21214)

70.1.4.3 TFilterComboBox.Destroy Destructor

Destroys an instance of TFilterComboBox (see page 13547).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFilterComboBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the filter combo box is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

70.1.4.4 TFilterComboBox Methods

The methods of the TFilterComboBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 13560)	This is BuildList, a member of class TFilterComboBox.
V	Change (see page 13560)	Generates an OnChange event.
V	Click (see page 13561)	Respond to user click.
V	CreateWnd (see page 13561)	Creates the Windows control that represents the combo box.
V	Notification (see page 13562)	Responds to notifications that components are being created or destroyed.

70.1.4.4.1 TFilterComboBox.BuildList Method

Pascal

```
procedure BuildList;
```

C++

```
__fastcall BuildList();
```

Description

This is BuildList, a member of class TFilterComboBox.

70.1.4.4.2 TFilterComboBox.Change Method

Generates an OnChange event.

Pascal

```
procedure Change; override;
```

C++

```
virtual __fastcall Change();
```

Description

Change is called automatically in response to notifications that the text has changed. It responds by generating an OnChange event. Override this method to add additional processing when the text changes, or to block the OnChange event.

See Also

OnChange (see page 21197)

Changed (see page 5742)

70.1.4.4.3 TFilterComboBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action (see page 5797)

OnExecute (see page 2716)

Execute (see page 2712)

DblClick (see page 5747)

OnClick (see page 5851)

70.1.4.4.4 TFilterComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle (see page 6135)

70.1.4.4.5 TFilterComboBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

70.1.4.5 TFilterComboBox Properties

The properties of the TFilterComboBox class are listed here.

Public Properties

	Name	Description
R	Mask (see page 13579)	Specifies the mask associated with the string selected in the filter combo box.
	Text (see page 13588)	Contains a text string associated with the control.

Published Properties

	Name	Description
	Align (see page 13563)	Determines how the control aligns within its container (parent control).
	Anchors (see page 13567)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 13567)	Positions to matching list items as you type.
	AutoDropDown (see page 13567)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 13568)	Specifies which edges of the control are beveled.
	BevelInner (see page 13568)	Specifies the cut of the inner bevel.
	BevelKind (see page 13569)	Specifies the control's bevel style.
	BevelOuter (see page 13569)	Specifies the cut of the outer bevel.

	Color (see page 13570)	Specifies the background color of the control.
	Constraints (see page 13570)	Specifies the size constraints for the control.
	Ctl3D (see page 13571)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 13571)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 13572)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 13573)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 13574)	Links the filter combo box to a file list box control.
	Filter (see page 13575)	Contains all the file masks displayed in the filter combo box.
	Font (see page 13576)	Controls the attributes of text written on or in the control.
	ImeMode (see page 13577)	Determines the behavior of the input method editor (IME).
	ImeName (see page 13578)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 13580)	Determines where a control looks for its color information.
	ParentCtl3D (see page 13580)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13580)	Determines where a control looks for its font information.
	ParentShowHint (see page 13581)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 13581)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 13586)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 13587)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 13588)	Determines if the user can tab to a control.
	Visible (see page 13590)	Determines whether the component appears onscreen.

70.1.4.5.1 TFilterComboBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
```

```
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}
```

```
var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

70.1.4.5.2 TFilterComboBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

70.1.4.5.3 TFilterComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay milliseconds between the characters typed and the autocomplete operation.

See Also

AutoCompleteDelay (see page 21220)

70.1.4.5.4 TFilterComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown: Boolean;
```

C++

```
__property Boolean AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

autocomplete (see page 21220)

OnDropDown (see page 21199)

DroppedDown (see page 21185)

70.1.4.5.5 TFilterComboBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

70.1.4.5.6 TFilterComboBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

70.1.4.5.7 TFilterComboBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

70.1.4.5.8 TFilterComboBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

70.1.4.5.9 TFilterComboBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

70.1.4.5.10 TFilterComboBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

70.1.4.5.11 TFilterComboBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

70.1.4.5.12 TFilterComboBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

70.1.4.5.13 TFilterComboBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);

  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}
```

```
void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

70.1.4.5.14 TFilterComboBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

70.1.4.5.15 TFilterComboBox.FileList Property

Links the filter combo box to a file list box control.

Pascal

```
property FileList: TFileListBox;
```

C++

```
__property TFileListBox FileList;
```

Description

If the form includes a TFileListBox (see page 13465) object to display a list of files to choose from, set FileList to allow the filter combo box to limit which files are displayed in the list box. Once the two controls are connected, whenever a new filter is selected using a filter combo box, the file list box displays the files that match the selected filter.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

Mask (see page 13579)

70.1.4.5.16 TFilterComboBox.Filter Property

Contains all the file masks displayed in the filter combo box.

Pascal

```
property Filter: string;
```

C++

```
__property AnsiString Filter;
```

Description

Set the Filter property to specify the names that appear in the filter combo box, along with the masks associated with each name. Each mask is a file name that may include wildcards. The asterisk (*) is a wildcard which matches any number of arbitrary characters. The question mark (?) is a wildcard which matches a single arbitrary character. When the application runs, the file filter the user selects in the filter combo box becomes the value of the Mask (see page 13579) property.

To create the value of Filter for a single file type, follow these steps:

1Type some meaningful text to indicate the type of file.

2Type a | character (vertical bar).

3Type the file filter.

Don't put in any spaces around the | character in the string.

Here's an example:

```
FilterComboBox1.Filter := 'Text files|*.TXT';
FilterComboBox1->Filter = "Text files|*.TXT";
```

If Filter is set to this string, the string "Text (see page 13588) files" appears in the filter combo box. When the user selects "Text (see page 13588) files", the mask is set to "*.TXT".

To specify multiple file filters, extend the value of Filter, separating each file name/mask combination with a | character. Filter

can specify an any number of file filters, as long as the string is less than 255 characters.

Here's an example of two file filters that could be specified as the value of the Filter property:

```
'Text files (*.TXT)|*.TXT|Pascal files (*.PAS)|*.PAS'
"Text files (*.TXT)|*.TXT|C++ files (*.CPP)|*.CPP"
```

The previous example includes the file filters in parentheses in the text parts. This isn't required, but it's a common convention that helps users understand what to expect when they select a file filter.

The mask portion can include multiple file specifiers if they are separated with semicolons:

```
'All files|*.TXT;*.PAS;*.WB1'
"All files|*.TXT;*.CPP;*.RC"
```

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

See Also

Mask (see page 13579)

70.1.4.5.17 TFilterComboBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

70.1.4.5.18 TFilterComboBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

70.1.4.5.19 TFilterComboBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

70.1.4.5.20 TFilterComboBox.Mask Property

Specifies the mask associated with the string selected in the filter combo box.

Pascal

```
property Mask: string;
```

C++

```
__property AnsiString Mask;
```

Description

Read Mask to obtain the mask that was selected by the user.

When the user uses the filter combo box to select a new filter, the mask associated with the selected file type becomes the value of the Mask property. If a file list box is linked to the filter combo box with the FileList (see page 13574) property, the file list will update when the value of Mask changes.

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

See Also

FileList (see page 13574)

Filter (see page 13575)

Mask (see page 13506)

70.1.4.5.21 TFilterComboBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

70.1.4.5.22 TFilterComboBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

70.1.4.5.23 TFilterComboBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

70.1.4.5.24 TFilterComboBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

70.1.4.5.25 TFilterComboBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
```

```
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
```

```
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

70.1.4.5.26 TFilterComboBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

70.1.4.5.27 TFilterComboBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

70.1.4.5.28 TFilterComboBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

70.1.4.5.29 TFilterComboBox.Text Property

Contains a text string associated with the control.

Pascal

```
property Text: TCaption;
```

C++

```
__property TCaption Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                        //Add room for null character
  char *Buffer = new char[Size];  //Creates Buffer dynamic variable
  Edit1->GetTextBuf(Buffer,Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer;
  delete [] Buffer;
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

See Also

Caption (see page 5806)

Lines (see page 21380)

70.1.4.5.30 TFilterComboBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
```

```
  This examples requires a TPageControl and a TCheckBox.  The
  form OnCreate event handler populates each sheet with an
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

70.1.4.6 TFilterComboBox Events

The events of the TFilterComboBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 13592)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 13594)	Occurs when the user clicks the control.
	OnContextPopup (see page 13596)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 13596)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 13597)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13599)	Occurs when the user drags an object over a control.
	OnDropDown (see page 13601)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 13603)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnEnter (see page 13604)	Occurs when a control receives the input focus.
	OnExit (see page 13606)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 13608)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13611)	Occurs when a key is pressed.
	OnKeyUp (see page 13612)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 13614)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13614)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 13614)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

70.1.4.6.1 TFilterComboBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
  if (pCB)
    PageControl1->ActivePage = (TTabSheet *)(pCB->Items->Objects[pCB->ItemIndex]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
    ComboBox1->Items->AddObject(PageControl1->Pages[i]->Name, PageControl1->Pages[i]);
```

```
    ComboBox1->ItemIndex = 0;
  }
}
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to PageControl1.PageCount - 1 do
    ComboBox1.Items.AddObject(PageControl1.Pages[i].Name,
      PageControl1.Pages[i]);
  ComboBox1.ItemIndex := 0;
end;

procedure TForm1.ComboBox1Change(Sender: TObject);
begin
  if (Sender is TComboBox) then
    with (Sender as TComboBox) do
      PageControl1.ActivePage := TTabSheet(Items.Objects[ItemIndex]);
end;
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.

the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

See Also

Text (see page 5842)

OnCloseUp (see page 21199)

70.1.4.6.2 TFilterComboBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

70.1.4.6.3 TFilterComboBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu (see page 5835)

AutoPopup (see page 16178)

70.1.4.6.4 TFilterComboBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

70.1.4.6.5 TFilterComboBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;

70.1.4.6.6 TFilterComboBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
```

```
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

70.1.4.6.7 TFilterComboBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if (((TForm1 *)Screen->CustomForms[i])->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
```

```
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

70.1.4.6.8 TFilterComboBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
```

```
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;
```

70.1.4.6.9 TFilterComboBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
```

```
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.4.6.10 TFilterComboBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
```

```
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

70.1.4.6.11 TFilterComboBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var

70.1.4.6.12 TFilterComboBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
```

```
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

70.1.4.6.13 TFilterComboBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
```

```
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
```

OnKeyDown (see page 6225)

OnKeyPress (see page 6227)

70.1.4.6.14 TFilterComboBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

70.1.4.6.15 TFilterComboBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

70.1.4.6.16 TFilterComboBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these

controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDragDrop (see page 5855)

70.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DirectoryExists (see page 13616)	Determines whether a specified directory exists.
	ForceDirectories (see page 13617)	Creates a new directory, including the creation of parent directories as needed.
	MinimizeName (see page 13617)	Shortens a fully qualified path name so that it can be drawn with a specified length limit.
	ProcessPath (see page 13618)	Parses a file name into its constituent parts.
	SelectDirectory (see page 13619)	Brings up a dialog to allow the user to enter a directory name.
	SelectDirectory (see page 13619)	Brings up a dialog to allow the user to enter a directory name.

70.2.1 FileCtrl.DirectoryExists Function

Determines whether a specified directory exists.

Pascal

```
function DirectoryExists(const Name: string): Boolean;
```

C++

```
Boolean DirectoryExists(const AnsiString Name);
```

File

FileCtrl

Description

Call DirectoryExists to determine whether the directory specified by the Name parameter exists. If the directory exists, the function returns true. If the directory does not exist, the function returns false.

If a full path name is entered, DirectoryExists searches for the directory along the designated path. Otherwise, the Name parameter is interpreted as a relative path name from the current directory.

Note: The FileCtrl (see page 13311) unit (Windows only) also contains a DirectoryExists function. However, the FileCtrl (see page 13311) version is deprecated, and the SysUtils (see page 22709) version preferred, even if the code does not need to be cross-platform.

See Also

ForceDirectories (see page 22895)

SelectDirectory

FileExists (see page 22860)

70.2.2 FileCtrl.ForceDirectories Function

Creates a new directory, including the creation of parent directories as needed.

Pascal

```
function ForceDirectories(const Dir: string): Boolean;
```

C++

```
Boolean ForceDirectories(const AnsiString Dir);
```

File

FileCtrl

Description

ForceDirectories creates a new directory as specified in Dir, which must be a fully-qualified path name. If the directories given in the path do not yet exist, ForceDirectories attempts to create them.

ForceDirectories returns true if it successfully creates all necessary directories, false if it could not create a needed directory.

Warning: Important:Do not call ForceDirectories with an empty string. Doing so causes ForceDirectories to raise an exception.

Note: The FileCtrl (see page 13311) unit (Windows only) also contains a ForceDirectories function. However, the FileCtrl (see page 13311) version is deprecated, and the SysUtils (see page 22709) version preferred, even if the code does not need to be cross-platform.

DirectoryExists (see page 22832)

SelectDirectory

70.2.3 FileCtrl.MinimizeName Function

Shortens a fully qualified path name so that it can be drawn with a specified length limit.

Pascal

```
function MinimizeName(const Filename: TFileName; Canvas: TCanvas; MaxLen: Integer): TFileName;
```

C++

```
TFileName MinimizeName(const TFileName Filename, TCanvas Canvas, int MaxLen);
```

File

FileCtrl

Description

Use MinimizeName to obtain a version of a file name and path that can be drawn on a limited size drawing surface. MinimizeName replaces directories in the path portion of the file name with dots until the resulting name fits the specified number of pixels in length.

MinimizeName returns the shortened name.

Filename is the fully qualified path name that (possibly) needs to be shortened.

Canvas is the drawing surface on which the resulting name is to be rendered. It is used to determine font metrics.

MaxLen is the length, in pixels, available for drawing the file name on the canvas.

See Also

AdjustLineBreaks

WrapText

70.2.4 FileCtrl.ProcessPath Function

Parses a file name into its constituent parts.

Pascal

```
procedure ProcessPath(const EditText: string; var Drive: Char; var DirPart: string; var
FilePart: string);
```

C++

```
ProcessPath(const AnsiString EditText, Char Drive, AnsiString DirPart, AnsiString FilePart);
```

File

FileCtrl

Description

Call ProcessPath to parse a file name into its drive, path, and file name.

Pass the full file name that should be parsed as the EditText parameter. EditText must refer to an existing file or directory name.

ProcessPath returns the indicated drive, directory, and file name as the Drive, DirPart, and FilePart parameters.

ExtractFileDir

ExtractFileDrive

ExtractFileExt

ExtractFileName

ExtractFilePath

70.2.5 FileCtrl.SelectDirectory Function

Brings up a dialog to allow the user to enter a directory name.

Pascal

```
function SelectDirectory(var Directory: string; Options: TSelectDirOpts; HelpCtx: Longint):
Boolean; overload;
function SelectDirectory(const Caption: string; const Root: WideString; var Directory: string;
Options: TSelectDirExtOpts = [sdNewUI]; Parent: TWinControl = nil): Boolean; overload;
```

C++

```
Boolean SelectDirectory(AnsiString Directory, TSelectDirOpts Options, Longint HelpCtx);
Boolean SelectDirectory(const AnsiString Caption, const BSTR Root, AnsiString Directory,
TSelectDirExtOpts Options = [sdNewUI], TWinControl * Parent = nil);
```

File

FileCtrl

Description

Call SelectDirectory to let the user enter a directory name.

Use the first syntax to call the Select Directory dialog box. The directory passed to the function with the Directory parameter appears as the currently selected directory when the dialog box appears. The name of the directory the user selects becomes the value of Directory when the function returns.

The HelpCtx parameter is the help context ID number.

Use the second syntax to display the Windows directory browser. The Caption parameter specifies a caption for the dialog. The Root parameter specifies the root directory from which to browse. The selected directory is returned as the Directory parameter. When using this syntax, SelectDirectory does not change the value of the current directory.

Warning: You can't use the same variable for the Root parameter and the Directory parameter.

The Options parameter is a set of values. If Options is the empty set, the user can only select a directory that already exists. No edit box is provided for the user to enter a new directory name. If Options is not empty, the included values determine how the dialog responds when the user types a nonexistent directory name.

With either syntax, SelectDirectory returns true if the user selected a directory and chose OK, and false if the user chose Cancel or closed the dialog box without selecting a directory.

DirectoryExists (see page 13616)

ForceDirectories (see page 13617)

70.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TDriveType (see page 13620)	This is record FileCtrl.TDriveType.
	TFileAttr (see page 13620)	TFileAttr and TFileType (see page 13624) determine which files a file list box displays.
	TSelectDirExtOpt (see page 13621)	This is record FileCtrl.TSelectDirExtOpt.
	TSelectDirOpt (see page 13622)	TSelectDirOpt and TSelectDirOpts (see page 13625) determine how a directory selection dialog responds when the user enters a nonexistent directory.
	TTextCase (see page 13623)	TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

70.3.1 FileCtrl.TDriveType Enumeration

Pascal

```
TDriveType = (
  dtUnknown,
  dtNoDrive,
  dtFloppy,
  dtFixed,
  dtNetwork,
  dtCDROM,
  dtRAM
);
```

C++

```
enum TDriveType {
  dtUnknown,
  dtNoDrive,
  dtFloppy,
  dtFixed,
  dtNetwork,
  dtCDROM,
  dtRAM
};
```

File

FileCtrl

Description

This is record FileCtrl.TDriveType.

70.3.2 FileCtrl.TFileAttr Enumeration

TFileAttr and TFileType (see page 13624) determine which files a file list box displays.

Pascal

```
TFileAttr = (
  ftReadOnly,
  ftHidden,
  ftSystem,
  ftVolumeID,
  ftDirectory,
  ftArchive,
  ftNormal
);
```

C++

```
enum TFileAttr {
  ftReadOnly,
  ftHidden,
  ftSystem,
  ftVolumeID,
  ftDirectory,
  ftArchive,
  ftNormal
};
```

File

FileCtrl

Description

TFileType (see page 13624) is a set of TFileAttr values. These are the possible TFileAttr values:

Value	Meaning
ftReadOnly	The list box displays files with the read-only attribute.
ftHidden	The list box displays files with the hidden attribute.
ftSystem	The list box displays system files.
ftVolumeID	The list box displays the volume name.
ftDirectory	The list box displays directories.
ftArchive	The list box displays files with archive attribute.
ftNormal	The list box displays files with no special attributes.

See Also

SelectDirectory

70.3.3 FileCtrl.TSelectDirExtOpt Enumeration

Pascal

```
TSelectDirExtOpt = (
  sdNewFolder,
  sdShowEdit,
  sdShowShares,
  sdNewUI,
  sdShowFiles,
  sdValidateDir
);
```

C++

```
enum TSelectDirExtOpt {
  sdNewFolder,
  sdShowEdit,
  sdShowShares,
  sdNewUI,
  sdShowFiles,
  sdValidateDir
};
```

File

FileCtrl

Description

This is record FileCtrl.TSelectDirExtOpt.

70.3.4 FileCtrl.TSelectDirOpt Enumeration

TSelectDirOpt and TSelectDirOpts (see page 13625) determine how a directory selection dialog responds when the user enters a nonexistent directory.

Pascal

```
TSelectDirOpt = (
  sdAllowCreate,
  sdPerformCreate,
  sdPrompt
);
```

C++

```
enum TSelectDirOpt {
  sdAllowCreate,
  sdPerformCreate,
  sdPrompt
};
```

File

FileCtrl

Description

These are the possible values that can be added to the set of options:

Value	Meaning
sdAllowCreate	An edit box allows the user to type in the name of a directory that does not exist. This option does not create a directory: the application must read the name of the selected directory and create it if desired.
sdPerformCreate	Used only in combination with sdAllowCreate. If the user enters a directory name that does not exist, the directory selection dialog creates it.
sdPrompt	Used only in combination with sdAllowCreate. Displays a message box that informs the user when the entered directory does not exist and asks if the directory should be created. If the user chooses OK, the directory is created if the option set includes sdPerformCreate. If the option set does not include sdPerformCreate, the directory is not created: the application must read the directory name and create it.

See Also

SelectDirectory

70.3.5 FileCtrl.TTextCase Enumeration

TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

Pascal

```
TTextCase = (
  tcLowerCase,
  tcUpperCase
);
```

C++

```
enum TTextCase {
  tcLowerCase,
  tcUpperCase
};
```

File

FileCtrl

Description

TTextCase can have one of the following values:

Value	Meaning
tcLowerCase	The volume name is displayed in lowercase letters.
tcUpperCase	The volume name is displayed in uppercase letters.

70.4 Types

The following table lists types in this documentation.

Types

Name	Description
TFileType (see page 13624)	TFileType describes possible combinations of file attributes.
TSelectDirExtOpts (see page 13624)	This is type FileCtrl.TSelectDirExtOpts.
TSelectDirOpts (see page 13625)	This is type FileCtrl.TSelectDirOpts.

70.4.1 FileCtrl.TFileType Type

TFileType describes possible combinations of file attributes.

Pascal

```
TFileType = set of TFileAttr;
```

C++

```
TFileAttr TFileType;
```

File

FileCtrl

Description

TFileType describes possible combinations of file attributes.

See Also

TFileListView

70.4.2 FileCtrl.TSelectDirExtOpts Type

Pascal

```
TSelectDirExtOpts = set of TSelectDirExtOpt;
```

C++

```
TSelectDirExtOpt TSelectDirExtOpts;
```

File

FileCtrl

Description

This is type FileCtrl.TSelectDirExtOpts.

70.4.3 FileCtrl.TSelectDirOpts Type

Pascal

```
TSelectDirOpts = set of TSelectDirOpt;
```

C++

```
TSelectDirOpt TSelectDirOpts;
```

File

FileCtrl

Description

This is type FileCtrl.TSelectDirOpts.

70.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WNTYPE_DRIVE (see page 13626)	This is constant FileCtrl.WNTYPE_DRIVE.

70.5.1 FileCtrl.WNTYPE_DRIVE Constant

Pascal

```
WNTYPE_DRIVE = 1;
```

C++

```
WNTYPE_DRIVE = 1;
```

File

FileCtrl

Description

This is constant FileCtrl.WNTYPE_DRIVE.

71 FMTBcd Namespace

This is namespace FMTBcd.

Topics

Name	Description
Classes (see page 13630)	The following table lists classes in this documentation.
Functions (see page 13632)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 13649)	The following table lists structs, records, enums in this documentation.
Types (see page 13650)	The following table lists types in this documentation.
Constants (see page 13651)	The following table lists constants in this documentation.

Classes

	Name	Description
	EBcdException (see page 13630)	EBcdException is the exception class for errors that occur when working with BCD values.
	EBcdOverflowException (see page 13630)	EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the requested precision and number of decimals.

Constants

Name	Description
_DefaultDecimals (see page 13651)	This is constant FMTBcd._DefaultDecimals.
_NoDecimal (see page 13651)	This is constant FMTBcd._NoDecimal.
DefaultFMTBcdScale (see page 13652)	This is constant FMTBcd.DefaultFMTBcdScale.
MaxBcdPrecision (see page 13652)	This is constant FMTBcd.MaxBcdPrecision.
MaxBcdScale (see page 13652)	This is constant FMTBcd.MaxBcdScale.
MaxFMTBcdDigits (see page 13653)	This is constant FMTBcd.MaxFMTBcdDigits.
MaxFMTBcdFractionSize (see page 13653)	This is constant FMTBcd.MaxFMTBcdFractionSize.
MaxStringDigits (see page 13653)	This is constant FMTBcd.MaxStringDigits.
NullBcd (see page 13654)	Represents a NULL TBcd (see page 13649) value.
SizeOfFraction (see page 13654)	This is constant FMTBcd.SizeOfFraction.
SizeOfTBCD (see page 13654)	This is constant FMTBcd.SizeOfTBCD.

Functions

	Name	Description
	BcdAdd (see page 13633)	Adds two TBcd (see page 13649) values.
	BcdCompare (see page 13633)	Compares two TBcd (see page 13649) values.

	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdFromBytes (see page 13635)	This is function FMTBcd.BcdFromBytes.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdPrecision (see page 13636)	Returns the precision of a binary-coded decimal (BCD) value.
	BcdScale (see page 13636)	Returns the number of decimal places for a binary-coded decimal (BCD) value.
	BcdSubtract (see page 13637)	Subtracts one BCD value from another.
	BcdToBytes (see page 13637)	This is function FMTBcd.BcdToBytes.
	BCDToCurr (see page 13637)	Converts a binary-coded decimal value (BCD) to the corresponding Currency value.
	BcdToDouble (see page 13638)	Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.
	BcdToInteger (see page 13638)	Converts a binary-coded decimal value (BCD) to an integer.
	BcdToStr (see page 13639)	Returns a string representation of a binary-coded decimal (BCD) value.
	BcdToStrF (see page 13639)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	CurrToBCD (see page 13640)	Converts a Currency value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 13641)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 13641)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	FormatBcd (see page 13641)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	IntegerToBcd (see page 13642)	Converts an integer value to the corresponding binary-coded decimal (BCD) value.
	IsBcdNegative (see page 13642)	Indicates whether a binary-coded decimal (BCD) value is less than 0.
	NormalizeBcd (see page 13643)	Converts a BCD value into another BCD value with a specified precision and number of decimals.
	OldBCDToCurr (see page 13643)	This is function FMTBcd.OldBCDToCurr.
	OldCurrToBCD (see page 13644)	This is function FMTBcd.OldCurrToBCD.
	RoundAt (see page 13644)	This is function FMTBcd.RoundAt.
	StrToBcd (see page 13644)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	TryStrToBcd (see page 13645)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	VarFMTBcd (see page 13646)	Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarIsFMTBcd (see page 13647)	Indicates whether a specified Variant represents a TBcd (see page 13649) value.
	VarToBcd (see page 13647)	Converts a Variant into a TBcd (see page 13649) type.

Structs, Records, Enums

	Name	Description
	TBcd (see page 13649)	TBcd stores a binary coded decimal value.

Types

Name	Description
PBcd (see page 13650)	This is type FMTBcd.PBcd.
TNibbleArray (see page 13650)	This is type FMTBcd.TNibbleArray.

71.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EBcdException (see page 13630)	EBcdException is the exception class for errors that occur when working with BCD values.
	EBcdOverflowException (see page 13630)	EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the requested precision and number of decimals.

71.1.1 EBcdException Class

EBcdException is the exception class for errors that occur when working with BCD values.

Class Hierarchy

Pascal

```
EBcdException = class(Exception);
```

C++

```
class EBcdException : public Exception;
```

File

FMTBcd

Description

EBcdException is raised when

An attempt to convert a Variant or string to a BCD value is unsuccessful.

An application tries to create a Variant that represents a BCD value, starting with a value that can't be successfully converted.

An application tries to divide by a BCD type whose value is 0.

See Also

VarFMTBcdCreate (see page 13646)

TBcd (see page 13649)

StrToBCD

BCDDivide

71.1.2 EBcdOverflowException Class

EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the

requested precision and number of decimals.

Class Hierarchy

Pascal

```
EBcdOverflowException = class(EBcdException);
```

C++

```
class EBcdOverflowException : public EBcdException;
```

File

FMTBcd

Description

EBcdOverflowException is raised when

A call to VarFMTBcdCreate (see page 13646) tries to create a BCD value with a precision and number of decimals that can't be supported.

An application tries to cast a Variant to a BCD value but it can't be expressed using the default precision and number of decimals.

See Also

VarFMTBcdCreate (see page 13646)

TBcd (see page 13649)

71.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	BcdAdd (see page 13633)	Adds two TBcd (see page 13649) values.
	BcdCompare (see page 13633)	Compares two TBcd (see page 13649) values.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdDivide (see page 13634)	Divides one BCD value by another.
	BcdFromBytes (see page 13635)	This is function FMTBcd.BcdFromBytes.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdMultiply (see page 13635)	Multiplies two BCD values.
	BcdPrecision (see page 13636)	Returns the precision of a binary-coded decimal (BCD) value.
	BcdScale (see page 13636)	Returns the number of decimal places for a binary-coded decimal (BCD) value.
	BcdSubtract (see page 13637)	Subtracts one BCD value from another.
	BcdToBytes (see page 13637)	This is function FMTBcd.BcdToBytes.
	BCDToCurr (see page 13637)	Converts a binary-coded decimal value (BCD) to the corresponding Currency value.
	BcdToDouble (see page 13638)	Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.
	BcdToInteger (see page 13638)	Converts a binary-coded decimal value (BCD) to an integer.
	BcdToStr (see page 13639)	Returns a string representation of a binary-coded decimal (BCD) value.
	BcdToStrF (see page 13639)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	CurrToBCD (see page 13640)	Converts a Currency value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 13641)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 13641)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	FormatBcd (see page 13641)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	IntegerToBcd (see page 13642)	Converts an integer value to the corresponding binary-coded decimal (BCD) value.
	IsBcdNegative (see page 13642)	Indicates whether a binary-coded decimal (BCD) value is less than 0.
	NormalizeBcd (see page 13643)	Converts a BCD value into another BCD value with a specified precision and number of decimals.
	OldBCDToCurr (see page 13643)	This is function FMTBcd.OldBCDToCurr.
	OldCurrToBCD (see page 13644)	This is function FMTBcd.OldCurrToBCD.
	RoundAt (see page 13644)	This is function FMTBcd.RoundAt.
	StrToBcd (see page 13644)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	TryStrToBcd (see page 13645)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	VarFMTBcd (see page 13646)	Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.

	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarFMTBcdCreate (see page 13646)	Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.
	VarIsFMTBcd (see page 13647)	Indicates whether a specified Variant represents a TBcd (see page 13649) value.
	VarToBcd (see page 13647)	Converts a Variant into a TBcd (see page 13649) type.

71.2.1 FMTBcd.BcdAdd Function

Adds two TBcd (see page 13649) values.

Pascal

```
procedure BcdAdd(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd); deprecated;
```

C++

```
BcdAdd(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdAdd adds bcdIn1 to bcdIn2 and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the addition. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 13643) procedure.

See Also

BcdSubtract

BcdMultiply

BcdDivide

NormalizeBcd

71.2.2 FMTBcd.BcdCompare Function

Compares two TBcd (see page 13649) values.

Pascal

```
function BcdCompare(const bcd1: TBcd; const bcd2: TBcd): Integer;
```

C++

```
int BcdCompare(const TBcd bcd1, const TBcd bcd2);
```

File

FMTBcd

Description

Call BcdCompare to compare two TBcd (see page 13649) values. The return value is indicated in the following table:

Return value	Condition
-1	bcd1< bcd2
0	bcd1= bcd2
1	bcd1 > bcd2

See Also

CompareValue

71.2.3 FMTBcd.BcdDivide Function

Divides one BCD value by another.

Pascal

```
procedure BcdDivide(Dividend: string; Divisor: string; var bcdOut: TBcd); overload; deprecated;
procedure BcdDivide(const Dividend: TBcd; const Divisor: TBcd; var bcdOut: TBcd); overload;
deprecated;
procedure BcdDivide(const Dividend: TBcd; const Divisor: Double; var bcdOut: TBcd); overload;
deprecated;
procedure BcdDivide(const Dividend: TBcd; const Divisor: string; var bcdOut: TBcd); overload;
deprecated;
```

C++

```
BcdDivide(AnsiString Dividend, AnsiString Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const TBcd Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const Double Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const AnsiString Divisor, TBcd bcdOut);
```

File

FMTBcd

Description

BcdDivide divides Dividend by Divisor and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the division, if possible. (The number of decimal places in the result, however, will never exceed 10.) You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 13643) procedure.

See Also

BcdSubtract

BcdMultiply

BcdAdd

NormalizeBcd

71.2.4 FMTBcd.BcdFromBytes Function

Pascal

```
function BcdFromBytes(const AValue: TBytes): TBcd;
```

C++

```
TBcd BcdFromBytes(const TBytes AValue);
```

File

FMTBcd

Description

This is function FMTBcd.BcdFromBytes.

71.2.5 FMTBcd.BcdMultiply Function

Multiplies two BCD values.

Pascal

```
procedure BcdMultiply(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd); overload;
deprecated;
procedure BcdMultiply(const bcdIn: TBcd; const DoubleIn: Double; var bcdOut: TBcd); overload;
deprecated;
procedure BcdMultiply(const bcdIn: TBcd; const StringIn: string; var bcdOut: TBcd); overload;
deprecated;
procedure BcdMultiply(StringIn1: string; StringIn2: string; var bcdOut: TBcd); overload;
deprecated;
```

C++

```
BcdMultiply(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
BcdMultiply(const TBcd bcdIn, const Double DoubleIn, TBcd bcdOut);
BcdMultiply(const TBcd bcdIn, const AnsiString StringIn, TBcd bcdOut);
BcdMultiply(AnsiString StringIn1, AnsiString StringIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdMultiply multiplies the first two arguments and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the multiplication, if possible. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 13643) procedure.

See Also

BcdSubtract

BcdDivide

BcdAdd

NormalizeBcd

71.2.6 FMTBcd.BcdPrecision Function

Returns the precision of a binary-coded decimal (BCD) value.

Pascal

```
function BcdPrecision(const Bcd: TBcd): Word;
```

C++

```
Word BcdPrecision(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdPrecision to determine the number of significant digits in a specified BCD value.

See Also

BcdScale

IsBcdNegative

NormalizeBcd

71.2.7 FMTBcd.BcdScale Function

Returns the number of decimal places for a binary-coded decimal (BCD) value.

Pascal

```
function BcdScale(const Bcd: TBcd): Word;
```

C++

```
Word BcdScale(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdScale to determine the number of decimal places in a specified BCD value.

See Also

BcdPrecision

IsBcdNegative

NormalizeBcd

71.2.8 FMTBcd.BcdSubtract Function

Subtracts one BCD value from another.

Pascal

```
procedure BcdSubtract(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd); deprecated;
```

C++

```
BcdSubtract(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdSubtract subtracts bcdIn2 from bcdIn1 and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the subtraction. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 13643) procedure.

See Also

BcdMultiply

BcdDivide

BcdAdd

NormalizeBcd

71.2.9 FMTBcd.BcdToBytes Function

Pascal

```
function BcdToBytes(const Value: TBcd): TBytes;
```

C++

```
TBytes BcdToBytes(const TBcd Value);
```

File

FMTBcd

Description

This is function FMTBcd.BcdToBytes.

71.2.10 FMTBcd.BCDToCurr Function

Converts a binary-coded decimal value (BCD) to the corresponding Currency value.

Pascal

```
function BCDToCurr(const BCD: TBcd; var Curr: Currency): Boolean;
```

C++

```
Boolean BCDToCurr(const TBcd BCD, Currency Curr);
```

File

FMTBcd

Description

Use BCDToCurr to convert a binary-coded decimal value, such as is stored in a physical BCD database field, into a Currency value, which is the representation used by TBCDField objects. BCDToCurr returns true if the BCD value passed as the BCD parameter is successfully converted into a Currency object which is passed out as the Curr parameter.

See Also

CurrToBCD

TBCDField

TField

71.2.11 FMTBcd.BcdToDouble Function

Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.

Pascal

```
function BcdToDouble(const Bcd: TBcd): Double;
```

C++

```
Double BcdToDouble(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdToDouble to convert a binary-coded decimal value into a double precision floating point value. If the Bcd parameter represents a value that can't be expressed in double precision, BcdToDouble raises an exception.

See Also

DoubleToBcd

BCDToCurr

BCDToInteger

71.2.12 FMTBcd.BcdToInteger Function

Converts a binary-coded decimal value (BCD) to an integer.

Pascal

```
function BcdToInteger(const Bcd: TBcd; Truncate: Boolean = False): Integer;
```

C++

```
int BcdToInteger(const TBcd Bcd, Boolean Truncate = False);
```

File

FMTBcd

Description

Use BcdToInteger to convert a binary-coded decimal value into an integer.

Bcd is the value to convert.

Truncate indicates how to handle values that include a decimal portion. If Truncate is true, BcdToInteger truncates the value specified by Bcd and converts only the integer portion. If Truncate is false, BcdToInteger raises an exception if the Bcd parameter does not represent an integer value.

See Also

IntegerToBcd

BCDToCurr

BCDToDouble

71.2.13 FMTBcd.BcdToStr Function

Returns a string representation of a binary-coded decimal (BCD) value.

Pascal

```
function BcdToStr(const Bcd: TBcd): string; overload;
```

C++

```
AnsiString BcdToStr(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdToStr to convert a binary-coded decimal value into a string. BcdToStr formats the string to display all of the digits stored in the BCD value.

See Also

BcdToStrF

StrToBcd

TryStrToBcd

71.2.14 FMTBcd.BcdToStrF Function

Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.

Pascal

```
function BcdToStrF(const Bcd: TBcd; Format: TFloatFormat; const Precision: Integer; const
Digits: Integer): string;
```

C++

```
AnsiString BcdToStrF(const TBcd Bcd, TFloatFormat Format, const int Precision, const int
Digits);
```

File

FMTBcd

Description

Use BcdToStrF to convert a binary-coded decimal value into a string.

Value is the BCD value to convert to a string.

Format is the formatting code that indicates the overall type of formatting to use.

Precision indicates the maximum number of significant digits in the resulting string.

Digits indicates the maximum number of digits past the decimal point in the resulting string.

See Also

BcdToStr

StrToBcd

FloatToStrF

FormatBcd

TryStrToBcd

71.2.15 FMTBcd.CurrToBCD Function

Converts a Currency value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function CurrToBCD(const Curr: Currency; var BCD: TBcd; Precision: Integer = 32; Decimals:
Integer = 4): Boolean;
```

C++

```
Boolean CurrToBCD(const Currency Curr, TBcd BCD, int Precision = 32, int Decimals = 4);
```

File

FMTBcd

Description

Use CurrToBCD to convert a Currency value, such as is used by TBCDField objects, into a binary-coded decimal value, such as is stored in a physical BCD database field. CurrToBCD returns true if the Currency object passed as the Curr parameter is successfully converted into a BCD value and passed out as the BCD parameter. The Precision parameter specifies the number of digits represented in the BCD value, and the Decimals parameter specifies the number of those digits that are after the decimal point.

See Also

BCDToCurr

TBCDField

TField

71.2.16 FMTBcd.DoubleToBcd Function

Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function DoubleToBcd(const AValue: Double): TBcd; overload;
procedure DoubleToBcd(const AValue: Double; var bcd: TBcd); overload;
```

C++

```
TBcd DoubleToBcd(const Double AValue);
DoubleToBcd(const Double AValue, TBcd bcd);
```

File

FMTBcd

Description

Use DoubleToBcd to convert a double precision floating point value into a binary-coded decimal value. DoubleToBcd infers the number of decimal places and significant digits from the specified value aValue, using only as many as necessary. It never sets the number of significant digits to a value greater than 15.

aValue is the value to convert.

bcd returns the resulting BCD value when using the second syntax. When using the first syntax, the BCD value is the return value of the function.

See Also

BCDToDouble

CurrToBcd

IntegerToBcd

71.2.17 FMTBcd.FormatBcd Function

Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.

Pascal

```
function FormatBcd(const Format: string; Bcd: TBcd): string;
```

C++

```
AnsiString FormatBcd(const AnsiString Format, TBcd Bcd);
```

File

FMTBcd

Description

Use FormatBcd to convert a binary-coded decimal value into a string.

Format indicates how the resulting string should be formatted. It uses the same format specifiers as pertain to the FormatFloat function.

Bcd is the value to convert to a string.

See Also

BcdToStrF

FormatFloat

BcdToStr

TryStrToBcd

StrToBcd

71.2.18 FMTBcd.IntegerToBcd Function

Converts an integer value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function IntegerToBcd(const AValue: Integer): TBcd;
```

C++

```
TBcd IntegerToBcd(const int AValue);
```

File

FMTBcd

Description

Use IntegerToBcd to convert an integer into a binary-coded decimal value.

See Also

BCDToInteger

CurrToBcd

DoubleToBcd

71.2.19 FMTBcd.IsBcdNegative Function

Indicates whether a binary-coded decimal (BCD) value is less than 0.

Pascal

```
function IsBcdNegative(const Bcd: TBcd): Boolean;
```

C++

```
Boolean IsBcdNegative(const TBcd Bcd);
```

File

FMTBcd

Description

IsBcdNegative returns true if Bcd is less than 0, false if Bcd is greater than or equal to 0.

See Also

BcdPrecision

BcdScale

NormalizeBcd

71.2.20 FMTBcd.NormalizeBcd Function

Converts a BCD value into another BCD value with a specified precision and number of decimals.

Pascal

```
function NormalizeBcd(const InBcd: TBcd; var OutBcd: TBcd; const Prec: Word; const Scale:
Word): Boolean;
```

C++

```
Boolean NormalizeBcd(const TBcd InBcd, TBcd OutBcd, const Word Prec, const Word Scale);
```

File

FMTBcd

Description

Call NormalizeBcd to give a TBcd (see page 13649) value a specific precision and number of decimal places. If the specified precision or number of decimal places is less than that of the original BCD value, NormalizeBcd truncates the value (as opposed to rounding).

InBcd is the BCD value to convert.

OutBcd returns the resulting BCD value with the specified precision and decimal places.

Prec is the number of significant digits in OutBcd.

Scale is the number of decimal places in OutBcd.

NormalizeBcd returns true if the conversion can be made with no loss of precision. It returns false if the conversion required some digits to be truncated.

71.2.21 FMTBcd.OldBCDToCurr Function

Pascal

```
function OldBCDToCurr(const BCD: TBcd; var Curr: Currency): Boolean;
```

C++

```
Boolean OldBCDToCurr(const TBcd BCD, Currency Curr);
```

File

FMTBcd

Description

This is function FMTBcd.OldBCDToCurr.

71.2.22 FMTBcd.OldCurrToBCD Function

Pascal

```
function OldCurrToBCD(const Curr: Currency; var BCD: TBcd; Precision: Integer = 32; Decimals:
Integer = 4): Boolean;
```

C++

```
Boolean OldCurrToBCD(const Currency Curr, TBcd BCD, int Precision = 32, int Decimals = 4);
```

File

FMTBcd

Description

This is function FMTBcd.OldCurrToBCD.

71.2.23 FMTBcd.RoundAt Function

Pascal

```
function RoundAt(const Value: string; Position: SmallInt): string;
```

C++

```
AnsiString RoundAt(const AnsiString Value, SmallInt Position);
```

File

FMTBcd

Description

This is function FMTBcd.RoundAt.

71.2.24 FMTBcd.StrToBcd Function

Converts a string to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function StrToBcd(const AValue: string): TBcd;
```

C++

```
TBcd StrToBcd(const AnsiString AValue);
```

File

FMTBcd

Description

Use StrToBcd to convert a string into a binary-coded decimal value. The decimals and precision are inferred from the digits present in the string.

StrToBcd converts the string specified by aValue and returns the resulting BCD value. If aValue does not represent a value that can be expressed as a TBcd (see page 13649), StrToBcd raises an exception.

Tip: To convert a string to a Bcd value without raising an exception for invalid strings, use the TryStrToBcd (see page 13645) function instead.

See Also

BcdToStr

BcdToStrF

FormatBcd

TryStrToBcd

71.2.25 FMTBcd.TryStrToBcd Function

Converts a string to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function TryStrToBcd(const AValue: string; var Bcd: TBcd): Boolean;
```

C++

```
Boolean TryStrToBcd(const AnsiString AValue, TBcd Bcd);
```

File

FMTBcd

Description

Use TryStrToBcd to convert a string into a binary-coded decimal value. The decimals and precision are inferred from the digits present in the string.

TryStrToBcd converts the string specified by aValue and returns the resulting BCD value as Bcd.

TryStrToBcd returns true if it successfully converts aValue to a TBcd (see page 13649) value. If aValue can't be successfully converted to a TBcd (see page 13649) value, TryStrToBcd returns false.

See Also

BcdToStr

BcdToStrF

FormatBcd

StrToBcd

71.2.26 FMTBcd.VarFMTBcd Function

Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 13649) value.

Pascal

```
function VarFMTBcd: TVarType;
```

C++

```
TVarType VarFMTBcd();
```

File

FMTBcd

Description

VarFMTBcd returns the Variant type code that identifies a TBcd (see page 13649)-valued Variant. This is the value that the VarType function returns when the Variant stores its value as a TBcd (see page 13649) value.

The Variant type codes for custom Variants (see page 23567) are dynamically allocated when the application loads the unit that implements them. VarFMTBcd allows the application to identify the Variant type code that is currently used for custom Variants (see page 23567) that represent a BCD value. This type code, however, may not match the type code used by another application that uses a different set of custom Variant types.

VarIsFMTBcd

VarType

TBcd

VarToBcd

71.2.27 FMTBcd.VarFMTBcdCreate Function

Creates a new Variant that stores its value internally as a TBcd (see page 13649) value.

Pascal

```
procedure VarFMTBcdCreate(var ADest: Variant; const ABcd: TBcd); overload;
function VarFMTBcdCreate: Variant; overload;
function VarFMTBcdCreate(const AValue: string; Precision: Word; Scale: Word): Variant;
overload;
function VarFMTBcdCreate(const AValue: Double; Precision: Word = 18; Scale: Word = 4):
Variant; overload;
function VarFMTBcdCreate(const ABcd: TBcd): Variant; overload;
```

C++

```
VarFMTBcdCreate(Variant ADest, const TBcd ABcd);
Variant VarFMTBcdCreate();
Variant VarFMTBcdCreate(const AnsiString AValue, Word Precision, Word Scale);
Variant VarFMTBcdCreate(const Double AValue, Word Precision = 18, Word Scale = 4);
Variant VarFMTBcdCreate(const TBcd ABcd);
```

File

FMTBcd

Description

Call VarBcdCreate to obtain a Variant that stores its value as a TBcd (see page 13649) value.

Using the first syntax, the Variant returned as aDest has the same value as ABcd.

Using the second syntax (passing no arguments), the returned Variant has a value of NullBcd (see page 13654).

Using the third syntax, the returned Variant has the same value as ABcd.

Using the fourth syntax, the returned Variant converts AValue (if necessary) to extract the value.

Using the remaining syntaxes, the AValue parameter is converted into a TBcd (see page 13649) value with the specified Precision and Scale and the result is the value of the Variant.

See Also

VarIsFMTBcd

VarToBcd

NullBcd

71.2.28 FMTBcd.VarIsFMTBcd Function

Indicates whether a specified Variant represents a TBcd (see page 13649) value.

Pascal

```
function VarIsFMTBcd(const AValue: Variant): Boolean; overload;
```

C++

```
Boolean VarIsFMTBcd(const Variant AValue);
```

File

FMTBcd

Description

VarIsBcd returns true if the Variant aValue stores its value internally as a TBcd (see page 13649) value. VarIsBcd returns false otherwise.

See Also

VarToBcd

TBcd

VarFMTBcd

71.2.29 FMTBcd.VarToBcd Function

Converts a Variant into a TBcd (see page 13649) type.

Pascal

```
function VarToBcd(const AValue: Variant): TBcd;
```

C++

```
TBcd VarToBcd(const Variant AValue);
```

File

FMTBcd

Description

Use VarDoubleAsBcd to obtain a TBcd (see page 13649) value from a Variant.

aValue is the Variant to convert.

VarIsFMTBcd

71.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TBcd (see page 13649)	TBcd stores a binary coded decimal value.

71.3.1 FMTBcd.TBcd Record

TBcd stores a binary coded decimal value.

Pascal

```
TBcd = packed record
  Precision: Byte;
  SignSpecialPlaces: Byte;
  Fraction: packed array [0..31] of Byte;
end;
```

C++

```
struct TBcd {
  Byte Precision;
  Byte SignSpecialPlaces;
  packed array [0..31] of Byte Fraction;
};
```

File

FMTBcd

Description

TBcd represents a binary coded decimal value. It contains the following fields:

Field	Contents
Precision	The number of digits in the decimal version of the value.
SignSpecialPlaces	The sign bit (0 is positive, any other value negative)
Fraction	An array of BCD nibbles, 00 to 99 per byte, high nibble first. Only the first Precision nibbles are used.

You can create a Variant that represents a TBcd value using the VarFMTBcdCreate (see page 13646) function. In fact, the easiest way to manipulate TBcd values is to create Variants (see page 23567) for them and use the built-in operators provided by the Variant type.

71.4 Types

The following table lists types in this documentation.

Types

Name	Description
PBcd (see page 13650)	This is type FMTBcd.PBcd.
TNibbleArray (see page 13650)	This is type FMTBcd.TNibbleArray.

71.4.1 FMTBcd.PBcd Type

Pascal

```
PBcd = ^TBcd;
```

C++

```
^TBcd PBcd;
```

File

FMTBcd

Description

This is type FMTBcd.PBcd.

71.4.2 FMTBcd.TNibbleArray Type

Pascal

```
TNibbleArray = array[0..63] of Byte;
```

C++

```
array[0..63] of Byte TNibbleArray;
```

File

FMTBcd

Description

This is type FMTBcd.TNibbleArray.

71.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
_DefaultDecimals (see page 13651)	This is constant FMTBcd._DefaultDecimals.
_NoDecimal (see page 13651)	This is constant FMTBcd._NoDecimal.
DefaultFMTBcdScale (see page 13652)	This is constant FMTBcd.DefaultFMTBcdScale.
MaxBcdPrecision (see page 13652)	This is constant FMTBcd.MaxBcdPrecision.
MaxBcdScale (see page 13652)	This is constant FMTBcd.MaxBcdScale.
MaxFMTBcdDigits (see page 13653)	This is constant FMTBcd.MaxFMTBcdDigits.
MaxFMTBcdFractionSize (see page 13653)	This is constant FMTBcd.MaxFMTBcdFractionSize.
MaxStringDigits (see page 13653)	This is constant FMTBcd.MaxStringDigits.
NullBcd (see page 13654)	Represents a NULL TBcd (see page 13649) value.
SizeOfFraction (see page 13654)	This is constant FMTBcd.SizeOfFraction.
SizeOfTBCD (see page 13654)	This is constant FMTBcd.SizeOfTBCD.

71.5.1 FMTBcd._DefaultDecimals Constant

Pascal

```
_DefaultDecimals = 10;
```

C++

```
_DefaultDecimals = 10;
```

File

FMTBcd

Description

This is constant FMTBcd._DefaultDecimals.

71.5.2 FMTBcd._NoDecimal Constant

Pascal

```
_NoDecimal = -255;
```

C++

```
_NoDecimal = -255;
```

File

FMTBcd

Description

This is constant FMTBcd._NoDecimal.

71.5.3 FMTBcd.DefaultFMTBcdScale Constant

Pascal

```
DefaultFMTBcdScale = 6;
```

C++

```
DefaultFMTBcdScale = 6;
```

File

FMTBcd

Description

This is constant FMTBcd.DefaultFMTBcdScale.

71.5.4 FMTBcd.MaxBcdPrecision Constant

Pascal

```
MaxBcdPrecision = 18;
```

C++

```
MaxBcdPrecision = 18;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxBcdPrecision.

71.5.5 FMTBcd.MaxBcdScale Constant

Pascal

```
MaxBcdScale = 4;
```

C++

```
MaxBcdScale = 4;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxBcdScale.

71.5.6 FMTBcd.MaxFMTBcdDigits Constant

Pascal

```
MaxFMTBcdDigits = 32;
```

C++

```
MaxFMTBcdDigits = 32;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxFMTBcdDigits.

71.5.7 FMTBcd.MaxFMTBcdFractionSize Constant

Pascal

```
MaxFMTBcdFractionSize = 64;
```

C++

```
MaxFMTBcdFractionSize = 64;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxFMTBcdFractionSize.

71.5.8 FMTBcd.MaxStringDigits Constant

Pascal

```
MaxStringDigits = 100;
```

C++

```
MaxStringDigits = 100;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxStringDigits.

71.5.9 FMTBcd.NullBcd Constant

Represents a NULL TBcd (see page 13649) value.

Pascal

```
NullBcd: TBcd = (Precision: 0; SignSpecialPlaces: 0; Fraction:
(0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0));
```

C++

```
TBcd NullBcd = (Precision: 0; SignSpecialPlaces: 0; Fraction:
(0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0));
```

File

FMTBcd

Description

Use NullBcd to indicate an unknown or missing TBcd (see page 13649) value. NullBcd is a TBcd (see page 13649) with all its fields set to 0.

See Also

Null

71.5.10 FMTBcd.SizeOfFraction Constant

Pascal

```
SizeOfFraction = 32;
```

C++

```
SizeOfFraction = 32;
```

File

FMTBcd

Description

This is constant FMTBcd.SizeOfFraction.

71.5.11 FMTBcd.SizeOfTBCD Constant

Pascal

```
SizeOfTBCD = 2 + SizeOfFraction;
```

C++

```
SizeOfTBCD = 2 + SizeOfFraction;
```

File

FMTBcd

Description

This is constant FMTBcd.SizeOfTBCD.

72 Forms Namespace

This is namespace Forms.

Topics

Name	Description
Classes (see page 13660)	The following table lists classes in this documentation.
Interfaces (see page 14334)	The following table lists interfaces in this documentation.
Functions (see page 14342)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 14353)	The following table lists structs, records, enums in this documentation.
Types (see page 14369)	The following table lists types in this documentation.
Variables (see page 14383)	The following table lists variables in this documentation.

Classes

	Name	Description
	TApplication (see page 13660)	TApplication is the type used for a GUI windowed application.
	TControlScrollBar (see page 13744)	TControlScrollBar displays a horizontal or vertical scroll bar.
	TCustomActiveForm (see page 13759)	TCustomActiveForm is the base class for Active (see page 13896) Forms.
	TCustomDockForm (see page 13829)	TCustomDockForm is the default floating dock site class for TControl objects.
	TCustomForm (see page 13849)	TCustomForm is the base class from which to derive a window such as a form or dialog.
	TCustomFrame (see page 13978)	TCustomFrame is the base class from which TFrame (see page 14114) descends.
	TForm (see page 13992)	TForm represents a standard application window (form).
	TFrame (see page 14114)	TFrame is a container for components; it can be nested within forms or other frames.
	TGlassFrame (see page 14186)	TGlassFrame controls Windows Vista Aero glass effects.
	TMonitor (see page 14191)	TMonitor represents a monitor on which an application runs.
	TScreen (see page 14197)	TScreen represents the state of the screen in which an application runs.
	TScrollBox (see page 14238)	TScrollBox represents a scrolling area (a scroll box) in a window.
	TScrollingWinControl (see page 14312)	TScrollingWinControl is the base class for controls that support scrolling.

Functions

	Name	Description
	AllocateHWnd (see page 14342)	Creates a window that implements a specified window procedure.
	DeallocateHWnd (see page 14343)	Frees a window that was created using AllocateHWnd (see page 14342).
	DisableTaskWindows (see page 14343)	This is function Forms.DisableTaskWindows.
	DoneCtl3D (see page 14344)	This is function Forms.DoneCtl3D.

	EnableTaskWindows (see page 14344)	This is function Forms.EnableTaskWindows.
	ForegroundTask (see page 14344)	Indicates whether the current thread is running in the foreground.
	FreeObjectInstance (see page 14345)	This is function Forms.FreeObjectInstance.
	GetApplicationMainFormOnTaskBar (see page 14345)	This is function Forms.GetApplicationMainFormOnTaskBar.
	GetCustomFormGlassFrame (see page 14345)	This is function Forms.GetCustomFormGlassFrame.
	GetParentForm (see page 14346)	Returns the form or property page that contains a specified control.
	InitCtl3D (see page 14346)	This is function Forms.InitCtl3D.
	IsAccel (see page 14346)	Indicates whether a particular character is an accelerator character (or hot key) within a given menu caption or other text string.
	KeyboardStateToShiftState (see page 14347)	Convert array of virtual keys to TShiftState.
	KeyboardStateToShiftState (see page 14347)	Convert array of virtual keys to TShiftState.
	KeyDataToShiftState (see page 14348)	Convert keyboard message data to TShiftState.
	KeysToShiftState (see page 14348)	Convert mouse event parameter to TShiftState.
	MakeObjectInstance (see page 14349)	This is function Forms.MakeObjectInstance.
	RestoreFocusState (see page 14349)	This is function Forms.RestoreFocusState.
	SaveFocusState (see page 14349)	This is function Forms.SaveFocusState.
	SetApplicationMainFormOnTaskBar (see page 14350)	This is function Forms.SetApplicationMainFormOnTaskBar.
	SetAutoSubClass (see page 14350)	This is function Forms.SetAutoSubClass.
	SetCustomFormGlassFrame (see page 14350)	This is function Forms.SetCustomFormGlassFrame.
	Subclass3DDlg (see page 14351)	This is function Forms.Subclass3DDlg.
	Subclass3DWnd (see page 14351)	This is function Forms.Subclass3DWnd.
	ValidParentForm (see page 14351)	Returns the form or property page that contains a specified control.

Interfaces

	Name	Description
	IDesignerHook (see page 14334)	IDesignerHook is an interface that allows component writers to interact with the form designer in the IDE.
	IOleForm (see page 14340)	IOleForm is designed to communicate with OLE containers. To embed a VCL form in an OLE container, CodeGear recommends using ActiveForms and TOleControl instead of IOleForm.

Structs, Records, Enums

	Name	Description
	TActiveFormBorderStyle (see page 14353)	Specifies the style of an active form's border.
	TBorderIcon (see page 14354)	TBorderIcons (see page 14370) and TBorderIcons (see page 14370) specify the buttons that appear on the title bar of a form window.
	TCloseAction (see page 14355)	TCloseAction describes how a form should respond when it is closed.
	TCMHintShow (see page 14355)	This is record Forms.TCMHintShow.
	TCMHintShowPause (see page 14356)	This is record Forms.TCMHintShowPause.
	TCursorRec (see page 14356)	This is record Forms.TCursorRec.
	TDefaultMonitor (see page 14357)	Specifies the monitor on which the form appears.
	TFormBorderStyle (see page 14357)	TFormBorderStyle is the type of the BorderStyle property for windows-only forms and TBorderStyle (see page 14371) is the type of the BorderStyle property for other controls in windows-only applications.
	TFormStyle (see page 14358)	TFormStyle describes form style.
	THintInfo (see page 14359)	THintInfo is used to define the appearance and behavior of the Help window.
	TMonitorDefaultTo (see page 14361)	TMonitorDefautlTo specifies which monitor to select when there is no match to the specified criteria.
	TPopupForm (see page 14362)	This is record Forms.TPopupForm.
	TPopupMode (see page 14362)	TPopupMode enumerates the possible values of a Form's PopupMode property.
	TPopupWnd (see page 14363)	This is record Forms.TPopupWnd.
	TPosition (see page 14363)	TPosition describes the positioning of a form.
	TPrintScale (see page 14364)	Represents the proportions of a printed form.
	TScrollBarKind (see page 14365)	TScrollBarKind indicates the orientation of a scrollbar.
	TScrollBarStyle (see page 14366)	TScrollBarStyle specifies a scroll bar style.
	TShowAction (see page 14366)	This is record Forms.TShowAction.
	TTileMode (see page 14367)	Represents how MDI child forms are arranged when the Tile method is called.

	TTimerMode (see page 14367)	This is record Forms.TTimerMode.
	TWindowState (see page 14368)	TWindowState indicates whether a form is maximized, minimized, or normally sized.

Types

Name	Description
PCursorRec (see page 14369)	This is type Forms.PCursorRec.
PHintInfo (see page 14370)	PHintInfo declares a pointer to a Help Window appearance record.
TBorderIcons (see page 14370)	TBorderIcons specifies the buttons that appear on the title bar of a form window.
TBorderStyle (see page 14371)	TBorderStyle is the type of the BorderStyle property for framed controls.
TCloseEvent (see page 14371)	TCloseEvent is the type of a form's OnClose event handle.
TCloseQueryEvent (see page 14372)	TCloseQueryEvent is used for event handlers that are called when a window is about to close.
TCustomFormClass (see page 14372)	TCustomFormClass defines the metaclass for TCustomForm (see page 13849).
TCustomFrameClass (see page 14373)	TCustomFrameClass defines the metaclass for TCustomFrame (see page 13978).
TExceptionEvent (see page 14373)	TExceptionEvent is the type of event handlers that respond when the application traps an unhandled exception.
TFocusState (see page 14374)	This is type Forms.TFocusState.
TFormClass (see page 14374)	TFormClass defines the metaclass for TForm (see page 13992).
TFormState (see page 14374)	TFormState describes the possible state of a form.
TGetHandleEvent (see page 14375)	This is type Forms.TGetHandleEvent.
THelpEvent (see page 14375)	THelpEvent is the type of an OnHelp event handler.
TIdleEvent (see page 14376)	TIdleEvent is the type of event handler that perform actions when the application is idle.
TMessageEvent (see page 14376)	TMessageEvent is the type of an OnMessage event handler.
TPopupFormArray (see page 14377)	This is type Forms.TPopupFormArray.
TPopupWndArray (see page 14377)	This is type Forms.TPopupWndArray.
TScrollBarInc (see page 14377)	TScrollBarInc represents a number of logical units on a TControlScrollBar (see page 13744).
TSetLayeredWindowAttributes (see page 14378)	This is type Forms.TSetLayeredWindowAttributes.
TSettingChangeEvent (see page 14378)	TSettingChangeEvent is the type of an OnSettingChange event handler.
TShortCutEvent (see page 14381)	TShortCutEvent is the type of an OnShortCut event handler.
TShowHintEvent (see page 14381)	TShowHintEvent is the type of the OnShowHint event handler.
TWindowHook (see page 14382)	TWindowHook is the type for a dialog procedure.

Variables

Name	Description
Application (see page 14383)	Represents application-level information.
Ctl3DBtnWndProc (see page 14383)	This is variable Forms.Ctl3DBtnWndProc.
Ctl3DCtlColorEx (see page 14384)	This is variable Forms.Ctl3DCtlColorEx.
Ctl3DDlgFramePaint (see page 14384)	This is variable Forms.Ctl3DDlgFramePaint.
HintWindowClass (see page 14384)	Specifies the class for the window used to display help hints.
Screen (see page 14385)	Represents a screen device.
SetLayeredWindowAttributes (see page 14385)	This is variable Forms.SetLayeredWindowAttributes.

72.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TApplication (see page 13660)	TApplication is the type used for a GUI windowed application.
	TControlScrollBar (see page 13744)	TControlScrollBar displays a horizontal or vertical scroll bar.
	TCustomActiveForm (see page 13759)	TCustomActiveForm is the base class for Active (see page 13896) Forms (see page 13657).
	TCustomDockForm (see page 13829)	TCustomDockForm is the default floating dock site class for TControl objects.
	TCustomForm (see page 13849)	TCustomForm is the base class from which to derive a window such as a form or dialog.
	TCustomFrame (see page 13978)	TCustomFrame is the base class from which TFrame (see page 14114) descends.
	TForm (see page 13992)	TForm represents a standard application window (form).
	TFrame (see page 14114)	TFrame is a container for components; it can be nested within forms or other frames.
	TGlassFrame (see page 14186)	TGlassFrame controls Windows Vista Aero glass effects.
	TMonitor (see page 14191)	TMonitor represents a monitor on which an application runs.
	TScreen (see page 14197)	TScreen represents the state of the screen in which an application runs.
	TScrollBox (see page 14238)	TScrollBox represents a scrolling area (a scroll box) in a window.
	TScrollingWinControl (see page 14312)	TScrollingWinControl is the base class for controls that support scrolling.

72.1.1 TApplication Class

TApplication is the type used for a GUI windowed application.

Class Hierarchy

Pascal

```
TApplication = class(TComponent);
```

C++

```
class TApplication : public TComponent;
```

File

Forms

Description

TApplication encapsulates a windowed application. The methods and properties introduced in TApplication reflect the fundamentals established in the Windows operating system to create, run, sustain, and destroy an application. TApplication thereby simplifies the interface between the developer and the Windows environment. For this purpose, TApplication encapsulates behavior for

Windows message processing.

Context-sensitive online help.

Menu accelerator and key processing.

Exception handling.

Managing the fundamental parts defined by the Windows operating system for an application, such as MainWindow, WindowClass, and so on

Each GUI application automatically declares an Application (see page 14383) variable as the instance of the application. If the application is not a Web server application, control panel applet, or NT service application, this variable is of type TApplication.

TApplication does not appear on the Component palette, nor is it available in the form designer to visually manipulate; so it has no published properties. Nevertheless, some of its public properties can be set or modified at design time in the Forms (see page 13657) and Application (see page 14383) pages of the Project|Options dialog box. In addition, you can add a TApplicationEvents component to any form in the project to intercept the application's events, and supply event handlers using the IDE.

Note: For application-wide properties and methods that affect the display, see TScreen (see page 14197).

Working at the Application Level

72.1.1.1 TApplication Members

The following tables list the members exposed by TApplication.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Idle (see page 13682)	This is Idle, a member of class TApplication.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsDlgMsg (see page 13685)	This is IsDlgMsg, a member of class TApplication.
	IsHintMsg (see page 13685)	This is IsHintMsg, a member of class TApplication.
	IsKeyMsg (see page 13685)	This is IsKeyMsg, a member of class TApplication.
	IsMDIMsg (see page 13685)	This is IsMDIMsg, a member of class TApplication.
	IsPreProcessMessage (see page 13685)	This is IsPreProcessMessage, a member of class TApplication.
	IsShortCut (see page 13686)	This is IsShortCut, a member of class TApplication.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Events

	Name	Description
	OnActionExecute (see page 13725)	Occurs when an action's Execute method is called and its action list has not already handled it.
	OnActionUpdate (see page 13726)	Occurs when an action's Update method is called and its action list has not already handled it.
	OnActivate (see page 13726)	Occurs when an application becomes active.
	OnDeactivate (see page 13727)	Occurs when an application becomes inactive.
	OnException (see page 13728)	Occurs when an unhandled exception occurs in the application.
	OnGetActiveFormHandle (see page 13729)	This is OnGetActiveFormHandle, a member of class TApplication.
	OnGetMainFormHandle (see page 13729)	This is OnGetMainFormHandle, a member of class TApplication.
	OnHelp (see page 13730)	Occurs when the application receives a request for help.
	OnHint (see page 13731)	Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 13712).
	OnIdle (see page 13733)	Occurs when an application becomes idle.
	OnMessage (see page 13737)	Occurs when the application receives a Windows message.
	OnMinimize (see page 13739)	Occurs when an application is minimized.
	OnModalBegin (see page 13740)	Occurs when a modal form is opened.
	OnModalEnd (see page 13740)	Occurs when a modal form is closed.
	OnRestore (see page 13741)	Occurs when the previously minimized application is restored to its normal size.
	OnSettingChange (see page 13741)	Occurs when Windows notifies the application that a system-wide setting has changed.
	OnShortCut (see page 13741)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShowHint (see page 13742)	Occurs when the application is about to display the hint window for a Help Hint (see page 13712).

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	ActivateHint (see page 13668)	Displays a hint window for the control at a specified position.
	AddPopupForm (see page 13669)	This is AddPopupForm, a member of class TApplication.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BringToFront (see page 13669)	Sets the last active window as the topmost window on the desktop above all other applications.
	CancelHint (see page 13669)	Cancels the display of a hint for a control.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ControlDestroyed (see page 13670)	Notifies the application when a control is destroyed.
V	Create (see page 13666)	Creates a new application.
	CreateForm (see page 13670)	Creates a new form.
	CreateHandle (see page 13672)	Generates a main window for the application if it does not already have one.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 13667)	Destroys the application instance and all of its associated memory.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.

	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoApplicationIdle (see page 13673)	Processes messages in the Message queue for certain events.
	ExecuteAction (see page 13673)	Generates an OnActionExecute (see page 13725) event.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HandleException (see page 13674)	Provides default handling of exceptions for the application.
	HandleMessage (see page 13674)	Interrupts the execution of an application while Windows processes a message in the Windows message queue.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HelpCommand (see page 13678)	Provides quick access to any of the Help commands in the WinHelp API (application programming interface).
	HelpContext (see page 13679)	Displays a specified help topic.
	HelpJump (see page 13679)	Displays a specified help topic.
	HelpKeyword (see page 13680)	Displays a specified help topic.
	HelpShowTableOfContents (see page 13680)	Shows the Table of Contents within the help system.
	HideHint (see page 13681)	Hides the current hint.
	HintMouseMessage (see page 13681)	Regulates the display of hint windows.
	HookMainWindow (see page 13681)	Enables a native Windows dialog box to receive messages sent to the application's main window.
	HookSynchronizeWakeup (see page 13682)	This is HookSynchronizeWakeup, a member of class TApplication.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	Initialize (see page 13682)	Provides an opportunity to initialize subsystems.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 13686)	Specifies whether the application adjusts its interface for Middle Eastern locales.
	MessageBox (see page 13686)	Displays a specified message to the user.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Minimize (see page 13688)	Shrinks an application to the Windows task bar.
	ModalFinished (see page 13689)	Track closing of modal form.
	ModalStarted (see page 13689)	Track opening of modal form.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	NormalizeAllTopMosts (see page 13690)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	NormalizeTopMosts (see page 13690)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	ProcessMessages (see page 13691)	Interrupts the execution of an application so that it can process the message queue.

	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	RemovePopupForm (see page 13694)	This is RemovePopupForm, a member of class TApplication.
	Restore (see page 13694)	Restores a minimized application to its normal size.
	RestoreTopMosts (see page 13695)	Restores forms designated as fsStayOnTop to be topmost again.
	Run (see page 13696)	Executes the application.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	ShowException (see page 13698)	Displays a message box for exceptions that are not caught by application code.
	Terminate (see page 13699)	Ends application execution.
	UnhookMainWindow (see page 13701)	Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 13681) method.
	UnhookSynchronizeWakeup (see page 13701)	Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 13682).
	UpdateAction (see page 13701)	Generates an OnActionUpdate (see page 13726) event.
	UseRightToLeftAlignment (see page 13702)	Specifies whether the application object is in a right-to-left alignment mode.
	UseRightToLeftReading (see page 13702)	Specifies whether the application object is in a right-to-left text mode.
	UseRightToLeftScrollBar (see page 13703)	Specifies whether the vertical scroll bar appears on the left side controls.

Public Properties

	Name	Description
	ActionUpdateDelay (see page 13704)	Delays the call to DoActionIdle.
R	Active (see page 13704)	Specifies whether the application is active and has focus.
R	ActiveFormHandle (see page 13705)	Gives the Windows handle of the currently active form.
	AllowTesting (see page 13705)	Represents information for the IDE.
	AutoDragDocking (see page 13705)	Indicates whether dragged windows are automatically docked.
	BiDiKeyboard (see page 13706)	Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.
	BiDiMode (see page 13706)	Indicates the layout of the application when running under Middle Eastern versions of Windows.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	CurrentHelpFile (see page 13707)	Indicates the current help file.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DialogHandle (see page 13707)	Provides a mechanism for using non-VCL dialog boxes in an application.
	EnumAllWindowsOnActivateHint (see page 13708)	This is EnumAllWindowsOnActivateHint, a member of class TApplication.
R	ExeName (see page 13709)	Contains the file name of the application's executable file including path information.
	Handle (see page 13710)	Provides access to the window handle of the main form (window) of the application.
	HelpFile (see page 13711)	Specifies the name of the default file the application uses to display Help.
R	HelpSystem (see page 13711)	Provides access to the interface for working with the help system.
	Hint (see page 13712)	Specifies the text string that appears in the Help Hint box.
	HintColor (see page 13715)	Determines the color of the hint boxes for the Help Hints for the application.
	HintHidePause (see page 13715)	Specifies the time interval to wait before hiding the Help Hint (see page 13712) if the mouse has not moved from the control or menu item.

	HintPause (see page 13715)	Specifies the time interval that passes before the control's Help Hint (see page 13712) appears when the user places the mouse pointer on a control or menu item.
	HintShortCuts (see page 13716)	Specifies whether the application's pop-up hints include shortcut information.
	HintShortPause (see page 13716)	Specifies the time period to wait before bringing up a hint if another hint has already been shown.
	Icon (see page 13717)	Determines which icon represents the application on the Windows task bar.
R	MainForm (see page 13718)	Identifies which form in the application is the main window.
R	MainFormHandle (see page 13719)	Gives the Windows handle of the application main form.
	MainFormOnTaskBar (see page 13719)	Controls (see page 5711) how Windows taskbar buttons are handled by VCL.
R	ModalLevel (see page 13720)	This is ModalLevel, a member of class TApplication.
	ModalPopupMode (see page 13720)	This is ModalPopupMode, a member of class TApplication.
	NonBiDiKeyboard (see page 13720)	Specifies the name of the keyboard map that should be used unless text reads from right to left.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	PopupControlWnd (see page 13721)	This is PopupControlWnd, a member of class TApplication.
	ShowHint (see page 13721)	Determines whether Help Hints are enabled or disabled for the entire application.
	ShowMainForm (see page 13722)	Determines whether the application shows its main form on startup.
R	Terminated (see page 13723)	Reports whether the application is in the process of shutting down.
	Title (see page 13723)	Contains the text that appears below the icon representing the application when it is minimized.
	UpdateFormatSettings (see page 13724)	Specifies whether format settings are updated automatically when the user alters the system configuration.
	UpdateMetricSettings (see page 13724)	Specifies whether the settings used for the hint window font and the icon title font are updated.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

72.1.1.2 TApplication.Create Constructor

Creates a new application.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TApplication(TComponent * AOwner);
```

Description

Do not call Create directly. Each GUI application automatically creates an instance of an application object.

For TApplication (see page 13660), the Create method initializes default values for some of its properties. It also prepares the application to run by setting up objects such as hint windows, the application icon, the main window handle, the instance handle, lists for managing child windows of the main window (form), and so on.

See Also

CreateForm (see page 13670)

CreateHandle (see page 13672)

Destroy (see page 13667)

Handle (see page 13710)

MainForm (see page 13718)

Run (see page 13696)

72.1.1.3 TApplication.Destroy Destructor

Destroys the application instance and all of its associated memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TApplication();
```

Description

Never call Application.Destroy or Application.Free. Instead, use the application's Terminate (see page 13699) method to end the application.

Destroy signals that the application has been deactivated before calling the inherited destructor. It then frees memory for hooked windows, the application instance, other object instances and lists that were created at application startup or that accumulated during execution

Since the Application (see page 14383) owns all forms (usually), it destroys these forms in its destructor.

See Also

Terminate (see page 13699)

Terminated (see page 13723)

OnDeactivate (see page 13727)

72.1.1.4 TApplication Methods

The methods of the TApplication class are listed here.

Protected Methods

	Name	Description
	Idle (see page 13682)	This is Idle, a member of class TApplication.
	IsDlgMsg (see page 13685)	This is IsDlgMsg, a member of class TApplication.
	IsHintMsg (see page 13685)	This is IsHintMsg, a member of class TApplication.
	IsKeyMsg (see page 13685)	This is IsKeyMsg, a member of class TApplication.
	IsMDIMsg (see page 13685)	This is IsMDIMsg, a member of class TApplication.
	IsPreProcessMessage (see page 13685)	This is IsPreProcessMessage, a member of class TApplication.
	IsShortCut (see page 13686)	This is IsShortCut, a member of class TApplication.

Public Methods

	Name	Description
	ActivateHint (see page 13668)	Displays a hint window for the control at a specified position.
	AddPopupForm (see page 13669)	This is AddPopupForm, a member of class TApplication.
	BringToFront (see page 13669)	Sets the last active window as the topmost window on the desktop above all other applications.
	CancelHint (see page 13669)	Cancels the display of a hint for a control.
	ControlDestroyed (see page 13670)	Notifies the application when a control is destroyed.
	CreateForm (see page 13670)	Creates a new form.

	CreateHandle (see page 13672)	Generates a main window for the application if it does not already have one.
	DoApplicationIdle (see page 13673)	Processes messages in the Message queue for certain events.
	ExecuteAction (see page 13673)	Generates an OnActionExecute (see page 13725) event.
	HandleException (see page 13674)	Provides default handling of exceptions for the application.
	HandleMessage (see page 13674)	Interrupts the execution of an application while Windows processes a message in the Windows message queue.
	HelpCommand (see page 13678)	Provides quick access to any of the Help commands in the WinHelp API (application programming interface).
	HelpContext (see page 13679)	Displays a specified help topic.
	HelpJump (see page 13679)	Displays a specified help topic.
	HelpKeyword (see page 13680)	Displays a specified help topic.
	HelpShowTableOfContents (see page 13680)	Shows the Table of Contents within the help system.
	HideHint (see page 13681)	Hides the current hint.
	HintMouseMessage (see page 13681)	Regulates the display of hint windows.
	HookMainWindow (see page 13681)	Enables a native Windows dialog box to receive messages sent to the application's main window.
	HookSynchronizeWakeup (see page 13682)	This is HookSynchronizeWakeup, a member of class TApplication.
	Initialize (see page 13682)	Provides an opportunity to initialize subsystems.
	IsRightToLeft (see page 13686)	Specifies whether the application adjusts its interface for Middle Eastern locales.
	MessageBox (see page 13686)	Displays a specified message to the user.
	Minimize (see page 13688)	Shrinks an application to the Windows task bar.
	ModalFinished (see page 13689)	Track closing of modal form.
	ModalStarted (see page 13689)	Track opening of modal form.
	NormalizeAllTopMosts (see page 13690)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	NormalizeTopMosts (see page 13690)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	ProcessMessages (see page 13691)	Interrupts the execution of an application so that it can process the message queue.
	RemovePopupForm (see page 13694)	This is RemovePopupForm, a member of class TApplication.
	Restore (see page 13694)	Restores a minimized application to its normal size.
	RestoreTopMosts (see page 13695)	Restores forms designated as fsStayOnTop to be topmost again.
	Run (see page 13696)	Executes the application.
	ShowException (see page 13698)	Displays a message box for exceptions that are not caught by application code.
	Terminate (see page 13699)	Ends application execution.
	UnhookMainWindow (see page 13701)	Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 13681) method.
	UnhookSynchronizeWakeup (see page 13701)	Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 13682).
	UpdateAction (see page 13701)	Generates an OnActionUpdate (see page 13726) event.
	UseRightToLeftAlignment (see page 13702)	Specifies whether the application object is in a right-to-left alignment mode.
	UseRightToLeftReading (see page 13702)	Specifies whether the application object is in a right-to-left text mode.
	UseRightToLeftScrollBar (see page 13703)	Specifies whether the vertical scroll bar appears on the left side controls.

72.1.1.4.1 TApplication.ActivateHint Method

Displays a hint window for the control at a specified position.

Pascal

```
procedure ActivateHint(CursorPos: TPoint);
```

C++

```
__fastcall ActivateHint(TPoint CursorPos);
```

Description

ActivateHint locates the control or menu item at the position specified by CursorPos, where CursorPos represents a screen coordinates in pixels. After locating the control, ActivateHint displays the control's Hint (see page 13712) in a hint window.

See Also

THintWindow (see page 6055)

Hint (see page 13712)

OnHint (see page 13731)

Hint (see page 5827)

72.1.1.4.2 TApplication.AddPopupForm Method

Pascal

```
function AddPopupForm(APopupForm: TCustomForm): Integer;
```

C++

```
__fastcall int AddPopupForm(TCustomForm APopupForm);
```

Description

This is AddPopupForm, a member of class TApplication.

72.1.1.4.3 TApplication.BringToFront Method

Sets the last active window as the topmost window on the desktop above all other applications.

Pascal

```
procedure BringToFront;
```

C++

```
__fastcall BringToFront();
```

Description

Use BringToFront to find the window owned by the MainForm (see page 13718) that was last active and bring it to the foreground. BringToFront also tests to see if the window is visible and enabled before making it the topmost window.

See Also

BringToFront (see page 5740)

MainForm (see page 13718)

72.1.1.4.4 TApplication.CancelHint Method

Cancels the display of a hint for a control.

Pascal

```
procedure CancelHint;
```

C++

```
__fastcall CancelHint();
```

Description

Applications rarely, if ever, call CancelHint directly. CancelHint is used internally to cancel the display of hints at appropriate times, such as when a window is not valid or when the application closes. CancelHint calls a series of routines that clean up the display and timing issues of the hint window for a control.

See Also

HideHint (see page 13681)

Hint (see page 13712)

72.1.1.4.5 TApplication.ControlDestroyed Method

Notifies the application when a control is destroyed.

Pascal

```
procedure ControlDestroyed(Control: TControl);
```

C++

```
__fastcall ControlDestroyed(TControl * Control);
```

Description

ControlDestroyed is for internal use and is called automatically by TControl. Do not call it directly.

ControlDestroyed notifies the application that the control passed as the Control parameter has been destroyed, so that the properties which refer to controls, such as MainForm (see page 13718) and ActiveCustomForm, can be updated to specify a valid object or nil (Delphi) or NULL (C++).

See Also

Destroy (see page 13667)

MainForm (see page 13718)

ActiveCustomForm (see page 14207)

72.1.1.4.6 TApplication.CreateForm Method

Creates a new form.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference);
```

C++

```
__fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Call CreateForm to dynamically create a form at runtime. Developers do not need to add code for creating most forms, because typically one or more calls to CreateForm are added automatically to the project's source when using the form designer.

CreateForm creates a new form of the type specified by the FormClass parameter and assigns it to the variable given by the Reference parameter. The owner of the new form is the Application (see page 14383) object.

Note: By default, the form created by the first call to CreateForm in a project becomes the application's main form.

C++ Examples:

```
/*
StepBy, CreateForm, Run, Show, Update, Initialize example
This example shows progress of loading forms as an application starts up. The code example is
placed in the project source (*.dpr) file. To see project source, select the View | Project
Source menu item.
You will need to set up your project with the following steps before using the code example:
```

```
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place Form5 on the available forms
list.
o          Change the code of your project (*.dpr) file to look like the example.
*/

    Form5->Update(); // force display of Form5
    Sleep(3000);
//  delete Form5;
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  return 0;
}
```

Delphi Examples:

```
{
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*.dpr) file.  To see project source, select
the View | Project Source menu item.
You will need to set up your project with the following steps
before using the code example:
    Add four additional forms to a default project.
```

```
      Place a TProgressBar on Form5
      Take the Project|Options|Forms menu option and place
            Form5 on the available forms list.
      Change the code of your project (*.dpr) file to look
            like the example.
  }
  begin
    Application.Initialize;
    with TForm5.Create(nil) do
    try
      Application.MainFormOnTaskbar := True;
      ProgressBar1.Max := 100;
      Show;  // show a splash screen contain ProgressBar control
      Update; // force display of Form5
      Application.CreateForm(TForm1, Form1);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form1 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm2, Form2);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form2 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm3, Form3);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form3 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm4, Form4);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form4 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
    finally
      Free;
    end;
    Application.Run;
```

CreateHandle (see page 13672)

Handle (see page 13710)

MainForm (see page 13718)

Run (see page 13696)

72.1.1.4.7 TApplication.CreateHandle Method

Generates a main window for the application if it does not already have one.

Pascal

```
procedure CreateHandle;
```

C++

```
__fastcall CreateHandle();
```

Description

Do not call CreateHandle directly. In EXEs, the application's constructor calls CreateHandle. In DLLs it does not.

CreateHandle encapsulates much of what traditional Windows programs write in WinMain. For example, CreateHandle registers the Window Class, creates the application window and determines how the application window is shown.

Create (see page 13666)

CreateForm (see page 13670)

Handle (see page 13710)

MainForm (see page 13718)

Run (see page 13696)

72.1.1.4.8 TApplication.DoApplicationIdle Method

Processes messages in the Message queue for certain events.

Pascal

```
procedure DoApplicationIdle;
```

C++

```
__fastcall DoApplicationIdle();
```

Description

The DoApplicationIdle method forces a call to the protected method TApplication.Idle (see page 13682). Idle (see page 13682) triggers the event OnIdle (see page 13733), processes the events OnMouseEnter and OnMouseLeave, and updates the hints.

72.1.1.4.9 TApplication.ExecuteAction Method

Generates an OnActionExecute (see page 13725) event.

Pascal

```
function ExecuteAction(Action: TBasicAction): Boolean; reintroduce;
```

C++

```
__fastcall Boolean ExecuteAction(TBasicAction Action);
```

Description

When the user invokes an action, a series of calls ensues to respond to that action. First, the action list that contains the action generates an OnExecute event. If the action list does not handle the OnExecute event, then the action is routed to the Application (see page 14383) object's ExecuteAction method, which invokes the OnActionExecute (see page 13725) event handler. (The application's ExecuteAction method responds to all unhandled actions in the application.) If the OnActionExecute (see page 13725) event handler does not handle the action, then it is routed to the action's OnExecute event handler. If that does not handle the action, the active control's ExecuteAction method is called, followed (if necessary) by the active form's ExecuteAction method.

Do not call ExecuteAction. It is called automatically when the user invokes an action. The Action parameter specifies the action that was invoked. ExecuteAction checks whether the application knows how to perform its function, and if so, executes the action and returns true. Otherwise, ExecuteAction returns false, and the default processing for the action continues.

Execute (see page 2712)

HandlesTarget (see page 2713)

ExecuteAction

72.1.1.4.10 TApplication.HandleException Method

Provides default handling of exceptions for the application.

Pascal

```
procedure HandleException(Sender: TObject);
```

C++

```
__fastcall HandleException(TObject * Sender);
```

Description

If an exception passes through all the try blocks in the application code, the application automatically calls HandleException, which displays a dialog box indicating an error occurred. Unless the exception object is EAbort, HandleException calls the OnException (see page 13728) event handler, if one exists. Otherwise, it calls ShowException (see page 13698) to display a message dialog box indicating an error occurred.

To assign other exception handling code for the application, use the OnException (see page 13728) event handler.

See Also

EAbort (see page 22722)

OnException (see page 13728)

ShowException (see page 13698)

72.1.1.4.11 TApplication.HandleMessage Method

Interrupts the execution of an application while Windows processes a message in the Windows message queue.

Pascal

```
procedure HandleMessage;
```

C++

```
__fastcall HandleMessage();
```

Description

HandleMessage interrupts the execution of the application so that Windows can process a single message from the Windows message queue before returning control to the application. If the message queue is empty, HandleMessage generates an OnIdle (see page 13733) event and starts the process of updating the actions in the application.

Note: If the application goes idle, HandleMessage may take a long time to return. Therefore, do not call HandleMessage when waiting for something message-based while priority actions are also being processed. Instead, call ProcessMessages (see page 13691) when processing more than just messages.

C++ Examples:

```
/*
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
*/
```

```
// global variables to show the order of events
int  XPos, YPos, Delta;

// This is a utility procedure to display messages
// add this at the beginning of the unit

void StatusMsg(TForm *Form, TCanvas *Canvas, char *Message, bool Bkg)
{
  if (!Bkg)
    Canvas->Font->Style = TFontStyles() << fsBold; // foreground messages are bold
  Canvas->TextOut(XPos, YPos, Message);
  if (!Bkg)
    Canvas->Font->Style = TFontStyles();
  // change Xpos and YPos to prepare for the next message
  YPos += Delta;
  if (YPos >= Form->ClientHeight - 10)
  {
    YPos = 10;
    XPos += 180;
  }
  if (XPos >= Form->ClientWidth - 100)
  {
    if (Canvas->Font->Color == clRed)
      Canvas->Font->Color = clBlack;
    else
      Canvas->Font->Color = clRed;
    XPos = 10;
  }
}

/*
This is the OnCreate event handler for Form1.  It
initializes global values and sets the application's OnIdle
event handler
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Button1->Caption = "Do not yield";
  Button2->Caption  = "Handle Message";
  Application->OnIdle = MyIdleHandler;
  XPos = 10;
  YPos = 10;
  if (Canvas->Font->Height > 0)
    Delta = Canvas->Font->Height + 1;
  else
    Delta = 1 - Canvas->Font->Height;
}

/*
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some background
processing for the application.  This one simply writes a
message to let you know when it's there.
*/
void __fastcall TForm1::MyIdleHandler(TObject *Sender, bool &Done)
{
  StatusMsg(Form1, Canvas, "This represents a background process.", true);
}

/*
This is the OnClick event handler for Button1.  It
simulates a lengthy process
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button1Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
      Y = random(J);
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button1Click handler is done", false);
}

/*
This is the OnClick event handler for button2.  It
simulates a lengthy process that allows other messages to be
processed.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button2Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
    {
      Y = random(J);
    }
    // Yield to OnIdle or other messages
    Application->HandleMessage();
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button2Click handler is done", false);
}
```

Delphi Examples:

```
{
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
}
var
{ global variables to show the order of events. }
  XPos, YPos, Delta: integer;

{ This is a utility procedure to display messages }
{ add this at the beginning of the implementation section }
procedure StatusMsg(
  MyForm : TForm1; Canvas : TCanvas; Message : string; Bkg : Boolean);
begin
  if not bkg then
    Canvas.Font.Style := [fsBold]; {foreground messages are bold }
  Canvas.TextOut(XPos, YPos, Message);
  if not bkg then
    Canvas.Font.Style := [];
  { change Xpos and YPos to prepare for the next message }
  Ypos := Ypos + Delta;
  if YPos >= MyForm.ClientHeight - 10 then
  begin
    YPos := 10;
    Xpos := Xpos + 180;
  end;
  if (Xpos >= MyForm.ClientWidth - 100) then
  begin
    if (Canvas.Font.Color = clRed) then
```

```
      Canvas.Font.Color := clBlack
    else
      Canvas.Font.Color := clRed;
    Xpos := 10;
  end;
end;

{This is the Form's OnCreate event handler.  }
{ It initializes global variables and sets the  the OnIdle
event handler }
procedure TForm1.FormCreate(Sender: TObject);
begin
  Button1.Caption := 'Do not yield';
  Button2.Caption := 'Handle Message';
  Application.OnIdle:= MyIdleHandler;
  XPos := 10;
  YPos := 10;
  Delta := Abs(Canvas.Font.Height) + 1;
 end;

{
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some
background processing for the application.  This one simply
writes a message to let you know when it's there.
}
procedure TForm1.MyIdleHandler(Sender: TObject; var Done: Boolean);
begin
  StatusMsg(
    Form1, Canvas, 'This represents a background process.', True);
end;

{
Set this method as the OnClick event handler of Button1.  It
performs a calculation without yielding to other messages or
idle time.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, X, Y: Word;
begin
  StatusMsg(
    Form1, Canvas, 'The synchronous handler is starting', False);
  I := 0;
  J := 0;
  while I < 10 do
  begin
    Randomize;
    while J < 10 do
    begin
      Y := Random(J);
      Inc(J);
    end;
    X := Random(I);
    Inc(I);
  end;
  StatusMsg(
    Form1, Canvas, 'The synchronous handler is done', False);
end;

{
Set this method as the OnClick event handler of Button2.  It
performs a calculation but calls HandleMessage to allow idle
time or asynchronous message processing.
}
```

```
procedure TForm1.Button2Click(Sender: TObject);
var
  I, J, X, Y: Word;
begin
 StatusMsg(
    Form1, Canvas, 'The asynchronous handler is starting', False);
  I := 0;
  J := 0;
  while I < 10 do
  begin
    Randomize;
    while J < 10 do
    begin
      Y := Random(J);
      Inc(J);
    end;
    X := Random(I);
    Inc(I);
    { yield to OnIdle or other messages }
    Application.HandleMessage;
  end;
  StatusMsg(
    Form1, Canvas, 'The asynchronous handler is done', False);
end;
```

72.1.1.4.12 TApplication.HelpCommand Method

Provides quick access to any of the Help commands in the WinHelp API (application programming interface).

Pascal

```
function HelpCommand(Command: Integer; Data: Longint): Boolean;
```

C++

```
__fastcall Boolean HelpCommand(int Command, Longint Data);
```

Description

Use HelpCommand to send a command to WinHelp. Before sending the help command to the Windows help engine, HelpCommand generates an OnHelp (see page 13730) event on the active form or on TApplication (see page 13660). Finally, the command is forwarded to WinHelp if there is no OnHelp (see page 13730) event handler or if the OnHelp (see page 13730) event handler indicates that WinHelp should be called.

For information about Windows help commands and the data passed to them, see the WinHelp topic in the Windows Help system.

HelpJump (see page 13679)

OnHelp (see page 13730)

OnHelp (see page 13959)

72.1.1.4.13 TApplication.HelpContext Method

Displays a specified help topic.

Pascal

```
function HelpContext(Context: THelpContext): Boolean;
```

C++

```
__fastcall Boolean HelpContext(THelpContext Context);
```

Description

Use HelpContext to bring up the help topic specified by the Context parameter from the file specified in the CurrentHelpFile (see page 13707) property. HelpContext generates an OnHelp (see page 13730) event (either on the active form or on the application object itself). If there is no OnHelp (see page 13730) event handler, or if the event handler indicates that WinHelp should be called, then HelpContext invokes the Windows help engine, passing it the context ID.

For example, if the Context value is 714, the HelpContext method displays the screen with the context help ID of 714 in the help file specified by CurrentHelpFile (see page 13707).

HelpContext returns false if CurrentHelpFile (see page 13707) is an empty string, meaning the application has no help file assigned. In all other cases, HelpContext returns true.

HelpFile (see page 13711)

HelpJump (see page 13679)

OnHelp (see page 13730)

CurrentHelpFile (see page 13707)

HelpKeyword (see page 13680)

Help and Hint Properties

72.1.1.4.14 TApplication.HelpJump Method

Displays a specified help topic.

Pascal

```
function HelpJump(const JumpID: string): Boolean;
```

C++

```
__fastcall Boolean HelpJump(const AnsiString JumpID);
```

Description

Call HelpJump to bring up a topic identified by its symbolic name. HelpJump displays the topic identified by the JumpID parameter from the file specified in the Current HelpFile (see page 13711) property. HelpJump generates an OnHelp (see page 13730) event (either on the active form or on the application object itself). If there is no OnHelp (see page 13730) event handler, or if the event handler indicates that WinHelp should be called, then HelpJump invokes the Windows help engine, passing it the topic name.

HelpJump returns false if CurrentHelpFile (see page 13707) is an empty string, meaning the application has no help file

assigned. In all other cases, HelpJump returns true.

See Also

HelpCommand (see page 13678)

HelpContext (see page 13679)

HelpFile (see page 13711)

OnHelp (see page 13730)

72.1.1.4.15 TApplication.HelpKeyword Method

Displays a specified help topic.

Pascal

```
function HelpKeyword(const Keyword: string): Boolean;
```

C++

```
__fastcall Boolean HelpKeyword(const AnsiString Keyword);
```

Description

Use HelpKeyword to bring up the help topic specified by the Keyword parameter from the file specified in the CurrentHelpFile (see page 13707) property. HelpKeyword invokes the current help system, passing it the string specified by Keyword. If the current system is WinHelp, this displays the topic that has an Alink of Keyword.

HelpKeyword returns false if the current help system does not support the keyword lookups.

See Also

HelpCommand (see page 13678)

HelpKeyword (see page 5826)

HelpFile (see page 13711)

HelpJump (see page 13679)

OnHelp (see page 13730)

CurrentHelpFile (see page 13707)

72.1.1.4.16 TApplication.HelpShowTableOfContents Method

Shows the Table of Contents within the help system.

Pascal

```
function HelpShowTableOfContents: Boolean;
```

C++

```
__fastcall Boolean HelpShowTableOfContents();
```

Description

Use HelpShowTableOfContents to bring up the table of contents for the help system specified in the CurrentHelpFile (see page 13707) property. This method is preferred to calling "Application.HelpSystem.ShowTableOfContents", which cannot be used as the first call into the help system.

72.1.1.4.17 TApplication.HideHint Method

Hides the current hint.

Pascal

```
procedure HideHint;
```

C++

```
__fastcall HideHint();
```

Description

Applications rarely, if ever, call HideHint directly. HideHint is used internally to hide the hint window at the appropriate times according to predetermined conditions and timer values. For example, CancelHint (see page 13669) calls HideHint.

See Also

CancelHint (see page 13669)

HintPause (see page 13715)

HintShortPause (see page 13716)

72.1.1.4.18 TApplication.HintMouseMessage Method

Regulates the display of hint windows.

Pascal

```
procedure HintMouseMessage(Control: TControl; var Message: TMessage);
```

C++

```
__fastcall HintMouseMessage(TControl * Control, TMessage Message);
```

Description

This method is called automatically when the mouse passes over a control with a Hint (see page 13712). Applications rarely, if ever, call HintMouseMessage directly. HintMouseMessage is used internally to manage the display of the hint windows.

See Also

CancelHint (see page 13669)

HintPause (see page 13715)

HintShortPause (see page 13716)

72.1.1.4.19 TApplication.HookMainWindow Method

Enables a native Windows dialog box to receive messages sent to the application's main window.

Pascal

```
procedure HookMainWindow(Hook: TWindowHook);
```

C++

```
__fastcall HookMainWindow(TWindowHook Hook);
```

Description

Use HookMainWindow to ensure that a native Windows dialog box behaves correctly as a child of the application, not as a stand-alone window. For example, switching among applications with Alt+Tab treats the application as a single task after calling

HookMainWindow, rather than treating the native Windows dialog box as a separate task.

When the window identified by the Handle (see page 13710) property receives relevant dialog messages, it passes them to the dialog procedure passed as the Hook parameter.

There is no problem with leaving a dialog box hooked into the main window, even for extended periods. However, should the dialog box close, call the UnhookMainWindow (see page 13701) method to release the hook.

See Also

Handle (see page 13710)

UnhookMainWindow (see page 13701)

72.1.1.4.20 TApplication.HookSynchronizeWakeup Method

Pascal

```
procedure HookSynchronizeWakeup;
```

C++

```
__fastcall HookSynchronizeWakeup();
```

Description

This is HookSynchronizeWakeup, a member of class TApplication.

72.1.1.4.21 TApplication.Idle Method

Pascal

```
procedure Idle(const Msg: TMsg);
```

C++

```
__fastcall Idle(const TMsg Msg);
```

Description

This is Idle, a member of class TApplication.

72.1.1.4.22 TApplication.Initialize Method

Provides an opportunity to initialize subsystems.

Pascal

```
procedure Initialize;
```

C++

```
__fastcall Initialize();
```

Description

Initialize is the first method called by the project source file. It calls the InitProc procedure pointer. By default, the call to Initialize for the application does nothing because the default InitProc pointer is nil (Delphi) or NULL (C++) .

To use Initialize, the InitProc pointer must be predefined. This can be accomplished in one of two ways:

In Delphi, you can include a unit that assigns a procedure to InitProc in its initialization section, such as the ComObj (see page 5525) unit. You can make this assignment in the initialization section of any of your units.

In both Delphi and C++, you can create a custom initialization procedure that assigns a value to the InitProc pointer, and add a

call to this procedure to the project source prior to the call to Initialize. (In Delphi, you can add it to the initialization section of the unit in which it is declared. In C++, you can use the pragma startup directive in that unit.)

Warning: Only one instance of InitProc can be defined in an application. If more than one unit assigns a value to InitProc, only the last assignment will work. You can, however, call the previous value of InitProc from an initialization procedure, so that all initialization procedures are executed.

For projects that do not assign a value to InitProc, the call to Initialize can be safely deleted from the project source.

Note: Although Initialize is the first method called in the main project source code, it is not the first code that is executed in a GUI application. For example, in Delphi, the application first executes the initialization section of all the units used by the application.

C++ Examples:

```
/*
StepBy, CreateForm, Run, Show, Update, Initialize example
This example shows progress of loading forms as an application starts up. The code example is
placed in the project source (*.dpr) file. To see project source, select the View | Project
Source menu item.
You will need to set up your project with the following steps before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place Form5 on the available forms
list.
o          Change the code of your project (*.dpr) file to look like the example.
*/

    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form1 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm2, Form2);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form2 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm3, Form3);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form3 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm4, Form4);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form4 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
  finally
    Free;
  end;
  Application.Run;
```

72.1.1.4.23 TApplication.IsDlgMsg Method

Pascal

```
function IsDlgMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsDlgMsg(TMsg Msg);
```

Description

This is IsDlgMsg, a member of class TApplication.

72.1.1.4.24 TApplication.IsHintMsg Method

Pascal

```
function IsHintMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsHintMsg(TMsg Msg);
```

Description

This is IsHintMsg, a member of class TApplication.

72.1.1.4.25 TApplication.IsKeyMsg Method

Pascal

```
function IsKeyMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsKeyMsg(TMsg Msg);
```

Description

This is IsKeyMsg, a member of class TApplication.

72.1.1.4.26 TApplication.IsMDIMsg Method

Pascal

```
function IsMDIMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsMDIMsg(TMsg Msg);
```

Description

This is IsMDIMsg, a member of class TApplication.

72.1.1.4.27 TApplication.IsPreProcessMessage Method

Pascal

```
function IsPreProcessMessage(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsPreProcessMessage(TMsg Msg);
```

Description

This is IsPreProcessMessage, a member of class TApplication.

72.1.1.4.28 TApplication.IsRightToLeft Method

Specifies whether the application adjusts its interface for Middle Eastern locales.

Pascal

```
function IsRightToLeft: Boolean;
```

C++

```
__fastcall Boolean IsRightToLeft();
```

Description

Use IsRightToLeft to determine whether the application makes any adjustments of control alignment, text direction, or scroll bar placement. IsRightToLeft returns true if the application's BiDiMode (see page 13706) indicates that any of these should be reversed and the application is running on a system with a Middle Eastern locale.

See Also

BiDiMode (see page 13706)

userighttoleftreading (see page 13702)

72.1.1.4.29 TApplication.IsShortCut Method

Pascal

```
function IsShortCut(var Message: TWMKey): Boolean;
```

C++

```
__fastcall Boolean IsShortCut(TWMKey Message);
```

Description

This is IsShortCut, a member of class TApplication.

72.1.1.4.30 TApplication.MessageBox Method

Displays a specified message to the user.

Pascal

```
function MessageBox(const Text: PChar; const Caption: PChar; Flags: Longint = MB_OK): Integer;
```

C++

```
__fastcall int MessageBox(const const char * Text, const const char * Caption, Longint Flags =
MB_OK);
```

Description

Use MessageBox to display a generic dialog box a message and one or more buttons. Caption is the caption of the dialog box and is optional.

MessageBox is an encapsulation of the Windows API MessageBox function. TApplication (see page 13660)'s encapsulation of MessageBox automatically supplies the missing window handle parameter needed for the Windows API function.

The value of the Text parameter is the message, which can be longer than 255 characters if necessary. Long messages are automatically wrapped in the message box.

The value of the Caption parameter is the caption that appears in the title bar of the dialog box. Captions can be longer than 255 characters, but don't wrap. A long caption results in a wide message box.

The Flags parameter specifies what buttons appear on the message box and the behavior (possible return values). The following table lists the possible values. These values can be combined to obtain the desired effect.

Value	Meaning
MB_ABORTRETRYIGNORE	The message box contains three push buttons: Abort, Retry, and Ignore.
MB_OK	The message box contains one push button: OK. This is the default.
MB_OKCANCEL	The message box contains two push buttons: OK and Cancel.
MB_RETRYCANCEL	The message box contains two push buttons: Retry and Cancel.
MB_YESNO	The message box contains two push buttons: Yes and No.
MB_YESNOCANCEL	The message box contains three push buttons: Yes, No, and Cancel.

MessageBox returns 0 if there isn't enough memory to create the message box. Otherwise it returns one of the following values:

ValueNumeric valueMeaning

Value	Numeric value	Meaning
IDOK	1	The user chose the OK button.
IDCANCEL	2	The user chose the Cancel button.
IDABORT	3	The user chose the Abort button.
IDRETRY	4	The user chose the Retry button.
IDIGNORE	5	The user chose the Ignore button.
IDYES	6	The user chose the Yes button.
IDNO	7	The user chose the No button.

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

72.1.1.4.31 TApplication.Minimize Method

Shrinks an application to the Windows task bar.

Pascal

```
procedure Minimize;
```

C++

```
__fastcall Minimize();
```

Description

Call Minimize to minimize the application. When the user minimizes the application, the Minimize method is automatically called.

Note: Don't confuse the Minimize method, which minimizes an entire application, with minimizing a form or window. To minimize, maximize, or restore a window or form, change the value of its WindowState property.

C++ Examples:

```
/*
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
*/
void __fastcall TForm1::AppDeactivate(TObject *Sender)
{
  Application->Minimize();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnDeactivate = AppDeactivate;
}
```

Delphi Examples:

```
{
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnDeactivate := AppDeactivate;
end;
```

```
procedure TForm1.AppDeactivate(Sender: TObject);
begin
  Application.Minimize;
end;
```

Restore (see page 13694)

WindowState (see page 13942)

72.1.1.4.32 TApplication.ModalFinished Method

Track closing of modal form.

Pascal

```
procedure ModalFinished;
```

C++

```
__fastcall ModalFinished();
```

Description

Call ModalFinished to indicate that a modal form is being closed. ModalFinished is called by the ShowModal method of TCustomForm (see page 13849).

ModalFinished calls the OnModalEnd (see page 13740) event handler, if defined.

See Also

OnModalEnd (see page 13740)

ModalStarted (see page 13689)

ShowModal (see page 13890)

72.1.1.4.33 TApplication.ModalStarted Method

Track opening of modal form.

Pascal

```
procedure ModalStarted;
```

C++

```
__fastcall ModalStarted();
```

Description

Call ModalStarted to indicate that a modal form is being opened. ModalStarted is called by the ShowModal method of TCustomForm (see page 13849).

ModalStarted calls the OnModalStart event handler, if defined.

See Also

OnModalStart

ModalFinished (see page 13689)

ShowModal (see page 13890)

72.1.1.4.34 TApplication.NormalizeAllTopMosts Method

Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.

Pascal

```
procedure NormalizeAllTopMosts;
```

C++

```
__fastcall NormalizeAllTopMosts();
```

Description

Use NormalizeAllTopMosts to allow other windows appear on top of a topmost form. Normally, topmost forms remain on top of other windows, and so may obscure other windows.

NormalizeAllTopMosts behaves like the NormalizeTopMosts (see page 13690) method, except that it also includes the application's Main Window.

See Also

FormStyle (see page 13912)

NormalizeTopMosts (see page 13690)

RestoreTopMosts (see page 13695)

MainForm (see page 13718)

72.1.1.4.35 TApplication.NormalizeTopMosts Method

Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.

Pascal

```
procedure NormalizeTopMosts;
```

C++

```
__fastcall NormalizeTopMosts();
```

Description

Use NormalizeTopMosts to allow a message box or dialog box that is displayed using the Windows API functions (such as MessageBox (see page 13686) and MessageDlg) directly, appear on top of a topmost form. Otherwise the topmost form remains on top, and may obscure the message box.

Calling NormalizeTopMosts is not necessary when using functions to display message boxes.

To return the forms designated as fsStayOnTop to be topmost again, call RestoreTopMosts (see page 13695).

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
```

```
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

See Also

FormStyle (see page 13912)

RestoreTopMosts (see page 13695)

NormalizeAllTopMosts (see page 13690)

MessageBox (see page 13686)

MessageDlg (see page 11535)

72.1.1.4.36 TApplication.ProcessMessages Method

Interrupts the execution of an application so that it can process the message queue.

Pascal

```
procedure ProcessMessages;
```

C++

```
__fastcall ProcessMessages();
```

Description

Call ProcessMessages to permit the application to process messages that are currently in the message queue. ProcessMessages cycles the Windows message loop until it is empty, and then returns control to the application.

Note: Neglecting message processing affects only the application calling ProcessMessages, not other applications. In lengthy operations, calling ProcessMessages periodically allows the application to respond to paint and other messages.

Note: ProcessMessages does not allow the application to go idle, whereas HandleMessage (see page 13674) does.

C++ Examples:

```
/*
This example uses two buttons that are long enough to
```

```
accommodate lengthy captions on a form. When the user clicks
the button with the caption Ignore Messages, the code begins
to generate a long series of random numbers. If the user
tries to resize the form while the handler is running,
nothing happens until the handler is finished. When the user
clicks the button with the caption Process Messages, more
random numbers are generated, but the application can still
respond to a series of events, such as resizing the form
and printing text.
Note: How quickly these event handlers run depends on the
microprocessor of your computer. A message appears on the
form informing you when the handler has finished executing.
*/

int magicnumber = 20;

void __fastcall TForm1::FormCreate(TObject* Sender)
{
  Button1->Caption = "Ignore Messages";
  Button2->Caption = "Handle Message";
}

void __fastcall TForm1::Button1Click(TObject* Sender)
{
  int x, y;
  Canvas->TextOut(10, 10, "The Button1Click handler has started");
  for (int i = 0; i < magicnumber; i++)
 {
    Randomize();
    for (int j = 0; j < magicnumber; j++)
    {
      Sleep(10);
      y = random(j);
    }
    x = random(i);
  }
  Canvas->TextOut(10, 10, "The Button1Click handler is finished   ");
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int x, y;
  Canvas->TextOut(10, 10, "The Button2Click handler has started");
  for (int i = 0; i < magicnumber; i++)
  {
    Randomize();
    for (int j = 0; j < magicnumber; j++)
    {
      y = random(j);
      Sleep(10);
      Application->ProcessMessages();
    }
    x = random(i);
  }
  Canvas->TextOut(10, 10, "The Button2Click handler is finished   ");
}
```

Delphi Examples:

```
{
This example uses two buttons that are long enough to
accommodate lengthy captions on a form. When the user clicks
the button with the caption Ignore Messages, the code begins
to generate a long series of random numbers. If the user
tries to resize the form while the handler is running,
nothing happens until the handler is finished. When the user
clicks the button with the caption Process Messages, more
```

```
  random numbers are generated, but the application can still
  respond to a series of events, such as resizing the form
  and printing text.
  Note: How quickly these event handlers run depends on the
  microprocessor of your computer. A message appears on the
  form informing you when the handler has finished executing.
  }
  const magicnumber = 500;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Button1.Caption := 'Ignore Messages';
    Button2.Caption := 'Process Messages';
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, J: Integer;
    X, Y: Word;
  begin
    I := 0;
    J := 0;
    Canvas.TextOut(10, 10, 'The Button1Click handler has started');
    while I < magicnumber do
    begin
      Randomize;
      while J < magicnumber do
      begin
        Sleep(10);
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
    end;
    Canvas.TextOut(10, 10, 'The Button1Click handler is finished   ');
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  var
    I, J: Integer;
    X, Y: Word;
  begin
    I := 0;
    J := 0;
    Canvas.TextOut(10, 10, 'The Button2Click handler has started');
    while I < magicnumber do
    begin
      Randomize;
      while J < magicnumber do
      begin
        Y := Random(J);
        Inc(J);
        Sleep(10);
        Application.ProcessMessages;
      end;
      X := Random(I);
      Inc(I);
    end;
    Canvas.TextOut(10, 10, 'The Button2Click handler is finished   ');
  end;
```

72.1.1.4.37 TApplication.RemovePopupForm Method

Pascal

```
procedure RemovePopupForm(APopupForm: TCustomForm);
```

C++

```
__fastcall RemovePopupForm(TCustomForm APopupForm);
```

Description

This is RemovePopupForm, a member of class TApplication.

72.1.1.4.38 TApplication.Restore Method

Restores a minimized application to its normal size.

Pascal

```
procedure Restore;
```

C++

```
__fastcall Restore();
```

Description

Use Restore to restore the application to its previous size before it was minimized. When the user restores the application to normal size, Restore is automatically called.

Note: Don't confuse the Restore method, which restores the entire application, with restoring a form or window to its original size. To minimize, maximize, and restore a window or form, change the value of its WindowState property.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

See Also

WindowState (see page 13942)

72.1.1.4.39 TApplication.RestoreTopMosts Method

Restores forms designated as fsStayOnTop to be topmost again.

Pascal

```
procedure RestoreTopMosts;
```

C++

```
__fastcall RestoreTopMosts();
```

Description

Use RestoreTopMosts to return forms that were originally designated as topmost forms (FormStyle is fsStayOnTop), then temporarily changed to be non-topmost forms with the NormalizeTopMosts (see page 13690) or NormalizeAllTopMosts (see page 13690) method, to a topmost position.

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
```

```
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

See Also

NormalizeTopMosts (see page 13690)

NormalizeAllTopMosts (see page 13690)

72.1.1.4.40 TApplication.Run Method

Executes the application.

Pascal

```
procedure Run;
```

C++

```
__fastcall Run();
```

Description

Do not call Run. When creating a new project, The IDE automatically creates a main program block in the project file that calls the Run method. When the application is executed, the application's Run method is called.

Run contains the application's main message loop. The call to Run does not return until the application's message loop terminates.

C++ Examples:

```
/*
StepBy, CreateForm, Run, Show, Update, Initialize example
This example shows progress of loading forms as an application starts up. The code example is
placed in the project source (*.dpr) file. To see project source, select the View | Project
Source menu item.
You will need to set up your project with the following steps before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place Form5 on the available forms
list.
o          Change the code of your project (*.dpr) file to look like the example.
*/
#include <vcl\vcl.h>
#include "Unit5.h"
#pragma hdrstop
//---------------------------------------------------------------------------
USEFORM("TAppCreateForm.cpp", Form1);
USERES("Project1.res");
```

```
USEFORM("Unit2.cpp", Form2);
USEFORM("Unit3.cpp", Form3);
USEFORM("Unit4.cpp", Form4);
USEFORM("Unit5.cpp", Form5);
//---------------------------------------------------------------------------
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
  {
    Application->Initialize();
    SetApplicationMainFormOnTaskBar(Application, true);
    Application->CreateForm(__classid(TForm5), &Form5);
    Form5->ProgressBar1->Max = 100;
    Form5->Show();   // show a splash screen contain ProgressBar control
    Form5->Update(); // force display of Form5
    Application->CreateForm(__classid(TForm1), &Form1);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form1 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm2), &Form2);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form2 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm3), &Form3);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form3 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm4), &Form4);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form4 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
//  delete Form5;
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  return 0;
}
```

Delphi Examples:

```
{

MainForm (see page 13718)

Terminate (see page 13699)

72.1.1.4.41 TApplication.ShowException Method

Displays a message box for exceptions that are not caught by application code.

Pascal

```
procedure ShowException(E: Exception);
```

C++

```
__fastcall ShowException(Exception E);
```

Description

The HandleException (see page 13674) method calls ShowException by default if no handler is specified for the OnException (see page 13728) event. If an exception handler filters exceptions, ShowException is called for those exceptions that are not filtered out.

To specify how exceptions are handled for an application, write a handler for the OnException (see page 13728) event.

Note: Calling ShowException is rarely necessary in a component-based application, since the default exception handler calls ShowException automatically.

C++ Examples:

```
/*
```

```
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;
procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

See Also

HandleException (see page 13674)

OnException (see page 13728)

72.1.1.4.42 TApplication.Terminate Method

Ends application execution.

Pascal

```
procedure Terminate;
```

C++

```
__fastcall Terminate();
```

Description

Call Terminate to end the application programmatically. By calling Terminate rather than freeing the application object, you allow the application to shut down in an orderly fashion.

Terminate calls the Windows API PostQuitMessage function to perform an orderly shutdown of the application. Terminate is not immediate.

Terminate is called automatically on a WM_QUIT message and when the main form closes.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;
procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

See Also

Terminated (see page 13723)

72.1.1.4.43 TApplication.UnhookMainWindow Method

Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 13681) method.

Pascal

```
procedure UnhookMainWindow(Hook: TWindowHook);
```

C++

```
__fastcall UnhookMainWindow(TWindowHook Hook);
```

Description

Use UnhookMainWindow to release the hooked window. Specify the dialog procedure as the value of the Hook parameter.

The TWindowHook (see page 14382) type is the parameter type used for UnhookMainWindow. It is a method-pointer type used for the dialog-procedures of non-VCL dialog boxes. The dialog procedure is similar to a window procedure for a window, in that it processes messages for the dialog box, but its syntax is somewhat different.

For more information about Windows hooks see the SetWindowsEx and UnhookWindowsEx functions in the Windows Help File.

See Also

HookMainWindow (see page 13681)

72.1.1.4.44 TApplication.UnhookSynchronizeWakeup Method

Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 13682).

Pascal

```
procedure UnhookSynchronizeWakeup;
```

C++

```
__fastcall UnhookSynchronizeWakeup();
```

Description

Applications rarely, if ever, call UnhookSynchronizeWakeup directly. UnhookSynchronizeWakeup is called from the TApplication (see page 13660) destructor. It resets the WakeMainThread variable to nil (Delphi) or NULL (C++) if that variable was set by the HookSynchronizeWakeup (see page 13682) method.

Warning: You should not modify WakeMainThread for GUI applications because a working handler has been assigned. Console applications may assign a handler to WakeMainThread if the application needs to be notified of a thread synchronization call. If your console application assigns a handler, this is an optimization that only accelerates deliver of notification that a synchronization request is available. You must use CheckSynchronize to perforrm the synchronization itself.

See Also

hooksynchronizewakeup (see page 13682)

WakeMainThread

Synchronize (see page 3126)

72.1.1.4.45 TApplication.UpdateAction Method

Generates an OnActionUpdate (see page 13726) event.

Pascal

```
function UpdateAction(Action: TBasicAction): Boolean; reintroduce;
```

C++

```
__fastcall Boolean UpdateAction(TBasicAction Action);
```

Description

When the application is idle, it makes a series of calls to update the properties (such as whether it is enabled, checked, and so on) of every action that is linked to a visible control or menu item. First, that action list that contains the action generates an OnUpdate event. If the action list does not handle the OnUpdate event, then the action is routed to the Application (see page 14383) object's UpdateAction method, which invokes the OnActionUpdate (see page 13726) event handler. (The application's UpdateAction method responds to all unhandled actions in the application.) If the OnActionUpdate (see page 13726) event handler does not update the action, then it is routed to the action's OnUpdate event handler. If that does not update the action, the active control's UpdateAction method is called, followed (if necessary) by the active form's UpdateAction method.

Do not call UpdateAction. It is called automatically when the application is idle. The Action parameter specifies the action to be updated. UpdateAction returns true if the action's properties are updated and require no further processing. Otherwise, UpdateAction returns false, and the default action processing continues.

See Also

OnActionUpdate (see page 13726)

ExecuteAction (see page 13673)

UpdateTarget (see page 2715)

HandlesTarget (see page 2713)

InitiateAction (see page 5769)

72.1.1.4.46 TApplication.UseRightToLeftAlignment Method

Specifies whether the application object is in a right-to-left alignment mode.

Pascal

```
function UseRightToLeftAlignment: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftAlignment();
```

Description

Use UseRightToLeftAlignment to determine whether the application’s controls alignment is reversed so that they are aligned from right to left. UseRightToLeftAlignment returns true for Middle Eastern locales if the BiDiMode (see page 13706) property is bdRightToLeft. Otherwise, it returns false.

See Also

BiDiMode

72.1.1.4.47 TApplication.UseRightToLeftReading Method

Specifies whether the application object is in a right-to-left text mode.

Pascal

```
function UseRightToLeftReading: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftReading();
```

Description

Call UseRightToLeftReading to determine which style and text drawing flags (used in ExTextOut or DrawText) to set for the application's controls.

UseRightToLeftReading returns true for for Middle Eastern locales if the BiDiMode (see page 13706) property is not bdLeftToRight. Otherwise, it returns false.

See Also

BiDiMode

72.1.1.4.48 TApplication.UseRightToLeftScrollBar Method

Specifies whether the vertical scroll bar appears on the left side controls.

Pascal

```
function UseRightToLeftScrollBar: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftScrollBar();
```

Description

Call UseRightToLeftScrollBar to determine whether the vertical scroll bars appear on the left sides of the application's controls. When UseRightToLeftScrollBar returns true, the vertical scroll bars appear on the left sides of the controls. When UseRightToLeftScrollBar returns false, the vertical scroll bars appear on the right.

UseRightToLeftScrollBar returns true for Middle Eastern locales if BiDiMode (see page 13706) is bdRightToLeft or bdRightToLeftNoAlign.

See Also

BiDiMode

72.1.1.5 TApplication Properties

The properties of the TApplication class are listed here.

Public Properties

	Name	Description
	ActionUpdateDelay (see page 13704)	Delays the call to DoActionIdle.
R	Active (see page 13704)	Specifies whether the application is active and has focus.
R	ActiveFormHandle (see page 13705)	Gives the Windows handle of the currently active form.
	AllowTesting (see page 13705)	Represents information for the IDE.
	AutoDragDocking (see page 13705)	Indicates whether dragged windows are automatically docked.
	BiDiKeyboard (see page 13706)	Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.
	BiDiMode (see page 13706)	Indicates the layout of the application when running under Middle Eastern versions of Windows.
R	CurrentHelpFile (see page 13707)	Indicates the current help file.
	DialogHandle (see page 13707)	Provides a mechanism for using non-VCL dialog boxes in an application.
	EnumAllWindowsOnActivateHint (see page 13708)	This is EnumAllWindowsOnActivateHint, a member of class TApplication.
R	ExeName (see page 13709)	Contains the file name of the application's executable file including path information.
	Handle (see page 13710)	Provides access to the window handle of the main form (window) of the application.
	HelpFile (see page 13711)	Specifies the name of the default file the application uses to display Help.

R	HelpSystem (see page 13711)	Provides access to the interface for working with the help system.
	Hint (see page 13712)	Specifies the text string that appears in the Help Hint box.
	HintColor (see page 13715)	Determines the color of the hint boxes for the Help Hints for the application.
	HintHidePause (see page 13715)	Specifies the time interval to wait before hiding the Help Hint (see page 13712) if the mouse has not moved from the control or menu item.
	HintPause (see page 13715)	Specifies the time interval that passes before the control's Help Hint (see page 13712) appears when the user places the mouse pointer on a control or menu item.
	HintShortCuts (see page 13716)	Specifies whether the application's pop-up hints include shortcut information.
	HintShortPause (see page 13716)	Specifies the time period to wait before bringing up a hint if another hint has already been shown.
	Icon (see page 13717)	Determines which icon represents the application on the Windows task bar.
R	MainForm (see page 13718)	Identifies which form in the application is the main window.
R	MainFormHandle (see page 13719)	Gives the Windows handle of the application main form.
	MainFormOnTaskBar (see page 13719)	Controls (see page 5711) how Windows taskbar buttons are handled by VCL.
R	ModalLevel (see page 13720)	This is ModalLevel, a member of class TApplication.
	ModalPopupMode (see page 13720)	This is ModalPopupMode, a member of class TApplication.
	NonBiDiKeyboard (see page 13720)	Specifies the name of the keyboard map that should be used unless text reads from right to left.
R	PopupControlWnd (see page 13721)	This is PopupControlWnd, a member of class TApplication.
	ShowHint (see page 13721)	Determines whether Help Hints are enabled or disabled for the entire application.
	ShowMainForm (see page 13722)	Determines whether the application shows its main form on startup.
R	Terminated (see page 13723)	Reports whether the application is in the process of shutting down.
	Title (see page 13723)	Contains the text that appears below the icon representing the application when it is minimized.
	UpdateFormatSettings (see page 13724)	Specifies whether format settings are updated automatically when the user alters the system configuration.
	UpdateMetricSettings (see page 13724)	Specifies whether the settings used for the hint window font and the icon title font are updated.

72.1.1.5.1 TApplication.ActionUpdateDelay Property

Delays the call to DoActionIdle.

Pascal

```
property ActionUpdateDelay: Integer;
```

C++

```
__property int ActionUpdateDelay;
```

Description

Use ActionUpdateDelay to delay the call to DoActionIdle. The following example demonstrates the usefulness of this property:

1. Create (see page 13666) an MDI project with a main form, a MDI Child and a TAction class.
2. Link the TAction OnUpdate event to a method.
3. Run (see page 13696) the program and maximize the MDI child.

If you open Windows Task Manager, you can see that CPU usage for the MDI application is nearly 100%. However, if you set Application.ActionUpdateDelay to a non-zero value, the CPU usage for the application is significantly lower than 100%.

See Also

Building a VCL Forms MDI Application Using a Wizard

72.1.1.5.2 TApplication.Active Property

Specifies whether the application is active and has focus.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Active is true while the application is active and false if it is not. Active is set to true in the constructor.

An application is active if the form or application has focus. An application becomes inactive when a window from a different application is about to become activated. When the application closes, Active is set to false in the destructor.

Note: Active is read-only.

See Also

OnActivate (see page 13726)

OnDeactivate (see page 13727)

72.1.1.5.3 TApplication.ActiveFormHandle Property

Gives the Windows handle of the currently active form.

Pascal

```
property ActiveFormHandle: HWND;
```

C++

```
__property HWND ActiveFormHandle;
```

Description

ActiveFormHandle gives the Windows handle of the currently active form.

See Also

MainFormHandle (see page 13719)

72.1.1.5.4 TApplication.AllowTesting Property

Represents information for the IDE.

Pascal

```
property AllowTesting: Boolean;
```

C++

```
__property Boolean AllowTesting;
```

Description

Do not use AllowTesting; it is for internal use only.

72.1.1.5.5 TApplication.AutoDragDocking Property

Indicates whether dragged windows are automatically docked.

Pascal

```
property AutoDragDocking: Boolean;
```

C++

```
__property Boolean AutoDragDocking;
```

Description

Set AutoDragDocking to enable drag-and-dock behavior when windows are dragged. When AutoDragDocking is true, dragged windows are automatically docked when the mouse is released over a docking site. When AutoDragDocking is false, dragged windows are only docked when the Ctrl key is pressed.

72.1.1.5.6 TApplication.BiDiKeyboard Property

Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.

Pascal

```
property BiDiKeyboard: string;
```

C++

```
__property AnsiString BiDiKeyboard;
```

Description

This name is a string composed of the hexadecimal value of the language identifier (low word) and a device identifier (high word). For example, Saudi Arabian Arabic has a language identifier of 0x0401, so its primary layout is named "00000401".

This keyboard layout is only used when the application runs in a middle eastern locale and the value of BiDiMode (see page 13706) indicates that text should read from right to left.

See Also

BiDiMode (see page 13706)

NonBiDiKeyboard (see page 13720)

72.1.1.5.7 TApplication.BiDiMode Property

Indicates the layout of the application when running under Middle Eastern versions of Windows.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to specify the bi-directional mode for the application. The bi-directional mode controls the direction in which text appears (left-to-right or right-to-left), the placement of vertical scroll bars, and the default alignment of text when the application runs in Middle Eastern locales.

The application's BiDiMode is used in the ShowMessage procedure and the MessageBox (see page 13686) method. It also serves as the ParentBiDiMode for forms and for popup menus that are not activated by a control.

See Also

ParentBiDiMode

ShowMessage (see page 11541)

MessageBox (see page 13686)

72.1.1.5.8 TApplication.CurrentHelpFile Property

Indicates the current help file.

Pascal

```
property CurrentHelpFile: string;
```

C++

```
__property AnsiString CurrentHelpFile;
```

Description

Read CurrentHelpFile to determine the name of the help file that is currently used by the application when it executes a help command (via the HelpCommand (see page 13678) method) or brings up context sensitive help (via the HelpContext (see page 13679) or HelpJump (see page 13679) method). If CurrentHelpFile is an empty string, the application ignores attempts to display Help.

If the active form has an associated help file, this is the value of CurrentHelpFile. Otherwise, CurrentHelpFile reflects the value of the application's HelpFile (see page 13711) property.

See Also

PropertyName

ActiveCustomForm (see page 14207)

HelpCommand (see page 13678)

HelpJump (see page 13679)

HelpSystem (see page 13711)

HelpContext (see page 13679)

72.1.1.5.9 TApplication.DialogHandle Property

Provides a mechanism for using non-VCL dialog boxes in an application.

Pascal

```
property DialogHandle: HWnd;
```

C++

```
__property HWnd DialogHandle;
```

Description

Use DialogHandle when displaying a modeless dialog box that was created using the CreateDialog API function. Assigning the handle of the modeless dialog box to DialogHandle allows the dialog to see messages from the application's message loop.

Assign the handle of the modeless dialog box to DialogHandle when it receives an activation message (WM_NCACTIVATE) and set DialogHandle to zero when the dialog box receives a deactivation message.

Delphi Examples:

```
{
Here is replacement of the window procedure for Delphi's
encapsulation of the Windows search-and-replace common dialog
box. Click on Button2 to activate an open dialog and send
a WM_NCACTIVATE to FindReplaceWndProc.
}
function FindReplaceWndProc(Wnd: HWND; Msg, WParam, LParam: Longint): Longint; stdcall;
```

```
    function CallDefWndProc: Longint;
    begin
      Result := CallWindowProc(Pointer(GetProp(Wnd,
        MakeIntAtom(WndProcPtrAtom))), Wnd, Msg, WParam, LParam);
    end;

  begin
    case Msg of
      WM_DESTROY:
        if Application.DialogHandle = Wnd then Application.DialogHandle := 0;
      WM_NCACTIVATE:
        if WParam <> 0 then
        begin
          if Application.DialogHandle = 0 then Application.DialogHandle := Wnd;
        end else
        begin
          if Application.DialogHandle = Wnd then Application.DialogHandle := 0;
        end;
      WM_NCDESTROY:
        begin
          Result := CallDefWndProc;
          RemoveProp(Wnd, MakeIntAtom(WndProcPtrAtom));
          Exit;
        end;
     end;
     Result := CallDefWndProc;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    ReplaceDialog1.Execute;
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    OpenDialog1.Execute;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    AtomText: array[0..31] of Char;
  begin
    WndProcPtrAtom := GlobalAddAtom(StrFmt(AtomText,
      'WndProcPtr%.8X%.8X', [HInstance, GetCurrentThreadID]));
    SetWindowLong(Application.Handle, GWL_WNDPROC, Longint(@FindReplaceWndProc));;
  end;
```

See Also

Handle (see page 13710)

72.1.1.5.10 TApplication.EnumAllWindowsOnActivateHint Property

Pascal

```
property EnumAllWindowsOnActivateHint: Boolean;
```

C++

```
__property Boolean EnumAllWindowsOnActivateHint;
```

Description

This is EnumAllWindowsOnActivateHint, a member of class TApplication.

72.1.1.5.11 TApplication.ExeName Property

Contains the file name of the application's executable file including path information.

Pascal

```
property ExeName: string;
```

C++

```
__property AnsiString ExeName;
```

Description

Use ExeName to obtain the name of the executable file for the application. ExeName is the fully-qualified name, including the path to the application's executable.

The name of the application is the root name of the project with an .EXE extension. By default, this name is PROJECT1.EXE. To change the ExeName, save the project by the desired new root name and rebuild the application. ExeName will reflect the change to the project file name.

ExeName is a read-only property.

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
*/
void __fastcall TForm1::Save1Click(TObject *Sender)
{
  AnsiString NewFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit1->Text);
  AnsiString OldFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit2->Text);
  AnsiString Msg = Format("Copy %s to %s", ARRAYOFCONST((OldFileName, NewFileName)));
  if (MessageDlg(Msg, mtCustom, TMsgDlgButtons() << mbOK << mbCancel, 0) == mrOk)
  {
    TFileStream *OldFile = new TFileStream(OldFileName, fmOpenRead);
    try
    {
      TFileStream *NewFile = new TFileStream(NewFileName, fmCreate);
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      }
    }
    __finally
    {
      FreeAndNil(&OldFile);
    }
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label3->Caption = "Current directory: " + ExtractFilePath(Application->ExeName);
```

```
}
```

Delphi Examples:

```
{
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label3.Caption:= 'Current directory: ' + ExtractFilePath(Application.ExeName);
end;

procedure TForm1.Save1Click(Sender: TObject);
var
  NewFileName, OldFileName: string;
  Msg: string;
  NewFile: TFileStream;
  OldFile: TFileStream;
begin
  NewFileName :=
    ExtractFilePath(Application.ExeName) +
    ExtractFileName(Edit1.Text);
  OldFileName :=
    ExtractFilePath(Application.ExeName) +
    ExtractFileName(Edit2.Text);
  Msg := Format('Copy %s to %s?', [OldFileName, NewFileName]);
  if MessageDlg(Msg, mtCustom, mbOKCancel, 0) = mrOK then
  begin
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;
```

See Also

ParamStr (see page 22496)

Title (see page 13723)

72.1.1.5.12 TApplication.Handle Property

Provides access to the window handle of the main form (window) of the application.

Pascal

```
property Handle: HWnd;
```

C++

```
__property HWnd Handle;
```

Description

Use Handle when calling Windows API functions that require a parent window handle. For example, a DLL that displays its own top-level pop-up windows needs a parent window to display its windows in the application. Using the Handle property makes such windows part of the application, so that they are minimized, restored, enabled, and disabled with the application.

Note: When writing a DLL that uses VCL forms, assign the window handle of the host EXE's main window to the DLL's Application.HandleApplication->Handle property. This makes the DLL's form part of the host application. Never assign to the Handle property in an EXE.

See Also

DialogHandle (see page 13707)

MainForm (see page 13718)

72.1.1.5.13 TApplication.HelpFile Property

Specifies the name of the default file the application uses to display Help.

Pascal

```
property HelpFile: string;
```

C++

```
__property AnsiString HelpFile;
```

Description

Use HelpFile to specify a default help file for applications that use the Help system. Either assign a file name to the HelpFile property at runtime, or specify a Help File on the Application (see page 14383) page of the Project|Options dialog box at design time.

The Help system specified by HelpSystem (see page 13711) displays help topics from the file specified by CurrentHelpFile (see page 13707). HelpFile supplies the value of CurrentHelpFile (see page 13707) unless there is a help file associated with the active form.

By default, HelpFile is a null string, and the application's Help method ignores attempts to display Help unless the active form has an associated help file.

See Also

HelpCommand (see page 13678)

HelpContext (see page 13679)

HelpJump (see page 13679)

CurrentHelpFile (see page 13707)

HelpSystem (see page 13711)

72.1.1.5.14 TApplication.HelpSystem Property

Provides access to the interface for working with the help system.

Pascal

```
property HelpSystem: IHelpSystem;
```

C++

```
__property IHelpSystem HelpSystem;
```

Description

TApplication (see page 13660) uses IHelpSystem to interact with a Help system manager. This interface includes methods for displaying help topics based on a keyword or topic ID.

Applications can use the HelpSystem property to interact directly with the Help system manager, or they can use the application's help-oriented methods such as HelpCommand (see page 13678) and HelpJump (see page 13679).

See Also

HelpCommand (see page 13678)

HelpContext (see page 13679)

HelpJump (see page 13679)

CurrentHelpFile (see page 13707)

HelpFile (see page 13711)

ShowTableOfContents (see page 15027)

72.1.1.5.15 TApplication.Hint Property

Specifies the text string that appears in the Help Hint box.

Pascal

```
property Hint: string;
```

C++

```
__property AnsiString Hint;
```

Description

TApplication (see page 13660)'s Hint property is assigned the Hint value of the control or menu item that the mouse is currently moving over. It can also be assigned a string value that informs the user of some action, error, or other type of information. Therefore, use Hint either to:

Transfer hints from controls to another area of display, such as a status bar, using the OnHint (see page 13731) event handler. This reads the Hint property.

Indicate the status of the application while it is processing some action. This sets the Hint property.

Help Hints appear when the OnHint (see page 13731) event occurs. Therefore, if TApplication (see page 13660)'s Hint property is assigned to the status bar's caption, for example, the caption of the status bar control displays the current string value of the Hint property during an OnHint (see page 13731) event.

There are two parts to the Hint string: short and long. Short hints are used by pop-up tool tips. Long hints are used by the status bar, separated by the | character. Use the global functions GetShortHint and GetLongHint, from the Controls (see page 5711) unit to extract the long and short hints from a hint string.

Note: When setting Hint to a message informing the user of an event occurring in the application, remember that, by default, the Hint string is reset to a control's Hint when the mouse cursor moves over a control.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
```

```
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
/*
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
*/

/*
Here is the code to add to the unit file.  It provides the
implementation of the DisplayHint method and assigns it to
the Application in the form's OnCreate event handler.
Note:   It is not actually necessary to write an OnHint event
handler to display hints on the status bar. This can be
accomplished more simply by setting the status bar's AutoHint
property.
*/
void __fastcall TForm1::DisplayHint(TObject *Sender)
{
  StatusBar1->SimpleText = GetLongHint(Application->Hint);
}

// Here is the form's OnCreate event handler.
// It assigns the application's OnHint event handler at
// runtime because the Application is not available in the
// Object Inspector
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHint = DisplayHint;
}
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
```

```
    I: Integer;
  begin
    Edit1.Hint := 'Enter your name';
    Edit1.ShowHint := True;
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }
  {
  Note:   It is not actually necessary to write an OnHint
  event handler to display hints on the status bar. This can
  be accomplished more simply by setting the status bar's
  AutoHint property and SimplePanel property.
  This shows how the OnHint event handler is declared as a
  public method of the form.
  }
  type
    TForm1 = class(TForm)
      Button1: TButton;
      StatusBar1: TStatusBar;
      Edit1: TEdit;
      procedure FormCreate(Sender: TObject);
    private
      { Private declarations }
    public
      procedure DisplayHint(Sender: TObject);
    end;
  var
    Form1: TForm1;
  implementation
  {$R *.dfm}

  { Here is the implementation of the OnHint event handler }
  { It displays the application's current hint in the status bar }
  procedure TForm1.DisplayHint(Sender: TObject);
  begin
    StatusBar1.SimpleText := GetLongHint(Application.Hint);
  end;
  { Here is the form's OnCreate event handler. }
  { It assign's the application's OnHint event handler at runtime }
  { because the Application is not available in the Object Inspector }
  { at design time }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnHint := DisplayHint;
  end;
```

THintWindow (see page 6055)

72.1.1.5.16 TApplication.HintColor Property

Determines the color of the hint boxes for the Help Hints for the application.

Pascal

```
property HintColor: TColor;
```

C++

```
__property TColor HintColor;
```

Description

Use HintColor to specify the hint box color. A default color value of clInfoBk is set for the HintColor property in the constructor when the application is created. To change the HintColor, assign it a new TColor value at runtime.

Tip: To further customize the hint window, create a custom descendant of THintWindow and assign it to the global HintWindowClass (see page 14384) variable.

See Also

Hint (see page 13712)

THintWindow (see page 6055)

HintWindowClass (see page 14384)

72.1.1.5.17 TApplication.HintHidePause Property

Specifies the time interval to wait before hiding the Help Hint (see page 13712) if the mouse has not moved from the control or menu item.

Pascal

```
property HintHidePause: Integer;
```

C++

```
__property int HintHidePause;
```

Description

Use HintHidePause to specify a wait time in milliseconds, which is different from the default value of 2500 ms or 2 1/2 seconds that is set in the constructor. The Help Hint (see page 13712) for the control or menu item is specified in the Hint (see page 13712) property.

Note: The default is a predefined constant value that is several times longer than HintPause (see page 13715).

See Also

Hint (see page 13712)

HintPause (see page 13715)

HintShortPause (see page 13716)

72.1.1.5.18 TApplication.HintPause Property

Specifies the time interval that passes before the control's Help Hint (see page 13712) appears when the user places the

mouse pointer on a control or menu item.

Pascal

```
property HintPause: Integer;
```

C++

```
__property int HintPause;
```

Description

Use HintPause to change the default pause time of 500 ms or 1/2 second that is set in the constructor. When assigning a value to HintPause, specify the interval in milliseconds. The Help Hint (see page 13712) displayed at the end of the pause is specified in the Hint (see page 13712) property.

See Also

HintHidePause (see page 13715)

Hint (see page 13712)

HintShortPause (see page 13716)

72.1.1.5.19 TApplication.HintShortCuts Property

Specifies whether the application's pop-up hints include shortcut information.

Pascal

```
property HintShortCuts: Boolean;
```

C++

```
__property Boolean HintShortCuts;
```

Description

Use HintShortCuts to specify whether the application's pop-up hints include shortcut information. If HintShortCuts is true, the shortcut information is displayed. For example, if HintShortCuts is true, the hint for the Cut command might be "Cut (Ctrl+X)" instead of "Cut".

72.1.1.5.20 TApplication.HintShortPause Property

Specifies the time period to wait before bringing up a hint if another hint has already been shown.

Pascal

```
property HintShortPause: Integer;
```

C++

```
__property int HintShortPause;
```

Description

Use HintShortPause to reduce the flicker when moving the mouse quickly over a set of buttons that all have help hints on. Specify a value in milliseconds that is different from the default value of 50 ms that is set in the constructor.

See Also

HintHidePause (see page 13715)

Hint (see page 13712)

HintPause (see page 13715)

72.1.1.5.21 TApplication.Icon Property

Determines which icon represents the application on the Windows task bar.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Use Icon to assign a specific icon to represent the application. Set the Icon property by either:

Assigning it a TIcon at runtime.

Loading an icon on the Application (see page 14383) page of the Project|Options dialog box at design time.

Icon represents the application when it is minimized and appears either on the Windows desktop or task bar.

C++ Examples:

```
/*
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
  OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
  OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
  OpenPictureDialog1->Options.Clear();
  OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
  while (true)
  {
    if (OpenPictureDialog1->Execute())
    {
      if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
      {
        Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
        break;
      }
      else // reset Options to remove ofExtensionDifferent
      {
        OpenPictureDialog1->Options.Clear();
        OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
      }
    }
    else // user cancelled
      break;
  }
}
```

Delphi Examples:

```
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
```

```
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
```

OnMinimize (see page 13739)

Restore (see page 13694)

Title (see page 13723)

72.1.1.5.22 TApplication.MainForm Property

Identifies which form in the application is the main window.

Pascal

```
property MainForm: TForm;
```

C++

```
__property TForm * MainForm;
```

Description

Use MainForm to determine the form that acts as the application's main window. The main form is the first form created in the main body of the application. When the main form closes, the application terminates.

When a new project is created, Form1 automatically becomes the value of the MainForm property. To assign a different form to the MainForm property, use the Forms (see page 13657) page of the Project|Options dialog box at design time. MainForm cannot be modified at runtime; it is read-only.

See Also

Create (see page 13666)

CreateForm (see page 13670)

Handle (see page 13710)

Terminate (see page 13699)

72.1.1.5.23 TApplication.MainFormHandle Property

Gives the Windows handle of the application main form.

Pascal

```
property MainFormHandle: HWND;
```

C++

```
__property HWND MainFormHandle;
```

Description

MainFormHandle gives the Windows handle of the application main form.

See Also

ActiveFormHandle (see page 13705)

72.1.1.5.24 TApplication.MainFormOnTaskBar Property

Controls (see page 5711) how Windows taskbar buttons are handled by VCL.

Pascal

```
property MainFormOnTaskBar: Boolean;
```

C++

```
__property Boolean MainFormOnTaskBar;
```

Description

The MainFormOnTaskBar property controls how Windows taskbar buttons are handled by VCL.

If the property is true, a taskbar button represents the application's main form and displays its caption. If false, a taskbar button represents the application's (hidden) main window and bears the application's Title (see page 13723).

MainFormOnTaskBar must be true to use Windows Vista Aero effects. These include live taskbar thumbnails, Dynamic Windows, Windows Flip, and Windows Flip 3D.

If a change to default behavior is required, MainFormOnTaskBar should be set in the .dpr file after Application.Initialize (see page 13682) and before main form creation. The MainFormOnTaskBar setting is intended to persist for the life of the application; later runtime changes of this property could result in unexpected behavior.

MainFormOnTaskBar defaults to `True` for applications created in Delphi 2007 and later products and `False` for earlier products.

The property can be applied to older applications. Note that it affects the Z-order of your MainForm (see page 13718) in case your application depends on this.

To update existing VCL applications, add the following line to the project's .dpr file after `Application.Initialize (see page 13682);`:

```
Application.MainFormOnTaskbar := True;
```

This line is automatically added to new projects.

For further information, see http://www.microsoft.com/windows/products/windowsvista/features/experiences/aero.mspx.

See Also

TApplication (see page 13660)

72.1.1.5.25 TApplication.ModalLevel Property

Pascal

```
property ModalLevel: Integer;
```

C++

```
__property int ModalLevel;
```

Description

This is ModalLevel, a member of class TApplication.

72.1.1.5.26 TApplication.ModalPopupMode Property

Pascal

```
property ModalPopupMode: TPopupMode;
```

C++

```
__property TPopupMode ModalPopupMode;
```

Description

This is ModalPopupMode, a member of class TApplication.

72.1.1.5.27 TApplication.NonBiDiKeyboard Property

Specifies the name of the keyboard map that should be used unless text reads from right to left.

Pascal

```
property NonBiDiKeyboard: string;
```

C++

```
__property AnsiString NonBiDiKeyboard;
```

Description

Use NonBiDiKeyboard to specify the keyboard map that should be used. This name is a string composed of the hexadecimal value of the language identifier (low word) and a device identifier (high word). For example, U.S. English has a language identifier of 0x0409, so the primary U.S. English layout is named "00000409". Variants (see page 23567) of U.S. English layout (such as the Dvorak layout) are named "00010409", "00020409", and so on.

If the application is running in a middle eastern locale and the value of BiDiMode (see page 13706) indicates that text should read from right to left, the application uses BiDiKeyboard (see page 13706) instead.

See Also

BiDiMode (see page 13706)

BiDiKeyboard (see page 13706)

72.1.1.5.28 TApplication.PopupControlWnd Property

Pascal

```
property PopupControlWnd: HWND;
```

C++

```
__property HWND PopupControlWnd;
```

Description

This is PopupControlWnd, a member of class TApplication.

72.1.1.5.29 TApplication.ShowHint Property

Determines whether Help Hints are enabled or disabled for the entire application.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

Use ShowHints to choose when to display Help Hints. If ShowHint is true, Help Hints are enabled; if ShowHint is false, Help Hints are disabled. The default value is true. Help Hints are specified in the Hint (see page 13712) property.

Setting ShowHint for the application to false disables all Help Hints, regardless of the value of the ShowHint properties for individual controls.

Tip: You can customize the hint window by creating a custom descendant of THintWindow and assigning it to the global HintWindowClass (see page 14384) variable.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
```

```
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

See Also

Hint (see page 13712)

OnHint (see page 13731)

ParentShowHint (see page 5835)

ShowHint (see page 5840)

THintWindow (see page 6055)

72.1.1.5.30 TApplication.ShowMainForm Property

Determines whether the application shows its main form on startup.

Pascal

```
property ShowMainForm: Boolean;
```

C++

```
__property Boolean ShowMainForm;
```

Description

Use ShowMainForm to control whether and when the application shows its main form.

The default value of true is set in the constructor. When ShowMainForm is true, the main window shows automatically when the application starts. The MainForm (see page 13718) property specifies which form is the main form.

To hide the main form at startup, set ShowMainForm to false in the main project file before the call to the Run (see page

13696) method. Make sure that the Visible property of the form is also false.

See Also

Create (see page 13666)

MainForm (see page 13718)

Run (see page 13696)

Visible (see page 5847)

Hiding the Main Form

72.1.1.5.31 TApplication.Terminated Property

Reports whether the application is in the process of shutting down.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

Terminated is used when calling the ProcessMessages (see page 13691) method so that the application doesn't perform unnecessary actions after the shut-down process has been triggered. ProcessMessages (see page 13691) sets Terminated to true when it receives a WM_QUIT message.

An application usually receives a WM_QUIT message because the main window of the application has closed, or because the Terminate (see page 13699) method has been called.

Note: For applications using calculation-intensive loops, call ProcessMessages (see page 13691) periodically, and also check Terminated to determine whether to abort the calculation and allow the application to terminate.

See Also

ProcessMessages (see page 13691)

Terminate (see page 13699)

72.1.1.5.32 TApplication.Title Property

Contains the text that appears below the icon representing the application when it is minimized.

Pascal

```
property Title: string;
```

C++

```
__property AnsiString Title;
```

Description

Use the Title property to modify the name of the text string appearing below the icon of the application. The default value is taken from the DLL or EXE file name at runtime.

Set the Title at runtime, or enter the value of the Title property on the Application (see page 14383) page of the Project | Options dialog box.

See Also

ExeName (see page 13709)

Icon (see page 13717)

72.1.1.5.33 TApplication.UpdateFormatSettings Property

Specifies whether format settings are updated automatically when the user alters the system configuration.

Pascal

```
property UpdateFormatSettings: Boolean;
```

C++

```
__property Boolean UpdateFormatSettings;
```

Description

Use UpdateFormatSettings to control automatic updating of format settings. The default of true is set in the constructor. UpdateFormatSettings is checked when the application receives a WM_WININICHANGE message.

Using the default format settings is recommended. These settings are initialized to the Windows local settings.

See Also

variables

72.1.1.5.34 TApplication.UpdateMetricSettings Property

Specifies whether the settings used for the hint window font and the icon title font are updated.

Pascal

```
property UpdateMetricSettings: Boolean;
```

C++

```
__property Boolean UpdateMetricSettings;
```

Description

Use UpdateMetricSettings to specify whether or not the hint window font and the icon title font on the desk top should be updated to reflect the system settings when those settings are changed.

The initial value of true is set in the constructor.

72.1.1.6 TApplication Events

The events of the TApplication class are listed here.

Public Events

	Name	Description
	OnActionExecute (see page 13725)	Occurs when an action's Execute method is called and its action list has not already handled it.
	OnActionUpdate (see page 13726)	Occurs when an action's Update method is called and its action list has not already handled it.
	OnActivate (see page 13726)	Occurs when an application becomes active.
	OnDeactivate (see page 13727)	Occurs when an application becomes inactive.
	OnException (see page 13728)	Occurs when an unhandled exception occurs in the application.

	OnGetActiveFormHandle (see page 13729)	This is OnGetActiveFormHandle, a member of class TApplication.
	OnGetMainFormHandle (see page 13729)	This is OnGetMainFormHandle, a member of class TApplication.
	OnHelp (see page 13730)	Occurs when the application receives a request for help.
	OnHint (see page 13731)	Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 13712).
	OnIdle (see page 13733)	Occurs when an application becomes idle.
	OnMessage (see page 13737)	Occurs when the application receives a Windows message.
	OnMinimize (see page 13739)	Occurs when an application is minimized.
	OnModalBegin (see page 13740)	Occurs when a modal form is opened.
	OnModalEnd (see page 13740)	Occurs when a modal form is closed.
	OnRestore (see page 13741)	Occurs when the previously minimized application is restored to its normal size.
	OnSettingChange (see page 13741)	Occurs when Windows notifies the application that a system-wide setting has changed.
	OnShortCut (see page 13741)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShowHint (see page 13742)	Occurs when the application is about to display the hint window for a Help Hint (see page 13712).

72.1.1.6.1 TApplication.OnActionExecute Event

Occurs when an action's Execute method is called and its action list has not already handled it.

Pascal

```
property OnActionExecute: TActionEvent;
```

C++

```
__property TActionEvent OnActionExecute;
```

Description

Use the OnExecute event handler to respond when a user invokes actions whose action lists do not have OnExecute event handlers.

If the action list that contains the action does not handle it in an OnExecute event handler, then the action is routed to the Application (see page 14383) object's ExecuteAction (see page 13673) method, which invokes the OnActionExecute event handler. (The application's ExecuteAction (see page 13673) method applies to all actions in the application.)

The Handled parameter of the event handler returns false by default. If the handler handles the event, it should change Handled to true, thereby preventing further attempts to handle the action. When the event handler exits with Handled set to false, the action's OnExecute event occurs. If the action remains unhandled after that, the active control's ExecuteAction (see page 13673) method is called to allow the action to execute with an identified target. Finally, the active form's ExecuteAction (see page 13673) method is called if all other handlers do not handle the action.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

What Happens When an Action Fires

72.1.1.6.2 TApplication.OnActionUpdate Event

Occurs when an action's Update method is called and its action list has not already handled it.

Pascal

```
property OnActionUpdate: TActionEvent;
```

C++

```
__property TActionEvent OnActionUpdate;
```

Description

Use the OnActionUpdate event handler to update the properties of an action when the application is idle if the action's action list does not handle it in an OnUpdate event handler.

If the action list that contains the action does not update it in an OnUpdate event handler, the action is routed to the Application (see page 14383) object's UpdateAction (see page 13701) method, which invokes the OnActionUpdate event handler. (The application's UpdateAction (see page 13701) method applies to all actions in the application.)

The Handled parameter of the event handler returns false by default. If the handler updates the event, it should change Handled to true, thereby ending the processing of the action. When the event handler exits with Handled set to false, the action's OnUpdate event occurs. If the action is not updated after that, the active control's UpdateAction (see page 13701) method is called to allow the target to update the action. Finally, the active form's UpdateAction (see page 13701) method is called if all other handlers do not handle the action.

Note: OnActionUpdate occurs after the application's OnIdle (see page 13733) event.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

72.1.1.6.3 TApplication.OnActivate Event

Occurs when an application becomes active.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Write an OnActivate event handler to perform special processing when the application becomes active.

An application becomes active when it is initially run or when focus moves from another Windows application back to any window of the application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

See Also

Active (see page 13704)

OnDeactivate (see page 13727)

OnActivate (see page 1355)

72.1.1.6.4 TApplication.OnDeactivate Event

Occurs when an application becomes inactive.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Write an OnDeactivate event handler to perform any special processing that should occur immediately before the application is deactivated. The OnDeactivate event occurs when the user switches from the application to another Windows application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
*/
void __fastcall TForm1::AppDeactivate(TObject *Sender)
{
  Application->Minimize();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnDeactivate = AppDeactivate;
}
```

Delphi Examples:

```
{
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnDeactivate := AppDeactivate;
end;
```

```
procedure TForm1.AppDeactivate(Sender: TObject);
begin
  Application.Minimize;
end;
```

See Also

OnActivate (see page 13726)

OnDeactivate (see page 1356)

72.1.1.6.5 TApplication.OnException Event

Occurs when an unhandled exception occurs in the application.

Pascal

```
property OnException: TExceptionEvent;
```

C++

```
__property TExceptionEvent OnException;
```

Description

Use OnException to change the default behavior that occurs when an exception is not handled by application code. The OnException event handler is called automatically in the HandleException (see page 13674) method.

OnException only handles exceptions that occur during message processing. Exceptions that occur before or after the execution of the application's Run (see page 13696) method do not generate OnException events.

If an exception passes through the tryblocks in the application code, the application automatically calls the HandleException (see page 13674) method. Unless the exception object is EAbort, HandleException (see page 13674) calls the OnException handler, if one exists. Otherwise, it calls ShowException (see page 13698) to display a message box indicating an error occurred.

TExceptionEvent (see page 14373) is the type of the OnException event. It points to a method that handles exceptions in the application. The Sender parameter is the object that raised the exception, and E is the exception object.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
```

```
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;
procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

72.1.1.6.6 TApplication.OnGetActiveFormHandle Event

Pascal

```
property OnGetActiveFormHandle: TGetHandleEvent;
```

C++

```
__property TGetHandleEvent OnGetActiveFormHandle;
```

Description

This is OnGetActiveFormHandle, a member of class TApplication.

72.1.1.6.7 TApplication.OnGetMainFormHandle Event

Pascal

```
property OnGetMainFormHandle: TGetHandleEvent;
```

C++

```
__property TGetHandleEvent OnGetMainFormHandle;
```

Description

This is OnGetMainFormHandle, a member of class TApplication.

72.1.1.6.8 TApplication.OnHelp Event

Occurs when the application receives a request for help.

Pascal

```
property OnHelp: THelpEvent;
```

C++

```
__property THelpEvent OnHelp;
```

Description

Write an OnHelp event handler to perform special processing when the user requests help. The HelpContext (see page 13679) and the HelpJump (see page 13679) methods automatically trigger the OnHelp event.

Set CallHelp to true if the application should still invoke the help system after the event. Set CallHelp to false to prevent the default response by the help system. All application help methods go through OnHelp. The application calls the help system only if OnHelp's CallHelp parameter returns true or if no OnHelp event handler is assigned.

The event handler returns true if it succeeds, false if it fails.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code changes the Help file depending on the
active form, before the help viewer is called. AppHelp is
assigned to the OnHelp event handler of Application in the
OnCreate event of Form1.
*/
bool __fastcall TForm1::AppHelp(Word Command, int Data, bool &CallHelp)
{
  Application->HelpFile = Screen->ActiveForm->Name + ".hlp";
  CallHelp = true;
  return true;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHelp = AppHelp;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  const DATANOTFOUND = 714;
  Application->HelpContext(DATANOTFOUND);
}
```

Delphi Examples:

```
{
The following code changes the Help file depending on the
active form, before the help viewer is called. AppHelp is
assigned to the OnHelp event handler of Application in the
OnCreate event of Form1.
}
function TForm1.AppHelp(
  Command: Word; Data: Longint; var CallHelp: Boolean) : Boolean;
var helpstring : String;
begin
```

```
    helpstring := Screen.ActiveForm.Name + '.hlp';
    MessageDlg(
      'Using ' + helpstring + ' as the help file.',
      mtInformation, [mbOK], 0);
    Application.HelpFile := helpstring;
    CallHelp := True;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  const DATANOTFOUND = 714;
  begin
    Application.HelpContext(DATANOTFOUND);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnHelp := AppHelp;
  end;
```

InvokeHelp

72.1.1.6.9 TApplication.OnHint Event

Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 13712).

Pascal

```
property OnHint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnHint;
```

Description

Write an OnHint event handler to perform special processing when the mouse pauses over a control or menu item whose Hint (see page 13712) property is not an empty string.

A common use of the OnHint event is to display the value of a control or menu item's Hint (see page 13712) property in another control. Note that it is not necessary to use an OnHint event handler to display hints on a status bar (TStatusBar): TStatusBar will automatically display hints if you set its AutoHint property to true.

The Hint (see page 13712) property of a control can specify both a short Help Hint (see page 13712) and a (usually) longer hint that appears elsewhere because of code in an OnHint event handler.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

Tip: Component writers can respond to the automatically-fired THintAction action in a component's ExecuteAction (see page 13673) method rather than relying on an OnHint event handler.

C++ Examples:

```
/*
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
*/

/*
Here is the code to add to the unit file.  It provides the
implementation of the DisplayHint method and assigns it to
the Application in the form's OnCreate event handler.
Note:   It is not actually necessary to write an OnHint event
handler to display hints on the status bar. This can be
accomplished more simply by setting the status bar's AutoHint
property.
*/
void __fastcall TForm1::DisplayHint(TObject *Sender)
{
  StatusBar1->SimpleText = GetLongHint(Application->Hint);
}

// Here is the form's OnCreate event handler.
// It assigns the application's OnHint event handler at
// runtime because the Application is not available in the
// Object Inspector
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHint = DisplayHint;
}
```

Delphi Examples:

```
{
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
}
type
  TForm1 = class(TForm)

72.1.1.6.10 TApplication.OnIdle Event

Occurs when an application becomes idle.

Pascal

```
property OnIdle: TIdleEvent;
```

C++

```
__property TIdleEvent OnIdle;
```

Description

Write an OnIdle event handler to perform special processing when an application is idle. An application is idle when it is not processing code. For example, an application is idle when it is waiting for input from the user.

OnIdle is called only once, as the application transitions into an idle state. It is not called continuously unless the Done parameter is set to false. Applications that set Done to false consume an inordinate amount of CPU time, which affects overall system performance.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
*/
// global variables to show the order of events
int  XPos, YPos, Delta;

// This is a utility procedure to display messages
// add this at the beginning of the unit

void StatusMsg(TForm *Form, TCanvas *Canvas, char *Message, bool Bkg)
```

```
{
  if (!Bkg)
    Canvas->Font->Style = TFontStyles() << fsBold; // foreground messages are bold
  Canvas->TextOut(XPos, YPos, Message);
  if (!Bkg)
    Canvas->Font->Style = TFontStyles();
  // change Xpos and YPos to prepare for the next message
  YPos += Delta;
  if (YPos >= Form->ClientHeight - 10)
  {
    YPos = 10;
    XPos += 180;
  }
  if (XPos >= Form->ClientWidth - 100)
  {
    if (Canvas->Font->Color == clRed)
      Canvas->Font->Color = clBlack;
    else
      Canvas->Font->Color = clRed;
    XPos = 10;
  }
}

/*
This is the OnCreate event handler for Form1.  It
initializes global values and sets the application's OnIdle
event handler
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Button1->Caption = "Do not yield";
  Button2->Caption  = "Handle Message";
  Application->OnIdle = MyIdleHandler;
  XPos = 10;
  YPos = 10;
  if (Canvas->Font->Height > 0)
    Delta = Canvas->Font->Height + 1;
  else
    Delta = 1 - Canvas->Font->Height;
}

/*
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some background
processing for the application.  This one simply writes a
message to let you know when it's there.
*/
void __fastcall TForm1::MyIdleHandler(TObject *Sender, bool &Done)
{
  StatusMsg(Form1, Canvas, "This represents a background process.", true);
}

/*
This is the OnClick event handler for Button1.  It
simulates a lengthy process
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button1Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
      Y = random(J);
```

```
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button1Click handler is done", false);
}

/*
This is the OnClick event handler for button2.  It
simulates a lengthy process that allows other messages to be
processed.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button2Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
    {
      Y = random(J);
    }
    // Yield to OnIdle or other messages
    Application->HandleMessage();
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button2Click handler is done", false);
}
```

Delphi Examples:

```
{
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
}
var
{ global variables to show the order of events. }
  XPos, YPos, Delta: integer;

{ This is a utility procedure to display messages }
{ add this at the beginning of the implementation section }
procedure StatusMsg(
  MyForm : TForm1; Canvas : TCanvas; Message : string; Bkg : Boolean);
begin
  if not bkg then
    Canvas.Font.Style := [fsBold]; {foreground messages are bold }
  Canvas.TextOut(XPos, YPos, Message);
  if not bkg then
    Canvas.Font.Style := [];
  { change Xpos and YPos to prepare for the next message }
  Ypos := Ypos + Delta;
  if YPos >= MyForm.ClientHeight - 10 then
  begin
    YPos := 10;
    Xpos := Xpos + 180;
  end;
  if (Xpos >= MyForm.ClientWidth - 100) then
  begin
    if (Canvas.Font.Color = clRed) then
      Canvas.Font.Color := clBlack
    else
      Canvas.Font.Color := clRed;
    Xpos := 10;
  end;
end;
```

```
{This is the Form's OnCreate event handler.  }
{ It initializes global variables and sets the  the OnIdle
event handler }
procedure TForm1.FormCreate(Sender: TObject);
begin
  Button1.Caption := 'Do not yield';
  Button2.Caption := 'Handle Message';
  Application.OnIdle:= MyIdleHandler;
  XPos := 10;
  YPos := 10;
  Delta := Abs(Canvas.Font.Height) + 1;
 end;

{
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some
background processing for the application.  This one simply
writes a message to let you know when it's there.
}
procedure TForm1.MyIdleHandler(Sender: TObject; var Done: Boolean);
begin
  StatusMsg(
    Form1, Canvas, 'This represents a background process.', True);
end;

{
Set this method as the OnClick event handler of Button1.  It
performs a calculation without yielding to other messages or
idle time.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, X, Y: Word;
begin
  StatusMsg(
    Form1, Canvas, 'The synchronous handler is starting', False);
  I := 0;
  J := 0;
  while I < 10 do
  begin
    Randomize;
    while J < 10 do
    begin
      Y := Random(J);
      Inc(J);
    end;
    X := Random(I);
    Inc(I);
  end;
  StatusMsg(
    Form1, Canvas, 'The synchronous handler is done', False);
end;

{
Set this method as the OnClick event handler of Button2.  It
performs a calculation but calls HandleMessage to allow idle
time or asynchronous message processing.
}
procedure TForm1.Button2Click(Sender: TObject);
var
  I, J, X, Y: Word;
begin
 StatusMsg(
    Form1, Canvas, 'The asynchronous handler is starting', False);
  I := 0;
```

```
    J := 0;
    while I < 10 do
    begin
      Randomize;
      while J < 10 do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
      { yield to OnIdle or other messages }
      Application.HandleMessage;
    end;
    StatusMsg(
      Form1, Canvas, 'The asynchronous handler is done', False);
  end;
```

72.1.1.6.11 TApplication.OnMessage Event

Occurs when the application receives a Windows message.

Pascal

```
property OnMessage: TMessageEvent;
```

C++

```
__property TMessageEvent OnMessage;
```

Description

Use OnMessage to trap any or all Windows messages posted to all windows in the application. The OnMessage event occurs when an application receives a Windows message. An OnMessage event handler allows an application to respond to messages other than those declared in the events for TApplication (see page 13660). If the application doesn't have a specific handler for an incoming message, the message is dispatched to the window for which it was intended, and Windows handles the message.

Note: OnMessage only receives messages that are posted to the message queue, not those sent directly with the Windows API SendMessage function.

Warning: Caution:Thousands of messages per second flow though this event. Be careful when coding the handler, because it can affect the performance of the entire application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code handles a custom message that the
application sends to itself when a file is ready for reading.
*/
```

```
const WM_FILEREADY = WM_USER + 2000;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  const PChar Path = "../overview.rtf";
  PostMessage(Application->Handle, WM_FILEREADY, 0, int(Path));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMessage = AppMessage;
}

void __fastcall TForm1::AppMessage(tagMSG &Msg, bool &Handled)
{
  if (Msg.message == WM_FILEREADY)
  {
    Memo1->Lines->LoadFromFile(AnsiString((char *)Msg.lParam));
    Handled = true;
  }
/*
For all other messages, Handled remains False so that other
message handlers can respond.
*/
}
```

Delphi Examples:

```
{
The following code handles a custom message that the
application sends to itself when a file is ready for reading.
}
const WM_FILEREADY = WM_USER + 2000;
procedure TForm1.Button1Click(Sender: TObject);
const Path: PChar = 'OverView.RTF';
begin
  PostMessage(Application.Handle, WM_FILEREADY, 0, integer(Path));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMessage := AppMessage;
end;

procedure TForm1.AppMessage(var Msg: TMsg; var Handled: Boolean);
var msgStr: String;
begin
  if Msg.hwnd = Application.Handle then
  begin
    if Msg.message = WM_FILEREADY then
    begin
      msgStr:= PChar(Msg.lParam);
      Memo1.Lines.LoadFromFile(msgStr);
      Handled := True;
    end;
  end;
  { for all other messages, Handled remains False }
  { so that other message handlers can respond }
end;
```

OnMessage (see page 1362)

72.1.1.6.12 TApplication.OnMinimize Event

Occurs when an application is minimized.

Pascal

```
property OnMinimize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMinimize;
```

Description

Write an OnMinimize event handler to perform special processing when the application is minimized. The application is minimized, either because the user minimizes the main window, or because of a call to the Minimize (see page 13688) method. The Icon (see page 13717) property determines the icon that represents the minimized application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

See Also

Icon (see page 13717)

Minimize (see page 13688)

OnRestore (see page 13741)

Restore (see page 13694)

OnMinimize (see page 1363)

72.1.1.6.13 TApplication.OnModalBegin Event

Occurs when a modal form is opened.

Pascal

```
property OnModalBegin: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnModalBegin;
```

Description

Write an OnModalBegin event handler to perform special processing when a modal form is opened.

See Also

OnModalEnd (see page 13740)

ModalStarted (see page 13689)

72.1.1.6.14 TApplication.OnModalEnd Event

Occurs when a modal form is closed.

Pascal

```
property OnModalEnd: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnModalEnd;
```

Description

Write an OnModalEnd event handler to perform special processing when a modal form is closed.

See Also

OnModalBegin (see page 13740)

ModalStarted (see page 13689)

72.1.1.6.15 TApplication.OnRestore Event

Occurs when the previously minimized application is restored to its normal size.

Pascal

```
property OnRestore: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnRestore;
```

Description

Write an OnRestore event handler to perform special processing when the application is restored from the minimized state in which it appears as an icon. An application is restored either because the user restores the application, or because the application calls the Restore (see page 13694) method.

Note: Don't confuse restoring an application with restoring a form or window to its original size. To minimize, maximize, and restore a window or form, change the value of the WindowState property.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

See Also

Icon (see page 13717)

Minimize (see page 13688)

Restore (see page 13694)

OnRestore (see page 1364)

WindowState (see page 13942)

72.1.1.6.16 TApplication.OnSettingChange Event

Occurs when Windows notifies the application that a system-wide setting has changed.

Pascal

```
property OnSettingChange: TSettingChangeEvent;
```

C++

```
__property TSettingChangeEvent OnSettingChange;
```

Description

Use OnSettingChange to respond when Windows informs the application that a system-wide setting or policy has changed.

72.1.1.6.17 TApplication.OnShortCut Event

Occurs when the user presses a key (before the OnKeyDown event).

Pascal

```
property OnShortCut: TShortCutEvent;
```

C++

```
__property TShortCutEvent OnShortCut;
```

Description

Use OnShortCut to dispatch shortcut keystrokes before the form or its controls handle them. When the user presses a key, the application can dispatch it as a shortcut key instead of allowing the standard keystroke processing (OnKeyDown, OnKeyPress, and OnKeyUp). Built-in shortcut processing is provided for menu shortcuts and actions associated with the form. OnShortCut lets the application implement additional shortcuts.

If the OnShortCut event handler responds to the keystroke, set its Handled parameter to true. This prevents the keystroke from being passed on to menus or actions associated with the application. It also prevents the standard keystroke processing in the same way that a menu or action shortcut does.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

See Also

OnShortCut (see page 13977)

OnKeyDown (see page 6225)

OnShortCut (see page 1366)

72.1.1.6.18 TApplication.OnShowHint Event

Occurs when the application is about to display the hint window for a Help Hint (see page 13712).

Pascal

```
property OnShowHint: TShowHintEvent;
```

C++

```
__property TShowHintEvent OnShowHint;
```

Description

Write an OnShowHint event handler to change the appearance and behavior of Help Hints.

In the event handler, set the HintStr parameter to change the text of the Help Hint (see page 13712). To obtain the text of a hint for a particular control, call the GetLongHint or GetShortHint function, and assign the result to HintStr.

Use the CanShow parameter to permit or prevent the Help Hint (see page 13712) from displaying.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
implementation part of the unit. Finally, in the OnCreate
event handler for the form, assign the method to the
OnShowHint event of the application.
```

```
*/
void __fastcall TForm1::DoShowHint(AnsiString &HintStr, bool &CanShow, THintInfo &HintInfo)
{
  if (HintInfo.HintControl == SpeedButton3)
  {
    HintInfo.HintColor = clAqua;// Changes only for this hint
    HintInfo.HintMaxWidth = 120; // Hint text word wraps if width is greater than 120
    HintInfo.HintPos.x += SpeedButton3->Width; // Move hint to right edge
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->ShowHint = true;
  Application->OnShowHint = DoShowHint;
}
```

Delphi Examples:

```
{
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
implementation part of the unit. Finally, in the OnCreate
event handler for the form, assign the method to the
OnShowHint event of the application.
}

procedure TForm1.DoShowHint(var HintStr: String; var CanShow: Boolean; var HintInfo:
THintInfo);
begin
  if HintInfo.HintControl = SpeedButton3 then
  begin
    with HintInfo do
    begin
      HintColor := clAqua;{ Changes only for this hint }
      HintMaxWidth := 120;{Hint text word wraps if width is greater than 120 }
      Inc(HintPos.X, SpeedButton3.Width); { Move hint to right edge }
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.ShowHint := True;
  Application.OnShowHint := DoShowHint;
end;
```

72.1.2 TControlScrollBar Class

TControlScrollBar displays a horizontal or vertical scroll bar.

Class Hierarchy

Pascal

```
TControlScrollBar = class(TPersistent);
```

C++

```
class TControlScrollBar : public TPersistent;
```

File

Forms

Description

Use TControlScrollBar to control the scroll bar in a scrolling windowed control such as TForm (see page 13992) or TScrollBox (see page 14238). TControlScrollBar introduces properties that control the size of the scrollable region and the position to which that region is scrolled, and when the scroll bar appears.

See Also

HorzScrollBar

TForm (see page 13992)

TScrollBox (see page 14238)

VertScrollBar

TScrollBar (see page 21821)

72.1.2.1 TControlScrollBar Members

The following tables list the members exposed by TControlScrollBar.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 13746)	Copies the contents of a TControlScrollBar (see page 13744) instance to another TControlScrollBar (see page 13744).
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ChangeBiDiPosition (see page 13746)	Changes the position of a horizontal scroll bar to match the current bi-directional mode.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsScrollBarVisible (see page 13747)	Returns true if the scroll bar is visible.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Kind (see page 13750)	Indicates whether the scroll bar is horizontal or vertical.
R	ScrollPos (see page 13756)	Indicates the position of the thumb tab.

Published Properties

	Name	Description
	ButtonSize (see page 13748)	Specifies the sizes of the buttons in the scroll bar.
	Color (see page 13748)	Specifies the scroll bar's color.
	Increment (see page 13748)	Determines how far the display moves when the user clicks one of the small end arrows on the scroll bar.
	Margin (see page 13750)	Determines when a scroll bar is generated.
	ParentColor (see page 13751)	Specifies whether the scroll bar should.
	Position (see page 13752)	Specifies the position of the thumb tab on the scroll bar.
	Range (see page 13753)	Determines how far the scrolling region of the associated control can move.
	Size (see page 13756)	Specifies the scroll bar's size.
	Smooth (see page 13756)	Specifies whether the amount the associated control scrolls is dynamically computed.
	Style (see page 13757)	Specifies the scroll bar's style.
	ThumbSize (see page 13757)	This is ThumbSize, a member of class TControlScrollBar.
	Tracking (see page 13757)	Determines whether the form or scroll box moves before the thumb tab is released.
	Visible (see page 13758)	Determines whether the scroll bar appears.

72.1.2.2 TControlScrollBar Methods

The methods of the TControlScrollBar class are listed here.

Public Methods

	Name	Description
	Assign (see page 13746)	Copies the contents of a TControlScrollBar (see page 13744) instance to another TControlScrollBar (see page 13744).
	ChangeBiDiPosition (see page 13746)	Changes the position of a horizontal scroll bar to match the current bi-directional mode.
	IsScrollBarVisible (see page 13747)	Returns true if the scroll bar is visible.

72.1.2.2.1 TControlScrollBar.Assign Method

Copies the contents of a TControlScrollBar (see page 13744) instance to another TControlScrollBar (see page 13744).

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the Visible (see page 13758), Range (see page 13753), Position (see page 13752), and Increment (see page 13748) properties from the source object to the TControlScrollBar (see page 13744) instance. If the Source parameter is not another scroll bar, Assign calls the TPersistent Assign method, which allows the source object to copy properties if it has an AssignTo method that knows how to copy to a control scroll bar.

See Also

Assign (see page 2930)

AssignTo (see page 2931)

Position (see page 13752)

Visible (see page 13758)

Range (see page 13753)

72.1.2.2.2 TControlScrollBar.ChangeBiDiPosition Method

Changes the position of a horizontal scroll bar to match the current bi-directional mode.

Pascal

```
procedure ChangeBiDiPosition;
```

C++

```
__fastcall ChangeBiDiPosition();
```

Description

Use ChangeBiDiPosition to change the position of a horizontal scroll bar to reflect the current bi-directional mode of its associated scrolling windowed control.

For example, TScrollingWinControl (see page 14312) calls ChangeBiDiPosition from its DoFlipChildren method to determine whether the scroll bar should be repositioned along with the child controls.

See Also

BiDiMode (see page 5803)

DoFlipChildren (see page 14327)

72.1.2.2.3 TControlScrollBar.IsScrollBarVisible Method

Returns true if the scroll bar is visible.

Pascal

```
function IsScrollBarVisible: Boolean;
```

C++

```
__fastcall Boolean IsScrollBarVisible();
```

Description

Call IsScrollBarVisible to determine whether the scroll bar is visible. IsScrollBarVisible returns true if the Visible (see page 13758) property is true and the associated scrolling windowed control contains child controls that lie within Margin (see page 13750) pixels from the edge.

See Also

Visible (see page 13758)

Margin (see page 13750)

72.1.2.3 TControlScrollBar Properties

The properties of the TControlScrollBar class are listed here.

Public Properties

	Name	Description
R	Kind (see page 13750)	Indicates whether the scroll bar is horizontal or vertical.
R	ScrollPos (see page 13756)	Indicates the position of the thumb tab.

Published Properties

	Name	Description
	ButtonSize (see page 13748)	Specifies the sizes of the buttons in the scroll bar.
	Color (see page 13748)	Specifies the scroll bar's color.
	Increment (see page 13748)	Determines how far the display moves when the user clicks one of the small end arrows on the scroll bar.
	Margin (see page 13750)	Determines when a scroll bar is generated.
	ParentColor (see page 13751)	Specifies whether the scroll bar should.
	Position (see page 13752)	Specifies the position of the thumb tab on the scroll bar.
	Range (see page 13753)	Determines how far the scrolling region of the associated control can move.
	Size (see page 13756)	Specifies the scroll bar's size.
	Smooth (see page 13756)	Specifies whether the amount the associated control scrolls is dynamically computed.
	Style (see page 13757)	Specifies the scroll bar's style.
	ThumbSize (see page 13757)	This is ThumbSize, a member of class TControlScrollBar.
	Tracking (see page 13757)	Determines whether the form or scroll box moves before the thumb tab is released.
	Visible (see page 13758)	Determines whether the scroll bar appears.

72.1.2.3.1 TControlScrollBar.ButtonSize Property

Specifies the sizes of the buttons in the scroll bar.

Pascal

```
property ButtonSize: Integer;
```

C++

```
__property int ButtonSize;
```

Description

Use ButtonSize to specify the sizes of the buttons in the scroll bar. If the scroll bar is horizontal, ButtonSize is the width of the arrow buttons in pixels. If the scroll bar is vertical, ButtonSize is the height of the arrow buttons in pixels.

See Also

Size (see page 13756)

Kind (see page 13750)

thumbsize (see page 13757)

72.1.2.3.2 TControlScrollBar.Color Property

Specifies the scroll bar's color.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to specify the scroll bar's color. When you explicitly assign a value to Color, the ParentColor (see page 13751) property is automatically set to false.

If the scroll bar's ParentColor (see page 13751) property is true, then the Color property reflects the Windows button highlight color (clBtnHighlight), and changing this color in the Windows control panel automatically updates the value of Color.

See Also

ParentColor (see page 13751)

72.1.2.3.3 TControlScrollBar.Increment Property

Determines how far the display moves when the user clicks one of the small end arrows on the scroll bar.

Pascal

```
property Increment: TScrollBarInc;
```

C++

```
__property TScrollBarInc Increment;
```

Description

Use Increment to control how the scroll bar affects the scrollable region of the control. If Increment is set to 1, each click scrolls by one position; if Increment is set to 2, each click scrolls by two positions; and so forth.

Note: Do not use the Increment property when Smooth (see page 13756) is set to true. When Smooth (see page 13756) is true, every time the range or visibility of the scroll bar changes, the value of Increment is dynamically recomputed.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
```

```
  Shift: TShiftState);
  const
    PageDelta = 10;
  begin
    With VertScrollbar do
      if Key = VK_NEXT then
        Position := Position + PageDelta
      else if Key = VK_PRIOR then
        Position := Position - PageDelta;
  end;
```

See Also

Smooth (see page 13756)

72.1.2.3.4 TControlScrollBar.Kind Property

Indicates whether the scroll bar is horizontal or vertical.

Pascal

```
property Kind: TScrollBarKind;
```

C++

```
__property TScrollBarKind Kind;
```

Description

Kind indicates whether the scroll bar has a vertical or horizontal orientation. This value is initialized in the constructor, when the scroll bar is created by a scrolling windowed control for its VertScrollBar or HorzScrollBar property.

See Also

VertScrollBar (see page 14330)

HorzScrollBar (see page 14329)

Create

72.1.2.3.5 TControlScrollBar.Margin Property

Determines when a scroll bar is generated.

Pascal

```
property Margin: Word;
```

C++

```
__property Word Margin;
```

Description

The Margin property determines the minimum number of pixels that must separate each control from the edge of the control that uses the scroll bar. At runtime, whenever a child control is less than Margin pixels from the edge and Visible (see page 13758) is set to true, a scroll bar appears.

C++ Examples:

```
/*
This example uses a button and a label on a form and needs
the AutoScroll property set on the form. Place the label
near the left side of the form, and place the button
somewhere near the middle of the form. When the user runs
the application, a horizontal scroll bar does not appear,
because no control on the form is close enough to the right
```

```
edge.  Each time the user clicks the button, the button moves
25 pixels to the right, and the calculated Range value is
reported in the caption of the label. Repeatedly clicking the
button eventually moves the button close enough to the edge
of the form (within the Margin amount) so that a horizontal
scroll bar appears.  Note that the Range property is
continuously updated as the button moves to the right.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Button1->Left = Button1->Left + 25;
  Label1->Caption = IntToStr(HorzScrollBar->Range);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  HorzScrollBar->Margin = 25;
  HorzScrollBar->Increment = 10;
}
```

Delphi Examples:

```
{
This example uses a button and a label on a form and needs
the AutoScroll property set on the form. Place the label
near the left side of the form, and place the button
somewhere near the middle of the form. When the user runs
the application, a horizontal scroll bar does not appear,
because no control on the form is close enough to the right
edge.  Each time the user clicks the button, the button moves
25 pixels to the right, and the calculated Range value is
reported in the caption of the label. Repeatedly clicking the
button eventually moves the button close enough to the edge
of the form (within the Margin amount) so that a horizontal
scroll bar appears.  Note that the Range property is
continuously updated as the button moves to the right.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with HorzScrollBar do
  begin
    Margin:= 25;
    Increment := 10;
    Visible := True;
  end;
end;
procedure TForm1.Button1Click(Sender: TObject);
begin
  Button1.Left := Button1.Left + 25;
  Label1.Caption := IntToStr(HorzScrollBar.Range);
end;
```

See Also

Visible (see page 13758)

IsScrollBarVisible (see page 13747)

72.1.2.3.6 TControlScrollBar.ParentColor Property

Specifies whether the scroll bar should.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

Use ParentColor to indicate that the scroll bar should always reflect the Windows button highlight color. Using ParentColor differs from setting the Color (see page 13748) property to clBtnHighlight in that when ParentColor is true, changing the button highlight color in the Windows control panel automatically updates the value of Color (see page 13748).

When the value of the Color (see page 13748) property is changed, its ParentColor property is automatically set to false.

See Also

Color (see page 13748)

TColor (see page 14648)

72.1.2.3.7 TControlScrollBar.Position Property

Specifies the position of the thumb tab on the scroll bar.

Pascal

```
property Position: Integer;
```

C++

```
__property int Position;
```

Description

Use Position to programmatically scroll the client area of the associated control. The value of Position changes (from 0 to Range (see page 13753)) at runtime as the user scrolls the scroll bar.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
```

```
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form’s logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

Range (see page 13753)

ScrollPos (see page 13756)

72.1.2.3.8 TControlScrollBar.Range Property

Determines how far the scrolling region of the associated control can move.

Pascal

```
property Range: Integer;
```

C++

```
__property int Range;
```

Description

Range represents the virtual size (in pixels) of the associated control's client area. For example, if the Range of a form's horizontal scroll bar is set to 500, and the width of the form is 200, the scroll bar's Position (see page 13752) can vary from 0 to 300.

If the Range of a horizontal scroll bar is less than the width of the form or scroll box, no horizontal scroll bar appears. If the

Range of a vertical scroll bar is less than the height of the form or scroll box, no vertical scroll bar appears.

The value of Range is set automatically, but can be overridden in the Object Inspector or in program code.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
This example uses a button and a label on a form and needs
the AutoScroll property set on the form. Place the label
near the left side of the form, and place the button
somewhere near the middle of the form. When the user runs
the application, a horizontal scroll bar does not appear,
because no control on the form is close enough to the right
edge.  Each time the user clicks the button, the button moves
25 pixels to the right, and the calculated Range value is
reported in the caption of the label. Repeatedly clicking the
button eventually moves the button close enough to the edge
of the form (within the Margin amount) so that a horizontal
scroll bar appears.  Note that the Range property is
continuously updated as the button moves to the right.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Button1->Left = Button1->Left + 25;
  Label1->Caption = IntToStr(HorzScrollBar->Range);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  HorzScrollBar->Margin = 25;
  HorzScrollBar->Increment = 10;
}
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
{
This example uses a button and a label on a form and needs
the AutoScroll property set on the form. Place the label
near the left side of the form, and place the button
somewhere near the middle of the form. When the user runs
the application, a horizontal scroll bar does not appear,
because no control on the form is close enough to the right
edge.  Each time the user clicks the button, the button moves
25 pixels to the right, and the calculated Range value is
reported in the caption of the label. Repeatedly clicking the
button eventually moves the button close enough to the edge
of the form (within the Margin amount) so that a horizontal
scroll bar appears.  Note that the Range property is
continuously updated as the button moves to the right.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  with HorzScrollBar do
  begin
    Margin:= 25;
    Increment := 10;
    Visible := True;
  end;
end;
procedure TForm1.Button1Click(Sender: TObject);
begin
  Button1.Left := Button1.Left + 25;
  Label1.Caption := IntToStr(HorzScrollBar.Range);
end;
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

Position (see page 13752)

Width (see page 5849)

Height (see page 5825)

72.1.2.3.9 TControlScrollBar.ScrollPos Property

Indicates the position of the thumb tab.

Pascal

```
property ScrollPos: Integer;
```

C++

```
__property int ScrollPos;
```

Description

The read-only ScrollPos property returns the current value of Position (see page 13752) when the scroll bar is visible. If the scroll bar is not visible, ScrollPos returns 0.

See Also

Position (see page 13752)

Visible (see page 13758)

72.1.2.3.10 TControlScrollBar.Size Property

Specifies the scroll bar's size.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

Use Size to specify the width of the scroll bar in pixels.

Note: The length of the scroll bar is determined by the width (for horizontal scroll bars) or height (for vertical scroll bars) of the associated scrolling windowed control.

See Also

ButtonSize (see page 13748)

thumbsize (see page 13757)

72.1.2.3.11 TControlScrollBar.Smooth Property

Specifies whether the amount the associated control scrolls is dynamically computed.

Pascal

```
property Smooth: Boolean;
```

C++

```
__property Boolean Smooth;
```

Description

Set Smooth to true to specify that the scroll bar should dynamically adjust its scrolling increment based on the size of the associated control's client area.

When Smooth is true, clicking the end arrows of the scroll bar scrolls the associated control by approximately one tenth of its client area, and clicking the scroll bar beside the thumb tab scrolls the control by the length of the client area minus the amount scrolled by the end arrows. When Smooth is false, the Increment (see page 13748) property controls the amount of scrolling when the user clicks the end arrows, and clicking beside the thumb tab scrolls the control by the entire length of the client area.

See Also

Increment (see page 13748)

Position (see page 13752)

72.1.2.3.12 TControlScrollBar.Style Property

Specifies the scroll bar's style.

Pascal

```
property Style: TScrollBarStyle;
```

C++

```
__property TScrollBarStyle Style;
```

Description

Use Style to specify the scroll bar's style. The style determines whether the scroll bar appears three-dimensional, flat, or uses hot tracking.

72.1.2.3.13 TControlScrollBar.ThumbSize Property

Pascal

```
property ThumbSize: Integer;
```

C++

```
__property int ThumbSize;
```

Description

This is ThumbSize, a member of class TControlScrollBar.

72.1.2.3.14 TControlScrollBar.Tracking Property

Determines whether the form or scroll box moves before the thumb tab is released.

Pascal

```
property Tracking: Boolean;
```

C++

```
__property Boolean Tracking;
```

Description

Use Tracking to control whether the scroll bar and associated control repaint while the thumb tab is dragged with the mouse. If Tracking is true, the image moves as the user drags the thumb tab. If Tracking is false, the image remains static until the thumb tab is released.

Repainting while the thumb tab is dragged can provide useful feedback to the user about how far the control has scrolled, but slows performance.

72.1.2.3.15 TControlScrollBar.Visible Property

Determines whether the scroll bar appears.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

If Visible is set to true, a scroll bar appears whenever a visual component is less than Margin (see page 13750) pixels from the edge of the form or scroll box. If Visible is set to false, the scroll bar is never visible. This is useful, for example, for programmatically controlling the scroll position of a form without allowing the user to control the scroll position.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
```

```
    with HorzScrollBar do
    begin
      { Set the range to twice the ClientWidth of the form }
      { This means that the form's logical size is twice as big }
      { as the physical window. }
      { Note that Range must always be larger than the ClientWidth }
      Range := 600;
      Position := Range - ClientWidth; { start form out fully scrolled }
      Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
      Visible := True;  { Show the scrollbar }
    end;
  end;
  {
  The following example demonstrates form scrolling with the
  PgUp and PgDn keys.
  }
  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
  Shift: TShiftState);
  const
    PageDelta = 10;
  begin
    With VertScrollbar do
      if Key = VK_NEXT then
        Position := Position + PageDelta
      else if Key = VK_PRIOR then
        Position := Position - PageDelta;
  end;
```

72.1.3 TCustomActiveForm Class

TCustomActiveForm is the base class for Active (see page 13896) Forms (see page 13657).

Class Hierarchy

Pascal

```
TCustomActiveForm = class(TCustomForm);
```

C++

```
class TCustomActiveForm : public TCustomForm;
```

File

Forms

Description

TCustomActiveForm is used in code that is generated automatically by the ActiveForm wizard. For more information, see Generating an ActiveX control based on a VCL form.

72.1.3.1 TCustomActiveForm Members

The following tables list the members exposed by TCustomActiveForm.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.

	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
V	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
V	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 13773)	Updates the active form's creation parameters according to the value of the AxBorderStyle (see page 13777) property.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
V	CreateWnd (see page 6137)	Creates the underlying window.

	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.

	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.

	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
V	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
V	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.

	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
V	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParent (see page 13887)	Sets the Parent property.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
V	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.

V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	FormStyle (see page 13912)	Determines the form's style.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	Position (see page 13933)	Represents the size and placement of the form.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.

	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 13773)	Creates a new TCustomActiveForm (see page 13759) object.
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.

	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.

V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13774)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.

	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 13797)	Indicates whether the form is visible.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnActivate (see page 13799)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnClick (see page 13803)	Occurs when the user clicks the control.
	OnContextPopup (see page 13805)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13805)	Occurs when the form is created.
	OnDblClick (see page 13807)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

	OnDeactivate (see page 13807)	Occurs when the form loses focus.
	OnDestroy (see page 13808)	Occurs when the form is destroyed.
	OnDragDrop (see page 13809)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13811)	Occurs when the user drags an object over a control.
	OnKeyDown (see page 13814)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13816)	Occurs when a key is pressed.
	OnKeyUp (see page 13817)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13819)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13820)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13822)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13823)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13823)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13825)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 13827)	Occurs when the form is redrawn.

Published Properties

	Name	Description
	ActiveControl (see page 13775)	Specifies the control that has focus on the form.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 13776)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 13777)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 13777)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AxBorderStyle (see page 13777)	Sets the active form's border style.
	BorderWidth (see page 13778)	Specifies the width of the control's border.
	Caption (see page 13778)	Specifies a text string that identifies the control to the user.
	Color (see page 13781)	Specifies the background color of the control.
	Constraints (see page 13782)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Font (see page 13782)	Controls the attributes of text written on or in the control.
	Height (see page 13783)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 13784)	Represents the horizontal scroll bar for the scrolling windowed control.
	KeyPreview (see page 13785)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 13788)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 13789)	Specifies the padding of a control.
	PixelsPerInch (see page 13789)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 13789)	Identifies the pop-up menu associated with the control.
	PrintScale (see page 13794)	Represents the proportions of a printed form.

	Scaled (see page 13794)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ShowHint (see page 13795)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 13796)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 13798)	Specifies the horizontal size of the control or form in pixels.

72.1.3.2 TCustomActiveForm.Create Constructor

Creates a new TCustomActiveForm (see page 13759) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomActiveForm(TComponent * AOwner);
```

Description

Create is the TCustomActiveForm (see page 13759) constructor.

AOwner specifies a component, typically the global application object, that becomes the value of the Owner property. The owner is responsible for initiating streaming of the active form and for freeing it.

See Also

Owner (see page 2807)

ParentWindow (see page 6210)

72.1.3.3 TCustomActiveForm Methods

The methods of the TCustomActiveForm class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 13773)	Updates the active form's creation parameters according to the value of the AxBorderStyle (see page 13777) property.

Public Methods

	Name	Description
	WantChildKey (see page 13774)	Indicates whether the form processes keyboard input for a control it owns.

72.1.3.3.1 TCustomActiveForm.CreateParams Method

Updates the active form's creation parameters according to the value of the AxBorderStyle (see page 13777) property.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams performs the following tasks:

Calls the inherited CreateParams method.

Removes the WS_CAPTION flag from the Style property of Params.

Adds flags to the Style and ExStyle properties of Params according to the value of the AxBorderStyle (see page 13777) property, as shown in the following table:

AxBorderStyleStyleExStyle

AxBorderStyle (see page 13777)	Style	ExStyle
afbNone	Nothing	Nothing
afbSingle	WS_BORDER	Nothing
afbSunken	Nothing	WS_EX_CLIENTEDGE
afbRaised	WS_DLGFRAME	WS_EX_WINDOWEDGE

Note: The creation parameters are not updated when the form is in design mode.

See Also

CreateParams2

72.1.3.3.2 TCustomActiveForm.WantChildKey Method

Indicates whether the form processes keyboard input for a control it owns.

Pascal

```
function WantChildKey(Child: TControl; var Message: TMessage): Boolean; override;
```

C++

```
virtual __fastcall Boolean WantChildKey(TControl * Child, TMessage Message);
```

Description

Do not call WantChildKey. It is used internally to ensure that keyboard events sent to child objects are handled correctly.

See Also

WantChildKey (see page 13893)

72.1.3.4 TCustomActiveForm Properties

The properties of the TCustomActiveForm class are listed here.

Public Properties

	Name	Description
	Visible (see page 13797)	Indicates whether the form is visible.

Published Properties

	Name	Description
	ActiveControl (see page 13775)	Specifies the control that has focus on the form.
	Anchors (see page 13776)	Specifies how the control is anchored to its parent.

	AutoScroll (see page 13777)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 13777)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AxBorderStyle (see page 13777)	Sets the active form's border style.
	BorderWidth (see page 13778)	Specifies the width of the control's border.
	Caption (see page 13778)	Specifies a text string that identifies the control to the user.
	Color (see page 13781)	Specifies the background color of the control.
	Constraints (see page 13782)	Specifies the size constraints for the control.
	Font (see page 13782)	Controls the attributes of text written on or in the control.
	Height (see page 13783)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13784)	Represents the horizontal scroll bar for the scrolling windowed control.
	KeyPreview (see page 13785)	Specifies whether the form should receive keyboard events before the active control.
	OldCreateOrder (see page 13788)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 13789)	Specifies the padding of a control.
	PixelsPerInch (see page 13789)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 13789)	Identifies the pop-up menu associated with the control.
	PrintScale (see page 13794)	Represents the proportions of a printed form.
	Scaled (see page 13794)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ShowHint (see page 13795)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	VertScrollBar (see page 13796)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 13798)	Specifies the horizontal size of the control or form in pixels.

72.1.3.4.1 TCustomActiveForm.ActiveControl Property

Specifies the control that has focus on the form.

Pascal

```
property ActiveControl: TWinControl;
```

C++

```
__property TWinControl * ActiveControl;
```

Description

Use ActiveControl to get or set the control that has focus on the form. Only one control can have focus at a given time in an application.

If the form does not have focus, ActiveControl is the control on the form that will receive focus when the form receives focus.

Note: When focus shifts to another control, ActiveControl is updated before the OnExit event occurs.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
```

```
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

See Also

ActiveOleControl (see page 13897)

OnExit (see page 6221)

OnEnter (see page 6219)

Active (see page 13896)

72.1.3.4.2 TCustomActiveForm.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

72.1.3.4.3 TCustomActiveForm.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

VertScrollBar (see page 14330)

72.1.3.4.4 TCustomActiveForm.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

72.1.3.4.5 TCustomActiveForm.AxBorderStyle Property

Sets the active form's border style.

Pascal

```
property AxBorderStyle: TActiveFormBorderStyle;
```

C++

```
__property TActiveFormBorderStyle AxBorderStyle;
```

Description

AxBorderStyle takes one of the following values:

ValuesMeaning

Values	Meaning	
afbNone	No border appears around the active form.	
afbSingle	A single line border appears around the active form.	
afbSunken	The active form gets a sunken border.	
afbRaised	The active form gets a raised border and no caption.	

See Also

BorderStyle (see page 13900)

72.1.3.4.6 TCustomActiveForm.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter (see page 6194)

72.1.3.4.7 TCustomActiveForm.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
```

```
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
```

```
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
    ToolBar1.Free;
  end;
```

72.1.3.4.8 TCustomActiveForm.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

72.1.3.4.9 TCustomActiveForm.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

72.1.3.4.10 TCustomActiveForm.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
```

```
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

72.1.3.4.11 TCustomActiveForm.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
```

```
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
    end;
end;
```

Using TDBListBox and TDBComboBox

72.1.3.4.12 TCustomActiveForm.HorzScrollBar Property

Represents the horizontal scroll bar for the scrolling windowed control.

Pascal

```
property HorzScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar HorzScrollBar;
```

Description

Use HorzScrollBar to hide, show, or manipulate the horizontal scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
```

See Also

AutoScroll (see page 14329)

VertScrollBar (see page 14330)

TControlScrollBar (see page 13744)

72.1.3.4.13 TCustomActiveForm.KeyPreview Property

Specifies whether the form should receive keyboard events before the active control.

Pascal

```
property KeyPreview: Boolean;
```

C++

```
__property Boolean KeyPreview;
```

Description

If KeyPreview is true, keyboard events occur on the form before they occur on the active control. (The active control is specified by the ActiveControl property.)

If KeyPreview is false, keyboard events occur only on the active control.

Navigation keys (Tab, BackTab, the arrow keys, and so on) are unaffected by KeyPreview because they do not generate keyboard events. Similarly, when a button has focus or when its Default property is true, the Enter key is unaffected by KeyPreview because it does not generate a keyboard events.

KeyPreview is false by default.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
```

```
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);

OnKeyUp (see page 6228)

OnKeyPress (see page 6227)

72.1.3.4.14 TCustomActiveForm.OldCreateOrder Property

Specifies when OnCreate and OnDestroy events occur.

Pascal

```
property OldCreateOrder: Boolean;
```

C++

```
__property Boolean OldCreateOrder;
```

Description

When OldCreateOrder is false (the default) the OnCreate event occurs after all constructors are finished and the OnDestroy event occurs before any destructors are called.

This differs from earlier versions of the library (distributed with Delphi version 3 and previous and C++Builder 1), where the OnCreate event occurred when the TCustomForm constructor executed and the OnDestroy event occurred when the TCustomForm destructor executed. Applications that require the OnCreate event and OnDestroy events to occur from the constructor and destructor of the form can set OldCreateOrder to true.

See Also

OnCreate (see page 13951)

OnDestroy (see page 13953)

BeforeDestruction (see page 13866)

AfterConstruction (see page 13866)

72.1.3.4.15 TCustomActiveForm.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding: TPadding;
```

C++

```
__property TPadding Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding (see page 6103)

72.1.3.4.16 TCustomActiveForm.PixelsPerInch Property

Represents the proportion of the font on the system on which the form was designed.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

Use PixelsPerInch at runtime to change how the form is scaled to the current screen resolution. If PixelsPerInch is changed from its default value, the form will not have the same proportion on every screen resolution.

At design time, PixelsPerInch is set automatically when the form is saved. Changes to PixelsPerInch made in the Object Inspector only affect the form at runtime.

The form's Scaled property must be true for PixelsPerInch to have an effect.

See Also

Scaled (see page 13935)

72.1.3.4.17 TCustomActiveForm.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
```

```
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
```

```
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
```

```
the menu item OnClick event.
}

type
  TForm1 = class(TForm)
    AddButton: TButton;
    EditButton: TButton;
    DestroyButton: TButton;
    PopupMenu1: TPopupMenu;
    procedure AddButtonClick(Sender: TObject);
    procedure EditButtonClick(Sender: TObject);

72.1.3.4.18 TCustomActiveForm.PrintScale Property

Represents the proportions of a printed form.

Pascal

```
property PrintScale: TPrintScale;
```

C++

```
__property TPrintScale PrintScale;
```

Description

Use PrintScale to get or set the proportions of the printed form. PrintScale can have one of the following TPrintScale values:

Value	Meaning
poNone	No special scaling occurs; therefore, the printed form and how the form appears onscreen may appear squished or stretched.
poProportional	The form is printed so that the printed image is approximately the same visible size as on the screen (WYSIWYG). The form image is scaled so that the printed image is approximately the same visible size as on the screen.
poPrintToFit	The form is printed using the same screen proportions, but in a size that just fits the printed page.

See Also

Print (see page 13883)

72.1.3.4.19 TCustomActiveForm.Scaled Property

Specifies whether the form is sized according to the value of the PixelsPerInch property.

Pascal

```
property Scaled: Boolean;
```

C++

```
__property Boolean Scaled;
```

Description

Scaled determines whether the form adjusts itself to differences between the font used at design time and the current system font used by a system at runtime. If Scaled is true, the form resizes itself and all its child controls to maintain the relationship

between the size of controls and the height of text displayed in the default font. If Scaled is false, no such resizing occurs.

By setting Scaled to true, the form can adjust to fonts that are not scalable (that is, fonts that only supply discrete point sizes) or to differences such as forms designed using small fonts at design time that are run on systems that use large fonts.

The degree of resizing is determined by the PixelsPerInch property, which measures the proportion of the font on the system used when designing the form.

See Also

PixelsPerInch (see page 13928)

Considerations When Dynamically Resizing Forms and Controls

72.1.3.4.20 TCustomActiveForm.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

72.1.3.4.21 TCustomActiveForm.VertScrollBar Property

Represents the vertical scroll bar for the scrolling windowed control.

Pascal

```
property VertScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar VertScrollBar;
```

Description

Use VertScrollBar to hide, show, or manipulate the vertical scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
```

```
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

AutoScroll (see page 14329)

HorzScrollBar (see page 14329)

TControlScrollBar (see page 13744)

72.1.3.4.22 TCustomActiveForm.Visible Property

Indicates whether the form is visible.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use Visible to determine whether the form is visible.

If Visible is true, the form is visible unless it is completely obscured by other forms. If Visible is false, the form is not visible.

The Show and ShowModal methods set Visible to true and bring the form to the front of all open windows.

C++ Examples:

```
/*
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must include Unit2.h in this
module.
*/
#include "Unit2.h"
```

```
void __fastcall TForm1::ShowPaletteButtonClick(TObject *Sender)
{
  if (!Form2->Visible)
  {
    Form2->Visible = true;
    Form2->BringToFront();
  }
}
```

Delphi Examples:

```
{
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must add Unit2 in the uses clause
of your unit.
}
procedure TForm1.ShowPaletteButtonClick(Sender: TObject);
begin
if Form2.Visible = False then Form2.Visible := True;
Form2.BringToFront;
end;
```

See Also

BringToFront (see page 5740)

Show (see page 13888)

ShowModal (see page 13890)

72.1.3.4.23 TCustomActiveForm.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

See Also

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

72.1.3.5 TCustomActiveForm Events

The events of the TCustomActiveForm class are listed here.

Published Events

	Name	Description
	OnActivate (see page 13799)	Occurs when the form becomes active.
	OnClick (see page 13803)	Occurs when the user clicks the control.
	OnContextPopup (see page 13805)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13805)	Occurs when the form is created.
	OnDblClick (see page 13807)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13807)	Occurs when the form loses focus.
	OnDestroy (see page 13808)	Occurs when the form is destroyed.
	OnDragDrop (see page 13809)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13811)	Occurs when the user drags an object over a control.
	OnKeyDown (see page 13814)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13816)	Occurs when a key is pressed.
	OnKeyUp (see page 13817)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13819)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13820)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 13822)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 13823)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13823)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13825)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 13827)	Occurs when the form is redrawn.

72.1.3.5.1 TCustomActiveForm.OnActivate Event

Occurs when the form becomes active.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Use OnActivate to perform special processing when the form receives focus. A form becomes active when focus is transferred to it (when the user clicks on the form, for example).

Note: The OnActivate event of the application (TApplication), not the form, occurs when Windows switches control from another application.

Delphi Examples:

```
{
Here is the code on Form1 that fills the list box.
}
var
  Form1: TForm1;
  Customers: TTable;
  Blobs: TTable;
  Form1Done : Boolean;
  procedure CreateMyTable;
  procedure CreateCustSource;
```

```
    procedure CreateBlobSource;

  implementation

  {$R *.dfm}

  procedure TForm1.FormCreate(Sender: TObject);
  var
    I: Integer;
  begin
    CreateCustSource;
    CreateBlobSource;
    for I := 0 to ComponentCount - 1 do
    begin
      if (Components[I] is TDataSource) then
        ListBox1.Items.AddObject(Components[I].Name,
          Components[I] as TObject);
    end;
  end;

  procedure CreateCustSource();
  begin
    Customers:= TTable.Create(Form1);
    with Customers do
    begin
      DatabaseName := 'DBDEMOS';
      TableType := ttParadox;
      TableName := 'MyCustInfo';
      ReadOnly:= False;

  //    Don't overwrite an existing table
      if (not Customers.Exists) then CreateMyTable
      else
      begin
        if (Customers.Exists AND
          (MessageDlg('MyCustInfo table already exists.  Do you want to rebuild it?',
  mtConfirmation, [mbYes, mbNo], 0) = mrYes)) then
        begin
          Customers.Close;
          Customers.DeleteTable;
          CreateMyTable;
        end;
      end;
    end;

OnDeactivate (see page 13953)

OnActivate (see page 13726)

72.1.3.5.2 TCustomActiveForm.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
```

```
    PageControl1Change(Sender);
end;
```

72.1.3.5.3 TCustomActiveForm.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

72.1.3.5.4 TCustomActiveForm.OnCreate Event

Occurs when the form is created.

Pascal

```
property OnCreate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCreate;
```

Description

Use OnCreate to perform special processing when the form is created and is invoked by TCustomForm's constructor. Either implement this event or override the constructor of the form; do not do both. Any objects created in the OnCreate event should be freed by the OnDestroy event.

When a form is being created and its Visible property is true, the following events occur in the order listed:

1. OnCreate2. OnShow3. OnActivate4. OnPaint

   Note: Use of the OnCreate event is discouraged in C++ code because it can interact badly with the form's constructor (see OldCreateOrder). It is recommended that you override the form constructor instead.

C++ Examples:

```
/*
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
const
  TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *page = new TTabSheet(PageControl1);
    page->PageControl = PageControl1;
    page->Caption = AnsiString("Page") + IntToStr(i);
    page->Brush->Color = colorPalette[i];
  }
}

void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  PageControl1->SelectNextPage(Button == btNext);
}
```

Delphi Examples:

```
{
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
```

```
  evaluates as true.  If Button is not btNext, the previous Tab Page
  is selected.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  const
    colorPalette: Array[0..11] of TColor =
      (clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
      clTeal, clNavy, clMaroon, clLime, clOlive, clPurple);
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet #' + IntToStr(i);
        Brush.Color := colorPalette[i];
      end;
  end;

  procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
  begin
    PageControl1.SelectNextPage(Button = btNext);
  end;
```

72.1.3.5.5 TCustomActiveForm.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

72.1.3.5.6 TCustomActiveForm.OnDeactivate Event

Occurs when the form loses focus.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Use OnDeactivate to perform special processing when the form transitions from being the active form to another form in the same application becoming the active form. If activation goes to another application, this event is not triggered. To determine if another application has become active, Use the TApplication object's OnDeactivate event.

See Also

OnActivate (see page 13943)

OnDeactivate (see page 13727)

72.1.3.5.7 TCustomActiveForm.OnDestroy Event

Occurs when the form is destroyed.

Pascal

```
property OnDestroy: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDestroy;
```

Description

Use OnDestroy to perform special processing when the form is destroyed. Either implement this event or override the destructor of the class, but not both. This event should destroy any objects created in the OnCreate event.

C++ Examples:

```
/*
The following code allocates a TBitmap object that is used
by the application when the main form is first created. The
OnDestroy method frees the bitmap as the application shuts
down.
*/
Graphics::TBitmap *LogoBmp;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  LogoBmp = new Graphics::TBitmap();
  LogoBmp->LoadFromFile("../FACTORY.BMP");
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete LogoBmp;
}

void __fastcall TForm1::FormPaint(TObject *Sender)
{
  Canvas->Brush->Bitmap = LogoBmp;
  Canvas->FillRect(Rect(0,0,100,100));
}
```

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
```

72.1.3.5.8 TCustomActiveForm.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
```

```
      DestList->DoubleBuffered = true;
      DestList->Color = clWindow;
    }
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    ListBox1->Items->Add("Not");
    ListBox1->Items->Add("In");
    ListBox1->Items->Add("Alphabetical");
    ListBox1->Items->Add("Order");

  }
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;
```

```
// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

72.1.3.5.9 TCustomActiveForm.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
```

```
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

72.1.3.5.10 TCustomActiveForm.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
```

```
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  I, X, Y: Integer;

72.1.3.5.11 TCustomActiveForm.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

72.1.3.5.12 TCustomActiveForm.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
```

```
    FormColor: TColor;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    KeyPreview := True;
    FormColor := Form1.Color;
  end;

  procedure TForm1.FormKeyDown(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;
      if (ComboBox1.Text = 'KeyDown') then
        ComboBox1.Text := 'KeyDown2'
      else
        ComboBox1.Text := 'KeyDown';
      WriteLn(ComboBox1.Text);
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;

72.1.3.5.13 TCustomActiveForm.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as

maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

72.1.3.5.14 TCustomActiveForm.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
```

```
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);

72.1.3.5.15 TCustomActiveForm.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

72.1.3.5.16 TCustomActiveForm.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

72.1.3.5.17 TCustomActiveForm.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

72.1.3.5.18 TCustomActiveForm.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled

  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

72.1.3.5.19 TCustomActiveForm.OnPaint Event

Occurs when the form is redrawn.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Use OnPaint to perform special processing when the form is redrawn. Any special painting on the form should be done in this event. OnPaint occurs before any controls on the form are painted.

To determine which portions of the form's canvas need to be repainted, use the ClipRect property of the canvas.

If you use the form's Canvas property outside the OnPaint event, it will be erased and drawn-over by the next OnPaint event.

C++ Examples:

```
/*
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
*/
Graphics::TBitmap *TheGraphic;

void __fastcall TForm1::FormPaint(TObject *Sender)// OnPaint event handler
{
  Form1->Canvas->Draw(0, 0, TheGraphic); // Draw the graphic on the Canvas
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TheGraphic = new Graphics::TBitmap(); // Create the bitmap object
  TheGraphic->LoadFromFile("..\\bigf.bmp"); // Load the bitmap from a file
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete TheGraphic;
}
```

Delphi Examples:

```
{
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
}
procedure TForm1.FormPaint(Sender: TObject); { OnPaint event handler}
begin
  Form1.Canvas.Draw(0, 0, TheGraphic); { Draw the graphic on the Canvas }
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  TheGraphic := TBitmap.Create; { Create the bitmap object }
  TheGraphic.LoadFromFile('bigf.bmp'); { Load the bitmap from a file}
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  (TheGraphic as TObject).Free;
end;
```

72.1.4 TCustomDockForm Class

TCustomDockForm is the default floating dock site class for TControl objects.

Class Hierarchy

Pascal

```
TCustomDockForm = class(TCustomForm);
```

C++

```
class TCustomDockForm : public TCustomForm;
```

File

Forms

Description

When a control is created, TCustomDockForm is the type assigned to its FloatingDockSiteClass property. You can use TCustomDockForm as the basis for your own floating dock site class, and then assign the new class to the a control's FloatingDockSiteClass property.

72.1.4.1 TCustomDockForm Members

The following tables list the members exposed by TCustomDockForm.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.

	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.

	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 13843)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.

	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
V	DoRemoveDockClient (see page 13844)	Performs actions when a control is undocked from the dock form.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
V	GetSiteInfo (see page 13844)	Returns docking information for the dock form.
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 13845)	Specifies actions to perform when the dock form is loaded.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
V	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
V	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.

	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.

	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.

	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.

	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 13843)	Creates an instance of TCustomDockForm (see page 13829).
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.

	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.

	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.

	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 13845)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13846)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	FormStyle (see page 13846)	Determines the form's style.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.

R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.

	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PixelsPerInch (see page 13848)	Represents the proportion of the font on the system on which the form was designed.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

72.1.4.2 TCustomDockForm.Create Constructor

Creates an instance of TCustomDockForm (see page 13829).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomDockForm(TComponent * AOwner);
```

Description

Typically, applications do not create instances of TCustomDockForm (see page 13829). Instead, this class is instantiated automatically as needed by controls that specify it as the value of their FloatingDockSiteClass property.

AOwner is the dock form's owner.

See Also

FloatingDockSiteClass (see page 5823)

Floating (see page 5823)

72.1.4.3 TCustomDockForm Methods

The methods of the TCustomDockForm class are listed here.

Protected Methods

	Name	Description
	DoAddDockClient (see page 13843)	Performs actions when a control is docked to the windowed control.
	DoRemoveDockClient (see page 13844)	Performs actions when a control is undocked from the dock form.
	GetSiteInfo (see page 13844)	Returns docking information for the dock form.
	Loaded (see page 13845)	Specifies actions to perform when the dock form is loaded.

72.1.4.3.1 TCustomDockForm.DoAddDockClient Method

Performs actions when a control is docked to the windowed control.

Pascal

```
procedure DoAddDockClient(Client: TControl; const ARect: TRect); override;
```

C++

```
virtual __fastcall DoAddDockClient(TControl * Client, const TRect ARect);
```

Description

DoAddDockClient is called automatically when a client control is docked to the windowed control. As implemented in TWinControl, DoAddDockClient sets the client's Parent property to the control.

Client is the control that has been docked.

ARect describes the boundaries of the region where Client has been docked.

Override DoAddDockClient to perform actions when a control is docked to the windowed control.

Note: DoAddDockClient is called in response to a message sent by the DockDrop method, before the OnDockDrop event.

See Also

Parent (see page 5832)

DockClients (see page 6201)

ManualDock (see page 5771)

DoRemoveDockClient (see page 6147)

DockDrop (see page 6142)

OnDockDrop (see page 6214)

72.1.4.3.2 TCustomDockForm.DoRemoveDockClient Method

Performs actions when a control is undocked from the dock form.

Pascal

```
procedure DoRemoveDockClient(Client: TControl); override;
```

C++

```
virtual __fastcall DoRemoveDockClient(TControl * Client);
```

Description

Client is the control being undocked.

DoRemoveDockClient calls the inherited DoRemoveDockClient method. Then, if the dock form contains no more clients, DoRemoveDockClient calls the Release (see page 13885) method.

See Also

Release (see page 13885)

doadddockclient (see page 13843)

72.1.4.3.3 TCustomDockForm.GetSiteInfo Method

Returns docking information for the dock form.

Pascal

```
procedure GetSiteInfo(Client: TControl; var InfluenceRect: TRect; MousePos: TPoint; var
CanDock: Boolean); override;
```

C++

```
virtual __fastcall GetSiteInfo(TControl * Client, TRect InfluenceRect, TPoint MousePos,
Boolean CanDock);
```

Description

GetSiteInfo overrides the inherited method, setting CanDock to true if the dock form contains one or more clients.

See Also

DockClientCount (see page 6199)

72.1.4.3.4 TCustomDockForm.Loaded Method

Specifies actions to perform when the dock form is loaded.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Loaded calls the inherited method. Then Loaded sets the dock form's active control, if possible.

72.1.4.4 TCustomDockForm Properties

The properties of the TCustomDockForm class are listed here.

Public Properties

	Name	Description
	AutoScroll (see page 13845)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	BorderStyle (see page 13846)	Specifies the appearance and behavior of the form border.
	FormStyle (see page 13846)	Determines the form's style.

Published Properties

	Name	Description
	PixelsPerInch (see page 13848)	Represents the proportion of the font on the system on which the form was designed.

72.1.4.4.1 TCustomDockForm.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.4.4.2 TCustomDockForm.BorderStyle Property

Specifies the appearance and behavior of the form border.

Pascal

```
property BorderStyle: TFormBorderStyle;
```

C++

```
__property TFormBorderStyle BorderStyle;
```

Description

Use BorderStyle to get or set the appearance and behavior of the form border. BorderStyle can be any of the following TForm BorderStyle values:

Value	Meaning
bsDialog	Not resizable; no minimize/maximize menu
bsSingle	Not resizable; minimize/maximize menu
bsNone	Not resizable; no visible border line
bsSizeable	Standard resizable border
bsToolWindow	like bsSingle but with a smaller caption
bsSizeToolWin	like bsSizeable with a smaller caption

Note: Changing the border style of an MDI child form to bsDialog or bsNone has no effect.

See Also

BorderIcons (see page 13899)

72.1.4.4.3 TCustomDockForm.FormStyle Property

Determines the form's style.

Pascal

```
property FormStyle: TFormStyle;
```

C++

```
__property TFormStyle FormStyle;
```

Description

Use FormStyle to get or set the form's style. FormStyle is one of the following values:

Value	Meaning
fsNormal	The form is neither an MDI parent window nor an MDI child window.
fsMDIChild	The form is an MDI child window.

fsMDIForm	The form is an MDI parent window.
fsStayOnTop	This form remains on top of the desktop and of other forms in the project, except any others that also have FormStyle set to fsStayOnTop. If one fsStayOnTop form launches another, neither form will consistently remain on top.

If the form is the main form of an MDI application, its FormStyle property must be set to fsMDIForm.

Note: It is not advisable to change FormStyle at runtime.

Warning: TGraphicControl descendants placed in the client area of a form with FormStyle set to fsMDIForm will not paint.

C++ Examples:

```
/*
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
*/
void __fastcall TForm1::MyArrangeIconsClick(TObject *Sender)
{
  Form1->ArrangeIcons();
}
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
  Tile();
}
```

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
}
procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
```

```
    Form1.ArrangeIcons;
  end;
  {
  This example ensures that the main form of the application
  is an MDI parent:
  }
  type
    TForm1 = class(TForm)
      Edit1: TEdit;
    private
      { Private declarations }
    public
      { Public declarations }
      constructor Create(AOwner : TComponent); override;
    end;

  var
    Form1: TForm1;

  implementation

  {$R *.dfm}

  constructor TForm1.Create(AOwner : TComponent);

  begin
    inherited Create(AOwner);
    if FormStyle <> fsMDIForm then
            FormStyle := fsMDIForm;
    if FormStyle = fsMDIForm then
            Edit1.Text := 'MDI form'
    else
      //This line never executes
      Edit1.Text := 'Not an MDI form';
  end;
  {
  This example uses three forms. The first form has its
  FormStyle property set to MDIForm. The other two have their
  FormStyle properties set to MDIChild and their Visible
  properties set to true. Add a main menu component and name
  one of the menu items TileForms. This is code for the
  TileFormsClick handler.  When the user chooses the TileForms
  command, the child forms tile vertically within the MDI frame
  form.
  }
  procedure TForm1.TileFormsClick(Sender: TObject);
  begin
    TileMode := tbVertical;
    Tile;
  end;
```

See Also

ArrangeIcons (see page 14006)

Tile (see page 14009)

Cascade (see page 14007)

Windows Overview

72.1.4.4.4 TCustomDockForm.PixelsPerInch Property

Represents the proportion of the font on the system on which the form was designed.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

Use PixelsPerInch at runtime to change how the form is scaled to the current screen resolution. If PixelsPerInch is changed from its default value, the form will not have the same proportion on every screen resolution.

At design time, PixelsPerInch is set automatically when the form is saved. Changes to PixelsPerInch made in the Object Inspector only affect the form at runtime.

The form's Scaled property must be true for PixelsPerInch to have an effect.

See Also

Scaled (see page 13935)

72.1.5 TCustomForm Class

TCustomForm is the base class from which to derive a window such as a form or dialog.

Class Hierarchy

Pascal

```
TCustomForm = class(TScrollingWinControl);
```

C++

```
class TCustomForm : public TScrollingWinControl;
```

File

Forms

Description

Derive from TCustomForm to create a custom window. The TCustomForm descendant can contain other objects, such as TButton, TCheckBox, and TComboBox objects.

See Also

TPropertyPage (see page 1603)

TActiveForm (see page 1489)

TForm (see page 13992)

72.1.5.1 TCustomForm Members

The following tables list the members exposed by TCustomForm.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.

	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 13869)	Creates the form window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.

	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.

	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.

V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.

	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 13861)	Creates and initializes a new TForm (see page 13992) object.
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 13862)	Removes the form from memory.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Print (see page 13883)	Prints the form.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.

V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.

R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.

	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

72.1.5.2 TCustomForm.Create Constructor

Creates and initializes a new TForm (see page 13992) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomForm(TComponent * AOwner);
```

Description

Use Create to instantiate a TForm (see page 13992) object or descendant of TForm (see page 13992) at runtime. AOwner is the owner of the TCustomForm (see page 13849) object.

For descendants of TCustomForm (see page 13849) that are not TForm (see page 13992) objects, use CreateNew (see page 13862) instead. Calling Create for a TCustomForm (see page 13849) descendant that is not a TForm (see page 13992) will raise an exception.

See Also

CreateNew (see page 13862)

TForm (see page 13992)

Owner (see page 2807)

72.1.5.3 TCustomForm.CreateNew Constructor

Creates and initializes a new form.

Pascal

```
constructor CreateNew(AOwner: TComponent; Dummy: Integer = 0); virtual;
```

C++

```
virtual __fastcall TCustomForm(TComponent * AOwner, int Dummy = 0);
```

Description

Use CreateNew instead of Create (see page 13861) to create a form without using the associated .DFM file to initialize it. Always use CreateNew if the TCustomForm (see page 13849) descendant is not a TForm (see page 13992) object or a descendant of TForm (see page 13992).

CreateNew bypasses the streaming in of the previously-associated .DFM file. If the form contains visual components, therefore, you must stream in an external .DFM to bind the visual components with their classes. If the newly created form has an external .DFM file, then you can follow the call to CreateNew with a call to InitInheritedComponent. If you need to create the .dfm file for the new form instance, bracket the call to CreateNew with calls to WriteComponentResFile and ReadComponentResFile. The following code sequence

1. streams out an external .DFM file;2. creates a new form disassociated from any .DFM resource file;3. streams in the external .DFM file and binds it to this new form.

```
WriteComponentResFile('Temp.dfm', Form1);
...
```

Form2 := TForm.CreateNew(Application (see page 14383));

```
ReadComponentResFile('Temp.dfm', Form2);
```

Warning: Using CreateNew instead of Create (see page 13861) can cause unpredictable results because most forms are written assuming their controls will be created from the .DFM file.

CreateNew is called by the Create (see page 13861) method.

The first argument, AOwner, is the owner of the form (usually the application or another form is the owner). The second argument, Dummy, defaults to 0 and is not used by this constructor. The system passes 0 by default if this constructor is passed only the first argument, AOwner.

See Also

Create (see page 13861)

Owner (see page 2807)

ReadComponentResFile

WriteComponentResFile

72.1.5.4 TCustomForm.Destroy Destructor

Removes the form from memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomForm();
```

Description

Do not call Destroy. Instead, call Release (see page 13885), which indirectly produces a call to the Free method, which in turn calls Destroy.

See Also

OnDestroy (see page 13953)

Release (see page 13885)

Free (see page 22300)

72.1.5.5 TCustomForm Fields

The fields of the TCustomForm class are listed here.

Protected Fields

	Name	Description
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.

72.1.5.5.1 TCustomForm.FFormState Field

Pascal

```
FFormState: TFormState;
```

C++

```
TFormState FFormState;
```

Description

This is FFormState, a member of class TCustomForm.

72.1.5.6 TCustomForm Methods

The methods of the TCustomForm class are listed here.

Protected Methods

	Name	Description
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
V	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
V	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
V	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.

	CreateWnd (see page 13869)	Creates the form window.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoShow (see page 13875)	Form show event dispatcher.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
	GetFloating (see page 13877)	Returns the value of the Floating property.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
	WndProc (see page 13893)	Provides specific message responses for the form.

Public Methods

	Name	Description
	AfterConstruction (see page 13866)	Construction event dispatcher.
	BeforeDestruction (see page 13866)	Destruction event dispatcher.
	Close (see page 13867)	Closes the form.
	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	GetFormImage (see page 13877)	Returns a bitmap of the form.

	Hide (see page 13879)	Hides the form.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
	Print (see page 13883)	Prints the form.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	SendCancelMode (see page 13886)	Cancels modes on the form.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

72.1.5.6.1 TCustomForm.Activate Method

Activation event dispatcher.

Pascal

```
procedure Activate; dynamic;
```

C++

```
__fastcall Activate();
```

Description

Activation is the event dispatcher for form activations.

The form component calls Activate in response to the CM_ACTIVATE message, sent when a form gets the focus either because of a change in active windows within an application or because of the application becoming active. As defined in TCustomForm (see page 13849), Activate simply calls the OnActivate (see page 13943) event handler.

See Also

Deactivate (see page 13870)

OnActivate (see page 13943)

72.1.5.6.2 TCustomForm.ActiveChanged Method

Active (see page 13896) state event dispatcher.

Pascal

```
procedure ActiveChanged; dynamic;
```

C++

```
__fastcall ActiveChanged();
```

Description

ActiveChanged is the event dispatcher for changes in the form's active status. As implemented in TCustomForm (see page 13849), ActiveChanged does nothing. Override this method in a descendant class to implement event handling or other response to a change in the active form.

See Also

ActiveControl (see page 13896)

72.1.5.6.3 TCustomForm.AfterConstruction Method

Construction event dispatcher.

Pascal

```
procedure AfterConstruction; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

AfterConstruction is the dispatcher for the event that occurs immediately after the form object's construction. As implemented in TCustomForm (see page 13849), AfterConstruction calls the OnCreate (see page 13951) event handler, provided the OldCreateOrder (see page 13926) property is false.

See Also

BeforeDestruction (see page 13866)

OnCreate (see page 13951)

OldCreateOrder (see page 13926)

72.1.5.6.4 TCustomForm.AlignControls Method

Aligns all child controls of the form that fall within a specified rectangle.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of the form. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly aligned controls.

See Also

Align (see page 5798)

72.1.5.6.5 TCustomForm.BeforeDestruction Method

Destruction event dispatcher.

Pascal

```
procedure BeforeDestruction; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

BeforeDestruction is the dispatcher for the event that occurs immediately before the form object's destruction. As implemented in TCustomForm (see page 13849), BeforeDestruction calls the OnDestroy (see page 13953) event handler, provided the OldCreateOrder (see page 13926) property is false.

See Also

AfterConstruction (see page 13866)

OnDestroy (see page 13953)

72.1.5.6.6 TCustomForm.BeginAutoDrag Method

Responds when the user starts dragging the form if DragMode is dmAutomatic.

Pascal

```
procedure BeginAutoDrag; override;
```

C++

```
virtual __fastcall BeginAutoDrag();
```

Description

BeginAutoDrag suppresses the default behavior of the BeginAutoDrag method. This is because forms do not change the mouse cursor when dragged.

See Also

DragMode (see page 5819)

Floating

72.1.5.6.7 TCustomForm.ChangeScale Method

Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.

Pascal

```
procedure ChangeScale(M: Integer; D: Integer); override;
```

C++

```
virtual __fastcall ChangeScale(int M, int D);
```

Description

TCustomForm (see page 13849) overrides ChangeScale to rescale any scroll bars and child controls.

See Also

ChangeScale (see page 5743)

72.1.5.6.8 TCustomForm.Close Method

Closes the form.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Call Close to close a form.

Attempts to close a form can be aborted by the CloseQuery (see page 13868) event dispatcher or the OnCloseQuery (see page 13950) event handler.

Note: When the main form of the application closes, the application terminates.

See Also

CloseQuery (see page 13868)

OnCloseQuery (see page 13950)

72.1.5.6.9 TCustomForm.CloseModal Method

Pascal

```
procedure CloseModal;
```

C++

```
__fastcall CloseModal();
```

Description

This is CloseModal, a member of class TCustomForm.

72.1.5.6.10 TCustomForm.CloseQuery Method

Close (see page 13867) attempt event dispatcher.

Pascal

```
function CloseQuery: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CloseQuery();
```

Description

CloseQuery is called automatically when an attempt is made to close the form. CloseQuery can allow the form to close by returning true, or prevent the form from closing by returning false.

As implemented in TCustomForm (see page 13849), CloseQuery polls any MDI children by calling their CloseQuery methods. If no child form aborts the close, CloseQuery then calls the OnCloseQuery (see page 13950) event handler, if it exists, to determine if the close should be allowed. If no such event handler exists, CloseQuery returns true.

See Also

Close (see page 13867)

OnCloseQuery (see page 13950)

72.1.5.6.11 TCustomForm.CreateParams Method

Initializes the window-creation parameter record when the form window is created.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 13869) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle (see page 13869). TCustomForm (see page 13849) overrides CreateParams to customize the way the form creates its Windows representation after calling the inherited method. You should never need to override this method in the context of a form class.

The fields of the Params parameter become the parameters to a call to the CreateWindowEx OS function.

See Also

CreateWindowHandle (see page 13869)

CreateWnd (see page 13869)

72.1.5.6.12 TCustomForm.CreateWindowHandle Method

Creates a form window given a set of window-creation parameters.

Pascal

```
procedure CreateWindowHandle(const Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateWindowHandle(const TCreateParams Params);
```

Description

The CreateWnd (see page 13869) method calls CreateWindowHandle to create the form window once it has been specified in the window-creation parameters. CreateWindowHandle creates the window by calling the CreateWindowEx API function, passing parameters from the record passed in the Params parameter. CreateWindowHandle removes the CS_HREDRAW and CS_VREDRAW class styles from the window class.

Params holds information needed when telling Windows to create a window handle.

See Also

CreateParams (see page 13868)

CreateWnd (see page 13869)

72.1.5.6.13 TCustomForm.CreateWnd Method

Creates the form window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called when the form is created, and whenever a change to the form requires the window to be recreated. CreateWnd calls (indirectly) the CreateParams (see page 13868) method to obtain the window creation parameters, and then

calls CreateWindowHandle (see page 13869) to direct Windows to create the underlying window for the form. It then initializes the newly-created window to reflect the property settings of the form.

See Also

CreateParams (see page 13868)

CreateWindowHandle (see page 13869)

Handle (see page 6207)

72.1.5.6.14 TCustomForm.Deactivate Method

Generates an OnDeactivate (see page 13953) event.

Pascal

```
procedure Deactivate; dynamic;
```

C++

```
__fastcall Deactivate();
```

Description

The form component calls Deactivate in response to the CM_DEACTIVATE message, sent when a form gets the focus either because of a change in active windows within an application or because of the application becoming active.

The default Deactivate method calls any event handler attached by the user to the OnDeactivate (see page 13953) event. Override this method to block the OnDeactivate (see page 13953) event or provide additional responses to the loss of activation.

See Also

Activate (see page 13865)

OnActivate (see page 13943)

72.1.5.6.15 TCustomForm.DefaultHandler Method

Provides message handling for all messages that the form does not fully process.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to change the default message handling for the form. This is seldom necessary because messages can be handled by creating message methods.

DefaultHandler passes any otherwise-unhandled messages to the form's window procedure by calling the CallWindowProc OS function.

Note: In Delphi code, calling inherited in a message-handling method results in a call to the ancestor's DefaultHandler method unless that ancestor specifies a handler for the message.

See Also

Dispatch

72.1.5.6.16 TCustomForm.DefineProperties Method

Designates methods for storing a form's unpublished data on a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties calls the inherited method and calls the filer object's DefineProperty method for the PixelsPerInch (see page 13928),and TextHeight properties. TForm (see page 13992) descendants can also specify methods that read and write data other than properties by overriding the DefineProperties method.

See Also

DefineProperty (see page 2838)

DefineBinaryProperty (see page 2837)

72.1.5.6.17 TCustomForm.DefocusControl Method

Removes focus from a control on the form.

Pascal

```
procedure DefocusControl(Control: TWinControl; Removing: Boolean);
```

C++

```
__fastcall DefocusControl(TWinControl * Control, Boolean Removing);
```

Description

Use DefocusControl to remove focus from a control on the form. This method is used internally by the VCL.

Control is the control from which to remove focus. If Control is the form's active control, DefocusControl sets the form's ActiveControl (see page 13896) property to nil (Delphi) or NULL (C++).

Removing specifies whether to set focus to the control's parent.

See Also

SetFocusedControl (see page 13887)

ActiveControl (see page 13896)

SetFocus (see page 13886)

FocusedControl

72.1.5.6.18 TCustomForm.DestroyHandle Method

Destroys the control's window without destroying the control.

Pascal

```
procedure DestroyHandle; override;
```

C++

```
virtual __fastcall DestroyHandle();
```

Description

Call DestroyHandle to dispose of the window, but leave the control intact. The control can later recreate the window if needed. DestroyHandle is the converse operation to CreateHandle. Applications should call the high-level CreateHandle and DestroyHandle methods, rather than the lower-level methods of CreateWnd and DestroyWnd, whenever possible.

If the control has TWinControl objects as child controls, DestroyHandle calls each of their DestroyHandle methods before calling DestroyWnd to destroy its own handle.

See Also

CreateHandle (see page 6135)

DestroyWnd (see page 6141)

72.1.5.6.19 TCustomForm.DestroyWindowHandle Method

Destroys the window created in the CreateWindowHandle (see page 13869) method.

Pascal

```
procedure DestroyWindowHandle; override;
```

C++

```
virtual __fastcall DestroyWindowHandle();
```

Description

DestroyWindowHandle is called automatically to destroy the window associated with a form before destroying the form.

See Also

CreateWindowHandle (see page 13869)

DestroyWnd (see page 6141)

Destroy (see page 13862)

72.1.5.6.20 TCustomForm.Dock Method

Handles automatic docking of the form into other windows.

Pascal

```
procedure Dock(NewDockSite: TWinControl; ARect: TRect); override;
```

C++

```
virtual __fastcall Dock(TWinControl * NewDockSite, TRect ARect);
```

Description

Do not call Dock in application code. It is called automatically when the form is released on a docking site that will accept it. To dock a form programmatically, use the ManualDock method instead.

See Also

DragMode (see page 5819)

ManualDock (see page 5771)

72.1.5.6.21 TCustomForm.DoClose Method

Form closing event dispatcher.

Pascal

```
procedure DoClose(var Action: TCloseAction); dynamic;
```

C++

```
__fastcall DoClose(TCloseAction Action);
```

Description

DoClose is called automatically when the form is about to close. DoClose can alter closing behavior by changing the Action (see page 13895) parameter. For more information, refer to the OnClose (see page 13949) event handler.

As implemented in TCustomForm (see page 13849), DoClose simply calls the OnClose (see page 13949) event handler.

See Also

OnClose (see page 13949)

72.1.5.6.22 TCustomForm.DoCreate Method

Form creation event dispatcher.

Pascal

```
procedure DoCreate; virtual;
```

C++

```
virtual __fastcall DoCreate();
```

Description

DoCreate is called automatically after form construction is complete. The precise way DoCreate is called can be modified by setting the OldCreateOrder (see page 13926) property.

As implemented in TCustomForm (see page 13849), DoCreate simply calls the OnCreate (see page 13951) event handler.

See Also

OnCreate (see page 13951)

FormState (see page 13911)

Visible (see page 5847)

OldCreateOrder (see page 13926)

72.1.5.6.23 TCustomForm.DoDestroy Method

Form destruction event dispatcher.

Pascal

```
procedure DoDestroy; virtual;
```

C++

```
virtual __fastcall DoDestroy();
```

Description

DoDestroy is called automatically when the TCustomForm (see page 13849) object is about to be deallocated. The precise

way DoDestroy is called can be modified by setting the OldCreateOrder (see page 13926) property.

As implemented in TCustomForm (see page 13849), DoDestroy simply calls the OnDestroy (see page 13953) event handler.

See Also

OnDestroy (see page 13953)

OldCreateOrder (see page 13926)

72.1.5.6.24 TCustomForm.DoDock Method

Docking event dispatcher.

Pascal

```
procedure DoDock(NewDockSite: TWinControl; var ARect: TRect); override;
```

C++

```
virtual __fastcall DoDock(TWinControl * NewDockSite, TRect ARect);
```

Description

DoDock supplements the inherited DoDock method by updating form borders.

See Also

DoDock (see page 5750)

Floating

Dock (see page 13872)

ManualDock (see page 5771)

ManualFloat (see page 5772)

72.1.5.6.25 TCustomForm.DoHide Method

Form hide event dispatcher.

Pascal

```
procedure DoHide; dynamic;
```

C++

```
__fastcall DoHide();
```

Description

DoHide is called automatically when the form is hidden.

As implemented in TCustomForm (see page 13849), DoHide calls the OnHide (see page 13960) event handler.

See Also

OnHide (see page 13960)

DoShow (see page 13875)

Hide (see page 13879)

72.1.5.6.26 TCustomForm.DoShow Method

Form show event dispatcher.

Pascal

```
procedure DoShow; dynamic;
```

C++

```
__fastcall DoShow();
```

Description

DoShow is called automatically when the application is about to show the form. As implemented in TCustomForm (see page 13849), DoShow simply calls the OnShow (see page 13977) event handler.

See Also

DoHide (see page 13874)

OnShow (see page 13977)

72.1.5.6.27 TCustomForm.FocusControl Method

Sets focus to a control on the form.

Pascal

```
procedure FocusControl(Control: TWinControl);
```

C++

```
__fastcall FocusControl(TWinControl * Control);
```

Description

Use FocusControl to set focus to a control on the form.

Control is a TWinControl object encapsulating the control on which to set focus. FocusControl sets the ActiveControl (see page 13896) property.

See Also

TWinControl (see page 6112)

ActiveControl (see page 13896)

72.1.5.6.28 TCustomForm.GetBorderIconStyles Method

Pascal

```
procedure GetBorderIconStyles(var Style: Cardinal; var ExStyle: Cardinal); dynamic;
```

C++

```
__fastcall GetBorderIconStyles(unsigned Style, unsigned ExStyle);
```

Description

This is GetBorderIconStyles, a member of class TCustomForm.

72.1.5.6.29 TCustomForm.GetBorderStyles Method

Pascal

```
procedure GetBorderStyles(var Style: Cardinal; var ExStyle: Cardinal; var ClassStyle:
Cardinal); dynamic;
```

C++

```
__fastcall GetBorderStyles(unsigned Style, unsigned ExStyle, unsigned ClassStyle);
```

Description

This is GetBorderStyles, a member of class TCustomForm.

72.1.5.6.30 TCustomForm.GetChildren Method

Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

The component streaming system calls GetChildren to request that the form execute a callback for every child component in the form. The callback must execute in creation order (the order the child components appear in the form file). A child component is defined as any component that returns this form from its GetParentComponent method.

Proc is the callback to execute for every child component.

Root specifies the top-level component (such as a form or data module) that is currently being loaded or saved.

In TCustomForm (see page 13849), GetChildren first calls the inherited method, which executes Proc for every control that lists the form as its Parent. Then, if the Root parameter identifies this form, GetChildren executes Proc for every child component that does not have a Parent.

See Also

GetParentComponent

72.1.5.6.31 TCustomForm.GetClientRect Method

Returns the value of the ClientRect property.

Pascal

```
function GetClientRect: TRect; override;
```

C++

```
virtual __fastcall TRect GetClientRect();
```

Description

GetClientRect is the protected access function for the ClientRect property. It returns the dimensions of the form window, indented by any scroll bars and menus.

Override this method to change the way the client area of the form is defined.

See Also

GetClientOrigin (see page 6153)

ClientRect

72.1.5.6.32 TCustomForm.GetFloating Method

Returns the value of the Floating property.

Pascal

```
function GetFloating: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetFloating();
```

Description

GetFloating is the protected access function for the Floating property. Override this method in descendants that implement floating windows in some class-specific way.

See Also

Floating

72.1.5.6.33 TCustomForm.GetFormImage Method

Returns a bitmap of the form.

Pascal

```
function GetFormImage: TBitmap;
```

C++

```
__fastcall TBitmap GetFormImage();
```

Description

Use the GetFormImage method to obtain a bitmap of the form.

C++ Examples:

```
/*
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
*/

#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *FormImage = GetFormImage();
  try
  {
    Clipboard()->Assign(FormImage);
    Image1->Picture->Assign(Clipboard());
  }
```

```
    __finally
    {
      delete FormImage;
    }
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Shape1->Shape = stEllipse;
    Shape1->Brush->Color = clLime;
    Image1->Stretch = true;
  }
```

Delphi Examples:

```
{
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FormImage: TBitmap;
begin
  FormImage := GetFormImage;
  try
    Clipboard.Assign(FormImage);
    Image1.Picture.Assign(Clipboard);
  finally
    FormImage.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Shape1.Shape := stEllipse;
  Shape1.Brush.Color := clLime;
  Image1.Stretch := True;
end;
```

See Also

Print (see page 13883)

72.1.5.6.34 TCustomForm.GetOwnerWindow Method

Pascal

```
function GetOwnerWindow: HWND; dynamic;
```

C++

```
__fastcall HWND GetOwnerWindow();
```

Description

This is GetOwnerWindow, a member of class TCustomForm.

72.1.5.6.35 TCustomForm.HandleCreateException Method

Handles exceptions that are raised by the OnCreate (see page 13951) event handler.

Pascal

```
function HandleCreateException: Boolean; dynamic;
```

C++

```
__fastcall Boolean HandleCreateException();
```

Description

The form calls HandleCreateException internally if the OnCreate (see page 13951) event handler raises an exception. HandleCreateException forwards the exception on to the application object, which generates an OnException event. If there is no OnException event handler, the application displays an exception message box.

HandleCreateException returns true if it handles the exception, false otherwise.

See Also

OnCreate (see page 13951)

OnException (see page 13728)

ShowException (see page 13698)

72.1.5.6.36 TCustomForm.Hide Method

Hides the form.

Pascal

```
procedure Hide;
```

C++

```
__fastcall Hide();
```

Description

Hide sets the Visible (see page 13940) property to false.

C++ Examples:

```
/*
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
reappears:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Timer1->Enabled = true;
  Hide();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Visible = true;
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
```

```
reappears:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Timer1.Interval := StrtoInt(MaskEdit1.Text);
  Timer1.Enabled := True;
  Hide;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Visible := True;
  Timer1.Enabled := False;
end;
```

See Also

Visible (see page 13940)

72.1.5.6.37 TCustomForm.IsShortCut Method

Processes shortcut keys when the form has focus.

Pascal

```
function IsShortCut(var Message: TWMKey): Boolean; dynamic;
```

C++

```
__fastcall Boolean IsShortCut(TWMKey Message);
```

Description

IsShortCut is called automatically when the user presses a key while the form has focus. It allows the form to dispatch shortcut keys and bypass the standard keystroke processing (OnKeyDown (see page 13962), OnKeyPress (see page 13964), and OnKeyUp (see page 13966) events).

The Message parameter encapsulates the Windows message describing the keypress. If a shortcut for the key exists, IsShortCut executes the appropriate command and returns true. Otherwise IsShortCut returns false.

IsShortCut generates an OnShortCut (see page 13977) event to allow the developer to insert shortcuts for the form. If the keystroke is not handled in an OnShortCut (see page 13977) event handler, IsShortCut checks for any shortcuts associated with the form's menus and actions.

See Also

OnShortCut (see page 13977)

OnKeyDown (see page 6225)

OnKeyPress (see page 6227)

OnKeyUp (see page 6228)

72.1.5.6.38 TCustomForm.Loaded Method

Performs fix-ups when the form is first loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Loaded overrides the inherited method to give focus to the ActiveControl (see page 13896) if it is assigned. Before assigning focus, Loaded calls the inherited method to perform any lower-level initialization.

See Also

ActiveControl (see page 13896)

Loaded (see page 2782)

72.1.5.6.39 TCustomForm.MakeFullyVisible Method

Ensures that the form is fully visible on a specified monitor.

Pascal

```
procedure MakeFullyVisible(AMonitor: TMonitor = nil);
```

C++

```
__fastcall MakeFullyVisible(TMonitor AMonitor = nil);
```

Description

Call MakeFullyVisible to ensure that the form does not appear split over more than one monitor in a multi-monitor application.

AMonitor is the monitor on which the form should appear. If AMonitor is nil (Delphi) or NULL (C++), MakeFullyVisible uses the Monitor (see page 13926) property.

MakeFullyVisible checks whether the form fits entirely on the specified monitor. If not, it repositions the form so that it fits, if possible.

See Also

DefaultMonitor (see page 13909)

Monitor (see page 13926)

72.1.5.6.40 TCustomForm.MouseWheelHandler Method

Directs mouse wheel messages to the appropriate control.

Pascal

```
procedure MouseWheelHandler(var Message: TMessage); override;
```

C++

```
virtual __fastcall MouseWheelHandler(TMessage Message);
```

Description

MouseWheelHandler is called automatically when the form or any windowed control contained in the form receives a message from a mouse wheel. The Message parameter encapsulates the message.

As implemented in TCustomForm (see page 13849), MouseWheelHandler performs no special processing, but simply redirects the message to the active control by calling its Perform method. By default, the Perform method generates the appropriate mouse wheel events.

See Also

ActiveControl (see page 13896)

Perform (see page 5776)

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

OnMouseWheelDown (see page 5869)

72.1.5.6.41 TCustomForm.Notification Method

Responds to notifications that objects are about to be inserted or removed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification is called when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, forms pass along the notification to their owned components, if any. In addition, Notification makes internal adjustments if the main menu is added or deleted.

A form can, if needed, override Notification to make other adjustments when components are inserted or removed. In particular, if a form has object fields or properties that contains references to other components, it might check the notifications of component removals and invalidate those references as needed.

See Also

InsertComponent (see page 2780)

72.1.5.6.42 TCustomForm.Paint Method

Generates an OnPaint (see page 13975) event.

Pascal

```
procedure Paint; dynamic;
```

C++

```
__fastcall Paint();
```

Description

The form component calls Paint in response to the WM_PAINT message (sent when the window needs to be painted) before rendering all controls on the form.

The default Paint method calls any event handler attached by the user to the OnPaint (see page 13975) event. Override Paint to block the OnPaint (see page 13975) event or to draw additional features before or after the OnPaint (see page 13975) event.

See Also

OnPaint (see page 13975)

72.1.5.6.43 TCustomForm.PaintWindow Method

Renders the image of the form.

Pascal

```
procedure PaintWindow(DC: HDC); override;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

Applications can't call this protected method. It is called when the form needs to be painted.

PaintWindow locks the canvas to prevent threading issues, assigns the DC parameter as the Handle of the form's canvas, and then calls the Paint (see page 13882) method to render the image of the form.

See Also

Paint (see page 13882)

Canvas (see page 13900)

Handle (see page 14489)

Lock (see page 14463)

72.1.5.6.44 TCustomForm.PaletteChanged Method

Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.

Pascal

```
function PaletteChanged(Foreground: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean PaletteChanged(Boolean Foreground);
```

Description

PaletteChanged is called automatically when the system palette changes. The Foreground parameter indicates whether the palette realization should treat this control's palette as being in the foreground or the background. The return value from PaletteChanged indicates whether the form actually realized its palette, returning true only if the form has an associated palette.

Most applications should not need to alter the default behavior of PaletteChanged.

See Also

PaletteChanged (see page 6170)

72.1.5.6.45 TCustomForm.Print Method

Prints the form.

Pascal

```
procedure Print;
```

C++

```
__fastcall Print();
```

Description

Call Print to print the form. Print uses the GetFormImage (see page 13877) method to obtain a bitmap of the form and draws that to the printer's HDC.

See Also

GetFormImage (see page 13877)

72.1.5.6.46 TCustomForm.QueryInterface Method

Returns a reference to a specified interface if that interface is supported by the form.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override;
```

C++

```
virtual __fastcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

For forms that support interfaces, QueryInterface calls the QueryInterface method of the interface supported by the form. QueryInterface returns a reference to the interface specified by the IID parameter, as the Obj parameter. If the form does not support the interface, the Obj parameter is nil (Delphi) or NULL (C++).

QueryInterface returns S_OK if the Obj parameter is successfully assigned.

See Also

_AddRef (see page 2769)

_Release (see page 2769)

Invoke (see page 2781)

72.1.5.6.47 TCustomForm.ReadState Method

Reads the form's published properties, stored data, and owned components from a reader object.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

ReadState is part of a sequence of calls used by the VCL streaming system that loads and saves VCL components. It reads the values of all the component's published properties, stored data, and owned components from the reader object passed in Reader. Do not call ReadState directly.

Any descendant classes overriding ReadState should end with a call to the inherited ReadState method.

See Also

TReader (see page 2933)

72.1.5.6.48 TCustomForm.RecreateAsPopup Method

Pascal

```
procedure RecreateAsPopup(AWindowHandle: HWND);
```

C++

```
__fastcall RecreateAsPopup(HWND AWindowHandle);
```

Description

This is RecreateAsPopup, a member of class TCustomForm.

72.1.5.6.49 TCustomForm.Release Method

Destroys the form and frees its associated memory.

Pascal

```
procedure Release;
```

C++

```
__fastcall Release();
```

Description

Use Release to destroy the form and free its associated memory.

Release does not destroy the form until all event handlers of the form and event handlers of components on the form have finished executing. Release also guarantees that all messages in the form's event queue are processed before the form is released. Any event handlers for the form or its children should use Release instead of Free (Delphi) or delete (C++). Failing to do so can cause a memory access error.

Note: Release returns immediately to the caller. It does not wait for the form to be freed before returning.

See Also

Free (see page 22300)

Destroy (see page 13862)

72.1.5.6.50 TCustomForm.RequestAlign Method

Instructs the form's parent (if any) to reposition the form, enforcing its Align property.

Pascal

```
procedure RequestAlign; override;
```

C++

```
virtual __fastcall RequestAlign();
```

Description

RequestAlign is called internally when changes are made to the size or position of the form, so that it remains properly aligned within a dock site or properly positioned on the screen.

See Also

Align (see page 5798)

Floating

72.1.5.6.51 TCustomForm.Resizing Method

Makes any required adjustments when the form changes size.

Pascal

```
procedure Resizing(State: TWindowState); override;
```

C++

```
virtual __fastcall Resizing(TWindowState State);
```

Description

This protected method is called automatically when the form is resized, including when it is maximized, minimized, or restored to normal size. Resizing adjusts the size and position of any child controls that are aligned to the form.

The State parameter indicates the state of the form after the resize.

72.1.5.6.52 TCustomForm.SendCancelMode Method

Cancels modes on the form.

Pascal

```
procedure SendCancelMode(Sender: TControl);
```

C++

```
__fastcall SendCancelMode(TControl * Sender);
```

Description

Use SendCancelMode to release the mouse capture and cancel scroll bar input and menu processing on the form.

See Also

ActiveControl (see page 13896)

72.1.5.6.53 TCustomForm.SetChildOrder Method

Changes the order in which Child appears when GetChildren (see page 13876) is called.

Pascal

```
procedure SetChildOrder(Child: TComponent; Order: Integer); override;
```

C++

```
virtual __fastcall SetChildOrder(TComponent * Child, int Order);
```

Description

Use SetChildOrder to change the order in which child components are loaded and saved. The Child moves as if it were an item in a list object: items previously below the child's old position move up, and those below the new position move down.

See Also

GetChildren (see page 13876)

72.1.5.6.54 TCustomForm.SetFocus Method

Sets focus to the form.

Pascal

```
procedure SetFocus; override;
```

C++

```
virtual __fastcall SetFocus();
```

Description

Use SetFocus to give the form input focus. SetFocus calls the SetFocus method of the active control, if one exists. To determine whether the form has focus, use the Active (see page 13896) property.

See Also

Active (see page 13896)

SetFocusedControl (see page 13887)

SetFocus (see page 6179)

72.1.5.6.55 TCustomForm.SetFocusedControl Method

Sets focus to a control on the form.

Pascal

```
function SetFocusedControl(Control: TWinControl): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean SetFocusedControl(TWinControl * Control);
```

Description

Use SetFocusedControl to give a control on the form input focus. SetFocusedControl returns false if the Control specified by the Control parameter was already in the process of receiving focus, true otherwise.

Note: A return value of true does not indicate the control has successfully received input focus. If the Control can't have focus (for example, if it is not visible), SetFocusedControl will still return true, indicating that an attempt was made.

See Also

Active (see page 13896)

SetFocus (see page 13886)

DefocusControl (see page 13871)

72.1.5.6.56 TCustomForm.SetParent Method

Sets the Parent property.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent property. It overrides the inherited method to regenerate the form's window when the Parent property is changed to nil (Delphi) or NULL (C++).

See Also

Parent

72.1.5.6.57 TCustomForm.SetParentBiDiMode Method

Sets the ParentBiDiMode property.

Pascal

```
procedure SetParentBiDiMode(Value: Boolean); override;
```

C++

```
virtual __fastcall SetParentBiDiMode(Boolean Value);
```

Description

SetParentBiDiMode is the protected implementation of the ParentBiDiMode property. It overrides the inherited method to obtain the BiDiMode property of the application if the form does not have a parent.

See Also

ParentBiDiMode

72.1.5.6.58 TCustomForm.Show Method

Shows the form.

Pascal

```
procedure Show;
```

C++

```
__fastcall Show();
```

Description

Use Show to set the form's Visible (see page 13940) property to true and to bring the form to the front of other forms on the screen.

C++ Examples:

```
/*
StepBy, CreateForm, Run, Show, Update, Initialize example
This example shows progress of loading forms as an application starts up. The code example is
placed in the project source (*.dpr) file. To see project source, select the View | Project
Source menu item.
You will need to set up your project with the following steps before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place Form5 on the available forms
list.
o          Change the code of your project (*.dpr) file to look like the example.
*/
#include <vcl\vcl.h>
#include "Unit5.h"
#pragma hdrstop
//---------------------------------------------------------------------------
USEFORM("TAppCreateForm.cpp", Form1);
USERES("Project1.res");
USEFORM("Unit2.cpp", Form2);
USEFORM("Unit3.cpp", Form3);
USEFORM("Unit4.cpp", Form4);
USEFORM("Unit5.cpp", Form5);
//---------------------------------------------------------------------------
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
  {
    Application->Initialize();
    SetApplicationMainFormOnTaskBar(Application, true);
    Application->CreateForm(__classid(TForm5), &Form5);
    Form5->ProgressBar1->Max = 100;
    Form5->Show();   // show a splash screen contain ProgressBar control
    Form5->Update(); // force display of Form5
    Application->CreateForm(__classid(TForm1), &Form1);
```

```
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form1 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm2), &Form2);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form2 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm3), &Form3);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form3 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm4), &Form4);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form4 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
//  delete Form5;
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  return 0;
}
```

Delphi Examples:

```
{
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*.dpr) file.  To see project source, select
the View | Project Source menu item.
You will need to set up your project with the following steps
before using the code example:
    Add four additional forms to a default project.
    Place a TProgressBar on Form5
    Take the Project|Options|Forms menu option and place
          Form5 on the available forms list.
    Change the code of your project (*.dpr) file to look
          like the example.
}
begin
  Application.Initialize;
  with TForm5.Create(nil) do
  try
    Application.MainFormOnTaskbar := True;
    ProgressBar1.Max := 100;
    Show;  // show a splash screen contain ProgressBar control
    Update; // force display of Form5
    Application.CreateForm(TForm1, Form1);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form1 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm2, Form2);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form2 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm3, Form3);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form3 loaded successfully.';
    Update; // force display of Form5
```

```
    Sleep(3000);
    Application.CreateForm(TForm4, Form4);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form4 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
  finally
    Free;
  end;
  Application.Run;
```

See Also

BringToFront (see page 5740)

Visible (see page 13940)

72.1.5.6.59 TCustomForm.ShowModal Method

Shows a form as a modal dialog.

Pascal

```
function ShowModal: Integer; virtual;
```

C++

```
virtual __fastcall int ShowModal();
```

Description

Use ShowModal to show a form as a modal form. A modal form is one where the application can't continue to run until the form is closed. Thus, ShowModal does not return until the form closes. When the form closes, it returns the value of the ModalResult (see page 13924) property.

To close a modal form, set its ModalResult (see page 13924) property to a nonzero value.

Note: If the form contains buttons with a ModalResult (see page 13924) property set to a value other than mrNone, the form automatically closes when the user clicks one of those buttons and returns the ModalResult (see page 13924) value as the return value of ShowModal.

You can check the return value against common return values using the global IsAbortResult, IsAnAllResult, IsNegativeResult, or IsPositiveResult functions.

C++ Examples:

```
/*
This code brings up the modal dialog from Unit2 when a
button is clicked.  It causes a Beep if the OK button is
clicked. Implement the modal form in Unit2 and then put
Unit2 in the uses clause for this module.
*/
#include "Unit2.h"
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (MyDialogBox1->ShowModal() == mrOk)
    MessageBeep(0);
}
/*
The following methods are used for buttons in a form that is
used as a modal dialog box. The methods cause the dialog box
to terminate when the user clicks either the OK or Cancel
button, returning mrOk or mrCancel from ShowModal,
respectively. You could also set the ModalResult value to
mrOk for the OK button and mrCancel for the Cancel button to
accomplish the same thing. When the user clicks either
```

```
button, the dialog box closes.
*/
void __fastcall TMyDialogBox1::OKButtonClick(TObject *Sender)
{
  ModalResult = mrOk;
}

void __fastcall TMyDialogBox1::CancelButtonClick(TObject *Sender)
{
  ModalResult = mrCancel;
}
```

Delphi Examples:

```
{
This code brings up the modal dialog from Unit2 when a
button is clicked.  It causes a Beep if the OK button is
clicked. Implement the modal form in Unit2 and then put
Unit2 in the uses clause for this module.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if MyDialogBox1.ShowModal = mrOK then
    Beep;
end;
{
The following methods are used for buttons in a form that is
used as a modal dialog box. The methods cause the dialog box
to terminate when the user clicks either the OK or Cancel
button, returning mrOk or mrCancel from ShowModal,
respectively. You could also set the ModalResult value to
mrOk for the OK button and mrCancel for the Cancel button to
accomplish the same thing. When the user clicks either
button, the dialog box closes.
}
procedure TMyDialogBox1.CancelButtonClick(Sender: TObject);
begin
  ModalResult := mrCancel;
end;

procedure TMyDialogBox1.OKButtonClick(Sender: TObject);
begin
  ModalResult := mrOK;
end;
```

See Also

ModalResult (see page 13924)

ModalResult (see page 20937)

IsAnALlResult

IsNegativeResult (see page 6260)

IsPositiveResult (see page 6260)

StripAllFromResult (see page 6265)

IsAbortResult (see page 6258)

72.1.5.6.60 TCustomForm.UpdateActions Method

Updates all actions associated with the form.

Pascal

```
procedure UpdateActions; virtual;
```

C++

```
virtual __fastcall UpdateActions();
```

Description

UpdateActions is called automatically when the application is idle to allow all components in the form an opportunity to update any actions for which the component is a target. This allows actions to be checked, grayed, and so on to reflect the current state of their targets.

UpdateActions updates all actions associated with the form, its menus, and the components contained in the form.

See Also

UpdateAction

InitiateAction (see page 5769)

72.1.5.6.61 TCustomForm.UpdateGlassFrame Method

Pascal

```
procedure UpdateGlassFrame(Sender: TObject);
```

C++

```
__fastcall UpdateGlassFrame(TObject * Sender);
```

Description

This is UpdateGlassFrame, a member of class TCustomForm.

72.1.5.6.62 TCustomForm.UpdateWindowState Method

Updates the WindowState (see page 13942) property to reflect the current state of the form.

Pascal

```
procedure UpdateWindowState;
```

C++

```
__fastcall UpdateWindowState();
```

Description

UpdateWindowState ensures that the WindowState (see page 13942) property reflects the current state of the form.

See Also

WindowState (see page 13942)

72.1.5.6.63 TCustomForm.ValidateRename Method

Determines if a form can rename one of its owned components.

Pascal

```
procedure ValidateRename(AComponent: TComponent; const CurName: string; const NewName:
string); override;
```

C++

```
virtual __fastcall ValidateRename(TComponent * AComponent, const AnsiString CurName, const
AnsiString NewName);
```

Description

The ValidateRename method checks to see if a form can rename one of its owned components, passed in AComponent, from its current name (CurName) to the string passed in NewName. If AComponent is nil (Delphi) or NULL (C++) or NewName is already the name of a component in the form's list, ValidateRename raises an EComponentError exception.

See Also

FindComponent (see page 2772)

72.1.5.6.64 TCustomForm.VisibleChanging Method

Responds just before the form changes the value of its Visible (see page 13940) property.

Pascal

```
procedure VisibleChanging; override;
```

C++

```
virtual __fastcall VisibleChanging();
```

Description

This protected method raises an exception if, for some reason, the form should not change its visible state.

See Also

Visible (see page 13940)

72.1.5.6.65 TCustomForm.WantChildKey Method

Indicates whether the form processes keyboard input for a control it owns.

Pascal

```
function WantChildKey(Child: TControl; var Message: TMessage): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean WantChildKey(TControl * Child, TMessage Message);
```

Description

WantChildKey is called by any control that the form owns when the control receives keyboard input. If WantChildKey returns true, the control performs no further processing in response to the keyboard input, instead deferring to its parent form to respond to the keystroke. In its default implementation, WantChildKey always returns false; it is overridden in TActiveForm to implement certain ActiveX functionality.

72.1.5.6.66 TCustomForm.WndProc Method

Provides specific message responses for the form.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method that receives messages for a form. After calling the inherited method, WndProc performs some window activation, focus, and position message handling necessary to keep in sync with Windows. Override WndProc to change how the form responds to Windows messages.

See Also

WndProc (see page 6187)

72.1.5.7 TCustomForm Properties

The properties of the TCustomForm class are listed here.

Protected Properties

	Name	Description
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.

Public Properties

	Name	Description
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	Color (see page 13908)	Specifies the background color of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Properties

	Name	Description
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

72.1.5.7.1 TCustomForm.Action Property

Designates the action associated with the control.

Pascal

```
property Action: TBasicAction;
```

C++

```
__property TBasicAction Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

72.1.5.7.2 TCustomForm.Active Property

Specifies whether the form has focus.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Use Active to determine whether the form has focus. The Active Form receives all keyboard input. If it has a title bar, it is drawn using the active colors specified in the Control panel.

If Active is true , the form has focus; if Active is false, the form does not have focus.

See Also

SetFocus (see page 13886)

OnActivate (see page 13943)

OnDeactivate (see page 13953)

ActiveControl (see page 13896)

72.1.5.7.3 TCustomForm.ActiveControl Property

Specifies the control that has focus on the form.

Pascal

```
property ActiveControl: TWinControl;
```

C++

```
__property TWinControl * ActiveControl;
```

Description

Use ActiveControl to get or set the control that has focus on the form. Only one control can have focus at a given time in an application.

If the form does not have focus, ActiveControl is the control on the form that will receive focus when the form receives focus.

Note: When focus shifts to another control, ActiveControl is updated before the OnExit event occurs.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

See Also

ActiveOleControl (see page 13897)

OnExit (see page 6221)

OnEnter (see page 6219)

Active (see page 13896)

72.1.5.7.4 TCustomForm.ActiveMDIChild Property

Specifies the MDI child that has focus.

Pascal

```
property ActiveMDIChild: TForm;
```

C++

```
__property TForm * ActiveMDIChild;
```

Description

Use ActiveMDIChild to get the MDI child that has focus.

If the form is not an MDI parent (that is, if the FormStyle (see page 13912) property of the form is not fsMDIForm), ActiveMDIChild returns nil (Delphi) or NULL (C++).

See Also

FormStyle (see page 13912)

MDIChildCount (see page 13921)

72.1.5.7.5 TCustomForm.ActiveOleControl Property

Specifies the OLE control on the form that reacts to changes in focus.

Pascal

```
property ActiveOleControl: TWinControl;
```

C++

```
__property TWinControl * ActiveOleControl;
```

Description

Use ActiveOLEControl to get or set an OLE control on the form that reacts to changes in focus.

If ActiveOLEControl is not nil (Delphi) or NULL (C++), the user interface for the specified OLE control is deactivated when it is not focused. Also, when the form receives or loses focus, the document window for the specified OLE control is activated or deactivated respectively.

See Also

ActiveControl (see page 13896)

TWinControl (see page 6112)

72.1.5.7.6 TCustomForm.AlphaBlend Property

Specifies whether the form is translucent.

Pascal

```
property AlphaBlend: Boolean;
```

C++

```
__property Boolean AlphaBlend;
```

Description

Set AlphaBlend to specify that the form represents a layered window that allows a translucent color. The AlphaBlendValue (see page 13898) property specifies the degree of translucency.

Note: AlphaBlend does not work on all systems. The application must be running under Windows 2000 or better, and the machine must be a P90 or better.

See Also

AlphaBlendValue (see page 13898)

TransparentColor (see page 13938)

72.1.5.7.7 TCustomForm.AlphaBlendValue Property

Specifies the degree of translucency on a translucent form.

Pascal

```
property AlphaBlendValue: Byte;
```

C++

```
__property Byte AlphaBlendValue;
```

Description

Set AlphaBlendValue to a value between 0 and 255 to indicate the degree of translucency when the AlphaBlend (see page 13898) property is true. A value of 0 indicates a completely transparent window. A value of 255 indicates complete opacity.

Note: AlphaBlendValue only has an effect when the AlphaBlend (see page 13898) property is true.

See Also

AlphaBlend (see page 13898)

TransparentColor (see page 13938)

TransparentColorValue (see page 13939)

72.1.5.7.8 TCustomForm.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.5.7.9 TCustomForm.BorderIcons Property

Specifies which icons appear on the title bar of the form.

Pascal

```
property BorderIcons: TBorderIcons;
```

C++

```
__property TBorderIcons BorderIcons;
```

Description

Use BorderIcons to get or set the icons that appear on the title bar of the form. BorderIcons can include any of the following TBorderIcons (see page 14370) values:

Value	Meaning
biSystemMenu	The form has a Control menu (also known as a System (see page 22079) menu).
biMinimize	The form has a Minimize button
biMaximize	The form has a Maximize button
biHelp	If BorderStyle (see page 13900) is bsDialog or biMinimize and biMaximize are excluded, a question mark appears in the form's title bar and when clicked, the cursor changes to crHelp; otherwise,no question mark appears.

Note: Certain combinations of the BorderIcons and BorderStyle (see page 13900) properties are mutually exclusive. For example, BorderIcons biMax, biMin with BorderStyle (see page 13900) of bsDialog are mutually exclusive.

Delphi Examples:

```
{
```

```
BorderIcons example
The following code removes a form's Maximize button when the user clicks a button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
BorderIcons := BorderIcons - [biMaximize];
end;
```

See Also

BorderStyle (see page 13900)

72.1.5.7.10 TCustomForm.BorderStyle Property

Specifies the appearance and behavior of the form border.

Pascal

```
property BorderStyle: TFormBorderStyle;
```

C++

```
__property TFormBorderStyle BorderStyle;
```

Description

Use BorderStyle to get or set the appearance and behavior of the form border. BorderStyle can be any of the following TForm (see page 13992) BorderStyle values:

Value	Meaning
bsDialog	Not resizable; no minimize/maximize menu
bsSingle	Not resizable; minimize/maximize menu
bsNone	Not resizable; no visible border line
bsSizeable	Standard resizable border
bsToolWindow	like bsSingle but with a smaller caption
bsSizeToolWin	like bsSizeable with a smaller caption

Note: Changing the border style of an MDI child form to bsDialog or bsNone has no effect.

See Also

BorderIcons (see page 13899)

72.1.5.7.11 TCustomForm.Canvas Property

Provides access to the drawing area of the form.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use TCanvas to draw on the client area of the form. Canvas is often used in the OnPaint (see page 13975) event handler.

C++ Examples:

```
/*
```

```
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *BrushBmp = new Graphics::TBitmap;
  try
  {
    BrushBmp->LoadFromFile("../bm1.BMP");
    Form1->Canvas->Brush->Bitmap = BrushBmp;
    Form1->Canvas->FillRect(Rect(0,0,100,100));
  }
  __finally
  {
    Form1->Canvas->Brush->Bitmap = NULL;
    delete BrushBmp;
  }
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TForm1 *myForm;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TForm1")
  {
    myForm = (TForm1 *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myForm->Canvas->MoveTo(myForm->ClientRect.Left, myForm->ClientRect.Top);
    myForm->Canvas->LineTo(myForm->ClientRect.Right, myForm->ClientRect.Bottom);
    myForm = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TForm1) then
  begin
    myForm:= (ListBox1.Items.Objects[Index] as TForm1);
    with myForm.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myForm.Canvas.MoveTo(Left, Top);
      myForm.Canvas.LineTo(Right, Bottom);
    end;
  myForm:= nil;
  end;
{
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
}
var
  Bitmap: TBitmap;

procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('bm1.BMP');
    Form1.Canvas.Brush.Bitmap := Bitmap;
    Form1.Canvas.FillRect(Rect(0,0,100,100));
  finally
    Form1.Canvas.Brush.Bitmap := nil;
    Bitmap.Free;
  end;
end;
```

See Also

TCanvas (see page 14441)

OnPaint (see page 13975)

72.1.5.7.12 TCustomForm.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
```

```
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

72.1.5.7.13 TCustomForm.ClientHandle Property

Provides access to the handle of the form's internal MDI client window.

Pascal

```
property ClientHandle: HWND;
```

C++

```
__property HWND ClientHandle;
```

Description

Use ClientHandle to get the handle for the form's internal MDI client window.

ClientHandle is meaningful only if the form is an MDI parent (that is, if the form's FormStyle (see page 13912) property is set to fsMDIForm).

Note: Use the Handle property instead to get the handle to the form window itself.

See Also

FormStyle (see page 13912)

Handle (see page 6207)

72.1.5.7.14 TCustomForm.ClientHeight Property

Specifies the height (in pixels) of the form's client area.

Pascal

```
property ClientHeight: Integer;
```

C++

```
__property int ClientHeight;
```

Description

Use ClientHeight to determine the height (in pixels) of the form's client area. The client area is the usable area inside the form's border, excluding the title bar, scroll bars, and so on.

Set ClientHeight to change the height of the form's window based on the desired client area. To change the height of the form's window based on the total size of the window (including the border, menu, status bar and so on), use the Height (see page 13915) property instead.

Delphi Examples:

```
{
This example reduces the height of the form's client area by
half when the user clicks the button on the form:
Note that only the client area is halved, not the entire form.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ClientHeight := ClientHeight div 2;
end;
```

See Also

ClientRect

ClientWidth (see page 13905)

Height (see page 5825)

72.1.5.7.15 TCustomForm.ClientWidth Property

Specifies the width (in pixels) of the form's client area.

Pascal

```
property ClientWidth: Integer;
```

C++

```
__property int ClientWidth;
```

Description

Use ClientWidth to determine the width (in pixels) of the form's client area. The client area is the usable area inside the form's border. Set ClientWidth to change the width of the form's window based on the desired client area. To change the width of the form's window based on the total size of the window (including the border, status bar and so on), use the Width (see page 13941) property instead.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;
```

```
  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

72.1.5.7.16 TCustomForm.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

72.1.5.7.17 TCustomForm.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

72.1.5.7.18 TCustomForm.DefaultMonitor Property

Specifies the monitor on which the form appears.

Pascal

```
property DefaultMonitor: TDefaultMonitor;
```

C++

```
__property TDefaultMonitor DefaultMonitor;
```

Description

Use DefaultMonitor to associate a form with a particular monitor in a multi-monitor application. The following table lists the possible values:

Value	Meaning
dmDesktop	No attempt is made to position the form on a specific monitor.
dmPrimary	The form is positioned on the first monitor listed in the global screen object's Monitors property.
dmMainForm	The form appears on the same monitor as the application's main form.
dmActiveForm	The form appears on the same monitor as the currently active form.

Note: DefaultMonitor has no effect if the application does not have a main form.

See Also

Monitors (see page 14228)

MainForm (see page 13718)

Active (see page 13896)

Monitor (see page 13926)

MakeFullyVisible (see page 13881)

72.1.5.7.19 TCustomForm.Designer Property

Specifies the designer interface for the form.

Pascal

```
property Designer: IDesignerHook;
```

C++

```
__property IDesignerHook Designer;
```

Description

The Designer property is used internally at design time. Never assign a value to this property. This is done automatically by the form designer. Only use this property when designing classes for use in the form designer, such as property editors and component editors.

See Also

TPropertyEditor (see page 11019)

TComponentEditor (see page 10927)

72.1.5.7.20 TCustomForm.DropTarget Property

Specifies whether the form is the target of a drag-and-drop operation.

Pascal

```
property DropTarget: Boolean;
```

C++

```
__property Boolean DropTarget;
```

Description

Use DropTarget to determine whether the form is currently the target of a drag-and-drop operation.

See Also

BeginDrag (see page 5740)

DragMode (see page 5819)

EndDrag (see page 5757)

OnDragOver (see page 5857)

72.1.5.7.21 TCustomForm.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

72.1.5.7.22 TCustomForm.FormState Property

Indicates transitional state information about the form.

Pascal

```
property FormState: TFormState;
```

C++

```
__property TFormState FormState;
```

Description

Read FormState to determine the state of the form. FormState indicates when the form is in various transitional states or when certain Windows operations have occurred. The following table lists the values that can be included in a form's state:

Value	Meaning
fsCreating	The form's constructor is currently executing.
fsVisible	The form's window is visible. This state is used to update the Visible (see page 13940) property.
fsShowing	The form's WindowState (see page 13942) property is changing. This state is used to prevent WindowState (see page 13942) changes from interfering with a transition that is in progress.
fsModal	The form was created as a modal window.
fsCreatedMDIChild	The form is an MDI parent window. This state is only set once the MDI client window has been created.
fsActivated	The form has received a CM_ACTIVATE message (because it received focus or the application became active) but has not yet called the Activate (see page 13865) method to generate an OnActivate (see page 13943) event.

See Also

Visible (see page 13940)

Create (see page 13861)

WindowState (see page 13942)

ShowModal (see page 13890)

FormStyle (see page 13912)

Activate (see page 13865)

72.1.5.7.23 TCustomForm.FormStyle Property

Determines the form's style.

Pascal

```
property FormStyle: TFormStyle;
```

C++

```
__property TFormStyle FormStyle;
```

Description

Use FormStyle to get or set the form's style. FormStyle is one of the following values:

Value	Meaning
fsNormal	The form is neither an MDI parent window nor an MDI child window.
fsMDIChild	The form is an MDI child window.
fsMDIForm	The form is an MDI parent window.

fsStayOnTop	This form remains on top of the desktop and of other forms in the project, except any others that also have FormStyle set to fsStayOnTop. If one fsStayOnTop form launches another, neither form will consistently remain on top.

If the form is the main form of an MDI application, its FormStyle property must be set to fsMDIForm.

Note: It is not advisable to change FormStyle at runtime.

Warning: TGraphicControl descendants placed in the client area of a form with FormStyle set to fsMDIForm will not paint.

C++ Examples:

```
/*
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
*/
void __fastcall TForm1::MyArrangeIconsClick(TObject *Sender)
{
  Form1->ArrangeIcons();
}
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
  Tile();
}
```

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
}
procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
```

```
end;
{
This example ensures that the main form of the application
is an MDI parent:
}
type
  TForm1 = class(TForm)
    Edit1: TEdit;
  private
    { Private declarations }
  public
    { Public declarations }
    constructor Create(AOwner : TComponent); override;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

constructor TForm1.Create(AOwner : TComponent);

begin
  inherited Create(AOwner);
  if FormStyle <> fsMDIForm then
          FormStyle := fsMDIForm;
  if FormStyle = fsMDIForm then
          Edit1.Text := 'MDI form'
  else
    //This line never executes
    Edit1.Text := 'Not an MDI form';
end;
{
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
}
procedure TForm1.TileFormsClick(Sender: TObject);
begin
  TileMode := tbVertical;
  Tile;
end;
```

Windows Overview

72.1.5.7.24 TCustomForm.GlassFrame Property

Pascal

```
property GlassFrame: TGlassFrame;
```

C++

```
__property TGlassFrame GlassFrame;
```

Description

This is GlassFrame, a member of class TCustomForm.

72.1.5.7.25 TCustomForm.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
```

```
      with TRichEdit.Create(Self) do
      begin
        Parent := Self;
        Top := Height * I;
        Text := 'This text will take the focus.';
        SelStart := 0;
        SelLength := Length(Text);
        if (I = 1) then
          HideSelection := False;
      end;
  end;
```

Width (see page 5849)

Using TDBListBox and TDBComboBox

72.1.5.7.26 TCustomForm.HelpFile Property

Specifies the name of the file the form uses to display Help.

Pascal

```
property HelpFile: string;
```

C++

```
__property AnsiString HelpFile;
```

Description

Use HelpFile for forms that have a help file to use with the Help system. Help topics are selected from the specified file.

See Also

HelpContext (see page 5826)

OnHelp (see page 13959)

HelpFile (see page 13711)

HelpKeyword (see page 5826)

72.1.5.7.27 TCustomForm.HorzScrollBar Property

Represents the horizontal scroll bar for the scrolling windowed control.

Pascal

```
property HorzScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar HorzScrollBar;
```

Description

Use HorzScrollBar to hide, show, or manipulate the horizontal scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
```

See Also

AutoScroll (see page 14329)

VertScrollBar (see page 14330)

TControlScrollBar (see page 13744)

72.1.5.7.28 TCustomForm.Icon Property

Specifies the icon that appears when the form is minimized.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Set the Icon property to provide an icon for the form. If Icon is not set, the system provides a default icon when the form is minimized.

Delphi Examples:

```
{
This code assigns an icon to a form when the form is created:
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Icon.LoadFromFile('MDIChild1.ICO');
end;
```

See Also

WindowState (see page 13942)

72.1.5.7.29 TCustomForm.KeyPreview Property

Specifies whether the form should receive keyboard events before the active control.

Pascal

```
property KeyPreview: Boolean;
```

C++

```
__property Boolean KeyPreview;
```

Description

If KeyPreview is true, keyboard events occur on the form before they occur on the active control. (The active control is specified by the ActiveControl (see page 13896) property.)

If KeyPreview is false, keyboard events occur only on the active control.

Navigation keys (Tab, BackTab, the arrow keys, and so on) are unaffected by KeyPreview because they do not generate keyboard events. Similarly, when a button has focus or when its Default property is true, the Enter key is unaffected by KeyPreview because it does not generate a keyboard events.

KeyPreview is false by default.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
```

```
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
```

```
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

    Printer.BeginDoc;
    X := 200;
    Y := 200;
    for I := 0 to 140 do
      if (not Printer.Aborted) then
      begin
        Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
        Y := Y + 80;
        if (Y > (Printer.PageHeight - 300)) then
        begin
          Y := 200;
          Printer.NewPage;
          Sleep(1000);  // to give you time to abort!
        end;
      end;
    if (not Printer.Aborted) then Printer.EndDoc;
  end;
end;

OnKeyUp (see page 6228)

OnKeyPress (see page 6227)

72.1.5.7.30 TCustomForm.Left Property

Specifies the horizontal coordinate of the left edge of a component relative to its parent.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

Use the Left property to determine where the left side of the control begins or to reposition the left side of the control.

If the control is contained in another control, the Left and Top properties are relative to the parent control. If the control is contained directly by the form, the property values are relative to the form. For forms, the value of the Left property is relative to the screen in pixels.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

72.1.5.7.31 TCustomForm.MDIChildCount Property

Specifies the number of open MDI child forms.

Pascal

```
property MDIChildCount: Integer;
```

C++

```
__property int MDIChildCount;
```

Description

Use MDIChildCount to get the number of open MDI child forms.

MDIChildCount is meaningful only if the form is an MDI parent (that is, if the form's FormStyle (see page 13912) property is set to fsMDIForm).

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items CloseChildren. This is code for the
```

```
CloseChildrenClick handler.  When the user chooses the
CloseChildren command, all the MDI children of Form1 are
closed.
}
procedure TForm1.CloseChildrenClick(Sender: TObject);
var
  I: Integer;
begin
  with Form1 do
    for I := MDIChildCount-1 downto 0 do
      MDIChildren[I].Close;
end;

procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;

procedure TForm1.MyCascadeClick(Sender: TObject);
begin
  Form1.Cascade;
end;
```

See Also

MDIChildren (see page 13922)

72.1.5.7.32 TCustomForm.MDIChildren Property

Provides indexed access to all MDI child forms.

Pascal

```
property MDIChildren [I: Integer]: TForm;
```

C++

```
__property TForm * MDIChildren[int I];
```

Description

Use MDIChildren to access a child form.

I is the index of the child form to access. The order of MDI children changes as different MDI forms are activated. Initially, forms are listed in creation order, with new forms being added to the end of the array. Whenever an MDI child is activated, however, it moves to the front of the list. Thus, use I to index over all forms in the array, but not to refer to a specific form.

MDIChildren is meaningful only if the form is an MDI frame (that is, if the form's FormStyle (see page 13912) property is set to fsMDIForm).

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items CloseChildren. This is code for the
CloseChildrenClick handler.  When the user chooses the
CloseChildren command, all the MDI children of Form1 are
closed.
}
procedure TForm1.CloseChildrenClick(Sender: TObject);
var
  I: Integer;
begin
```

```
  with Form1 do
    for I := MDIChildCount-1 downto 0 do
      MDIChildren[I].Close;
end;

procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;

procedure TForm1.MyCascadeClick(Sender: TObject);
begin
  Form1.Cascade;
end;
```

See Also

MDIChildCount (see page 13921)

FormStyle (see page 13912)

72.1.5.7.33 TCustomForm.Menu Property

Specifies the form's main menu.

Pascal

```
property Menu: TMainMenu;
```

C++

```
__property TMainMenu Menu;
```

Description

Use Menu to get or set the form's main menu. At design time, Menu is set to the first TMainMenu component added to the form.

C++ Examples:

```
/*
This code displays a new menu named MyMenu when the user
clicks the button. MyOnExecute must be included in the
definition of the TForm1 class.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMenuItem *Item1 = NewItem("New item", TextToShortCut("Ctrl+N"), false, true, MyOnExecute,
0, "Item1");
  Menu = NewMenu(this, "MyMenu", &Item1, 0);
}

void __fastcall TForm1::MyOnExecute(TObject *Sender)
{
  MessageDlg("Item1 has been executed.", mtInformation, TMsgDlgButtons() << mbOK, 0);
}
/*
To create a toolbar that corresponds to an existing menu:

1   Drop a ToolBar on the form and add a ToolButton for each
  top-level menu item you wish to create.
2   Set the MenuItem property of each ToolButton to correspond
  to the top level menu items.
3   Set the Grouped property of each ToolButton to true.
4   Clear the Menu property of the Form (if it is assigned)
5   Set the Visible property on the ToolBar and ToolButtons to
  true.
6   Set the ShowCaptions property on the ToolBar to true.
```

```
7   Set the MenuItem | Visible property of each ToolButton to
  true.
*/
```

Delphi Examples:

```
{
This code displays a new menu named MyMenu when the user
clicks the button. MyOnExecute must be included in the
definition of the TForm1 class.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Menu := NewMenu(Self, 'MyMenu',
            [NewItem('New item', TextToShortCut('Ctrl+N'),
            False, True, MyOnExecute, 0, 'Item1')]);
end;

procedure TForm1.MyOnExecute(Sender: TObject);
begin
  MessageDlg('Item1 has been executed.', mtInformation, [mbOK], 0);
end;
{
To create a toolbar that corresponds to an existing menu:

1   Drop a ToolBar on the form and add a ToolButton for each top-level menu item you wish to
create.
2   Set the MenuItem property of each ToolButton to correspond to the top level menu items.
3   Set the Grouped property of each ToolButton to true.
4   Clear the Menu property of the Form (if it is assigned)
5   Set the Visible property on the ToolBar and ToolButtons to true.
6   Set the ShowCaptions property on the ToolBar to true.
7   Set the MenuItem | Visible property of each ToolButton to true.
}
```

TMainMenu (see page 16056)

72.1.5.7.34 TCustomForm.ModalResult Property

Represents the return value of a form that is used as a modal dialog.

Pascal

```
property ModalResult: TModalResult;
```

C++

```
__property TModalResult ModalResult;
```

Description

Use ModalResult to close the form when it is displayed modally.

By default, ModalResult is mrNone. Set ModalResult to any nonzero value to close the form. The value assigned to ModalResult becomes the return value of the ShowModal (see page 13890) function call used to display the form.

Note: This property is modified automatically by some components such as the TButton object.

C++ Examples:

```
/*
This code brings up the modal dialog from Unit2 when a
button is clicked.  It causes a Beep if the OK button is
```

```
clicked. Implement the modal form in Unit2 and then put
Unit2 in the uses clause for this module.
*/
#include "Unit2.h"
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (MyDialogBox1->ShowModal() == mrOk)
    MessageBeep(0);
}
/*
The following methods are used for buttons in a form that is
used as a modal dialog box. The methods cause the dialog box
to terminate when the user clicks either the OK or Cancel
button, returning mrOk or mrCancel from ShowModal,
respectively. You could also set the ModalResult value to
mrOk for the OK button and mrCancel for the Cancel button to
accomplish the same thing. When the user clicks either
button, the dialog box closes.
*/
void __fastcall TMyDialogBox1::OKButtonClick(TObject *Sender)
{
  ModalResult = mrOk;
}

void __fastcall TMyDialogBox1::CancelButtonClick(TObject *Sender)
{
  ModalResult = mrCancel;
}
```

Delphi Examples:

```
{
This code brings up the modal dialog from Unit2 when a
button is clicked.  It causes a Beep if the OK button is
clicked. Implement the modal form in Unit2 and then put
Unit2 in the uses clause for this module.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if MyDialogBox1.ShowModal = mrOK then
    Beep;
end;
{
The following methods are used for buttons in a form that is
used as a modal dialog box. The methods cause the dialog box
to terminate when the user clicks either the OK or Cancel
button, returning mrOk or mrCancel from ShowModal,
respectively. You could also set the ModalResult value to
mrOk for the OK button and mrCancel for the Cancel button to
accomplish the same thing. When the user clicks either
button, the dialog box closes.
}
procedure TMyDialogBox1.CancelButtonClick(Sender: TObject);
begin
  ModalResult := mrCancel;
end;

procedure TMyDialogBox1.OKButtonClick(Sender: TObject);
begin
  ModalResult := mrOK;
end;
```

See Also

ShowModal (see page 13890)

ModalResult (see page 20937)

72.1.5.7.35 TCustomForm.Monitor Property

Provides access to the monitor on which the form appears.

Pascal

```
property Monitor: TMonitor;
```

C++

```
__property TMonitor Monitor;
```

Description

Use Monitor to access information about the monitor on which the form appears if the application runs on a multi-monitor system. The monitor is determined by the DefaultMonitor (see page 13909) property.

See Also

Monitors (see page 14228)

BoundsRect (see page 5803)

DefaultMonitor (see page 13909)

MakeFullyVisible (see page 13881)

72.1.5.7.36 TCustomForm.ObjectMenuItem Property

Represents an OLE object menu item that reacts to selections of OLE objects.

Pascal

```
property ObjectMenuItem: TMenuItem;
```

C++

```
__property TMenuItem ObjectMenuItem;
```

Description

Use ObjectMenuItem to get or set a menu item that becomes enabled or disabled when an OLE object on the form is selected or unselected respectively.

The OLE object menu item can be used for standard OLE commands, such as Activate (see page 13865) or Convert. (The implementations of these commands are provided by the OLE server.)

See Also

OleFormObject (see page 13927)

72.1.5.7.37 TCustomForm.OldCreateOrder Property

Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.

Pascal

```
property OldCreateOrder: Boolean;
```

C++

```
__property Boolean OldCreateOrder;
```

Description

When OldCreateOrder is false (the default) the OnCreate (see page 13951) event occurs after all constructors are finished

and the OnDestroy (see page 13953) event occurs before any destructors are called.

This differs from earlier versions of the library (distributed with Delphi version 3 and previous and C++Builder 1), where the OnCreate (see page 13951) event occurred when the TCustomForm (see page 13849) constructor executed and the OnDestroy (see page 13953) event occurred when the TCustomForm (see page 13849) destructor executed. Applications that require the OnCreate (see page 13951) event and OnDestroy (see page 13953) events to occur from the constructor and destructor of the form can set OldCreateOrder to true.

See Also

OnCreate (see page 13951)

OnDestroy (see page 13953)

BeforeDestruction (see page 13866)

AfterConstruction (see page 13866)

72.1.5.7.38 TCustomForm.OleFormObject Property

Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.

Pascal

```
property OleFormObject: IOleForm;
```

C++

```
__property IOleForm OleFormObject;
```

Description

OleFormObject is used to communicate resize and destroy notifications when a form is used as a frame for an in-place OLE object.

See Also

ObjectMenuItem (see page 13926)

72.1.5.7.39 TCustomForm.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

72.1.5.7.40 TCustomForm.PixelsPerInch Property

Represents the proportion of the font on the system on which the form was designed.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

Use PixelsPerInch at runtime to change how the form is scaled to the current screen resolution. If PixelsPerInch is changed from its default value, the form will not have the same proportion on every screen resolution.

At design time, PixelsPerInch is set automatically when the form is saved. Changes to PixelsPerInch made in the Object Inspector only affect the form at runtime.

The form's Scaled (see page 13935) property must be true for PixelsPerInch to have an effect.

See Also

Scaled (see page 13935)

72.1.5.7.41 TCustomForm.PopupChildren Property

Pascal

```
property PopupChildren: TList;
```

C++

```
__property TList PopupChildren;
```

Description

This is PopupChildren, a member of class TCustomForm.

72.1.5.7.42 TCustomForm.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
```

```
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
```

```
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}
```

```

72.1.5.7.43 TCustomForm.PopupMode Property

Pascal

```
property PopupMode: TPopupMode;
```

C++

```
__property TPopupMode PopupMode;
```

Description

This is PopupMode, a member of class TCustomForm.

72.1.5.7.44 TCustomForm.PopupParent Property

Sets an order for stacked forms that users cannot change.

Pascal

```
property PopupParent: TCustomForm;
```

C++

```
__property TCustomForm PopupParent;
```

Description

If the PopupMode (see page 13933) property is set to pmExplicit and PopupParent is nil, then the Application.MainForm is implicitly used as the PopupParent. If no Application.MainForm is assigned, then Application.Handle is used as the PopupParent.

If the PopupMode (see page 13933) property is set to pmAuto, Screen.ActiveForm is used as the PopupParent property.

72.1.5.7.45 TCustomForm.Position Property

Represents the size and placement of the form.

Pascal

```
property Position: TPosition;
```

C++

```
__property TPosition Position;
```

Description

Use Position to get or set the size and placement of the form. Position can have one of the following TPosition (see page 14363) values:

Value	Meaning
poDesigned	The form appears positioned on the screen and with the same height and width as it had at design time.
poDefault	The form appears in a position on the screen and with a height and width determined by the operating system. Each time you run the application, the form moves slightly down and to the right. The right side of the form is always near the far right side of the screen, and the bottom of the form is always near the bottom of the screen, regardless of the screen's resolution. The operating system only supports this for overlapped windows. For a pop-up or child window (that has a BorderStyle (see page 13900) of bsDialog or bsNone, for example), the window is positioned in the upper left corner of the screen.
poDefaultPosOnly	The form displays with the size you created it at design time, but the operating system chooses its position on the screen. Each time you run the application, the form moves slightly down and to the right. When the form can no longer move down and to the right and keep the same size while remaining entirely visible on the screen, the form displays at the top-left corner of the screen. The operating system only supports this for overlapped windows. For a pop-up or child window (that has a BorderStyle (see page 13900) of bsDialog or bsNone, for example), the window is positioned in the upper left corner of the screen.
poDefaultSizeOnly	The form appears in the position you left it at design time, but the operating system chooses its size. The right side of the form is always near the far right side of the screen, and the bottom of the form is always near the bottom of the screen, regardless of the screen's resolution.
poScreenCenter	The form remains the size you left it at design time, but is positioned in the center of the screen. In multi-monitor applications, the form may be moved from this center position so that it falls entirely on one monitor, as specified by the DefaultMonitor (see page 13909) property.
poDesktopCenter	The form remains the size you left it at design time, but is positioned in the center of the screen. No adjustments are made for multi-monitor applications.
poMainFormCenter	The form remains the size you left it at design time, but is positioned in the center of the application's main form. No adjustments are made for multi-monitor applications. This position should only be used with secondary forms. If set for a main form, it acts like poScreenCenter.
poOwnerFormCenter	The form remains the size you left it at design time, but is positioned in the center of the form specified by the Owner property. If the Owner property does not specify a form, this position acts like poMainFormCenter.

SetInitialBounds

72.1.5.7.46 TCustomForm.PrintScale Property

Represents the proportions of a printed form.

Pascal

```
property PrintScale: TPrintScale;
```

C++

```
__property TPrintScale PrintScale;
```

Description

Use PrintScale to get or set the proportions of the printed form. PrintScale can have one of the following TPrintScale (see page 14364) values:

Value	Meaning
poNone	No special scaling occurs; therefore, the printed form and how the form appears onscreen may appear squished or stretched.
poProportional	The form is printed so that the printed image is approximately the same visible size as on the screen (WYSIWYG). The form image is scaled so that the printed image is approximately the same visible size as on the screen.
poPrintToFit	The form is printed using the same screen proportions, but in a size that just fits the printed page.

See Also

Print (see page 13883)

72.1.5.7.47 TCustomForm.Scaled Property

Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.

Pascal

```
property Scaled: Boolean;
```

C++

```
__property Boolean Scaled;
```

Description

Scaled determines whether the form adjusts itself to differences between the font used at design time and the current system font used by a system at runtime. If Scaled is true, the form resizes itself and all its child controls to maintain the relationship between the size of controls and the height of text displayed in the default font. If Scaled is false, no such resizing occurs.

By setting Scaled to true, the form can adjust to fonts that are not scalable (that is, fonts that only supply discrete point sizes) or to differences such as forms designed using small fonts at design time that are run on systems that use large fonts.

The degree of resizing is determined by the PixelsPerInch (see page 13928) property, which measures the proportion of the font on the system used when designing the form.

See Also

PixelsPerInch (see page 13928)

Considerations When Dynamically Resizing Forms and Controls

72.1.5.7.48 TCustomForm.ScreenSnap Property

Specifies whether form snaps to edge of screen.

Pascal

```
property ScreenSnap: Boolean;
```

C++

```
__property Boolean ScreenSnap;
```

Description

ScreenSnap determines whether the edges of the form snap to the edge of the screen when the user moves the form. To control the snap distance, set the SnapBuffer (see page 13936) property.

See Also

SnapBuffer (see page 13936)

72.1.5.7.49 TCustomForm.SnapBuffer Property

Specifies distance for screen snap.

Pascal

```
property SnapBuffer: Integer;
```

C++

```
__property int SnapBuffer;
```

Description

If ScreenSnap (see page 13935) is true, SnapBuffer determines the maximum number of pixels that be between the form edge and the screen edge before the form snaps to the screen edge.

See Also

ScreenSnap (see page 13935)

72.1.5.7.50 TCustomForm.TileMode Property

Represents how MDI child forms are arranged when the Tile method is called.

Pascal

```
property TileMode: TTileMode;
```

C++

```
__property TTileMode TileMode;
```

Description

TileMode can have one of the following TTileMode (see page 14367) values:

Value	Meaning
tbHorizontal	Each form stretches across the width of the parent form
tbVertical	Each form stretches along the height of the parent form

TileMode is meaningful only if the form is an MDI child (that is, if the form's FormStyle (see page 13912) property is set to fsMDIChild).

C++ Examples:

```
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
  Tile();
}
```

Delphi Examples:

```
{
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
}
procedure TForm1.TileFormsClick(Sender: TObject);
begin
  TileMode := tbVertical;
  Tile;
end;
```

See Also

FormStyle (see page 13912)

Tile (see page 14009)

72.1.5.7.51 TCustomForm.Top Property

Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

Use Top to locate the top of the control or reposition the control to a different Y coordinate. The Top property, like the Left property, is the position of the control relative to its container. Thus, if a control is contained in a TPanel, the Left and Top properties are relative to the panel. If the control is contained directly by the form, it is relative to the form. For forms, the value of the Top property is relative to the screen in pixels.

C++ Examples:

```
/*
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
*/
void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  int I;
  TControl *ChildControl;

  for (I = 0; I < GroupBox1->ControlCount; I++)
  {
    ChildControl = GroupBox1->Controls[I];
    if (Button == btNext)
      ChildControl->Top = ChildControl->Top + 15;
    else
      ChildControl->Top = ChildControl->Top - 15;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  const TColor colorarray[5] = {clYellow, clGreen, clBlue, clLime, clFuchsia};
  GroupBox1->Brush->Color = clRed;
  for (int i = 0; i < GroupBox1->ControlCount; i++)
    ((TWinControl *)GroupBox1->Controls[i])->Brush->Color = colorarray[i];
}
```

Delphi Examples:

```
{
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
const
  colorarray : Array[0..4] of TColor = (clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
   GroupBox1.Brush.Color := clRed;
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    TWinControl(GroupBox1.Controls[I]).Brush.Color := colorarray[I];
  end;
end;

procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
var
  I: Integer;
  ChildControl: TControl;
begin
  for I:= 0 to GroupBox1.ControlCount -1 do
  begin
    ChildControl := GroupBox1.Controls[I];
    if Button = btNext then
      ChildControl.Top := ChildControl.Top + 15
    else
      ChildControl.Top := ChildControl.Top - 15;
  end;
end;
```

See Also

Left (see page 5830)

72.1.5.7.52 TCustomForm.TransparentColor Property

Specifies whether a color on the form appears transparent.

Pascal

```
property TransparentColor: Boolean;
```

C++

```
__property Boolean TransparentColor;
```

Description

Use TransparentColor to indicate that one of the colors on the form should be treated as transparent, allowing windows behind the form to completely show through. The TransparentColorValue (see page 13939) property indicates the color that appears completely transparent.

Note: To make the entire form transparent, or to make it translucent rather than transparent, use the AlphaBlend (see page 13898) and AlphaBlendValue (see page 13898) properties.

Note: TransparentColor does not work on all systems. The application must be running under Windows 2000 or better, with adequate hardware.

See Also

TransparentColorValue (see page 13939)

AlphaBlend (see page 13898)

AlphaBlendValue (see page 13898)

72.1.5.7.53 TCustomForm.TransparentColorValue Property

Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.

Pascal

```
property TransparentColorValue: TColor;
```

C++

```
__property TColor TransparentColorValue;
```

Description

Use TransparentColorValue to indicate the color that appears transparent when the TransparentColor (see page 13938) property is true.

Note: If the application uses a 16-bit color palette, TransparentColorValue must be a basic color.

See Also

TransparentColor (see page 13938)

72.1.5.7.54 TCustomForm.VertScrollBar Property

Represents the vertical scroll bar for the scrolling windowed control.

Pascal

```
property VertScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar VertScrollBar;
```

Description

Use VertScrollBar to hide, show, or manipulate the vertical scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
```

```
}
```

Delphi Examples:

```
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

See Also

AutoScroll (see page 14329)

HorzScrollBar (see page 14329)

TControlScrollBar (see page 13744)

72.1.5.7.55 TCustomForm.Visible Property

Indicates whether the form is visible.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use Visible to determine whether the form is visible.

If Visible is true, the form is visible unless it is completely obscured by other forms. If Visible is false, the form is not visible.

The Show (see page 13888) and ShowModal (see page 13890) methods set Visible to true and bring the form to the front of all open windows.

C++ Examples:

```
/*
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must include Unit2.h in this
module.
*/
#include "Unit2.h"

void __fastcall TForm1::ShowPaletteButtonClick(TObject *Sender)
{
  if (!Form2->Visible)
  {
    Form2->Visible = true;
    Form2->BringToFront();
  }
}
```

Delphi Examples:

```
{
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must add Unit2 in the uses clause
of your unit.
}
procedure TForm1.ShowPaletteButtonClick(Sender: TObject);
begin
if Form2.Visible = False then Form2.Visible := True;
Form2.BringToFront;
end;
```

See Also

BringToFront (see page 5740)

Show (see page 13888)

ShowModal (see page 13890)

72.1.5.7.56 TCustomForm.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

See Also

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

72.1.5.7.57 TCustomForm.WindowMenu Property

Specifies the Window menu for an MDI parent form.

Pascal

```
property WindowMenu: TMenuItem;
```

C++

```
__property TMenuItem WindowMenu;
```

Description

Use WindowMenu to get or set the Window menu for an MDI parent form. The Window menu is a standard menu in MDI applications. It contains commands that let the user manage the windows in the application. Menu (see page 13923) items usually include Cascade, Arrange Icons, Tile, and so on.

The Window menu also lists (at the bottom) the child windows that are currently open in the application. When the user selects one of these windows from the menu, the window becomes the active window in the application.

Although this menu is commonly called the Window menu, it can have any name that corresponds to an existing menu item on the menu bar. The names of open child forms are merged onto the menu automatically at run-time.

WindowMenu is meaningful only if the form is an MDI parent (that is, if the form's FormStyle (see page 13912) property is set to fsMDIForm).

See Also

FormStyle (see page 13912)

72.1.5.7.58 TCustomForm.WindowState Property

Represents how the form appears on the screen.

Pascal

```
property WindowState: TWindowState;
```

C++

```
__property TWindowState WindowState;
```

Description

Set WindowState to minimize, maximize, or restore the form window. Read WindowState to determine whether the form is minimized, maximized, or in a normal state.

See Also

Icon (see page 13917)

BorderStyle (see page 13900)

72.1.5.8 TCustomForm Events

The events of the TCustomForm class are listed here.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.
	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.

	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).
	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).

72.1.5.8.1 TCustomForm.OnActivate Event

Occurs when the form becomes active.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Use OnActivate to perform special processing when the form receives focus. A form becomes active when focus is transferred to it (when the user clicks on the form, for example).

Note: The OnActivate event of the application (TApplication (see page 13660)), not the form, occurs when Windows switches control from another application.

Delphi Examples:

```
{
Here is the code on Form1 that fills the list box.
}
var
  Form1: TForm1;
  Customers: TTable;
  Blobs: TTable;
  Form1Done : Boolean;
  procedure CreateMyTable;
  procedure CreateCustSource;
  procedure CreateBlobSource;

implementation

{$R *.dfm}

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  CreateCustSource;
  CreateBlobSource;
  for I := 0 to ComponentCount - 1 do
  begin
    if (Components[I] is TDataSource) then
```

```
      ListBox1.Items.AddObject(Components[I].Name,
        Components[I] as TObject);
  end;
end;

procedure CreateCustSource();
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'MyCustInfo';
    ReadOnly:= False;

//    Don't overwrite an existing table
    if (not Customers.Exists) then CreateMyTable
    else
    begin
      if (Customers.Exists AND
        (MessageDlg('MyCustInfo table already exists.  Do you want to rebuild it?',
mtConfirmation, [mbYes, mbNo], 0) = mrYes)) then
      begin
        Customers.Close;
        Customers.DeleteTable;
        CreateMyTable;
      end;
    end;
  end;
  Form1.CustomerDS.DataSet:= Customers;
  Customers.Active:= True;
end;

procedure CreateMyTable();
var
  i: Integer;
begin
//      The Table component must not be active

        { it a name }
        { Next, describe the fields in the table }
        with FieldDefs do
        begin
          Clear;
          with AddFieldDef do
          begin
            Name := 'Field1';
```

```
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftBlob;
          Size := 30;
        end;
      end;
      { Next, describe any indexes }
      with IndexDefs do
      begin
        Clear;
        { The 1st index has no name because it is
        { a Paradox primary key }
        with AddIndexDef do
        begin
          Name := '';
          Fields := 'Field1';
          Options := [ixPrimary];
        end;
{
        with AddIndexDef do
        begin
          Name := 'Fld2Indx';
          Fields := 'Field2';
          Options := [ixCaseInsensitive];
        end;
}
      end;
      { Call the CreateTable method to create the table }
      CreateTable;
      Blobs.Active:= True;
      for i := 1 to 20 do
        Blobs.AppendRecord([i*111, IntToStr(i*222)]);
    end;
  end;
  Form1.BlobDS.DataSet:= Blobs;
  Blobs.Active:= True;
end;

procedure TForm1.ListBox1MouseDown(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
begin
  Form1Done := True;
end;

initialization

Form1Done := False;
{
The following code sets the DataSource for a DBGrid
component in Form2 to the currently selected data source in
a list provided in Form1. This allows users to specify the
desired information in Form1, and then move to Form2 to view
the information. Select an item in the listbox and then
activate Form2 by clicking in it.
}
procedure TForm2.FormActivate(Sender: TObject);
begin
  if (Form1Done) then
  begin
    DBGrid2.DataSource :=
      Form1.ListBox1.Items.Objects[Form1.ListBox1.ItemIndex] as TDataSource;
    DBNavigator2.DataSource :=
```

```
      Form1.ListBox1.Items.Objects[Form1.ListBox1.ItemIndex] as TDataSource;
    end;
  end;
```

FormStyle (see page 13912)

OnDeactivate (see page 13953)

OnActivate (see page 13726)

72.1.5.8.2 TCustomForm.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize (see page 5853)

SetBounds (see page 5783)

OnResize (see page 5870)

72.1.5.8.3 TCustomForm.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.

- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

72.1.5.8.4 TCustomForm.OnClose Event

Occurs when the form closes.

Pascal

```
property OnClose: TCloseEvent;
```

C++

```
__property TCloseEvent OnClose;
```

Description

Use OnClose to perform special processing when the form closes. The OnClose event specifies which event handler to call when a form is about to close. The handler specified by OnClose might, for example, test to make sure all fields in a data-entry form have valid contents before allowing the form to close.

A form is closed by the Close (see page 13867) method or when the user chooses Close (see page 13867) from the form's system menu.

The TCloseEvent (see page 14371) type points to a method that handles the closing of a form. The value of the Action (see page 13895) parameter determines if the form actually closes. These are the possible values of Action (see page 13895):

Value	Meaning
caNone	The form is not allowed to close, so nothing happens.
caHide	The form is not closed, but just hidden. Your application can still access a hidden form.
caFree	The form is closed and all allocated memory for the form is freed.

caMinimize	The form is minimized, rather than closed. This is the default action for MDI child forms.

If a form is an MDI child form, and its BorderIcons (see page 13899) property is biMinimize, then the default Action (see page 13895) is caMinimize. If a MDI child form does not have these settings, the default Action (see page 13895) is caNone, meaning that nothing happens when the user attempts to close the form.

If a form is an SDI child form, Action (see page 13895) defaults to caHide.

To close the form and free it in an OnClose event, set Action (see page 13895) to caFree.

Note: When the application shuts down, the main form receives an OnClose event, but any child forms do not receive the OnClose event.

C++ Examples:

```
/*
This example displays a message dialog box when the user
attempts to close the form. If the user clicks the Yes
button, the form closes; otherwise, the form only minimizes.
TCustomForm.Close does not allow an action of caMinimize
for a form closing itself.  Close Form2 from Form1 (from
a button?) and implement the OnClose in Form2.  Place
"Application.CreateForm(TForm2, Form2);" in the project dpr
file to open Form2 and set the Form2 Visible property to
True.
*/
void __fastcall TForm2::FormClose(TObject *Sender, TCloseAction &Action)
{
  if (MessageDlg("Close application ?", mtConfirmation, TMsgDlgButtons() << mbYes << mbNo,0)
== mrYes)
    Action = caFree;
  else
    Action = caMinimize;
}
```

OnCreate (see page 13951)

OnCloseQuery (see page 13950)

OnDestroy (see page 13953)

72.1.5.8.5 TCustomForm.OnCloseQuery Event

Occurs when close is attempted.

Pascal

```
property OnCloseQuery: TCloseQueryEvent;
```

C++

```
__property TCloseQueryEvent OnCloseQuery;
```

Description

Use OnCloseQuery to specify the conditions under which the form can close. An OnCloseQuery event handler returns a Boolean CanClose value that determines whether a form is allowed to close. Its default value is true.

You can use an OnCloseQuery event handler to ask users if they are sure they really want the form closed immediately. For example, you can use the handler to display a message box that prompts the user to save a file before closing the form.

The TCloseQueryEvent (see page 14372) type points to the method that determines whether a form can be closed. The value of the CanClose parameter determines if the form can close or not.

C++ Examples:

```
/*
When the user attempts to close the form in this example, a
message dialog appears that asks the user if it is OK to
close the form. If the user chooses the OK button, the form
closes. If the user chooses Cancel, the form doesn't close.
Populate the OnCloseQuery event handler of the form.
*/
void __fastcall TForm1::FormCloseQuery(TObject *Sender, bool &CanClose)
{
  if (MessageDlg("Close the form?", mtConfirmation, TMsgDlgButtons() << mbOK << mbCancel,0) ==
mrCancel)
    CanClose = false;
}
```

Delphi Examples:

```
{
When the user attempts to close the form in this example, a
message dialog appears that asks the user if it is OK to
close the form. If the user chooses the OK button, the form
closes. If the user chooses Cancel, the form doesn't close.
Populate the OnCloseQuery event handler of the form.
}
procedure TForm1.FormCloseQuery(Sender: TObject; var CanClose: Boolean);
begin
  if MessageDlg('Close the form?', mtConfirmation,
    [mbOk, mbCancel], 0) = mrCancel then
     CanClose := False;
end;
```

See Also

OnClose (see page 13949)

72.1.5.8.6 TCustomForm.OnCreate Event

Occurs when the form is created.

Pascal

```
property OnCreate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCreate;
```

Description

Use OnCreate to perform special processing when the form is created and is invoked by TCustomForm (see page 13849)'s constructor. Either implement this event or override the constructor of the form; do not do both. Any objects created in the OnCreate event should be freed by the OnDestroy (see page 13953) event.

When a form is being created and its Visible (see page 13940) property is true, the following events occur in the order listed:

1. OnCreate2. OnShow3. OnActivate4. OnPaint (see page 13975)

   Note: Use of the OnCreate event is discouraged in C++ code because it can interact badly with the form's constructor (see OldCreateOrder (see page 13926)). It is recommended that you override the form constructor instead.

C++ Examples:

```
/*
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
const
  TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *page = new TTabSheet(PageControl1);
    page->PageControl = PageControl1;
    page->Caption = AnsiString("Page") + IntToStr(i);
    page->Brush->Color = colorPalette[i];
  }
}

void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  PageControl1->SelectNextPage(Button == btNext);
}
```

Delphi Examples:

```
{
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
const
  colorPalette: Array[0..11] of TColor =
    (clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple);
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet #' + IntToStr(i);
      Brush.Color := colorPalette[i];
    end;
end;

procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
begin
  PageControl1.SelectNextPage(Button = btNext);
end;
```

72.1.5.8.7 TCustomForm.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

72.1.5.8.8 TCustomForm.OnDeactivate Event

Occurs when the form loses focus.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Use OnDeactivate to perform special processing when the form transitions from being the active form to another form in the same application becoming the active form. If activation goes to another application, this event is not triggered. To determine if another application has become active, Use the TApplication (see page 13660) object's OnDeactivate event.

See Also

OnActivate (see page 13943)

OnDeactivate (see page 13727)

72.1.5.8.9 TCustomForm.OnDestroy Event

Occurs when the form is destroyed.

Pascal

```
property OnDestroy: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDestroy;
```

Description

Use OnDestroy to perform special processing when the form is destroyed. Either implement this event or override the destructor of the class, but not both. This event should destroy any objects created in the OnCreate (see page 13951) event.

C++ Examples:

```
/*
The following code allocates a TBitmap object that is used
by the application when the main form is first created. The
OnDestroy method frees the bitmap as the application shuts
down.
*/
Graphics::TBitmap *LogoBmp;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  LogoBmp = new Graphics::TBitmap();
  LogoBmp->LoadFromFile("../FACTORY.BMP");
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete LogoBmp;
}

void __fastcall TForm1::FormPaint(TObject *Sender)
{
  Canvas->Brush->Bitmap = LogoBmp;
  Canvas->FillRect(Rect(0,0,100,100));
}
```

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
```

Free (see page 22300)

Destroy (see page 13862)

OldCreateOrder (see page 13926)

72.1.5.8.10 TCustomForm.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
```

```
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

72.1.5.8.11 TCustomForm.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
```

```
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

72.1.5.8.12 TCustomForm.OnHelp Event

Occurs when the form receives a request for help.

Pascal

```
property OnHelp: THelpEvent;
```

C++

```
__property THelpEvent OnHelp;
```

Description

Write an OnHelp event handler to perform special processing when the user requests help. The HelpContext and the HelpJump methods automatically trigger the OnHelp event.

Set the CallHelp parameter to true if the application should still invoke the help system after the event. Set CallHelp to false to prevent the default response by the help system. The form calls the help system only if OnHelp's CallHelp parameter returns true or if no OnHelp event handler is assigned.

To find the possible values of the Command and Data parameters, search for WinHelp in the Win32 Developer's Reference Help (Win32.HLP) file, which explains the WinHelp API (application programming interface). The possible values for the Data parameter depend upon the value of the Command parameter.

The event handler returns true if it succeeds, false if it fails.

72.1.5.8.13 TCustomForm.OnHide Event

Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).

Pascal

```
property OnHide: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnHide;
```

Description

Use OnHide to perform special processing when the form is hidden (that is, when the form's Visible (see page 13940) property is set to false).

C++ Examples:

```
/*
This example uses two forms, each with a label and a button.

72.1.5.8.14 TCustomForm.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
```

```
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.

72.1.5.8.15 TCustomForm.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

72.1.5.8.16 TCustomForm.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/

72.1.5.8.17 TCustomForm.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

72.1.5.8.18 TCustomForm.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

72.1.5.8.19 TCustomForm.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit

      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
      }
      else
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
      }
    }
  }
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
```

```
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;
```

72.1.5.8.20 TCustomForm.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
```

```
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else

Responding to a Mouse-up Action

72.1.5.8.21 TCustomForm.OnPaint Event

Occurs when the form is redrawn.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Use OnPaint to perform special processing when the form is redrawn. Any special painting on the form should be done in this event. OnPaint occurs before any controls on the form are painted.

To determine which portions of the form's canvas need to be repainted, use the ClipRect property of the canvas.

If you use the form's Canvas (see page 13900) property outside the OnPaint event, it will be erased and drawn-over by the next OnPaint event.

C++ Examples:

```
/*
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
*/
Graphics::TBitmap *TheGraphic;

void __fastcall TForm1::FormPaint(TObject *Sender)// OnPaint event handler
{
  Form1->Canvas->Draw(0, 0, TheGraphic); // Draw the graphic on the Canvas
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TheGraphic = new Graphics::TBitmap(); // Create the bitmap object
  TheGraphic->LoadFromFile("..\\bigf.bmp"); // Load the bitmap from a file
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete TheGraphic;
}
```

Delphi Examples:

```
{
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
}
procedure TForm1.FormPaint(Sender: TObject); { OnPaint event handler}
begin
  Form1.Canvas.Draw(0, 0, TheGraphic); { Draw the graphic on the Canvas }
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  TheGraphic := TBitmap.Create; { Create the bitmap object }
  TheGraphic.LoadFromFile('bigf.bmp'); { Load the bitmap from a file}
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  (TheGraphic as TObject).Free;
end;
```

72.1.5.8.22 TCustomForm.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
```

```
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

SetBounds (see page 5783)

AutoSize (see page 5803)

OnConstrainedResize (see page 5853)

72.1.5.8.23 TCustomForm.OnShortCut Event

Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).

Pascal

```
property OnShortCut: TShortCutEvent;
```

C++

```
__property TShortCutEvent OnShortCut;
```

Description

Use OnShortCut to dispatch shortcut keystrokes before the form handles them. When the user presses a key, the form can dispatch it as a shortcut key instead of allowing the standard keystroke processing (OnKeyDown (see page 13962), OnKeyPress (see page 13964), and OnKeyUp (see page 13966)). Built-in shortcut processing is provided for menu shortcuts and actions associated with the form. OnShortCut allows the form to implement additional shortcuts.

If the OnShortCut implements a response to the keystroke, set the Handled parameter of the event handler to true. This prevents the keystroke from being passed on to menus or actions associated with the form. It also prevents the standard keystroke processing in the same way that a menu or action shortcut does.

OnKeyDown (see page 6225)

IsShortCut (see page 13880)

IsShortCut (see page 322)

IsShortCut (see page 16078)

72.1.5.8.24 TCustomForm.OnShow Event

Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).

Pascal

```
property OnShow: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnShow;
```

Description

Use OnShow to perform special processing when the form is shown (that is, when the form's Visible (see page 13940) property is set to true).

C++ Examples:

```
/*
This project requires a Page Control.  You will need to
populate the Page Control by right clicking and selecting
New Page from the context menu. As the tabs are selected by
the user, the Page Control OnChange event fires, which
causes the form caption to display the captions of each of
the TTabSheets attached to the Page Control.
Note the use of the Form's OnShow event handler to set the
caption when the form first appears.  This occurs before
any changes trigger the OnChange event of the Page Control.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  Caption = AnsiString("Now working on tab: " + PageControl1->ActivePage->Caption);
}

void __fastcall TForm1::FormShow(TObject *Sender)
{
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This project requires a Page Control.  You will need to
populate the Page Control by right clicking and selecting
New Page from the context menu. As the tabs are selected by
the user, the Page Control OnChange event fires, which
causes the form caption to display the captions of each of
the TTabSheets attached to the Page Control.
Note the use of the Form's OnShow event handler to set the
caption when the form first appears.  This occurs before
any changes trigger the OnChange event of the Page Control.
}
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  Caption := ' Now working on tab:  ' + PageControl1.ActivePage.Caption;
end;

procedure TForm1.FormShow(Sender: TObject);
begin
  PageControl1Change(Sender);
end;
```

72.1.6 TCustomFrame Class

TCustomFrame is the base class from which TFrame (see page 14114) descends.

Class Hierarchy

Pascal

```
TCustomFrame = class(TScrollingWinControl);
```

C++

```
class TCustomFrame : public TScrollingWinControl;
```

File

Forms

Description

TCustomFrame is the base class for frames. A frame, like a form, is a container for controls and components. It uses the same ownership mechanism as forms for automatic instantiation and destruction of the components on it, and the same parent-child relationships for synchronization of component properties. Unlike forms, however, frames can be nested within forms or other frames, and can be saved on the Component palette for easy reuse. After a frame is created and saved, it continues to function as a unit and to inherit changes from the components (including other frames) it contains. Moreover, an embedded frame continues to inherit changes made to the frame from which it is derived.

Do not create instances of TCustomFrame. Instead, to create and work with frames, define a TCustomFrame descendant by choosing File|New|Frame, and adding the controls and components that you want your frame to encapsulate.

TForm (see page 13992)

TScrollingWinControl (see page 14312)

TFrame (see page 14114)

72.1.6.1 TCustomFrame Members

The following tables list the members exposed by TCustomFrame.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.

	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 13990)	Initializes frame creation parameters for efficient redrawing.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.

	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 13990)	Calls a specified method for each child of the frame.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.

	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 13991)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.

	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 13991)	Sets the Parent property.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 13989)	Creates and initializes a TCustomFrame (see page 13978) object.

	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.

	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.

	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.

	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

72.1.6.2 TCustomFrame.Create Constructor

Creates and initializes a TCustomFrame (see page 13978) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomFrame(TComponent * AOwner);
```

Description

Use Create to create and initialize a frame.

AOwner is the component that owns the frame.

See Also

TFrame (see page 14114)

Owner (see page 2807)

ParentWindow (see page 6210)

72.1.6.3 TCustomFrame Methods

The methods of the TCustomFrame class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 13990)	Initializes frame creation parameters for efficient redrawing.
	GetChildren (see page 13990)	Calls a specified method for each child of the frame.
	PaintWindow (see page 13991)	Renders the image of a windowed control.
	SetParent (see page 13991)	Sets the Parent property.

72.1.6.3.1 TCustomFrame.CreateParams Method

Initializes frame creation parameters for efficient redrawing.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 14327) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle.

See Also

CreateParams (see page 14326)

CreateWnd (see page 14327)

CreateWindowHandle (see page 6137)

72.1.6.3.2 TCustomFrame.GetChildren Method

Calls a specified method for each child of the frame.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the component streaming system that loads and saves forms and data modules. Applications seldom need to call this routine.

Proc is a callback to execute for every component in the frame.

Root indicates the top-level component that is the entry point for the entire streaming process. This can be a form, data module, or frame.

GetChildren executes the method specified by Proc for every component contained by the frame. It provides extra support for components that do not have parents if the Root parameter identifies this frame.

See Also

GetChildren (see page 6153)

72.1.6.3.3 TCustomFrame.PaintWindow Method

Renders the image of a windowed control.

Pascal

```
procedure PaintWindow(DC: HDC); override;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

Call PaintWindow to repaint the control. PaintWindow sends a WM_PAINT message to the windowed control's DefaultHandler method, setting the message record's WParam field to the value passed in DC and the other parameter and result fields to zeros.

See Also

DefaultHandler (see page 6139)

PaintTo (see page 6167)

DoubleBuffered (see page 6205)

72.1.6.3.4 TCustomFrame.SetParent Method

Sets the Parent property.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent property. TCustomFrame (see page 13978) overrides the method inherited from TControl to

Update the parent form so that it is aware of any action lists in the frame.

Regenerate the frame's window so that it fits properly into its new parent.

See Also

Parent (see page 5832)

72.1.7 TForm Class

TForm represents a standard application window (form).

Class Hierarchy

Pascal

```
TForm = class(TCustomForm);
```

C++

```
class TForm : public TCustomForm;
```

File

Forms

Description

When you create forms in the Form designer at design time, they are implemented as descendants of TForm. Forms (see page 13657) can represent the application's main window, or dialog boxes, or MDI children. A form can contain other objects, such as TButton, TCheckBox, and TComboBox objects.

Examples of forms include TLoginDialog and TPasswordDialog objects.

72.1.7.1 TForm Members

The following tables list the members exposed by TForm.

Protected Events

	Name	Description
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.

	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 13868)	Initializes the window-creation parameter record when the form window is created.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.

	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.

	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.

	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.

	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WndProc (see page 13893)	Provides specific message responses for the form.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	ArrangeIcons (see page 14006)	Arranges the icons of minimized MDI child forms.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	Cascade (see page 14007)	Arranges MDI child forms so they overlap.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 13861)	Creates and initializes a new TForm (see page 13992) object.
V	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.

	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Next (see page 14008)	Activates the next child form in the form sequence.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.

	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Previous (see page 14009)	Activates the previous MDI child form in the form sequence.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
	Tile (see page 14009)	Arranges MDI child forms so that they are all the same size.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveMDIChild (see page 14013)	Specifies the MDI child that has focus.

	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	ClientHandle (see page 14024)	Provides access to the handle of the form's internal MDI client window.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 14029)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	MDIChildCount (see page 14044)	Specifies the number of open MDI child forms.
	MDIChildren (see page 14044)	Provides indexed access to all MDI child forms.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.

	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TileMode (see page 14059)	Represents how MDI child forms are arranged when the Tile method is called.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnActivate (see page 14065)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.
	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.
	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.

	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.
	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.
	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Menu (see page 14045)	Specifies the form's main menu.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.

	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.
	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.
	WindowState (see page 14063)	Represents how the form appears on the screen.

72.1.7.2 TForm Methods

The methods of the TForm class are listed here.

Public Methods

	Name	Description
	ArrangeIcons (see page 14006)	Arranges the icons of minimized MDI child forms.
	Cascade (see page 14007)	Arranges MDI child forms so they overlap.
	Next (see page 14008)	Activates the next child form in the form sequence.
	Previous (see page 14009)	Activates the previous MDI child form in the form sequence.
	Tile (see page 14009)	Arranges MDI child forms so that they are all the same size.

72.1.7.2.1 TForm.ArrangeIcons Method

Arranges the icons of minimized MDI child forms.

Pascal

```
procedure ArrangeIcons;
```

C++

```
__fastcall ArrangeIcons();
```

Description

Use ArrangeIcons to arrange the icons of minimized MDI child forms so they are evenly spaced and don't overlap.

ArrangeIcons works only if the form is an MDI parent form (that is, if the form's FormStyle (see page 14036) property is fsMDIForm).

C++ Examples:

```
/*
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
*/
void __fastcall TForm1::MyArrangeIconsClick(TObject *Sender)
{
  Form1->ArrangeIcons();
}
```

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
}
procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;
```

See Also

Cascade (see page 14007)

Tile (see page 14009)

FormStyle (see page 13912)

72.1.7.2.2 TForm.Cascade Method

Arranges MDI child forms so they overlap.

Pascal

```
procedure Cascade;
```

C++

```
__fastcall Cascade();
```

Description

Use Cascade to arrange MDI child forms so they overlap.

Cascade works only if the form is an MDI parent form (that is, if the form's FormStyle (see page 14036) property is fsMDIForm).

C++ Examples:

```
/*
This example uses several forms. The first form has its
FormStyle property set to fsMDIForm. The others have their
FormStyle properties set to fsMDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyCascade. This is code for the
MyCascadeClick handler.  When the user chooses the
Cascade command, restored forms are arranged
so that they overlap.  DO NOT name the menu items "Cascade"
as that will override the TForm method.
*/
void __fastcall TForm1::MyCascadeClick(TObject *Sender)
{
  Form1->Cascade();
}
```

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to fsMDIForm. The others have their
FormStyle properties set to fsMDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyCascade. This is code for the
MyCascadeClick handler.  When the user chooses the
Cascade command, restored forms are arranged
so that they overlap.  DO NOT name the menu items "Cascade"
as that will override the TForm method.
}
procedure TForm1.MyCascadeClick(Sender: TObject);
begin
  Form1.Cascade;
end;
```

See Also

Tile (see page 14009)

ArrangeIcons (see page 14006)

FormStyle (see page 13912)

72.1.7.2.3 TForm.Next Method

Activates the next child form in the form sequence.

Pascal

```
procedure Next;
```

C++

```
__fastcall Next();
```

Description

Use Next to change the active child form of an MDI parent. For example, if you have three child forms within a parent form and Form2 is the active form, the Next method makes Form3 the active form. Calling Next again makes Form4 active. The next time your application calls Next, the sequence starts over again and Form2 becomes the active form once again.

The Next method applies only to forms that are MDI parent forms (have a FormStyle (see page 14036) property value of fsMDIForm).

See Also

Previous (see page 14009)

FormStyle (see page 13912)

72.1.7.2.4 TForm.Previous Method

Activates the previous MDI child form in the form sequence.

Pascal

```
procedure Previous;
```

C++

```
__fastcall Previous();
```

Description

Use Previous to change the active child form of an MDI parent. For example, if you have three child forms within a parent form and Form4 is the active form, the Previous method makes Form3 the active form. Calling Previous again makes Form2 active. The next time your application calls Previous, the sequence starts over again and Form4 becomes the active form once again.

The Previous method applies only to forms that are MDI parent forms (have a FormStyle (see page 14036) property value of fsMDIForm).

See Also

Next (see page 14008)

72.1.7.2.5 TForm.Tile Method

Arranges MDI child forms so that they are all the same size.

Pascal

```
procedure Tile;
```

C++

```
__fastcall Tile();
```

Description

Use Tile to arrange MDI child forms so that they are all the same size. Tiled forms completely fill up the client area of the parent form. How the forms arrange themselves depends upon the values of their TileMode (see page 14059) properties.

Tile works only if the form is an MDI parent form (that is, if the form's FormStyle (see page 14036) property is fsMDIForm).

C++ Examples:

```
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
```

```
  Tile();
}
```

Delphi Examples:

```
{
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
}
procedure TForm1.TileFormsClick(Sender: TObject);
begin
  TileMode := tbVertical;
  Tile;
end;
```

See Also

TileMode (see page 13936)

72.1.7.3 TForm Properties

The properties of the TForm class are listed here.

Public Properties

	Name	Description
	ActiveMDIChild (see page 14013)	Specifies the MDI child that has focus.
	ClientHandle (see page 14024)	Provides access to the handle of the form's internal MDI client window.
	DockManager (see page 14029)	Specifies the control's docking manager interface.
	MDIChildCount (see page 14044)	Specifies the number of open MDI child forms.
	MDIChildren (see page 14044)	Provides indexed access to all MDI child forms.
	TileMode (see page 14059)	Represents how MDI child forms are arranged when the Tile method is called.

Published Properties

	Name	Description
	Action (see page 14011)	Designates the action associated with the control.
	ActiveControl (see page 14012)	Specifies the control that has focus on the form.
	Align (see page 14013)	Determines how the control aligns within its container (parent control).
	AlphaBlend (see page 14017)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 14017)	Specifies the degree of translucency on a translucent form.
	Anchors (see page 14017)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14018)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14018)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14019)	Specifies the bi-directional mode for the control.
	BorderIcons (see page 14019)	Specifies which icons appear on the title bar of the form.
	BorderStyle (see page 14020)	Specifies the appearance and behavior of the form border.
	BorderWidth (see page 14021)	Specifies the width of the control's border.
	Caption (see page 14021)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 14024)	Specifies the height (in pixels) of the form's client area.
	ClientWidth (see page 14025)	Specifies the width (in pixels) of the form's client area.
	Color (see page 14027)	Specifies the background color of the control.
	Constraints (see page 14028)	Specifies the size constraints for the control.

	Ctl3D (see page 14028)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 14029)	Specifies the monitor on which the form appears.
	DockSite (see page 14031)	Specifies whether the control can be the target of drag-and-dock operations.
	DragKind (see page 14032)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14033)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14035)	Controls the attributes of text written on or in the control.
	FormStyle (see page 14036)	Determines the form's style.
	Height (see page 14038)	Specifies the vertical size of the control in pixels.
	HelpFile (see page 14039)	Specifies the name of the file the form uses to display Help.
	HorzScrollBar (see page 14040)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 14041)	Specifies the icon that appears when the form is minimized.
	KeyPreview (see page 14041)	Specifies whether the form should receive keyboard events before the active control.
	Menu (see page 14045)	Specifies the form's main menu.
	ObjectMenuItem (see page 14047)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 14047)	Specifies when OnCreate and OnDestroy events occur.
	Padding (see page 14047)	Specifies the padding of a control.
	ParentBiDiMode (see page 14048)	Specifies whether the control uses its parent's BiDiMode.
	ParentFont (see page 14048)	Determines where a control looks for its font information.
	PixelsPerInch (see page 14049)	Represents the proportion of the font on the system on which the form was designed.
	PopupMenu (see page 14049)	Identifies the pop-up menu associated with the control.
	PopupMode (see page 14054)	Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.
	PopupParent (see page 14054)	Sets an order for stacked forms that users cannot change.
	Position (see page 14055)	Represents the size and placement of the form.
	PrintScale (see page 14056)	Represents the proportions of a printed form.
	Scaled (see page 14056)	Specifies whether the form is sized according to the value of the PixelsPerInch property.
	ScreenSnap (see page 14056)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 14057)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SnapBuffer (see page 14058)	Specifies distance for screen snap.
	TransparentColor (see page 14060)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 14060)	Indicates the color on the form that appears transparent when TransparentColor is true.
	UseDockManager (see page 14060)	Specifies whether the docking manager is used in drag-and-dock operations.
	VertScrollBar (see page 14061)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14062)	Indicates whether the form is visible.
	Width (see page 14063)	Specifies the horizontal size of the control or form in pixels.
	WindowMenu (see page 14063)	Specifies the Window menu for an MDI parent form.
	WindowState (see page 14063)	Represents how the form appears on the screen.

72.1.7.3.1 TForm.Action Property

Designates the action associated with the control.

Pascal

```
property Action: TBasicAction;
```

C++

```
__property TBasicAction Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user

commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list editor, they appear in the drop-down list for the Action property in the Object Inspector.

72.1.7.3.2 TForm.ActiveControl Property

Specifies the control that has focus on the form.

Pascal

```
property ActiveControl: TWinControl;
```

C++

```
__property TWinControl * ActiveControl;
```

Description

Use ActiveControl to get or set the control that has focus on the form. Only one control can have focus at a given time in an application.

If the form does not have focus, ActiveControl is the control on the form that will receive focus when the form receives focus.

Note: When focus shifts to another control, ActiveControl is updated before the OnExit event occurs.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

See Also

ActiveOleControl (see page 13897)

OnExit (see page 6221)

OnEnter (see page 6219)

Active (see page 13896)

72.1.7.3.3 TForm.ActiveMDIChild Property

Specifies the MDI child that has focus.

Pascal

```
property ActiveMDIChild: TForm;
```

C++

```
__property TForm * ActiveMDIChild;
```

Description

Use ActiveMDIChild to get the MDI child that has focus.

If the form is not an MDI parent (that is, if the FormStyle property of the form is not fsMDIForm), ActiveMDIChild returns nil (Delphi) or NULL (C++).

See Also

FormStyle (see page 13912)

MDIChildCount (see page 13921)

72.1.7.3.4 TForm.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
```

```
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}
```

```
var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

Parent (see page 5832)

Anchors (see page 5802)

72.1.7.3.5 TForm.AlphaBlend Property

Specifies whether the form is translucent.

Pascal

```
property AlphaBlend: Boolean;
```

C++

```
__property Boolean AlphaBlend;
```

Description

Set AlphaBlend to specify that the form represents a layered window that allows a translucent color. The AlphaBlendValue property specifies the degree of translucency.

Note: AlphaBlend does not work on all systems. The application must be running under Windows 2000 or better, and the machine must be a P90 or better.

See Also

AlphaBlendValue (see page 13898)

TransparentColor (see page 13938)

72.1.7.3.6 TForm.AlphaBlendValue Property

Specifies the degree of translucency on a translucent form.

Pascal

```
property AlphaBlendValue: Byte;
```

C++

```
__property Byte AlphaBlendValue;
```

Description

Set AlphaBlendValue to a value between 0 and 255 to indicate the degree of translucency when the AlphaBlend property is true. A value of 0 indicates a completely transparent window. A value of 255 indicates complete opacity.

Note: AlphaBlendValue only has an effect when the AlphaBlend property is true.

See Also

AlphaBlend (see page 13898)

TransparentColor (see page 13938)

TransparentColorValue (see page 13939)

72.1.7.3.7 TForm.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

72.1.7.3.8 TForm.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.7.3.9 TForm.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

72.1.7.3.10 TForm.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

72.1.7.3.11 TForm.BorderIcons Property

Specifies which icons appear on the title bar of the form.

Pascal

```
property BorderIcons: TBorderIcons;
```

C++

```
__property TBorderIcons BorderIcons;
```

Description

Use BorderIcons to get or set the icons that appear on the title bar of the form. BorderIcons can include any of the following TBorderIcons values:

Value	Meaning
biSystemMenu	The form has a Control menu (also known as a System menu).

biMinimize	The form has a Minimize button
biMaximize	The form has a Maximize button
biHelp	If BorderStyle is bsDialog or biMinimize and biMaximize are excluded, a question mark appears in the form's title bar and when clicked, the cursor changes to crHelp; otherwise,no question mark appears.

Note: Certain combinations of the BorderIcons and BorderStyle properties are mutually exclusive. For example, BorderIcons biMax, biMin with BorderStyle of bsDialog are mutually exclusive.

Delphi Examples:

```
{
BorderIcons example
The following code removes a form’s Maximize button when the user clicks a button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
BorderIcons := BorderIcons - [biMaximize];
end;
```

See Also

BorderStyle (see page 13900)

72.1.7.3.12 TForm.BorderStyle Property

Specifies the appearance and behavior of the form border.

Pascal

```
property BorderStyle: TFormBorderStyle;
```

C++

```
__property TFormBorderStyle BorderStyle;
```

Description

Use BorderStyle to get or set the appearance and behavior of the form border. BorderStyle can be any of the following TForm BorderStyle values:

Value	Meaning
bsDialog	Not resizable; no minimize/maximize menu
bsSingle	Not resizable; minimize/maximize menu
bsNone	Not resizable; no visible border line
bsSizeable	Standard resizable border
bsToolWindow	like bsSingle but with a smaller caption
bsSizeToolWin	like bsSizeable with a smaller caption

Note: Changing the border style of an MDI child form to bsDialog or bsNone has no effect.

See Also

BorderIcons (see page 13899)

72.1.7.3.13 TForm.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter (see page 6194)

72.1.7.3.14 TForm.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
```

```
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

72.1.7.3.15 TForm.ClientHandle Property

Provides access to the handle of the form's internal MDI client window.

Pascal

```
property ClientHandle: HWND;
```

C++

```
__property HWND ClientHandle;
```

Description

Use ClientHandle to get the handle for the form's internal MDI client window.

ClientHandle is meaningful only if the form is an MDI parent (that is, if the form's FormStyle property is set to fsMDIForm).

Note: Use the Handle property instead to get the handle to the form window itself.

See Also

FormStyle (see page 13912)

Handle (see page 6207)

72.1.7.3.16 TForm.ClientHeight Property

Specifies the height (in pixels) of the form's client area.

Pascal

```
property ClientHeight: Integer;
```

C++

```
__property int ClientHeight;
```

Description

Use ClientHeight to determine the height (in pixels) of the form's client area. The client area is the usable area inside the form's border, excluding the title bar, scroll bars, and so on.

Set ClientHeight to change the height of the form's window based on the desired client area. To change the height of the form's window based on the total size of the window (including the border, menu, status bar and so on), use the Height property instead.

Delphi Examples:

```
{
This example reduces the height of the form's client area by
half when the user clicks the button on the form:
Note that only the client area is halved, not the entire form.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ClientHeight := ClientHeight div 2;
end;
```

See Also

ClientRect

ClientWidth (see page 13905)

Height (see page 5825)

72.1.7.3.17 TForm.ClientWidth Property

Specifies the width (in pixels) of the form's client area.

Pascal

```
property ClientWidth: Integer;
```

C++

```
__property int ClientWidth;
```

Description

Use ClientWidth to determine the width (in pixels) of the form's client area. The client area is the usable area inside the form's border. Set ClientWidth to change the width of the form's window based on the desired client area. To change the width of the form's window based on the total size of the window (including the border, status bar and so on), use the Width property instead.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
```

```
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form’s logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form’s width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
```

```
end;
```

ClientRect

Width (see page 5849)

72.1.7.3.18 TForm.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

72.1.7.3.19 TForm.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

72.1.7.3.20 TForm.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

72.1.7.3.21 TForm.DefaultMonitor Property

Specifies the monitor on which the form appears.

Pascal

```
property DefaultMonitor: TDefaultMonitor;
```

C++

```
__property TDefaultMonitor DefaultMonitor;
```

Description

Use DefaultMonitor to associate a form with a particular monitor in a multi-monitor application. The following table lists the possible values:

Value	Meaning
dmDesktop	No attempt is made to position the form on a specific monitor.
dmPrimary	The form is positioned on the first monitor listed in the global screen object's Monitors property.
dmMainForm	The form appears on the same monitor as the application's main form.
dmActiveForm	The form appears on the same monitor as the currently active form.

Note: DefaultMonitor has no effect if the application does not have a main form.

Active (see page 13896)

Monitor (see page 13926)

MakeFullyVisible (see page 13881)

72.1.7.3.22 TForm.DockManager Property

Specifies the control's docking manager interface.

Pascal

```
property DockManager: IDockManager;
```

C++

```
__property IDockManager DockManager;
```

Description

Use DockManager to specify the control's docking manager. The docking manager handles the layout of docking zones (where controls are docked) and any painting associated with docking zones.

If you set DockSite and UseDockManager to true, but do not assign a value to DockManager, the windowed control generates a

default docking manager, using the global DefaultDockTreeClass variable.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
```

```
    Source: TDragDockObject; X, Y: Integer);
  begin
    //OnDockDrop gets called AFTER the client has actually docked,
    //so we check for DockClientCount = 1 before making the dock panel visible.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, True, nil);
    (Sender as TPanel).DockManager.ResetBounds(True);
    //Make DockManager repaints it's clients.
  end;

  procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
    Source: TDragDockObject; X, Y: Integer; State: TDragState;
    var Accept: Boolean);
  var
    ARect: TRect;
  begin
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

See Also

DockSite (see page 6204)

UseDockManager (see page 6212)

DefaultDockTreeClass (see page 6321)

72.1.7.3.23 TForm.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite: Boolean;
```

C++

```
__property Boolean DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

72.1.7.3.24 TForm.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

72.1.7.3.25 TForm.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
```

```
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;
```

Arranging the Order of Persistent Columns

72.1.7.3.26 TForm.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

72.1.7.3.27 TForm.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;
```

```
procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

72.1.7.3.28 TForm.FormStyle Property

Determines the form's style.

Pascal

```
property FormStyle: TFormStyle;
```

C++

```
__property TFormStyle FormStyle;
```

Description

Use FormStyle to get or set the form's style. FormStyle is one of the following values:

Value	Meaning
fsNormal	The form is neither an MDI parent window nor an MDI child window.
fsMDIChild	The form is an MDI child window.
fsMDIForm	The form is an MDI parent window.
fsStayOnTop	This form remains on top of the desktop and of other forms in the project, except any others that also have FormStyle set to fsStayOnTop. If one fsStayOnTop form launches another, neither form will consistently remain on top.

If the form is the main form of an MDI application, its FormStyle property must be set to fsMDIForm.

Note: It is not advisable to change FormStyle at runtime.

Warning: TGraphicControl descendants placed in the client area of a form with FormStyle set to fsMDIForm will not paint.

C++ Examples:

```
/*
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
*/
void __fastcall TForm1::MyArrangeIconsClick(TObject *Sender)
{
```

```
  Form1->ArrangeIcons();
}
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
  Tile();
}
```

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items MyArrangeIcons. This is code for the
MyArrangeIconsClick handler.  When the user chooses the
ArrangeIcons command, minimized child forms are arranged
so that they are evenly spaced and don't overlap.  DO NOT
name the menu items "ArrangeIcons" as that will override
the TForm method.
}
procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;
{
This example ensures that the main form of the application
is an MDI parent:
}
type
  TForm1 = class(TForm)
    Edit1: TEdit;
  private
    { Private declarations }
  public
    { Public declarations }
    constructor Create(AOwner : TComponent); override;
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

constructor TForm1.Create(AOwner : TComponent);

begin
  inherited Create(AOwner);
  if FormStyle <> fsMDIForm then
          FormStyle := fsMDIForm;
  if FormStyle = fsMDIForm then
          Edit1.Text := 'MDI form'
  else
    //This line never executes
```

```
    Edit1.Text := 'Not an MDI form';
end;
{
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
}
procedure TForm1.TileFormsClick(Sender: TObject);
begin
  TileMode := tbVertical;
  Tile;
end;
```

Windows Overview

72.1.7.3.29 TForm.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
```

```
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
    end;
end;
```

Using TDBListBox and TDBComboBox

72.1.7.3.30 TForm.HelpFile Property

Specifies the name of the file the form uses to display Help.

Pascal

```
property HelpFile: string;
```

C++

```
__property AnsiString HelpFile;
```

Description

Use HelpFile for forms that have a help file to use with the Help system. Help topics are selected from the specified file.

See Also

HelpContext (see page 5826)

OnHelp (see page 13959)

HelpFile (see page 13711)

HelpKeyword (see page 5826)

72.1.7.3.31 TForm.HorzScrollBar Property

Represents the horizontal scroll bar for the scrolling windowed control.

Pascal

```
property HorzScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar HorzScrollBar;
```

Description

Use HorzScrollBar to hide, show, or manipulate the horizontal scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
```

See Also

AutoScroll (see page 14329)

VertScrollBar (see page 14330)

TControlScrollBar (see page 13744)

72.1.7.3.32 TForm.Icon Property

Specifies the icon that appears when the form is minimized.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Set the Icon property to provide an icon for the form. If Icon is not set, the system provides a default icon when the form is minimized.

Delphi Examples:

```
{
This code assigns an icon to a form when the form is created:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Icon.LoadFromFile('MDIChild1.ICO');
end;
```

See Also

WindowState (see page 13942)

72.1.7.3.33 TForm.KeyPreview Property

Specifies whether the form should receive keyboard events before the active control.

Pascal

```
property KeyPreview: Boolean;
```

C++

```
__property Boolean KeyPreview;
```

Description

If KeyPreview is true, keyboard events occur on the form before they occur on the active control. (The active control is specified by the ActiveControl property.)

If KeyPreview is false, keyboard events occur only on the active control.

Navigation keys (Tab, BackTab, the arrow keys, and so on) are unaffected by KeyPreview because they do not generate keyboard events. Similarly, when a button has focus or when its Default property is true, the Enter key is unaffected by KeyPreview because it does not generate a keyboard events.

KeyPreview is false by default.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
```

```
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
```

```
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
  {
  The following code aborts a print job if the user presses
  Esc. Note that you should set KeyPreview to true to ensure
  that the OnKeyDown event handler of Form1 is called.
  }

  uses Printers;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, X, Y: Integer;
    Memo1 : TMemo;
    r: TRect;
  begin
    Memo1 := TMemo.Create(Form1);
    Memo1.Parent := Form1;
    Memo1.Visible := True;
    Memo1.Width := 700;
    if (OpenDialog1.Execute) then
    begin
      Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
     KeyPreview := True;
  end;

  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
  if (Key=VK_ESCAPE) and Printer.Printing then
    begin
    Printer.Abort;
    MessageDlg('Printing aborted', mtInformation, [mbOK],0);
    end;
  end;
```

72.1.7.3.34 TForm.MDIChildCount Property

Specifies the number of open MDI child forms.

Pascal

```
property MDIChildCount: Integer;
```

C++

```
__property int MDIChildCount;
```

Description

Use MDIChildCount to get the number of open MDI child forms.

MDIChildCount is meaningful only if the form is an MDI parent (that is, if the form's FormStyle property is set to fsMDIForm).

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items CloseChildren. This is code for the
CloseChildrenClick handler.  When the user chooses the
CloseChildren command, all the MDI children of Form1 are
closed.
}
procedure TForm1.CloseChildrenClick(Sender: TObject);
var
  I: Integer;
begin
  with Form1 do
    for I := MDIChildCount-1 downto 0 do
      MDIChildren[I].Close;
end;

procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;

procedure TForm1.MyCascadeClick(Sender: TObject);
begin
  Form1.Cascade;
end;
```

See Also

MDIChildren (see page 13922)

72.1.7.3.35 TForm.MDIChildren Property

Provides indexed access to all MDI child forms.

Pascal

```
property MDIChildren [I: Integer]: TForm;
```

C++

```
__property TForm * MDIChildren[int I];
```

Description

Use MDIChildren to access a child form.

I is the index of the child form to access. The order of MDI children changes as different MDI forms are activated. Initially, forms are listed in creation order, with new forms being added to the end of the array. Whenever an MDI child is activated, however, it moves to the front of the list. Thus, use I to index over all forms in the array, but not to refer to a specific form.

MDIChildren is meaningful only if the form is an MDI frame (that is, if the form's FormStyle property is set to fsMDIForm).

Delphi Examples:

```
{
This example uses several forms. The first form has its
FormStyle property set to MDIForm. The others have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items CloseChildren. This is code for the
CloseChildrenClick handler.  When the user chooses the
CloseChildren command, all the MDI children of Form1 are
closed.
}
procedure TForm1.CloseChildrenClick(Sender: TObject);
var
  I: Integer;
begin
  with Form1 do
    for I := MDIChildCount-1 downto 0 do
      MDIChildren[I].Close;
end;

procedure TForm1.MyArrangeIconsClick(Sender: TObject);
begin
  Form1.ArrangeIcons;
end;

procedure TForm1.MyCascadeClick(Sender: TObject);
begin
  Form1.Cascade;
end;
```

See Also

MDIChildCount (see page 13921)

FormStyle (see page 13912)

72.1.7.3.36 TForm.Menu Property

Specifies the form's main menu.

Pascal

```
property Menu: TMainMenu;
```

C++

```
__property TMainMenu Menu;
```

Description

Use Menu to get or set the form's main menu. At design time, Menu is set to the first TMainMenu component added to the form.

C++ Examples:

```
/*
This code displays a new menu named MyMenu when the user
clicks the button. MyOnExecute must be included in the
definition of the TForm1 class.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMenuItem *Item1 = NewItem("New item", TextToShortCut("Ctrl+N"), false, true, MyOnExecute,
0, "Item1");
  Menu = NewMenu(this, "MyMenu", &Item1, 0);
}

void __fastcall TForm1::MyOnExecute(TObject *Sender)
{
  MessageDlg("Item1 has been executed.", mtInformation, TMsgDlgButtons() << mbOK, 0);
}
/*
To create a toolbar that corresponds to an existing menu:

1   Drop a ToolBar on the form and add a ToolButton for each
  top-level menu item you wish to create.
2   Set the MenuItem property of each ToolButton to correspond
  to the top level menu items.
3   Set the Grouped property of each ToolButton to true.
4   Clear the Menu property of the Form (if it is assigned)
5   Set the Visible property on the ToolBar and ToolButtons to
  true.
6   Set the ShowCaptions property on the ToolBar to true.
7   Set the MenuItem | Visible property of each ToolButton to
  true.
*/
```

Delphi Examples:

```
{
This code displays a new menu named MyMenu when the user
clicks the button. MyOnExecute must be included in the
definition of the TForm1 class.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Menu := NewMenu(Self, 'MyMenu',
            [NewItem('New item', TextToShortCut('Ctrl+N'),
            False, True, MyOnExecute, 0, 'Item1')]);
end;

procedure TForm1.MyOnExecute(Sender: TObject);
begin
  MessageDlg('Item1 has been executed.', mtInformation, [mbOK], 0);
end;
{
To create a toolbar that corresponds to an existing menu:

1   Drop a ToolBar on the form and add a ToolButton for each top-level menu item you wish to
create.
2   Set the MenuItem property of each ToolButton to correspond to the top level menu items.
3   Set the Grouped property of each ToolButton to true.
4   Clear the Menu property of the Form (if it is assigned)
5   Set the Visible property on the ToolBar and ToolButtons to true.
6   Set the ShowCaptions property on the ToolBar to true.
7   Set the MenuItem | Visible property of each ToolButton to true.
}
```

See Also

TMainMenu (see page 16056)

72.1.7.3.37 TForm.ObjectMenuItem Property

Represents an OLE object menu item that reacts to selections of OLE objects.

Pascal

```
property ObjectMenuItem: TMenuItem;
```

C++

```
__property TMenuItem ObjectMenuItem;
```

Description

Use ObjectMenuItem to get or set a menu item that becomes enabled or disabled when an OLE object on the form is selected or unselected respectively.

The OLE object menu item can be used for standard OLE commands, such as Activate or Convert. (The implementations of these commands are provided by the OLE server.)

See Also

OleFormObject (see page 13927)

72.1.7.3.38 TForm.OldCreateOrder Property

Specifies when OnCreate and OnDestroy events occur.

Pascal

```
property OldCreateOrder: Boolean;
```

C++

```
__property Boolean OldCreateOrder;
```

Description

When OldCreateOrder is false (the default) the OnCreate event occurs after all constructors are finished and the OnDestroy event occurs before any destructors are called.

This differs from earlier versions of the library (distributed with Delphi version 3 and previous and C++Builder 1), where the OnCreate event occurred when the TCustomForm constructor executed and the OnDestroy event occurred when the TCustomForm destructor executed. Applications that require the OnCreate event and OnDestroy events to occur from the constructor and destructor of the form can set OldCreateOrder to true.

See Also

OnCreate (see page 13951)

OnDestroy (see page 13953)

BeforeDestruction (see page 13866)

AfterConstruction (see page 13866)

72.1.7.3.39 TForm.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding: TPadding;
```

C++

```
__property TPadding Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding (see page 6103)

72.1.7.3.40 TForm.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

72.1.7.3.41 TForm.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

72.1.7.3.42 TForm.PixelsPerInch Property

Represents the proportion of the font on the system on which the form was designed.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

Use PixelsPerInch at runtime to change how the form is scaled to the current screen resolution. If PixelsPerInch is changed from its default value, the form will not have the same proportion on every screen resolution.

At design time, PixelsPerInch is set automatically when the form is saved. Changes to PixelsPerInch made in the Object Inspector only affect the form at runtime.

The form's Scaled property must be true for PixelsPerInch to have an effect.

See Also

Scaled (see page 13935)

72.1.7.3.43 TForm.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
```

```
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.

    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
```

```
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.

72.1.7.3.44 TForm.PopupMode Property

Controls (see page 5711) how the top-level form behaves with respect to Window's WS_POPUP style.

Pascal

```
property PopupMode: TPopupMode;
```

C++

```
__property TPopupMode PopupMode;
```

Description

The PopupMode property controls how the top-level form behaves with respect to Window's WS_POPUP style. A window that has the WS_POPUP style is always above its "owner" in Z-order. You can use the PopupMode property in conjunction with the PopupParent (see page 14054) property to avoid the appearance of a hung application caused by a modal dialog showing up behind another form on the screen.

Note: Using the PopupMode property is similar to specifying fsStayOnTop for the FormStyle (see page 14036) property, but allows better control over the layering.

The PopupMode property is automatically set to pmAuto when the ShowModal (see page 13890) method is called. However, this causes the window handle to be recreated, which is not usually desirable. To avoid the re-creation of window handles, you can explicitly set the PopupMode property to pmAuto prior to calling the ShowModal (see page 13890) method (such as at design time).

Set the PopupMode property to pmExplicit for non-modal design windows such as tool palettes and other floating tool windows. This causes the windows to always remain on top of the main form. In the case of a snapped together design (in which the window is docked to the main form), the design window remains on top of the designer.

Note: For undocked windows, the design window remains above the main form, allowing other top-level forms to obscure the design window.

Set thePopupMode property to pmNone if you want the popup window to have the pre-Delphi 8 behavior (except for the ShowModal (see page 13890) item mentioned above).

You can force the Z-Ordering of your forms and create a "stacked" appearance that the user cannot change by setting the PopupParent (see page 14054) property to an explicit TCustomForm (see page 13849). If the PopupMode property is pmExplicit and PopupParent (see page 14054) is nil, then the Application.MainForm is implicitly used as the PopupParent (see page 14054). If no Application.MainForm is assigned, then Application.Handle is used as the PopupParent (see page 14054). If the PopupMode property is set to pmAuto, Screen.ActiveForm is used as the PopupParent (see page 14054).

72.1.7.3.45 TForm.PopupParent Property

Sets an order for stacked forms that users cannot change.

Pascal

```
property PopupParent: TCustomForm;
```

C++

```
__property TCustomForm PopupParent;
```

Description

If the PopupMode property is set to pmExplicit and PopupParent is nil, then the Application.MainForm is implicitly used as the

PopupParent. If no Application.MainForm is assigned, then Application.Handle is used as the PopupParent.

If the PopupMode property is set to pmAuto, Screen.ActiveForm is used as the PopupParent property.

72.1.7.3.46 TForm.Position Property

Represents the size and placement of the form.

Pascal

```
property Position: TPosition;
```

C++

```
__property TPosition Position;
```

Description

Use Position to get or set the size and placement of the form. Position can have one of the following TPosition values:

Value	Meaning
poDesigned	The form appears positioned on the screen and with the same height and width as it had at design time.
poDefault	The form appears in a position on the screen and with a height and width determined by the operating system. Each time you run the application, the form moves slightly down and to the right. The right side of the form is always near the far right side of the screen, and the bottom of the form is always near the bottom of the screen, regardless of the screen's resolution. The operating system only supports this for overlapped windows. For a pop-up or child window (that has a BorderStyle of bsDialog or bsNone, for example), the window is positioned in the upper left corner of the screen.
poDefaultPosOnly	The form displays with the size you created it at design time, but the operating system chooses its position on the screen. Each time you run the application, the form moves slightly down and to the right. When the form can no longer move down and to the right and keep the same size while remaining entirely visible on the screen, the form displays at the top-left corner of the screen. The operating system only supports this for overlapped windows. For a pop-up or child window (that has a BorderStyle of bsDialog or bsNone, for example), the window is positioned in the upper left corner of the screen.
poDefaultSizeOnly	The form appears in the position you left it at design time, but the operating system chooses its size. The right side of the form is always near the far right side of the screen, and the bottom of the form is always near the bottom of the screen, regardless of the screen's resolution.
poScreenCenter	The form remains the size you left it at design time, but is positioned in the center of the screen. In multi-monitor applications, the form may be moved from this center position so that it falls entirely on one monitor, as specified by the DefaultMonitor property.
poDesktopCenter	The form remains the size you left it at design time, but is positioned in the center of the screen. No adjustments are made for multi-monitor applications.
poMainFormCenter	The form remains the size you left it at design time, but is positioned in the center of the application's main form. No adjustments are made for multi-monitor applications. This position should only be used with secondary forms. If set for a main form, it acts like poScreenCenter.
poOwnerFormCenter	The form remains the size you left it at design time, but is positioned in the center of the form specified by the Owner property. If the Owner property does not specify a form, this position acts like poMainFormCenter.

SetInitialBounds

72.1.7.3.47 TForm.PrintScale Property

Represents the proportions of a printed form.

Pascal

```
property PrintScale: TPrintScale;
```

C++

```
__property TPrintScale PrintScale;
```

Description

Use PrintScale to get or set the proportions of the printed form. PrintScale can have one of the following TPrintScale values:

Value	Meaning
poNone	No special scaling occurs; therefore, the printed form and how the form appears onscreen may appear squished or stretched.
poProportional	The form is printed so that the printed image is approximately the same visible size as on the screen (WYSIWYG). The form image is scaled so that the printed image is approximately the same visible size as on the screen.
poPrintToFit	The form is printed using the same screen proportions, but in a size that just fits the printed page.

See Also

Print (see page 13883)

72.1.7.3.48 TForm.Scaled Property

Specifies whether the form is sized according to the value of the PixelsPerInch property.

Pascal

```
property Scaled: Boolean;
```

C++

```
__property Boolean Scaled;
```

Description

Scaled determines whether the form adjusts itself to differences between the font used at design time and the current system font used by a system at runtime. If Scaled is true, the form resizes itself and all its child controls to maintain the relationship between the size of controls and the height of text displayed in the default font. If Scaled is false, no such resizing occurs.

By setting Scaled to true, the form can adjust to fonts that are not scalable (that is, fonts that only supply discrete point sizes) or to differences such as forms designed using small fonts at design time that are run on systems that use large fonts.

The degree of resizing is determined by the PixelsPerInch property, which measures the proportion of the font on the system used when designing the form.

See Also

PixelsPerInch (see page 13928)

Considerations When Dynamically Resizing Forms and Controls

72.1.7.3.49 TForm.ScreenSnap Property

Specifies whether form snaps to edge of screen.

Pascal

```
property ScreenSnap: Boolean;
```

C++

```
__property Boolean ScreenSnap;
```

Description

ScreenSnap determines whether the edges of the form snap to the edge of the screen when the user moves the form. To control the snap distance, set the SnapBuffer property.

See Also

SnapBuffer (see page 13936)

72.1.7.3.50 TForm.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
```

```
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Hint (see page 5827)

ParentShowHint (see page 5835)

ShowHint (see page 13721)

Displaying Fly-over Help

72.1.7.3.51 TForm.SnapBuffer Property

Specifies distance for screen snap.

Pascal

```
property SnapBuffer: Integer;
```

C++

```
__property int SnapBuffer;
```

Description

If ScreenSnap is true, SnapBuffer determines the maximum number of pixels that be between the form edge and the screen edge before the form snaps to the screen edge.

See Also

ScreenSnap (see page 13935)

72.1.7.3.52 TForm.TileMode Property

Represents how MDI child forms are arranged when the Tile method is called.

Pascal

```
property TileMode: TTileMode;
```

C++

```
__property TTileMode TileMode;
```

Description

TileMode can have one of the following TTileMode values:

Value	Meaning
tbHorizontal	Each form stretches across the width of the parent form
tbVertical	Each form stretches along the height of the parent form

TileMode is meaningful only if the form is an MDI child (that is, if the form's FormStyle property is set to fsMDIChild).

C++ Examples:

```
/*
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
*/
void __fastcall TForm1::TileFormsClick(TObject *Sender)
{
  TileMode = tbVertical;
  Tile();
}
```

Delphi Examples:

```
{
This example uses three forms. The first form has its
FormStyle property set to MDIForm. The other two have their
FormStyle properties set to MDIChild and their Visible
properties set to true. Add a main menu component and name
one of the menu items TileForms. This is code for the
TileFormsClick handler.  When the user chooses the TileForms
command, the child forms tile vertically within the MDI frame
form.
}
procedure TForm1.TileFormsClick(Sender: TObject);
begin
  TileMode := tbVertical;
  Tile;
end;
```

See Also

FormStyle (see page 13912)

Tile (see page 14009)

72.1.7.3.53 TForm.TransparentColor Property

Specifies whether a color on the form appears transparent.

Pascal

```
property TransparentColor: Boolean;
```

C++

```
__property Boolean TransparentColor;
```

Description

Use TransparentColor to indicate that one of the colors on the form should be treated as transparent, allowing windows behind the form to completely show through. The TransparentColorValue property indicates the color that appears completely transparent.

Note: To make the entire form transparent, or to make it translucent rather than transparent, use the AlphaBlend and AlphaBlendValue properties.

Note: TransparentColor does not work on all systems. The application must be running under Windows 2000 or better, with adequate hardware.

See Also

TransparentColorValue (see page 13939)

AlphaBlend (see page 13898)

AlphaBlendValue (see page 13898)

72.1.7.3.54 TForm.TransparentColorValue Property

Indicates the color on the form that appears transparent when TransparentColor is true.

Pascal

```
property TransparentColorValue: TColor;
```

C++

```
__property TColor TransparentColorValue;
```

Description

Use TransparentColorValue to indicate the color that appears transparent when the TransparentColor property is true.

Note: If the application uses a 16-bit color palette, TransparentColorValue must be a basic color.

See Also

TransparentColor (see page 13938)

72.1.7.3.55 TForm.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager: Boolean;
```

C++

```
__property Boolean UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

See Also

DockManager (see page 6202)

72.1.7.3.56 TForm.VertScrollBar Property

Represents the vertical scroll bar for the scrolling windowed control.

Pascal

```
property VertScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar VertScrollBar;
```

Description

Use VertScrollBar to hide, show, or manipulate the vertical scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

See Also

AutoScroll (see page 14329)

HorzScrollBar (see page 14329)

TControlScrollBar (see page 13744)

72.1.7.3.57 TForm.Visible Property

Indicates whether the form is visible.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use Visible to determine whether the form is visible.

If Visible is true, the form is visible unless it is completely obscured by other forms. If Visible is false, the form is not visible.

The Show and ShowModal methods set Visible to true and bring the form to the front of all open windows.

C++ Examples:

```
/*
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must include Unit2.h in this
module.
*/
#include "Unit2.h"

void __fastcall TForm1::ShowPaletteButtonClick(TObject *Sender)
{
  if (!Form2->Visible)
  {
    Form2->Visible = true;
    Form2->BringToFront();
  }
}
```

Delphi Examples:

```
{
The following code uses two forms. Form1 has a button on it. The
second form is used as a tool palette. This code makes the palette
form visible, and ensures it is the top form by bringing it to the
front.  To run this example, you must add Unit2 in the uses clause
of your unit.
}
procedure TForm1.ShowPaletteButtonClick(Sender: TObject);
begin
if Form2.Visible = False then Form2.Visible := True;
Form2.BringToFront;
end;
```

See Also

BringToFront (see page 5740)

Show (see page 13888)

ShowModal (see page 13890)

72.1.7.3.58 TForm.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

See Also

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

72.1.7.3.59 TForm.WindowMenu Property

Specifies the Window menu for an MDI parent form.

Pascal

```
property WindowMenu: TMenuItem;
```

C++

```
__property TMenuItem WindowMenu;
```

Description

Use WindowMenu to get or set the Window menu for an MDI parent form. The Window menu is a standard menu in MDI applications. It contains commands that let the user manage the windows in the application. Menu items usually include Cascade, Arrange Icons, Tile, and so on.

The Window menu also lists (at the bottom) the child windows that are currently open in the application. When the user selects one of these windows from the menu, the window becomes the active window in the application.

Although this menu is commonly called the Window menu, it can have any name that corresponds to an existing menu item on the menu bar. The names of open child forms are merged onto the menu automatically at run-time.

WindowMenu is meaningful only if the form is an MDI parent (that is, if the form's FormStyle property is set to fsMDIForm).

72.1.7.3.60 TForm.WindowState Property

Represents how the form appears on the screen.

Pascal

```
property WindowState: TWindowState;
```

C++

```
__property TWindowState WindowState;
```

Description

Set WindowState to minimize, maximize, or restore the form window. Read WindowState to determine whether the form is minimized, maximized, or in a normal state.

72.1.7.4 TForm Events

The events of the TForm class are listed here.

Published Events

	Name	Description
	OnActivate (see page 14065)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14069)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14070)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14070)	Occurs when the user clicks the control.
	OnClose (see page 14072)	Occurs when the form closes.
	OnCloseQuery (see page 14073)	Occurs when close is attempted.
	OnConstrainedResize (see page 14074)	Adjust resize constraints.
	OnContextPopup (see page 14075)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 14076)	Occurs when the form is created.
	OnDblClick (see page 14077)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 14078)	Occurs when the form loses focus.
	OnDestroy (see page 14078)	Occurs when the form is destroyed.
	OnDockDrop (see page 14079)	Occurs when another control is docked to the control.
	OnDockOver (see page 14081)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14083)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnGetSiteInfo (see page 14088)	Returns the control's docking information.
	OnHelp (see page 14090)	Occurs when the form receives a request for help.
	OnHide (see page 14091)	Occurs when the form is hidden (that is, when its Visible property is set to false).
	OnKeyDown (see page 14093)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14095)	Occurs when a key is pressed.
	OnKeyUp (see page 14096)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14098)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14099)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14101)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14102)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14102)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14104)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

	OnMouseWheel (see page 14107)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14107)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14107)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 14108)	Occurs when the form is redrawn.
	OnResize (see page 14109)	Occurs immediately after the control is resized.
	OnShortCut (see page 14109)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShow (see page 14110)	Occurs when the form is shown (that is, when its Visible property is set to true).
	OnStartDock (see page 14111)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnUnDock (see page 14111)	Occurs when the application tries to undock a control that is docked to the windowed control.

72.1.7.4.1 TForm.OnActivate Event

Occurs when the form becomes active.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Use OnActivate to perform special processing when the form receives focus. A form becomes active when focus is transferred to it (when the user clicks on the form, for example).

Note: The OnActivate event of the application (TApplication), not the form, occurs when Windows switches control from another application.

Delphi Examples:

```
{
Here is the code on Form1 that fills the list box.
}
var
  Form1: TForm1;
  Customers: TTable;
  Blobs: TTable;
  Form1Done : Boolean;
  procedure CreateMyTable;
  procedure CreateCustSource;
  procedure CreateBlobSource;

implementation

{$R *.dfm}

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  CreateCustSource;
  CreateBlobSource;
  for I := 0 to ComponentCount - 1 do
  begin
    if (Components[I] is TDataSource) then
      ListBox1.Items.AddObject(Components[I].Name,
        Components[I] as TObject);
  end;
end;
```

```
procedure CreateCustSource();
begin
  Customers:= TTable.Create(Form1);
  with Customers do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'MyCustInfo';
    ReadOnly:= False;

//    Don't overwrite an existing table
    if (not Customers.Exists) then CreateMyTable
    else
    begin
      if (Customers.Exists AND
        (MessageDlg('MyCustInfo table already exists.  Do you want to rebuild it?',
mtConfirmation, [mbYes, mbNo], 0) = mrYes)) then
      begin
        Customers.Close;
        Customers.DeleteTable;
        CreateMyTable;
      end;
    end;
  end;
  Form1.CustomerDS.DataSet:= Customers;
  Customers.Active:= True;
end;

procedure CreateMyTable();
var
  i: Integer;
begin
//      The Table component must not be active
//      First, describe the type of table and give
//      it a name
//      Next, describe the fields in the table
  with Customers do
  begin
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
        begin
          Name := 'Field2';
          DataType := ftString;
          Size := 30;
        end;
        with AddFieldDef do
        begin
          Name := 'Field3';
          DataType := ftString;
          Size := 30;
        end;
        with AddFieldDef do
        begin
          Name := 'Field4';
          DataType := ftString;
          Size := 30;
        end;
```

```
      end;

//    Take out this part to remove indexing
//    Next, describe any indexes
      with IndexDefs do
      begin
        Clear;
//        The 1st index has no name because it is
//        a Paradox primary key
        with AddIndexDef do
        begin
          Name := '';
          Fields := 'Field1';
          Options := [ixPrimary];
        end;
        with AddIndexDef do
        begin
          Name := 'Fld2Indx';
          Fields := 'Field2';
          Options := [ixCaseInsensitive];
        end;
      end;

//      Call the CreateTable method to create the table
      CreateTable;
      Customers.Active:= True;
      for i := 1 to 20 do
        Customers.AppendRecord([i*111, i*222, i*333, i*444]);
    end;
end;

procedure CreateBlobSource;
var
  i: Integer;
begin
  Blobs:= TTable.Create(Form1);
  with Blobs do
  begin
    DatabaseName := 'DBDEMOS';
    TableType := ttParadox;
    TableName := 'MyBlobInfo';
    Blobs.Active := False;
    { Don't overwrite an existing table }
//    if Blobs.Exists then
//      MessageDlg('CustInfo table already exists.', mtWarning, [mbOK], 0)
//    else
    begin
      if (Blobs.Exists) then
      begin
        Blobs.Close;
        Blobs.DeleteTable;
      end;
      { The Table component must not be active }
      { First, describe the type of table and give }
      { it a name }
      { Next, describe the fields in the table }
      with FieldDefs do
      begin
        Clear;
        with AddFieldDef do
        begin
          Name := 'Field1';
          DataType := ftInteger;
          Required := True;
        end;
        with AddFieldDef do
```

```
          begin
            Name := 'Field2';
            DataType := ftBlob;
            Size := 30;
          end;
        end;
        { Next, describe any indexes }
        with IndexDefs do
        begin
          Clear;
          { The 1st index has no name because it is
          { a Paradox primary key }
          with AddIndexDef do
          begin
            Name := '';
            Fields := 'Field1';
            Options := [ixPrimary];
          end;
{
          with AddIndexDef do
          begin
            Name := 'Fld2Indx';
            Fields := 'Field2';
            Options := [ixCaseInsensitive];
          end;
}
        end;
        { Call the CreateTable method to create the table }
        CreateTable;
        Blobs.Active:= True;
        for i := 1 to 20 do
          Blobs.AppendRecord([i*111, IntToStr(i*222)]);
      end;
    end;
    Form1.BlobDS.DataSet:= Blobs;
    Blobs.Active:= True;
  end;

  procedure TForm1.ListBox1MouseDown(Sender: TObject; Button: TMouseButton;
    Shift: TShiftState; X, Y: Integer);
  begin
    Form1Done := True;
  end;

  initialization

  Form1Done := False;
  {
  The following code sets the DataSource for a DBGrid
  component in Form2 to the currently selected data source in
  a list provided in Form1. This allows users to specify the
  desired information in Form1, and then move to Form2 to view
  the information. Select an item in the listbox and then
  activate Form2 by clicking in it.
  }
  procedure TForm2.FormActivate(Sender: TObject);
  begin
    if (Form1Done) then
    begin
      DBGrid2.DataSource :=
        Form1.ListBox1.Items.Objects[Form1.ListBox1.ItemIndex] as TDataSource;
      DBNavigator2.DataSource :=
        Form1.ListBox1.Items.Objects[Form1.ListBox1.ItemIndex] as TDataSource;
    end;
  end;
```

OnDeactivate (see page 13953)

OnActivate (see page 13726)

72.1.7.4.2 TForm.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

72.1.7.4.3 TForm.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

72.1.7.4.4 TForm.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize (see page 5853)

SetBounds (see page 5783)

OnResize (see page 5870)

72.1.7.4.5 TForm.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

72.1.7.4.6 TForm.OnClose Event

Occurs when the form closes.

Pascal

```
property OnClose: TCloseEvent;
```

C++

```
__property TCloseEvent OnClose;
```

Description

Use OnClose to perform special processing when the form closes. The OnClose event specifies which event handler to call when a form is about to close. The handler specified by OnClose might, for example, test to make sure all fields in a data-entry form have valid contents before allowing the form to close.

A form is closed by the Close method or when the user chooses Close from the form's system menu.

The TCloseEvent type points to a method that handles the closing of a form. The value of the Action parameter determines if the form actually closes. These are the possible values of Action:

Value	Meaning
caNone	The form is not allowed to close, so nothing happens.
caHide	The form is not closed, but just hidden. Your application can still access a hidden form.
caFree	The form is closed and all allocated memory for the form is freed.
caMinimize	The form is minimized, rather than closed. This is the default action for MDI child forms.

If a form is an MDI child form, and its BorderIcons property is biMinimize, then the default Action is caMinimize. If a MDI child form does not have these settings, the default Action is caNone, meaning that nothing happens when the user attempts to close the form.

If a form is an SDI child form, Action defaults to caHide.

To close the form and free it in an OnClose event, set Action to caFree.

Note: When the application shuts down, the main form receives an OnClose event, but any child forms do not receive the OnClose event.

C++ Examples:

```
/*
This example displays a message dialog box when the user
attempts to close the form. If the user clicks the Yes
button, the form closes; otherwise, the form only minimizes.
TCustomForm.Close does not allow an action of caMinimize
for a form closing itself.  Close Form2 from Form1 (from
a button?) and implement the OnClose in Form2.  Place
"Application.CreateForm(TForm2, Form2);" in the project dpr
file to open Form2 and set the Form2 Visible property to
True.
*/
void __fastcall TForm2::FormClose(TObject *Sender, TCloseAction &Action)
{
  if (MessageDlg("Close application ?", mtConfirmation, TMsgDlgButtons() << mbYes << mbNo,0)
== mrYes)
    Action = caFree;
  else
    Action = caMinimize;
}
```

OnCreate (see page 13951)

OnCloseQuery (see page 13950)

OnDestroy (see page 13953)

72.1.7.4.7 TForm.OnCloseQuery Event

Occurs when close is attempted.

Pascal

```
property OnCloseQuery: TCloseQueryEvent;
```

C++

```
__property TCloseQueryEvent OnCloseQuery;
```

Description

Use OnCloseQuery to specify the conditions under which the form can close. An OnCloseQuery event handler returns a Boolean CanClose value that determines whether a form is allowed to close. Its default value is true.

You can use an OnCloseQuery event handler to ask users if they are sure they really want the form closed immediately. For example, you can use the handler to display a message box that prompts the user to save a file before closing the form.

The TCloseQueryEvent type points to the method that determines whether a form can be closed. The value of the CanClose parameter determines if the form can close or not.

C++ Examples:

```
/*
When the user attempts to close the form in this example, a
message dialog appears that asks the user if it is OK to
close the form. If the user chooses the OK button, the form
closes. If the user chooses Cancel, the form doesn't close.
Populate the OnCloseQuery event handler of the form.
*/
void __fastcall TForm1::FormCloseQuery(TObject *Sender, bool &CanClose)
{
  if (MessageDlg("Close the form?", mtConfirmation, TMsgDlgButtons() << mbOK << mbCancel,0) ==
mrCancel)
    CanClose = false;
}
```

Delphi Examples:

```
{
When the user attempts to close the form in this example, a
message dialog appears that asks the user if it is OK to
close the form. If the user chooses the OK button, the form
closes. If the user chooses Cancel, the form doesn't close.
Populate the OnCloseQuery event handler of the form.
}
procedure TForm1.FormCloseQuery(Sender: TObject; var CanClose: Boolean);
begin
  if MessageDlg('Close the form?', mtConfirmation,
    [mbOk, mbCancel], 0) = mrCancel then
     CanClose := False;
end;
```

See Also

OnClose (see page 13949)

72.1.7.4.8 TForm.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize: TConstrainedResizeEvent;
```

C++

```
__property TConstrainedResizeEvent OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's

Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

72.1.7.4.9 TForm.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

72.1.7.4.10 TForm.OnCreate Event

Occurs when the form is created.

Pascal

```
property OnCreate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCreate;
```

Description

Use OnCreate to perform special processing when the form is created and is invoked by TCustomForm's constructor. Either implement this event or override the constructor of the form; do not do both. Any objects created in the OnCreate event should be freed by the OnDestroy event.

When a form is being created and its Visible property is true, the following events occur in the order listed:

1. OnCreate2. OnShow3. OnActivate4. OnPaint

Note: Use of the OnCreate event is discouraged in C++ code because it can interact badly with the form's constructor (see OldCreateOrder). It is recommended that you override the form constructor instead.

C++ Examples:

```
/*
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
page of the component palette.  The form OnCreate event handler
adds several new TabSheet controls to the Page Control.  The
UpDown1Click event handler fires when the user clicks the up or
down button on the TUpDown control.  The SelectNextPage method of
the Page Control goes forward the comparison (Button = btNext)
evaluates as true.  If Button is not btNext, the previous Tab Page
is selected.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
const
  TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *page = new TTabSheet(PageControl1);
    page->PageControl = PageControl1;
    page->Caption = AnsiString("Page") + IntToStr(i);
    page->Brush->Color = colorPalette[i];
  }
}

void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  PageControl1->SelectNextPage(Button == btNext);
}
```

Delphi Examples:

```
{
This example requires a new TPageControl, as-is, with no new pages
created at design time, and a TUpDown control, also from the Win95
```

```
  page of the component palette.  The form OnCreate event handler
  adds several new TabSheet controls to the Page Control.  The
  UpDown1Click event handler fires when the user clicks the up or
  down button on the TUpDown control.  The SelectNextPage method of
  the Page Control goes forward the comparison (Button = btNext)
  evaluates as true.  If Button is not btNext, the previous Tab Page
  is selected.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  const
    colorPalette: Array[0..11] of TColor =
      (clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
      clTeal, clNavy, clMaroon, clLime, clOlive, clPurple);
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet #' + IntToStr(i);
        Brush.Color := colorPalette[i];
      end;
  end;

  procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
  begin
    PageControl1.SelectNextPage(Button = btNext);
  end;
```

72.1.7.4.11 TForm.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

72.1.7.4.12 TForm.OnDeactivate Event

Occurs when the form loses focus.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Use OnDeactivate to perform special processing when the form transitions from being the active form to another form in the same application becoming the active form. If activation goes to another application, this event is not triggered. To determine if another application has become active, Use the TApplication object's OnDeactivate event.

See Also

OnActivate (see page 13943)

OnDeactivate (see page 13727)

72.1.7.4.13 TForm.OnDestroy Event

Occurs when the form is destroyed.

Pascal

```
property OnDestroy: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDestroy;
```

Description

Use OnDestroy to perform special processing when the form is destroyed. Either implement this event or override the destructor of the class, but not both. This event should destroy any objects created in the OnCreate event.

C++ Examples:

```
/*
The following code allocates a TBitmap object that is used
by the application when the main form is first created. The
OnDestroy method frees the bitmap as the application shuts
down.
*/
Graphics::TBitmap *LogoBmp;
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  LogoBmp = new Graphics::TBitmap();
  LogoBmp->LoadFromFile("../FACTORY.BMP");
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete LogoBmp;
}

void __fastcall TForm1::FormPaint(TObject *Sender)
{
  Canvas->Brush->Bitmap = LogoBmp;
  Canvas->FillRect(Rect(0,0,100,100));
}
```

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
```

72.1.7.4.14 TForm.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop: TDockDropEvent;
```

C++

```
__property TDockDropEvent OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
```

```
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
